APPENDIX F

ANNOTATED TRACIN-FILE INPUT DATA FOR THE W3LOOP TRANSIENT CALCULATION

An annotated listing of the TRACIN-file input data for a Westinghouse three-loop, full-plant model, steady-state calculation is provided in Appendix E. An annotated listing of the TRACIN-file input data for its transient calculation, that restarts from the steady-state calculation's last data dump, is provided in this appendix. This document was originally developed for TRAC-P, but it is also valid for TRAC-M. As recommended in Section 5.0., the full-plant model has been defined by the TRACIN-file input data for the steady-state calculation. This transient-calculation TRACIN file does not specify control-parameter data, but it does replace the data of a few hydraulic components. The remaining input data will be obtained from the restart-data TRCRST file.

The TRAC–M user may specify a replacement for or modification of an existing hydraulic component for a restart calculation by assigning it the same ID number in the transient-calculation TRACIN-file input data. FILL components 91 and 92 are reinput in this transient calculation with their VLSCL liquid-velocity table scaling factor set to zero to turn off their steady-state calculation defined letdown and makeup flows during the transient calculation. A hydraulic component can be added to or deleted from the transient calculation by adding its new component number to the IORDER array and inputting its component data or deleting its component number from the IORDER array. The steam-generator single-tube rupture is initiated in this transient calculation by replacing the two no-flow FILL components 202 and 203 connected to junctions 201 and 203 with a new PIPE component 202 connected to junctions 201 and 203. The PIPE provides the single-tube rupture flow path between the steam-generator primary and secondary sides of TEE components 22 and 200. Component number 203 is deleted from the IORDER array to make this change. The NCOMP (Word 3 on Main-Data Card 5) total number of components is decreased by 1 to reflect this change in the number of components.

The TRAC–M user can specify a replacement for or modification to an existing control parameter (signal variable, control block, or trip) or specify a new control parameter; however, the user cannot delete a control parameter in the control procedure (see exception is last sentence). If the NTSV, NTCB, or NTRP number of a control-parameter type increases, its value will need to be changed on Main-Data Card 7. For example, the user could decide to change or extend a control procedure after having evaluated the steady-state calculation. Changing the control parameters of already defined ID numbers or defining new ID number control parameters allows the user to make such changes without having to reevaluate the steady-state calculation. However, it is not possible to delete control parameters unless the deleted items are at the end of their respective lists by having the largest magnitude ID numbers.

F.1. Notes on the TRACIN-File Input Data for the Transient Calculation

In the following notes, reference is made to the input-data file listing in Setion. F.2. by callouts that are marked on the listing; for example, · is note 1. Items already discussed in Appendix E for the steady-state calculation TRACIN-file input data will not be discussed here.

1. The following changes were made to the steady-state calculation input-data NAMELIST variables.

   a. DTSTRT = 0.001 s defines the initial timestep size for the transient calculation; if DTSTRT were not specified, the steady-state calculation 0.2 s timestep size from the last restart-data dump would be used as the initial timestep size for the transient calculation.

   b. IPOWR and TPOWR are no longer defined because they are only used during the steady-state calculation to specify when the reactor-core power is set ON.

2. DSTEP = –1 specifies that the last data dump on the TRCRST file (the TRCDMP file from the steady-state calculation) is to be used to restart the transient calculation. Because DSTEP is less than zero, the initial problem time is defined from the last data dump (0.0 s) rather than by TIMET = 0.0000E+00 s.

3. A transient calculation is to be performed when STDYST = 0 and TRANSI = 1.

4. The NCOMP number of components is decreased by 1 and the NJUN number of junctions is not changed from the steady-state calculation because one component was deleted and three components were changed by this transient-calculation TRACIN-file input data.

5. Because this is a transient calculation, no CSS controllers (NCONTR = 0) are defined in this TRACIN-file input data.

6. The number of signal variables is increased by 1 and the number of control blocks, values of control-block tabular data, and trips are not changed from the steady-state calculation.

7. One new signal variable is defined by this TRACIN file for the new PIPE component 202. The subsequent record of five integer 0s indicates that the remaining NTSV–1 = 65 signal variables are to be defined by the TRCRST-file restart data from the steady-state calculation.

8. The NAMELIST variable IUNLAB = 8 number of user-defined units-name labels need to be reinput because they were not output as part of the TRCDMP-file data dump.

9. One control block is reinput by this TRACIN file. Its defined form is the same as in the steady-state calculation; therefore, inputting it again only demonstrates that a control block can be modified by reinputting it. The subsequent record of five integer 0s indicates that the remaining NTCB–1 = 237 control blocks are to be defined by the TRCRST-file restart data from the steady-state calculation.

10. This record provides values needed for dimensioning array storage for the NTRP = 72 trips.

11. No trips are defined by this TRACIN file. The record of five integer 0s indicates that the remaining NTRP = 72 trips are to be defined by the TRCRST-file restart data.

12. FILL components 91 and 92 are reinput with VMSCL = 0.0000E+00 to turn off their FILL-table defined letdown and makeup flows, respectively, during the transient calculation.

13. PIPE component 202 is input to replace FILL component 202 and provide fluid flow between junctions 201 and 203 to model a loop 2 steam-generator single-tube rupture during the transient calculation.

14. The "END" record indicates the end of the component data. Because the data for three components are specified before it, the remaining NCOMP–3 = 128 components are to be defined by the TRCRST-file restart data. The last data dump to the TRCDMP file defines the remaining components with the steady-state calculation's evaluated thermal-hydraulic steady-state condition of the modeled system.

15. One set of timestep data is specified. The transient calculation will be evaluated for TEND = 6.0000E+02 s of problem time starting with a DTSTRT = 0.001 s timestep size (see note 1) rather than a DTMIN = 1.0000E-05 s timestep size. Thereafter the timestep size is constrained to be no less than DTMIN = 1.0000E-05 s and no greater than DTMAX = 5.0000E-01 s. A small and large TRCOUT edit is to be generated every SEDINT = EDINT = 1.0000E+02 s, a graphics edit is to be generated every GFINT = 5.0000E+00 s, and a data dump edit is to be generated every DMPINT = 2.0000E+02 s. When problem time reaches 600.0 s, the next timestep data set reads in a DTMIN = –1.0000e+00 < 0.0, which terminates the TRAC-M transient calculation

F.2. Input-Data Listing of the TRACIN File for the Transient Calculation

Annotation for the callouts that are marked on the following input-data listing is provided by the referenced note of the same number in Section F.1. of this appendix.

this is a h.b.robinson-2 steam-generator one-tube-rupture transient.
hbr-2 is a 2300 mwt, three-loop westinghouse nuclear plant located
in hartsville, s.c., that is owned and operated by the carolina
power and light company (cp&l).  this plant model was developed for
reactor-coolant pump (rcp) trip analysis by james lime for trac-pf1
/mod1 on 7/84.  it was converted for trac-pf1/mod2 by robert steinke
and james lime on 5/96.  the trac-pf1/mod2 steady-state calculation
plant model has been modified to handle the following loss-of-coolant
accidents, through transient input-data tracin-file changes, allowing
the same steady-state restart data-dump file to be used:
  1) cold-leg small break without pump trip,
  2) cold-leg small break with pump trip,
  3) one-tube steam generator tube rupture,
  4) two-tube steam generator tube rupture, and
  5) 100% cold-leg degb large break.
this input-data model contains the following components and subsystems:
  1) three-dimensional (r=2,t=6,z=12) reactor vessel;
  2) vessel upper-plenum guide tubes;
  3) powered-rod and unpowered-slab heat structures in the vessel;
  4) three primary- and secondary-coolant loops modeled individually;
  5) makeup, letdown, and pressurizer-sprayer cvcs flows;
  6) accumulator and hpsi fills in each primary-coolant loop;
  7) pressurizer and pressurizer porv and srv;
  8) pressurizer, steam generator, and steam-dump control systems;
  9) single-tube degb leakage path in loop 2 steam generator;
 10) main-steam and steam-dump lines;
 11) high-pressure feedwater system after hp heaters; and
 12) auxiliary-feedwater fills (motor and steam driven).

APPENDIX G

ANNOTATED TRCMSG FILES FROM THE W3LOOP STEADY-STATE AND TRANSIENT CALCULATIONS

TRAC-P Version 5.4.19 has been executed on the steady-state and transient input-data files in Apps. E and F. Except where noted, the following commentary on these uses is still valid for TRAC–M. The TRCMSG file from each of these calculations is discussed and annotated in this appendix with Section G.1. discussing the steady-state calculation TRCMSG file output in Section G.2. and Section G.3. discusses the restart transient calculation TRCMSG file output in Section G.4. The purpose of this discussion is not to dwell on the physical nature of the solution, but to focus on the type and form of the information provided by the TRCMSG file. These TRCMSG-file examples provide representative information. Only eight of several hundred different warning error messages were generated by TRAC-P during these two calculations because of the nature of their numerical solutions.

G.1. Notes on the TRCMSG File From the Steady-State Calculation

The output from the steady-state calculation to the TRCMSG file is reviewed in this section to provide a description of its contents. Notes in this section are referenced in the TRCMSG file by callouts that are marked on the output listing in Section G.2. For example, [1] is note 1.

1. The TRAC-P logo is on the initial printout page. Most of the TRCMSG-file information also is sent to the ITTY or terminal I/O channel (which for most terminals needs to be less than 80-columns to prevent longer line clipping or wrap-around that is hard to read).

   Note: The code logo has not been reimplemented in TRAC-M.

2. Quality-control identification of the current version of TRAC-P, the date the TRAC-P executable was created, the history of TRAC-P versions since version 5.4, and a list of each version's updates is provided for the purpose of verification and traceability.

   Note: This identification information has been modified in TRAC-M.

3. TRAC-P internally defines the coolant with H_2O or D_2O properties. The coolant-type properties to be used in the TRAC-P calculation are specified by ID2O (Word 5 on Main-Data Card 2) and identified by this output line.

4. An echo output of the 27 problem title cards from the input-data TRACIN file is shown here.

5. The input-specified IORDER-array component numbers are reordered by TRAC-P into subgroupings of hydraulic components that connect to each other sequentially with each subgroup forming a flow channel called a "loop." The equations of the components in each subgroup loop are

evaluated simultaneously by TRAC with coupling of TEE side tubes to other loops or across a PLENUM cell to other loops evaluated by the network matrix-equation solution. The list of component numbers shown here has the reordered hydraulic component numbers (in the order they will be processed by TRAC-P and their large-edit parameter information output to the TRCOUT file) followed by the heat-structure component numbers (ordered as input). Note that the TRAC-P short-edit debug and timestep control information is presented in the same order as this edit of the IORDER array. For example, the timestep-size control edit in the short edit, which lists the number of times a hydraulic component was the last component to converge in the outer iteration, is presented in the same order as in this listing of the IORDER array.

Note: Item 6 is not written by TRAC-M.

6. When the plant system model has one or more VESSEL components, this message gives the size of the VESSEL coefficient matrix solved as a VESSEL-matrix equation by TRAC-M for all VESSEL components in one matrix equation. In this problem, the VESSEL coefficient matrix has 12 diagonal rows above and below the main diagonal with elements that potentially can be nonzero valued. This defines the banded-matrix portion of the VESSEL coefficient matrix as having a bandwidth of 12 + 1 + 12 = 25 diagonal rows. The output message indicates that 12 of the VESSEL-matrix rows have 1 or more nonzero elements outside the matrix bandwidth. These nonzero elements represent the source-connection junction coupling of nonadjacent VESSEL mesh cells to 1D component loops. These nonzero elements outside the matrix bandwidth are coupled to the banded portion of the VESSEL coefficient matrix by a capacitance-matrix solution.

   Note: Item 7 is not written by TRAC-M.

7. Problem-size specifications define the computer memory required under various categories. This problem was executed on a SUN Sparc II workstation computer with 1.475256 MWords of RAM memory required. Small-core memory (SCM) and large-core memory (LCM) now are the same fast or RAM memory of the computer.

8. A data dump is generated at the start of every TRAC-M calculation (after the input data are processed and all other parameters are initialized but before the first timestep is evaluated). Restarting from this data dump would produce results identical to that of starting with the TRACIN input-data file for the initial calculation of this problem example.

9. The first set of timestep data that is input is echoed to output. The minimum and maximum timestep sizes, heat-transfer to hydraulic calculation timestep ratio, convective energy-error controller level, and the various output time intervals will be used from the start of the calculation at 0.0 s to the time domain end at TEND = 10.0 s.

10. During the first and second timesteps, water packing occurred in the steam-generator downcomers of TEE components 190, 290, and 390. The liquid is at rest initially and packs under a pressure spike because of feedwater flow and establishing a hydraulic head in the vertical portion of the downcomer. Starting the steady-state calculation with a timestep size smaller than 0.001 s could have avoided these warning error messages during the first and second outer iterations. TRAC-M gives warning messages when it is having a numerical-solution difficulty, and gets around the difficulty with internal logic (such as for water packing or stretching, backup calculation, timestep size control, etc.) in almost all situations and is able to converge the timestep solution.

11. The liquid-level trip signal of the pressurizer's low-level trip –407 rises above the S_2 = 1.5000E-01 m setpoint causing TRAC-P to change the trip set status from OFF to $ON_{Forward}$ with no setpoint delay time. Trip –407 is the only trip with a negative ID number that is evaluated during the steady-state calculation. A trip must be evaluated and its trip signal must reach or cross a setpoint value to change the trip's set status. Such a trip message is generated when the trip's ITST input parameter has a positive value.

12. Status information about the numerical solution is printed in table form with column heading labels. The first five columns show the timestep number, problem time, timestep size, number of outer iterations required for convergence of the pressure-matrix solution, and the accumulated CPU execution time. This information is printed every 100 timesteps and when a large edit is output to the TRCOUT file. Those 5 columns and the last 5 columns, defining the 1D and 3D hydraulic-component material-Courant numbers, the VESSEL's SETS3D evaluation flag, and the component and cell number where the maximum of the 2 Courant numbers is located, are printed every NAMELIST-variable defined IADDED = 10 timesteps. Interspersed between groups of those one-line edits are other information and messages generated during the calculation.

13. The reactor-core power is set to its RPOWRI = 2.3×10^9 W (7.8479×10^9 Btu h^{-1}) steady-state power level at or after NAMELIST variable TPOWR = 2.0 s problem time because NAMELIST variable IPOWR = –1. This power is generated in the powered fuel ROD elements of HTSTR component 900. The actual problem time was 2.071103 s rather than 2.0 s because the previous timestep size was >0.071103 s and the problem time at the beginning of the previous timestep was <2.0 s.

14. During a steady-state calculation, TRAC-M tests for steady-state solution convergence every 5 timesteps and for every timestep when a large edit is output to the TRCOUT file. That information in the following table is sent to the TRCMSG file every 100 timesteps and for every timestep when a large edit is output to the TRCOUT file. The steady-state solution convergence test is based on comparing the maximum fractional change

per second of seven hydraulic parameters (pressure, liquid velocity, gas velocity, gas volume fraction, liquid temperature, gas temperature, and noncondensable-gas pressure) everywhere in the modeled system with the user input EPSS convergence criterion. All the maximum fractional-change per second values must be less than EPSS for steady-state solution convergence to be satisfied and for TRAC-M to end the calculation before the time domains of all timestep data have been evaluated. We see in this table at timestep number 100 that the maximum fractional-change per second values are large compared with EPSS = 1.0000E-04 that was input. At problem time 2.234650 s, the input specified state of the plant model is still undergoing a rapid transient to get to steady-state conditions. Testing the maximum fractional change per second rather than per timestep provides a better test of steady-state conditions because it does not depend on the timestep size that is being used. A similar steady-state convergence test and output edit can be generated during a transient calculation that evaluates the asymptotic steady-state condition by setting NAMELIST variable ISSCVT = 1.

15. When the steady-state calculation is a CSS calculation, a table showing the current status of all CSS controllers is printed after the steady-state convergence-test table discussed in note 14. The columns denoting the component type and number, the minimum and maximum values of the adjusted parameter, and the desired value for the monitored parameter are input specified values for each of the controllers. The current status of the controller action is seen in the values of the adjusted parameter and the monitored parameter. By making changes in the adjusted parameter, the controller is trying to affect the solution state of the plant model in a way that causes the monitored parameter value to change to the desired value. Adjustment is not allowed outside the minimum to maximum value range. When the adjusted parameter reaches either limit, the controller has no further ability to affect the system model until the controller adjustment changes direction. Constraining an adjusted parameter to a reasonable adjustment range keeps inappropriate conditions of a rapidly changing solution from causing a controller to make inappropriate adjustments that may hinder or prevent a steady-state solution from being determined. Before steady-state convergence-test conditions can be satisfied, CSS controller adjustments must become very small. Because local conditions of the monitored parameter can change somewhat irregularly at times as the solution approaches steady-state conditions, constraining the rate of change of the component actions controlled by the CSS controllers is sometimes necessary to achieve steady-state convergence. That is done with the component-action maximum rate of change input parameter that is part of the component data (for example, ROMGMX for a PUMP component).

16. Five backup calculations that reevaluate the timestep with a smaller timestep size were performed between 7.8 and 15.8 s problem time. All 5 backups were from subroutine POST during the post stage of the

calculation. All were affected by numerical-solution difficulties encountered on the secondary sides of the steam generators in their steam dome and downcomer sections.

17. The second set of timestep data that is input for problem time 10.0 to 100.0 s is echoed to output. The maximum timestep size, output time intervals, and heat-transfer to hydraulic calculation timestep ratio have changed from the first set of timestep data.

18. After 20.0 s problem time, the TRAC-P CSS calculation executes with its maximum 0.2 s timestep size and generally requires only 2 outer iterations to converge the outer-stage pressure-matrix solution. The dynamics of the solution appear to have settled down in that the maximum fractional change per second in the parameters tested for steady-state convergence continue to get smaller with each table edit until 65.773748 s problem time. Thereafter their maximum fractional change per second values increase and decrease with each table printout but don't appear as a whole to decrease further to satisfy the EPSS steady-state convergence-test criterion.

19. The third and final set of timestep data that is input for problem time 100.0 to 200.0 s is echoed to output. The maximum timestep size, output time intervals, and heat-transfer to hydraulic calculation timestep ratio have changed. At TEND = 2.0000E+02 s, TRAC-P ends the CSS calculation without having satisfied the EPSS = 1.0000E-04 steady-state convergence test criterion. Maximum fractional-change per second values in the pressure of the feedwater control valves and in the phasic velocities and temperatures and the gas volume fraction on the secondary sides of the steam generators indicate the secondary-side solution is not settling down. It is felt that the nature of the secondary-side model has created oscillatory behavior. To diagnose the cause and introduce appropriate modeling changes to converge the steady-state solution, the secondary-side solution behavior would need to be examined and the source of its oscillatory behavior would need to be understood. This can be done most effectively with graphics output.

20. A final large edit is output to the TRCOUT file and a final data dump is sent to the TRCDMP file at 200.069335 s by TRAC-M automatically at the end of the steady-state calculation. The short, large, and dump output time intervals were defined so that they generated no output. Our interest is in the final end-of-calculation output of the hopefully converged steady-state solution. After 20 s problem time, the material Courant limit ranged from 10 to 20. The total CPU run time of 18,418 s (5.16 h) for the steady-state calculation was on a SUN Sparc 2 workstation.

G.2. Listing of the TRCMSG File From the Steady-State Calculation

Version 5.4.01   created from version 5.4      using the following updates:
    fxchfit     pltvar      fxrfdz      fsurflx     vector2
    upnljf      fans792     fxibf       fxcidc      fxwpkxx
    fixml3      fxmfg       fxbktrl     fxtss       upnvp1
    fxcvm       fxmrod      fxblb2      upxtvp2     fxbit
    morml3      fxsmvt      v5p4p01
Version 5.4.02   created from version 5.4.01   using the following updates:
    uphtmlb     fxlptre     no360       dcomer      fxnffz2
    fxtee       fxltfcb3    fxincb      fxtkf       uphsp
    uphsrd2     ieeeg       upmld       brksat      genbrk
    fxlabc      v5p4p02
Version 5.4.03   created from version 5.4.02   using the following updates:
    upmld2      modig       upjfl       fxisrb      fxfxtkf
    hpconv      v5p4p03
Version 5.4.04   created from version 5.4.03   using the following updates:
    updmfc      fxsave      fixcpu      realfix     fxigmod
    fhtbdc      fxetime     cifblas     v5p4p04
Version 5.4.05   created from version 5.4.04   using the following updates:
    fixcdeq     fixsg       v5p4p05
```

```
Version 5.4.06   created from version 5.4.05   using the following updates:
    fixtype    units      v5p4p06
Version 5.4.07   created from version 5.4.06   using the following updates:
    cpuprt     v5p4p07
Version 5.4.08   created from version 5.4.07   using the following updates:
    fixbr      fxfachk    fxudid     rstub      v5p4p08
Version 5.4.09   created from version 5.4.08   using the following updates:
    uphsbu     up1dpt     fxrgs      upnouc     fixhsft
    hsflip2    cnlist     xtvi3e     fxgbit     fixbu1
    gnwkst2    fxnul      ssavg      aenergy    upenwrt
    labout09   upencyl    upenhts    fixb21     v5p4p09
Version 5.4.10   created from version 5.4.09   using the following updates:
    fxnst1     uprad3n    radhyd     radhts     fxshstr
    radrd      radi       gamht1     gamht2     upfind5
    fprad      vmatrix    raddmp3    uplinalg   csst5c
    fxuphts    v5p4p10
Version 5.4.11   created from version 5.4.10   using the following updates:
    fxivsl     fxdef      fxuc2      fixfr      fxifdf
    labout11   fxvstp     v5p4p11
Version 5.4.12   created from version 5.4.11   using the following updates:
    fxvadj2    hpssi      labout12   fxdsln2    fxsct
    fxsahs1    xtv12b     fixfr2     upenwrt2   fxcnlist
    fxsedit    fxradln    upfxrad    upenrad    ngenwks2
    v5p4p12
Version 5.4.13   created from version 5.4.12   using the following updates:
    fxencyl    rmcom      xtvibm     fxency2    smatsol
    fxname     v5p4p13
Version 5.4.14   created from version 5.4.13   using the following updates:
    newlogo    fxunits    faxbugs    v5p4p14
Version 5.4.15   created from version 5.4.14   using the following updates:
    fxflowin   fxrsudu1   fxwhtstr   v5p4p15
Version 5.4.16   created from version 5.4.15   using the following updates:
    ifrd       hp9kdef    rs6kdef    sundef     unixdef
    v5p4p16
Version 5.4.17   created from version 5.4.16   using the following updates:
    prgast     v5p4p17
Version 5.4.18   created from version 5.4.17   using the following updates:
    d2o        fxface2    chdefs     tsdiag2    labout18
    v5p4p18
Version 5.4.19   created from version 5.4.18   using the following updates:
    vectrz     unixdef    v5p4p19
--------------------------------------------------------------------------------
```

```
                    input data is being processed

                      h2o properties are used  <-- 3

number of title cards is:   27
this is a sample problem for the trac-p users guide manual.  it models   <-- 4
a westinghouse 2308-mwt powered nuclear-core, three-loop pressurized
water reactor with constrained steady-state and transient calculations.
this full-plant model evaluates a steam-generator single-tube double-
ended-guillotine break transient with primary-coolant pumps operating.
this input-data model contains the following components and subsystems:
  1) three-dimensional (r=2,t=6,z=12) reactor vessel;
  2) vessel upper-plenum guide tubes;
  3) powered-rod and unpowered-slab heat structures in the vessel;
  4) three primary- and secondary-coolant loops modeled individually;
  5) makeup, letdown, and pressurizer-sprayer cvcs flows;
  6) accumulator and hpsi fills in each primary-coolant loop;
  7) pressurizer and pressurizer porv and srv;
  8) pressurizer, steam generator, and steam-dump control systems;
  9) single-tube degb leakage path in loop 2 steam generator;
 10) main-steam and steam-dump lines;
 11) high-pressure feedwater system after hp heaters; and
 12) auxiliary-feedwater fills (motor and steam driven).
the w3loop input-data model has the following developmental history:
  james lime created the trac-pf1/mod1 input-data model on 7/84.
  robert steinke converted the trac-pf1/mod1 input-data model with
  gocnvt to a trac-pf1/mod2 input-data model and added component-
  network diagrams on 9/90. marvin salazar added units labels to
  the control blocks and trips for si/english units i/o on 10/93.
  robert steinke replaced stgen components with htstr, pipe, and tee
  components on 2/96.  James lime upgraded the w3loop input-data model
  to be consistent with the current h.b.robinson plant model on 5/96.

graphics data is defined in si units
```

G.3. Notes on the TRCMSG File From the Transient Calculation

The printout from the transient calculation TRCMSG file is reviewed in this section to provide a description of its contents. Items already discussed in Section G.1. for the steady-state calculation TRCMSG file will not be discussed here unless additional comments are needed on that item. Notes in this section are referenced in the TRCMSG file by callouts that are marked on the printout in Section G.4. For example, 1 is note 1.

1. This is a restart transient calculation from the last data dump of the steady-state calculation. After the title cards, the number of signal variables, control blocks, and trips that the TRCRST file defines are noted. The IORDER-array component numbers, excluding the component numbers whose component data are input-specified in the TRACIN file, are listed in their input order. These are the component numbers whose component data are defined by the TRCRST file. Then all the component numbers, reordered for their evaluation, are listed. The TRACIN file for this transient calculation in Appendix F inputs the redefined FILL components 91 and 92 and a new PIPE component 202 to replace FILL component 202 from the

restart-data components. FILL component 203 is deleted by no longer being defined in the IORDER array. The restart data comes from the steady-state calculation data dump at timestep number 1262 where the 200.069335 s problem time has been reset to 0.0 s.

2. The transient calculation is evaluated for TEND = 600.0 s of problem time with one timestep data set. A steam-generator single-tube rupture, initiated at 0.0 s problem time, causes a mild loss-of-primary-coolant transient. NAMELIST variable DTSTRT = 1.0000E-03 s starts the transient calculation at a timestep size of 0.001 s rather than at the 0.2 s timestep size from the data dump.

3. All trips are evaluated at the start of each timestep in a transient calculation. During the first three timesteps, trip ID numbers 34, 26, 10, 16, and 18 have their ITST = 3 trip-controlled-trip signals changed from 0.0 to 1.0 (because one of their controlling trips was set ON and their controlling-trip set status are summed to define their trip signal). Being ISRT = 2 trips, when their trip signal crosses setpoint S2 = 0.9, a pending set status change from OFF to ON after the T2 delay time is set up. That delay time is 0.0 s for Trip ID numbers 34, 10, 16, and 18, so their set status is changed to ON ($ON_{forward}$). The set status of trip ID 26 will not be changed until 30.0019 s because its T2 delay time is 30.0 s. Other trips that were input with a negative value for their ITST parameter may also have changed their set status, but messages to that effect are not printed to the TRCMSG file. That is the case for the controlling trips that affected the set status change of these trip-controlled trips. Only trips of interest that control component actions should have their change of set status messages output to the TRCMSG (and TRCOUT) file.

4. At 6.7 s problem time, steam-dump VALVE component 432 begins to open under the control of control blocks –4342 and –4336 (and other control blocks that have not yet been activated in the control network). Depressurization of the secondary-side coolant of all three steam generators that are hydraulically coupled initially causes numerical-solution difficulty in TEE component 430 that is connected to opening VALVE component 432. The TEE's linearly projected pressure is a poor timestep-solution estimate because the ~0.18 s timestep size is too large. Backups and timestep-size control reduce the timestep size to 0.0026 s in the last *TF1DS3* warning message before this initial secondary-side depressurization phase of the transient can be numerically evaluated. By 11.0 s, the timestep size has recovered to ~0.1 s.

5. Depressurization of the primary-side coolant occurs because of the single-tube rupture in the loop 2 steam generator. At 14.95 s, trip ID number 54 is set ON because of a low pressure signal in the pressurizer that activates its power-deposited-in-the-liquid-coolant heater. At 25.59 s, trip ID number –407 is set OFF because of a low liquid level in the pressurizer that turns off

the power-deposited-in-the-liquid-coolant heater in pressurizer PIPE component 40 because of POWOFF = 0.0 W.

6. Depressurization effects and velocity reversals that oscillate on the secondary-side of the loop 1 steam generator require two outer-iteration backups at 25.95 s that reduce the timestep size from 0.1122 to 0.02805 s. TRAC-P recovers from numerical-solution difficulty be performing backups that reduce the timestep size until the linearly projected numerical solution is able to converge to a solution state that is simultaneously satisfied among all state equations.

7. From 30.8 to 30.9 s, six trip signals cross their setpoints for change of set status. Four of the trips change their set status because their setpoint delay time is 0.0 s; trip ID numbers 21 and 28 have setpoint delay times of 20.0 s and 30.0 s, respectively, that delay the change of their set status.

8. Velocity reversal oscillations at ~42, ~46, and ~72 s and extremely low liquid-temperature estimates at ~63 s in the steam dome of the loop 3 steam generator periodically require backups to reduce the timestep size to obtain a converged numerical solution.

9. After 75 s, the numerical solution evaluated more robustly with the timestep size increasing to between 0.2 and 0.4 s for the remainder of the 600 s problem-time calculation. Material Courant limits of 10 to 40 were evaluated. A DTMAX maximum timestep size of 0.3 s rather than 0.5 s would have been more appropriate for this transient calculation because timesteps of 0.4 s required a smaller timestep size. Short and large edits were output to the TRCOUT file every 100 s and data dumps were output every 200 s to the TRCDMP file.

10. The total CPU run time of 42,924 s (11.92 h) for the transient calculation involved an overnight evaluation on a SUN Sparc 2 workstation. A faster workstation could reduce that run time to a few hours. That is an acceptable calculation time for a rather elaborate system model of 131 components with a complex control procedure of 66 signal variables, 238 control blocks, and 72 trips.

G.4. Listing of the TRCMSG File From the Transient Calculation

```

    labout09   upencyl    upenhts    fixb21     v5p4p09
Version 5.4.10   created from version 5.4.09   using the following updates:
    fxnst1     uprad3n    radhyd     radhts     fxshstr
    radrd      radi       gamht1     gamht2     upfind5
    fprad      vmatrix    raddmp3    uplinalg   csst5c
    fxuphts    v5p4p10
Version 5.4.11   created from version 5.4.10   using the following updates:
    fxivs1     fxdef      fxuc2      fixfr      fxifdf
    labout11   fxvstp     v5p4p11
Version 5.4.12   created from version 5.4.11   using the following updates:
    fxvadj2    hpssi      labout12   fxdsln2    fxsct
    fxsahs1    xtv12b     fixfr2     upenwrt2   fxcnlist
    fxsedit    fxradln    upfxrad    upenrad    ngenwks2
    v5p4p12
Version 5.4.13   created from version 5.4.12   using the following updates:
    fxencyl    rmcom      xtvibm     fxency2    smatsol
    fxname     v5p4p13
Version 5.4.14   created from version 5.4.13   using the following updates:
    newlogo    fxunits    faxbugs    v5p4p14
Version 5.4.15   created from version 5.4.14   using the following updates:
    fxflowin   fxrsudul   fxwhtstr   v5p4p15
Version 5.4.16   created from version 5.4.15   using the following updates:
    ifrd       hp9kdef    rs6kdef    sundef     unixdef
    v5p4p16
Version 5.4.17   created from version 5.4.16   using the following updates:
    prgast     v5p4p17
Version 5.4.18   created from version 5.4.17   using the following updates:
    d2o        fxface2    chdefs     tsdiag2    labout18
    v5p4p18
Version 5.4.19   created from version 5.4.18   using the following updates:
    vectrz     unixdef    v5p4p19

                          h2o properties are used

number of title cards is:   28
this is a h.b.robinson-2 steam-generator one-tube-rupture transient.
hbr-2 is a 2300 mwt, three-loop westinghouse nuclear plant located
in hartsville, s.c., that is owned and operated by the carolina
power and light company (cp&l).  this plant model was developed for
reactor-coolant pump (rcp) trip analysis by james lime for trac-pf1
/mod1 on 7/84.  it was converted for trac-pf1/mod2 by robert steinke
and james lime on 5/96.  the trac-pf1/mod2 steady-state calculation
plant model has been modified to handle the following loss-of-coolant
accidents, through transient input-data tracin-file changes, allowing
the same steady-state restart data-dump file to be used:
  1) cold-leg small break without pump trip,
  2) cold-leg small break with pump trip,
  3) one-tube steam generator tube rupture,
  4) two-tube steam generator tube rupture, and
  5) 100% cold-leg degb large break.
this input-data model contains the following components and subsystems:
  1) three-dimensional (r=2,t=6,z=12) reactor vessel;
  2) vessel upper-plenum guide tubes;
  3) powered-rod and unpowered-slab heat structures in the vessel;
  4) three primary- and secondary-coolant loops modeled individually;
  5) makeup, letdown, and pressurizer-sprayer cvcs flows;
  6) accumulator and hpsi fills in each primary-coolant loop;
  7) pressurizer and pressurizer porv and srv;
  8) pressurizer, steam generator, and steam-dump control systems;
  9) single-tube degb leakage path in loop 2 steam generator;
 10) main-steam and steam-dump lines;
 11) high-pressure feedwater system after hp heaters; and
 12) auxiliary-feedwater fills (motor and steam driven).

APPENDIX H

ANNOTATED TRCOUT-FILE SEGMENTS

The steady-state and transient input-data TRACIN files in Appendices E and F were executed upon by TRAC-P Version 5.4.19. Except where noted, the following commentary is valid for TRAC-M. Their steady-state and transient calculation TRCOUT files have 145 double-sided pages (37 217 lines) and 338 double-sided pages (86 447 lines), respectively. Most of the output results are associated with an initial input-data output echo having variable-name labels and unit symbols, a initial short and large edit at problem time 0.0 s, and 1 steady-state and 6 transient calculation short and large edits that were user requested in the Timestep Data from each calculation. The large size of these TRCOUT files makes it impractical to present them in their entirety in this appendix. We have chosen instead to present segments of each file that have items of interest for annotation. The steady-state and transient calculation segmented TRCOUT files shown in this appendix have 4794 and 10 205 lines, respectively. The deleted portions of each TRCOUT file are marked by the inserted message

"########## xxxx lines deleted here ##########"

at locations in the output where xxxx lines from the original TRCOUT file were deleted and replaced by this comment. Section H.1. discusses the steady-state calculation segmented TRCOUT file output listing in Section H.2.; Section H.3. discusses the transient calculation segmented TRCOUT file output listing in Section H.4. The purpose of the discussion in this appendix is not to dwell on the physical nature of the solution, but to focus on the type and form of the information provided by the TRCOUT file.

H.1. Notes on the Steady-State Calculation TRCOUT-File Segments

The output segments from the steady-state calculation TRCOUT file are reviewed in this section to provide a description of their contents. Notes in this section are referenced by callouts that are marked on the TRCOUT-file output segments in Section H.2. For example, 1 corresponds to note 1.

Note: The logo has not been reimplemented in TRAC–M.

1. The TRAC-P logo is on the first output page.

Note: This identification information has been modified in TRAC-M.

2. Quality-control identification of the version of TRAC-P, the date the TRAC-P executable was created, and a list of updates included in TRAC-P since version 5.4 is printed here for the purpose of verification and traceability.

3. TRAC-P internally has H_2O or D_2O properties available to define the coolant. ID20 = 0 or 1 (Word 5 on Main-Data Card 2) selects H_2O or D_2O properties and identifies that choice on these output lines.

4. An output echo of the NUMTCR = 27 problem title cards from the input-data TRACIN file is shown here.

5. The values of all namelist variables are printed here. The values of FDFHL, IADDED, ICFLOW, IKFAC, IMFR, IOLAB, IPOWR, IUNLAB, NEWRFD, NFRC1, NHTSTR, NOAIR, and TPOWR were defined by the TRACIN file shown in Section E.7.; all other NAMELIST variables have their default values.

6. The metric SI units-name labels and their units symbols defined internally by TRAC-P are output as user information. Only SI units are shown because the input TRACIN file and output TRCMSG, TRCOUT, and TRCGRF files are in SI units based on the default values of NAMELIST variable IOINP = 0, IOOUT = 0, and IOGRF = 0. Had any one or more of their values been 1 or the INLAB file been output by NAMELIST variable INLAB = 3 with IOLAB = 1, the English units-name labels and their units symbols would have to be output here as well.

7. Namelist variable NFRC1 = 2 results in this output message that forward-flow and reverse-flow direction additive loss coefficients are to be input for all 1D hydraulic components.

8. This message states that the default solubility-parameter values shown are used to dissolve SN-array solute or to plate-out CONC-array solute that are defined because NAMELIST variable ISOLCN = 0 (default value).

9. The Main-Data card parameter values are output here with their FORTRAN variable-name in the order that they were input.

10. This message states that the boiling-curve minimum temperature for not rewetting a heated surface is based on homogeneous nucleation because ITMIN = 0 is initialized in subroutine BLKDAT. If TRAC-P were to be reprogrammed with ITMIN > 0, the maximum value of the boiling-curve minimum temperature based on the homogeneous nucleation model or the Iloeje model would be used instead.

11. This message indicates that the solute-tracking option is on because ISOLUT = 1 was input on Main-Data card 6. This requires the input specification of ICONC for each hydraulic component. ICONC = 0 requires no solute-parameter input, ICONC = 1 requires the dissolved-solute-to-liquid mass-ratio array CONC be input, and ICONC = 2 requires array CONC and the plated-out solute concentration array SN be input for the hydraulic component.

12. The IORDER-array hydraulic and heat-structure component numbers are shown in ascending numerical order. This order is different from the order they were input where their component numbers were grouped according to their similar components in the three coolant loops. The total number of component numbers shown is NCOMP = 132 (word 3 on Main-Data card 4). Refer to note 23 where these component numbers have been reordered and

printed in the order that TRAC-P evaluates them in their computational loops.

13. The input parameters defining the NCONTR = 3 constrained steady-state controllers have their values printed here. These input-parameter values (and for most of the other input-parameter values that follow) are printed in the order they were input and are labeled with their FORTRAN variable or array names (defined in the input-data format description of Section 6.0.).

14. All NTSV = 65 signal variables have their input-data parameter values shown on the output.

15. The NAMELIST variable IUNLAB = 8 user-defined units-name labels, in addition to TRAC-P's internally defined 50 units-name labels (see note 6), are shown here on the output.

16. There are 26 examples shown (of the 20 different function-operator-type control blocks defined) on the output from among the NTCB = 238 control blocks input. The output presents a schematic of each control block with the function-operator label in a starred box having zero to three input-signal positive signal-variable or negative control-block ID numbers on the left side of the box and the control block's output-signal negative control-block ID number on the right side of the box.

17. The trip-dimension variables card enables TRAC-P to reserve computer memory storage for NTSE = 3 signal-expression trip signals and NTCT = 20 trip-controlled-trip trip signals.

18. There are 9 of the NTRP = 72 trips shown with their input-data parameter values echoed to the output.

19. This message states that there are 48 signal-variable/control-block trip-signal trips, 3 signal-expression trip-signal trips, and 21 trip-controlled-trip trip-signal trips among the NTRP = 72 trips input. The later 2 trip-signal types require NTSE = 3 different signal-expression trip signals whose input-parameter values are output next and NTCT = 20 different trip-controlled-trip trip signals whose input-parameter values are printed thereafter (see note 17).

20. The Component Data input-data parameter values are echoed to the output in the order they were input. The first component is VESSEL component 1. Of its NASX = 12 axial-cell levels, all of the level 1 array data and parts of level 2, 3, 7, and 12 array data input are shown in the segmented output. Input data for levels 4, 5, and 6 repeat level 3 input data to define the reactor-core and downcomer region within the VESSEL component.

21. All or part of the input-data parameter values output echoed for hydraulic components PIPE 2, PIPE 12, PUMP 16, and FILL 93 for the primary-side coolant and PIPE 100, TEE 105, TEE 110, TEE 200, FILL 202, FILL 203, and TEE 205 for the secondary-side coolant are shown in the segmented output. This output provides a representative example of how the input-data

parameter values for these hydraulic components are echoed to the TRCOUT file.

22. All or part of the input-data parameter values output echoed for HTSTR (heat-structure) components ROD 900, SLAB 901, ROD 910, ROD 920, SLAB 931, and ROD 932 are shown in this segmented output. ROD 900 is a powered (NOPOWR = 0) HTSTR component that models the reactor-core fuel rods. It has the same input-data parameters as an unpowered HTSTR component plus additional scalar and array input-data parameters defining its power-generating option. The power generation of ROD 900 is defined by a point-reactor kinetics model (IRPWTY = 4) with no reactivity feedback modeled (IRPWTY < 11) and with the programmed reactivity of control-rod insertion defined by a trip IRPWTR = 10 controlled component-action RPWTBR table. See Appendix I for an example of modeling reactivity feedback in the input data of ROD 900. The remaining HTSTR components are unpowered (NOPOWR = 1). SLABs 901 to 909 model the internal structure of the reactor vessel; RODs 910, 920, and 930 model the tubes of the loop 1, 2, and 3 steam generators, respectively; and SLAB 931 plus RODs 932 to 938 model the internal structure of all three steam generators. TRAC-P requires that the heat-structure component data be input after the hydraulic component data, and that the heat-structure component ID numbers be numerically larger than the hydraulic component ID numbers.

23. This IORDER-array listing of the hydraulic and heat-structure component ID numbers has been reordered to reflect the order in which the hydraulic components are evaluated by TRAC-P in their computational loops and the order in which their component thermal-hydraulic state solution results are output to the TRCOUT file for each large edit.

24. When the system model has one or more VESSEL components, this message gives the size of the vessel coefficient matrix solved as a vessel-matrix equation by TRAC-P for all VESSEL components. For this problem the vessel coefficient matrix has 12 diagonal rows above and below the main diagonal with elements that potentially can be nonzero valued. This defines the banded-matrix portion of the vessel coefficient matrix as having a bandwidth of 12 + 1 + 12 = 25 diagonal rows. Twelve of the vessel-matrix rows have one or more nonzero elements outside the matrix bandwidth. These nonzero elements represent the source-connection junction coupling of VESSEL mesh cells in different axial levels by 1D hydraulic-component coolant-flow loops.

25. This output information is from the power initialization-stage calculation for powered HTSTR component ROD 900. The output shows the linear-power generation rate in W m^{-1} (Btu h^{-1} ft^{-1}) units for each of the five NZ node rows (radially integrated) of the first two powered average rods and the last powered supplemental rod that has a power-peaking factor of 1.678. The linear-power generation rate has been normalized to give a total power of 2.300000E+09 W (7.875223E+03 Btu h^{-1}) from the NCRX = 6 average-

power RODs wherein each average-power ROD element represents RDX = 5.33800E+03 fuel-rod elements.

26. The VOL, FAYT, FAZ, and FAXR values printed for VESSEL component 1 are the coolant mesh-cell volumes and interface flow areas determined during the initialization stage of the calculation from the geometric dimensions of the VESSEL component and the volume and flow-area fractions input. All of the level 1 and 12 output is shown along with the initial part of the level 2 output. The summed coolant volume of each level and of all levels up to and including that level is shown as well. We see from the level 12 output that the VESSEL component has a total coolant volume of 9.517555E+01 m^3 (3.361093E+03 ft^3).

27. This output shows the internally computed (during the initialization stage) vertical-height change across each 1D hydraulic component based on its DX and GRAV input data. Only the height changes across PIPE 10, PIPE 12, PIPE 14, PIPE 7, PIPE 100, TEE 105, TEE 110, TEE 190, and VALVE 316 are shown in the segmented output. The TRAC-P user can use this information from the full output to sum the vertical height changes around a computational loop to verify a net vertical height change equal and opposite to the height change between its interface-centered source-connection junctions to VESSEL component 1.

28. Because NAMELIST variable IKFAC = 1 and K-factors are input, the j interface $FRIC_j$ = K-$factor_j$ * HD_j / ($\Delta X_{j-1} + \Delta X_j$) values that were evaluated during the initialization stage of the calculation are output. This information is useful because it provides FRIC values based on the abrupt flow-area change irreversible flow-loss K-factors internally evaluated by TRAC-P for interfaces having NFF < 0 values. Inputting K-factor values is more physically intuitive to the user than inputting FRIC values.

29. A restart data dump is generated at the start of every TRAC-P calculation (after the input and restart data are processed and all other parameters initialized but before the first timestep is evaluated). Restarting a CSS calculation from this data dump would produce results identical to that of starting with the input-data TRACIN file shown in Section E.7.

30. The first set of Timestep Data is echoed from input. These minimum and maximum timestep sizes, heat-transfer calculation timestep ratio, convective energy-error limit, and the various output-edit time intervals will be used from the start of the CSS calculation at 0.0 s to the time domain end at TEND = 1.0000E+01 s.

31. This warning message indicates that the initial axial-power shape of powered HTSTR component ROD 900 at axial-power-shape table abscissa coordinate ZPWIN = 1.0000E+00 s is not consistent with the axial-power shape defined at the table's initial independent-variable value of 0.0 s problem time. The input-data preparer did not take care in defining the initial condition of these two input quantities (ZPWIN and TIMET = 0.0000E+00 s) consistently. ZPWIN = 0.0000E+00 s should have been input.

Because the axial-power-shape table has only one axial-power shape, the calculational results will not be affected by this, because there will not be an initial step change in axial-power shape because of this inconsistent input definition of the initial abscissa-coordinate value.

32. The first short and large (long) edit is generated by TRAC-P at time TIMET = 0.0000E+00 s (word 2 on Main-Data card 3) before starting its timestep calculation. The user does not have control through Timestep Data of not generating this initial short and large edit. Through Timestep Data, the user has selected that the next short and large edit will be at TIMET + EDINT or SEDINT = 0.0 s + 10.1 s = 10.1 s. With TEND = 1.0000E+01 s and DTMAX = 1.0000E-01 s, the problem time will not reach 10.1 s while this Timestep-Data set is in effect. As a result, the user has selected no short and large edit during this Timestep-Data set by defining EDINT or SEDINT ≥ TEND + DTMAX.

33. The short edit at problem time TIMET = 0.0000E+00 s contains information about the nature of the numerical solution. Because the timestep calculation has not been evaluated yet, this initial short edit has mostly default values. The problem time is 0.000000E+00 s and the timestep size is the value of DTMIN = 1.0000E–03 s, which is the default at the start of an initial (nonrestart) calculation (where the TRACIN file defines all input data). These undefined short-edit parameters will be discussed later in note 46 for the next short edit where the significance of these calculation-determined values can be discussed.

34. Output at the end of a short edit is the current CPU execution time of this calculation, current total CPU time of the initial and all restart calculations, and the number of timesteps thus far required by the TRAC-P calculation/s. The billing time at Los Alamos is based on the accumulated CPU execution time and computer-dependent fractions the I/O plus MEM usage times, which makes the billing time more than the CPU execution time. The number of timesteps includes the number of timesteps from prior calculations that TRAC-P may have restarted from. For an initial calculation, the number of timesteps is 0 in the initial short edit.

35. The first part of a large edit contains the values of the control-parameter signal variables, control blocks, trip set status, and trip signals at the start of the previous timestep when they were last evaluated. For this initial large edit, the values correspond to the start of the present timestep based on the input-data for the modeled system. Note that in the signal-variable and control-block outputs, the values for signal variable ID numbers 9901, 9902, and 9903 and control-block ID numbers –9901, –9902, and –9903 are shown even though these control parameters were not user specified through input. These signal variables and control blocks were generated internally by TRAC-P for the NCONTR = 3 (word 4 on Main-Data card 6) CSS controllers that the user selected for the STDYST = 2 (word 1 on Main-Data card 4) CSS calculation. For system models to be evaluated by a CSS calculation, signal variable IDs 9901 to 9900+2*NCONTR and control block

IDs –9901 to –9900–NCONTR must not be defined by the user in the TRACIN file. Twice as many signal variable ID numbers than control block ID numbers are reserved because CSS type 3 controllers require two internally defined signal variables and one control block while all other CSS controllers require one signal variable and one control block.

36. A maximum Stanton number of 1.759790E+03 in the plant-model heat-structure components was determined by TRAC-P to be in unpowered HTSTR component SLAB 931 (the loop 1 steam-generator wrapper wall between the boiler and downcomer). The dimensionless Stanton number is the ratio of the dimensionless Nusselt number divided by the product of the dimensionless Reynolds and Prandtl numbers for a heat-transfer surface coupled to a hydraulic channel.

37. Only the large-edit output from the first PIPE component 10 and last HTSTR component ROD 938 is shown with 9119 lines deleted in between. The PIPE component 10 output shows hydraulic-parameter values in its first table and pipe-wall heat-transfer parameters in its second table. The power from the pipe wall is zero because the wall and single-phase liquid coolant temperatures are initially the same at 591.1 K (604.3°F). The last line shows the current component-summed coolant mass and energy. The calculated initial mass is the current coolant mass plus the net coolant-mass inflow since the start of the calculation. This value should not change from large edit to large edit if the calculated coolant mass of the component is conserved.

38. The HTSTR component ROD 938 output shows for each of its NCRX = 3 (loop 1, 2, and 3 steam-generator dryer structure) ROD elements the r vs z node temperatures in its first table and the inner and outer surface heat-transfer parameters for coupling to their hydraulic channels in its second and third tables. Both hydraulic channels only have steam; therefore, the liquid heat-transfer coefficients are zero. Surface and volume-averaged thermal conductivities (0.00000E+00 in this initial large edit because they are not yet evaluated), total surface areas, and total power across each surface are shown at the end of the ROD 938 output. These total values are summed over all NCRX = 3 ROD elements.

39. The current total coolant mass and energy in the entire system model and the total mass discharged to all BREAK components and total mass injected from all FILL components during the calculation are printed at the end of each large edit. The computed system initial total coolant mass (which should not change from large edit to large edit if the calculated system coolant mass is conserved) is the current total coolant mass minus the total mass discharged by all BREAK components plus the total mass injected by all FILL components.

40. The liquid-level trip signal of pressurizer-heater low-level trip –407 rises above the trip's S_2 = 1.5000E-01 setpoint causing TRAC-P to change the trip set status from OFF to $ON_{forward}$ with no setpoint delay time. Trip –407 is the

only trip with a negative ID number that is evaluated during the steady-state calculation. When the trip's ITST input-data parameter has a positive value, a trip must be evaluated and its trip signal must cross a tested setpoint to output the first two lines of this message. Its setpoint delay time then must pass before the third line is output indicating a change in the trip's set status.

41. At problem time 2.071103 s, the steady-state power level is reset to 2.30000E+09 W (7.84792E+09 Btu h^{-1}) in the powered fuel rods of the reactor-core region modeled by HTSTR component ROD 900. Before this time, the power in the fuel rods was 0.0 W (0.0 Btu h^{-1}). NAMELIST variables IPOWR = –1 and TPOWR = 2.0 s controlled the TRAC-P logic for turning the steady-state reactor-core power on at the start of the first timestep after 2.0 s.

42. During a steady-state calculation, TRAC-P tests for steady-state solution convergence every 5 timesteps and for every timestep when a large edit is output to the TRCOUT file (except for the initial large edit discussed above). The information in this steady-state convergence-test results table is output to the TRCOUT file every 100 timesteps and for every timestep when a large edit is output to the TRCOUT file. The steady-state solution convergence test is based on comparing the maximum fractional change per second of each of the seven thermal-hydraulic parameters shown in the table (total pressure, liquid velocity, gas velocity, gas volume fraction, liquid temperature, gas temperature, and noncondensable-gas pressure) everywhere in the system model with the user input-specified EPSS (word 2 on Main-Data card 5) steady-state convergence criterion. All seven maximum fractional change per second values must be less than EPSS for steady-state solution convergence to be satisfied and for TRAC-P to end the calculation before the time domains of all Timestep Data have been evaluated. We see in this output table at timestep number 100 and problem time 2.234650 s that the maximum fractional change per second values are large compared with EPSS = 1.0000E-04. The solution state of the system model still is changing rather rapidly. Testing against the maximum fractional change per second rather than per timestep provides a better test for steady-state convergence because it doesn't depend on the timestep size that is being used.

43. When the steady-state calculation is a CSS calculation, a table showing the current status of all CSS controllers is printed after the steady-state convergence-test table discussed in note 42. The columns denoting component type and number, minimum and maximum values of the adjusted parameter, and the desired value for the monitored parameter are input-specified values for each of the controllers. The current status of the controller action is seen in the values of the adjusted parameter and the monitored parameter. By making changes in the adjusted parameter, the controller is attempting to affect the solution state of the system model in a way that causes the monitored parameter value to change to the desired value. Adjustment is not allowed outside the minimum to maximum value

range. When the adjusted parameter reaches either limit, the controller has no further ability to affect the system model until the controller adjustment changes direction. Constraining an adjusted parameter to a reasonable adjustment range keeps inappropriate conditions of a rapidly changing solution from causing a controller to make inappropriate adjustments that may hinder or prevent a steady-state solution from being determined. Before steady-state convergence EPSS-test conditions can be satisfied, CSS controller adjustments must become very small. Because local conditions of the monitored parameter can change somewhat irregularly at times as the solution approaches steady-state conditions, constraining the rate of change of the component actions controlled by the CSS controllers is sometimes necessary to achieve steady-state convergence. This is done with the component-action maximum rate of change input parameter that is part of the component data (for example, ROMGMX = 5.0000E+01 rad s^{-2} for the PUMP components).

44. The second and third Timestep-Data sets do not output short and large edits because their values of TEND – set-use start time < EDINT or SEDINT + DTMAX.

45. A steady-state convergence-test results table and a constrained steady-state calculation parameters table are output every 100 timesteps. The CSS pump controller adjustments have settled down and become small by the timestep number 200 edit at problem time 12.539873 s and thereafter. The maximum fractional change per second of the liquid velocity, gas velocity, and gas volume fraction in secondary-side components does not settle down and stays large through the entire TEND = 2.0000E+02 s calculation.

46. At problem time 200.0693 s, TEND = 2.0000E+02 s of the third Timestep-Data set is exceeded. DTMIN = –1.0000E+00 is read in and defines the end flag for TRAC-P terminating the steady-state calculation.

47. TRAC–M outputs a final short and large edit with problem time reset to 0.0 s to signify that this is the solution-state data output to the final data dump. This is done when a short and large edit isn't output by TRAC-P at the final problem time of 200.0693 s based on the EDINT and SEDINT time intervals of the final Timestep-Data set. This large edit shows the steady-state solution of interest that will be used to restart the transient calculation. Having only an initial and final large edit from a steady-state calculation generally provides sufficient calculative information for most users. Generating a hard copy of the TRCOUT file may require only printing the last large-edit portion of the file. With a text editor, the user can search for the character string "large" to find the first line of each large edit. The last large-edit portion of the TRCOUT file can then be copied to another file for printing.

48. Items in the final short edit will be discussed that were not commented on in note 33 for the initial short edit (because they did not have calculational values). The final timestep number 1262 required 2 outer iterations to converge the outer-stage pressure-matrix solution. The maximum con-

vective power difference was a large 5.423525E+07 W (1.8506E+08 Btu h^{-1}) in HTSTR component ROD 900 early in the calculation (a wrong problem time of –1.0 s is output by this new programmed feature). The coolant-flow material-Courant limit in mesh cell 1 of the loop 2 main steam-line TEE component 210 would have limited the current timestep size to 1.1290E-02 s without the SETS1D numerical method. Instead, the current timestep size was 2.1930E-01 s. The average number of outer iterations per timestep was 2.279 over the last 1267 timesteps. That means that 5 of those timesteps were backup calculations because the current timestep number is 1262. For the 1262 timestep calculations whose outer-iteration converged, the maximum number of outer iterations was 6 at timestep number 100. The tabular data defines the number of timesteps since the last short edit at the beginning of the calculation where each hydraulic component was the last to satisfy the EPSO (word 1 on Main-Data card 5) convergence criterion for the outer-stage pressure-matrix solution. The hydraulic-component numbers (shown in parentheses) are ordered according to the reordered IORDER-array output list discussed in note 23. Note that outer-iteration convergence was limited primarily by the secondary-side components. The different timestep size maximum values are shown next. They are based on criteria for a stable numerical evaluation of various transient phenomena. Values of 1.0000E+08 s indicate that this criterion currently does not limit the timestep size or that its limit exceeds the 1.05*DELT maximum-increased timestep size for the next timestep. The number of timesteps since the last short edit where that criterion limited the timestep size is shown by the integer values. Only 74+1+1 = 76 timesteps were limited by these criteria. This does not included the timesteps where DTMAX limited the timestep size. The total CPU execution time was 1.841768E+04 s (5.1160 h) for the steady-state calculation on a SUN Sparc 2 workstation.

49. The signal-variable, control-block and trip parameter values output define the control-procedure logic state of the assumed (because convergence wasn't satisfied) steady-state solution. The signal-variable parameter labels and the units symbols help define the values. Their comment lines in the TRACIN file and operator diagrams in the input-data echoed portion of this TRCOUT file provide further defining information.

50. PIPE component 100 and TEE components 105 and 190 model the secondary side of the loop 1 steam generator. The initial liquid drained state, with the liquid being in the boiler and lower downcomer sections, now for the steady-state solution, has a significant amount of liquid (0.2 to 0.3 liquid volume fraction) in the separator and (0.6 to 1.0 liquid volume fraction) in the upper downcomer. The initial total coolant mass inventories of 2.51389E+04 kg, 1.58817E+03 kg, and 8.75076E+03 kg for these components from the initial large edit closely agree with their final large edit computed initial total coolant mass inventories of 2.51389E+04 kg, 1.58810E+03 kg, and 8.75075E+03 kg, respectively. The largest mass conservation error is –0.07 kg in TEE component 105.

51. The VESSEL component 1 output is organized by levels with the array parameters of levels 1 and 12 shown in their entirety and of levels 2 and 11 shown in part. The total power to the single-phase liquid in the VESSEL is 2.29951E+09 W (7.84625E+09 Btu h^{-1}) in the summary output after the level array data. This is the heat flux summed over the outer surface of all HTSTR components coupled to VESSEL component 1. The heat flux is summed over the outer surfaces of powered HTSTR component ROD 900 [which has a steady-state power of 2.3000E+09 W (7.8479E+09 Btu h^{-1})] and unpowered HTSTR component SLABs 901 through 909. For a fully converged steady-state solution, 2.29951E+09 W would be 2.3000E+09 W (HTSTR power in equals HTSTR power out). Volume summed and averaged parameters are shown for the lower plenum, reactor core, upper plenum and downcomer regions in the VESSEL. The calculated initial total coolant mass of 6.78684E+04 kg is identical to the initial total coolant mass in VESSEL component 1 in the initial large edit.

52. The HTSTR component ROD 900 output shows the node temperatures and outer-surface heat-transfer parameters for the NCRX = 6 powered average ROD elements and the NRODS–NCRX = 6 powered supplemental ROD elements that have power peaking factors of 1.6780. The total power generated in these average ROD elements is shown in the second output line to be a reactor-core power of 2.300000E+09 W (7.8479E+09 Btu h^{-1}). The total power from the outer surface of these average ROD elements is shown in the summary output after the data of all 12 ROD elements to be 2.29995E+09 W (7.84791E+09 Btu h^{-1}). The difference of the later from 2.29951E+09 W (7.84625E+09 Btu h^{-1}) transferred to the VESSEL coolant (see note 51) is 4.4E+05 W (1.66E+05 Btu h^{-1}), which is still heating up the HTSTR components that are couple to the VESSEL.

53. The HTSTR component ROD 938 outputs NCRX = 3 ROD elements that model the structure of the steam dryers of the loop 1, 2, and 3 steam generators. We see slight differences in the steady-state solution among the 3 ROD elements. That is because the secondary-side piping of each steam generator is slightly different.

54. The summary parameters at the end of the large edit show the steady-state solution 4.544427E+13 kg (1.001874E+14 lb_m) total coolant mass of the system model hasn't changed (to within the ±5.0E+06 kg significant-digit accuracy of the output value) from its initial solution estimate that was input. The summed BREAK and FILL inflows of 3.882591E+04 kg + 1.751353E+03 kg = 4.057726E+04 kg (8.945752E+04 lb_m) on the secondary side are less than that roundoff.

55. The constrained steady-state calculation parameters table was output to the TRCOUT file at problem time 200.0693 s because a large edit was generated. A steady-state convergence-test table was not output because the EDINT large-edit frequency did not control the output of the large edit, and the timestep number 1262 was not a multiple of 5. Either one of these needs to

be satisfied for the seven maximum fractional change per second parameters to be evaluated by TRAC-P and their values output by the table.

56. A data dump is not sent to the TRCDMP file up to problem time 200.0693 s because the DMPINT = 1.0030E+02 s data-dump edit time interval (specified in the last Timestep-Data set) defined an unreachable later edit time (100.174 s + 100.30 s = 200.474 s) because TEND = 2.0000E+02 s and DTMAX = 3.0000E-01 s. A final data dump, labeled with problem time 0.000000 s, is generated automatically by TRAC-P at the end of a steady-state calculation. It is the data dump that will be used for the restart transient calculation.

57. At TEND = 2.0000E+02 s of the last Timestep-Data set, TRAC-P ends the CSS calculation without having satisfied the EPSS = 1.0000E-04 steady-state convergence test criterion. A warning message to that effect is output 7 lines from the end of the TRCOUT file. Timestep number 1200 maximum fractional change per second values of –3.315537 s^{-1} for the liquid velocity, –1.849876 s^{-1} for the gas velocity, and -0.696953 s^{-1} for the gas volume fraction at the TEE component 305 internal-junction JCELL = 6 of the loop 3 steam-generator separator indicate the secondary-side solution is not settling down. It is felt that the nature of the steam-generator secondary-side model has created oscillatory behavior. To diagnose the cause and be able to better converge the steady-state solution by introducing appropriate modeling changes, the steam-generator secondary-side solution behavior would need to be examined and its cause-and-effect understood. This can be done most effectively with graphics output.

58. The CPU execution time of 1.8424E+04 s (5.1178 h) for the TRAC-P steady-state calculation was on a SUN Sparc 2 workstation.

H.2. Listing of the Steady-State Calculation TRCOUT-File Segments.

 this is a sample problem for the trac-p users guide manual.  it models
 a westinghouse 2308-mwt powered nuclear-core, three-loop pressurized
 water reactor with constrained steady-state and transient calculations.
 this full-plant model evaluates a steam-generator single-tube double-
 ended-guillotine break transient with primary-coolant pumps operating.
 this input-data model contains the following components and subsystems:
```

```
  1) three-dimensional (r=2,t=6,z=12) reactor vessel;
  2) vessel upper-plenum guide tubes;
  3) powered-rod and unpowered-slab heat structures in the vessel;
  4) three primary- and secondary-coolant loops modeled individually;
  5) makeup, letdown, and pressurizer-sprayer cvcs flows;
  6) accumulator and hpsi fills in each primary-coolant loop;
  7) pressurizer and pressurizer porv and srv;
  8) pressurizer, steam generator, and steam-dump control systems;
  9) single-tube degb leakage path in loop 2 steam generator;
 10) main-steam and steam-dump lines;
 11) high-pressure feedwater system after hp heaters; and
 12) auxiliary-feedwater fills (motor and steam driven).
the w3loop input-data model has the following developmental history:
  james lime created the trac-pf1/mod1 input-data model on 7/84.
  robert steinke converted the trac-pf1/mod1 input-data model with
  gocnvt to a trac-pf1/mod2 input-data model and added component-
  network diagrams on 9/90. marvin salazar added units labels to
  the control blocks and trips for si/english units i/o on 10/93.
  robert steinke replaced stgen components with htstr, pipe, and tee
  components on 2/96.  James lime upgraded the w3loop input-data model
  to be consistent with the current h.b.robinson plant model on 5/96.

total convective energy to the fluid during hydro solution:
                  inside surface=  0.0000000E+00 w*s      outside surface=  0.0000000E+00 w*s

errors in conservation of convective energy at the wall between hydro and conduction solutions:
      inside convective energy error: absolute=  0.00000E+00 w*s     effective=  0.00000E+00 w*s
     outside convective energy error: absolute=  0.00000E+00 w*s     effective=  0.00000E+00 w*s

inner-surface node-interval thermal conductivity is  0.00000E+00    w/m/k
outer-surface node-interval thermal conductivity is  0.00000E+00    w/m/k
effective  r-direction wall thermal conductivity is  0.00000E+00    w/m/k
which have been axially averaged over all   3 average-power rod s

total inner surface area is  6.61197E+02 m2  and
total outer surface area is  6.62564E+02 m2  of all   3 average-power rod s

total power from the heat-structure inner surface is -8.94663E+04   w    and outer surface is -8.96513E+04   w

system results

                    system total coolant energy is  9.312152E+18 w*s

                      system total coolant mass is  4.544427E+13 kg

total coolant mass discharged by break components is  0.000000E+00 kg

   total coolant mass injected by fill components is  0.000000E+00 kg

       system computed initial total coolant mass is  4.544427E+13 kg

trac large edit ← 47

problem time is 0.000000E+00 s, time-step size is 2.1930E-01 s, time-step number is 1262, outer-iteration number is 2

maximum convective power difference has been 0.5423525E+08 w in component 900 at time-1.0000000E+00 s
time-step size was limited by component 210 at cell 1 to 1.1290E-02 s
average outer-iteration count over the last 1267 time steps was 2.279
last minimum number of outer iterations was 2 at time step 1261 (limited by component 190 with fr.error of 2.8460E-06)
last maximum number of outer iterations was 6 at time step 100 (limited by component 300 with fr.error of 9.9536E-06)
total number of times that each component (id#) was the last to converge since the last short edit

inner-surface node-interval thermal conductivity is 2.77658E+00 w/m/k
outer-surface node-interval thermal conductivity is 1.64769E+01 w/m/k
effective r-direction wall thermal conductivity is 3.59039E+00 w/m/k
which have been axially averaged over all 6 average-power rod s

total inner surface area is 0.00000E+00 m2 and
total outer surface area is 3.96347E+03 m2 of all 6 average-power rod s

52

total power from the heat-structure inner surface is 0.00000E+00 w and outer surface is 2.29995E+09 w

```
average-power rod   6 has the peak surface temperature of  6.09177E+02 k
supplemental  rod  12 has the peak surface temperature of  6.21962E+02 k

total mass of hydrogen (based on the average temperature of all average-power rod s) is  0.00000E+00 kg

H.3. Notes on the Transient Calculation TRCOUT-File Segments.

The output from the transient calculation TRCOUT file is reviewed in this section to provide a description of its contents. Items already discussed in Sec. H.1 for the steady-state calculation TRCOUT file will not be discussed here unless additional comments are needed on that item. Notes in this section are referenced by callouts that are marked on the TRCOUT-file segmented output in Section H.4. For example, [1] is note 1.

1. This is a restart transient calculation from the last restart data dump of the steady-state calculation. The values of all the NAMELIST variables are output. The NAMELIST variables defined by the user in the steady-state calculation have their same values defined for the transient calculation. The only exceptions are IPOWR and TPOWR (which are not defined for the transient calculation because they control the logic for setting the steady-state calculation reactor-core power on) and DTSTRT = 1.0000E-03 s (which defines the initial timestep size for the restart calculation rather than using DELT = 0.219304 s from the last data dump).

2. NCOMP = 131 for the transient calculation is 1 less than for the steady-state calculation because FILL components 202 and 203 are replaced by PIPE component 202 to model the double-ended-guillotine break, single-tube flow path between the primary and secondary sides of the loop 2 steam generator.

3. A new signal variable IDSV = 2020 defines the ISVN = 69 coolant mixture mass flow of the single-tube, double-ended-guillotine break at interface ICN1 = 1 of PIPE component ILCN = 202. This required increasing the 65 signal variables from the steady-state calculation (which will be input from the restart data dump) by 1 to NTSV = 66 signal variables in the transient calculation. An existing control block IDCB = –414 on the restart data dump of the steady-state calculation is reinput by the TRACIN file with no change in its definition as an example of reinputting a control block with the potential of changing its definition. The NTCB = 238 total number of control blocks stays the same.

4. FILL components 91 and 92 are reinput (rather than being input from the restart data dump) to redefine the VMSCL = 0.0000e+00 scalar factor for the VMTBM table to turn off the letdown and makeup flows during the transient calculation.

5. A new PIPE component 202 is input to replace no-flow FILL components 202 and 203 and model the double-ended-guillotine break, single-tube flow path between the TEE component 22 primary-coolant side and TEE component 200 secondary-coolant side of the loop 2 steam generator. Its liquid coolant temperature and pressure are initialized to 5.66000E+02 K (5.5913E+02°F) and 1.54000E+07 Pa (2.2336E+03 psia), which are intermediate values between the JCELL steady-state values of 5.749E+02 K (5.7515E+02°F) and 1.5462E+07 Pa (2.2426E+03 psia) of TEE component 22

and 5.451E+02 K (5.2151E+02°F) and 5.6465E+06 Pa (8.1896E+02 psia) of TEE component 200, respectively.

6. The TRCRST file will be searched for the as yet undefined 65 signal variables, 237 control blocks, 72 trips, and 131 components.

7. The input-data output echo from the TRACIN file ends here. Because the control-parameter and component data were not all defined by the input-data TRACIN file, TRAC-P reads the restart data-dump TRCRST file and outputs the following header information: the date and time the restart data file was created for traceability, the problem title cards, and the timestep number of the restart data dump that is used. Main-Data card 3 variable DSTEP = –1 from the TRACIN file specifies that the last data dump on the TRCRST file is to be used for this restart transient calculation; i.e., the steady-state calculation data dump at timestep number 1262 where problem time 200.0693 s was redefined to be 0.00000E+00 s for the start of the transient calculation.

8. The parameter values from the TRCRST file are output echoed to the TRCOUT file in the same format as if they were defined by the TRACIN file. More parameter values are read from the restart data dump than are shown in the input-data format output echo. The other parameter values that are not output here are defined by the restart data dump to initialize the restart continuation of a time-dependent solution correctly. Had the input-data format parameter values been defined from the TRACIN file, these other parameters would have their values initialized by TRAC-P during the initialization-phase calculation based on assumed steady-state conditions. For the most part, TRAC-P initializes their values to the values that would come from the restart TRCRST file for a steady-state solution data dump (except for the effect of round-off due to fewer digits being defined by the TRACIN-file format). Some parameters, however, will have different values because of their being initialized to the solution state one timestep later or because of their having lost time-history effects from the prior calculation because they are time-constant averaged. In summary, the TRAC-P user should recognize that more parameters are defined from the TRCRST file than from the TRACIN file in defining the control-parameter or component solution state. Some of the parameter values that are initialized by TRAC-P (because they are not defined by the TRACIN file) may have different values than if they were defined from the TRCRST file. This can result in a restart calculation being slightly different based on the initial solution state being defined by the TRCRST file for a time-dependent solution state rather than by the TRACIN file for an assumed steady-state solution state.

9. The initial data dump generated by TRAC-P is identical to the final data dump input from the TRCRST file except for the changes made by the TRACIN file.

10. The loop 2 steam-generator single-tube, double-ended-guillotine break rupture causes a mild transient that depressurizes the primary-coolant

system in < 1000.0 s of problem time. TRAC-P will evaluate TEND = 6.0000E+02 s of that transient with timestep and output-edit control by one Timestep-Data set. NAMELIST variable DTSTRT = 0.001 s rather than DTMIN = 1.0000E-05 s defines the initial timestep size. Short and large edits are to be output every SEDINT = EDINT = 1.0000E+02 s to the TRCOUT file, graphics data are to be output every GFINT = 5.0000E+00 s to the TRCGRF file, and data dumps are to be output every DMPINT = 2.0000E+02 s to the TRCDMP file.

11. The following edit of the reactor-core total power and neutron multiplication constant K_{eff} (plus the core-region averaged reactivity feedback parameters and their associated feedback reactivities if IRPWTY > 10) is generated every NRTS timesteps. Both IRPWTY = 4 and NRTS = 10 were defined on card number 11 of HTSTR component ROD 900. When the reactor-core power is scrammed by trip IRPWTR=10 being set to $ON_{forward}$ at problem time 0.003050 s, this output shows the point-reactor kinetics solution's value of K_{eff} prompt plus decay-heat total power deposited in the fueled rods of the reactor-core region. The value of K_{eff} is affected by the programmed reactivity of the inserted safety control rods (defined by the RPWTBR array component-action table) and the feedback reactivity from changing thermal-hydraulic conditions in the reactor core (if IRPWTY > 10).

12. The initial large edit at the start of this restart transient calculation is the same as the final large edit at the end of the steady-state calculation (at the time of the final data dump) except for the TRACIN-file defined signal variable ID 2020, control block ID–414, and components FILL 91, FILL 92, and PIPE 202 and deleted FILL components 202 and 203. The control-parameter values and some of the component global parameters that are defined one timestep later may have slightly different values.

13. From problem time 0 to 61 s during the transient, messages are output that the trip signals of trip IDs 10, 16, 18, 20, 21, 26, 28, 32, 34, 46, 54, 60, –407, and 422 crossed a tested setpoint and their set status was changed. These messages were output because ITST > 0 for these trips. Other trips with ITST < 0 may have had their trip signal cross a tested setpoint followed by a change of their set status, but messages were not output because their ITST < 0. To control the amount of these trip messages, users generally only define component-action controlling trips with ITST > 0. For example, a coincidence trip controlling a component action would have ITST = 3 > 0 for change messages to be output (trip ID 10 with ITST = 3 controls the reactor-core power scram), but its trip-controlled-trip trip-signal defining trips would have ITST < 0 (the trip ID 10 trip signal is the summed set status of trip IDs 12 and 14, which have ITST = –3). Note that trip ID 21 has a 20.0 s set-status change delay time and trip IDs 26 and 28 have a 30.0 s set-status change delay time as defined by the user through input.

14. Short and large edits are output every SEDINT = EDINT = 1.0000E+02 s and data dumps are output every DMPINT = 2.0000E+02 s. Each of those large edits show only 1141 lines of control-parameter and PIPE IDs 10 and 7,

VESSEL ID 1, and HTSTR RODs 900 and 938 solution-state results, while 8604 lines of the solution-state results for the other 126 components are deleted. These segmented portions of each large edit present a reasonable amount of information and demonstrate the solution state of five components at six different problem times during the transient calculation. The set status of all trips are shown as part of the control-parameter data of each large edit. Trips whose set status changed without a descriptive message being output because ITST < 0 (see note 13) have their set status indicated in each large edit.

H.4. Listing of the Transient Calculation TRCOUT-File Segments.

                        input data is being processed
main control card parameters

    numctr =         28,      ieos =           0,      inopt =          1,      nmat =           0,      id2o =           0

                           h2o properties are used

number of title cards is:   28
this is a h.b.robinson-2 steam-generator one-tube-rupture transient.
hbr-2 is a 2300 mwt, three-loop westinghouse nuclear plant located
in hartsville, s.c., that is owned and operated by the carolina
power and light company (cp&l).  this plant model was developed for
reactor-coolant pump (rcp) trip analysis by james lime for trac-pf1
```

```
/mod1 on 7/84.  it was converted for trac-pf1/mod2 by robert steinke
and james lime on 5/96.  the trac-pf1/mod2 steady-state calculation
plant model has been modified to handle the following loss-of-coolant
accidents, through transient input-data tracin-file changes, allowing
the same steady-state restart data-dump file to be used:
  1) cold-leg small break without pump trip,
  2) cold-leg small break with pump trip,
  3) one-tube steam generator tube rupture,
  4) two-tube steam generator tube rupture, and
  5) 100% cold-leg degb large break.
this input-data model contains the following components and subsystems:
  1) three-dimensional (r=2,t=6,z=12) reactor vessel;
  2) vessel upper-plenum guide tubes;
  3) powered-rod and unpowered-slab heat structures in the vessel;
  4) three primary- and secondary-coolant loops modeled individually;
  5) makeup, letdown, and pressurizer-sprayer cvcs flows;
  6) accumulator and hpsi fills in each primary-coolant loop;
  7) pressurizer and pressurizer porv and srv;
  8) pressurizer, steam generator, and steam-dump control systems;
  9) single-tube degb leakage path in loop 2 steam generator;
 10) main-steam and steam-dump lines;
 11) high-pressure feedwater system after hp heaters; and
 12) auxiliary-feedwater fills (motor and steam driven).

 restart file header
```

```
the restart file was created on 05/21/96 at 10:46:03 with  132 components.

the problem id was
this is a sample problem for the trac-p users guide manual.  it models
a westinghouse 2308-mwt powered nuclear-core, three-loop pressurized
water reactor with constrained steady-state and transient calculations.
this full-plant model evaluates a steam-generator single-tube double-
ended-guillotine break transient with primary-coolant pumps operating.
this input-data model contains the following components and subsystems:
  1) three-dimensional (r=2,t=6,z=12) reactor vessel;
  2) vessel upper-plenum guide tubes;
  3) powered-rod and unpowered-slab heat structures in the vessel;
  4) three primary- and secondary-coolant loops modeled individually;
  5) makeup, letdown, and pressurizer-sprayer cvcs flows;
  6) accumulator and hpsi fills in each primary-coolant loop;
  7) pressurizer and pressurizer porv and srv;
  8) pressurizer, steam generator, and steam-dump control systems;
  9) single-tube degb leakage path in loop 2 steam generator;
 10) main-steam and steam-dump lines;
 11) high-pressure feedwater system after hp heaters; and
 12) auxiliary-feedwater fills (motor and steam driven).
the w3loop input-data model has the following developmental history:
  james lime created the trac-pf1/mod1 input-data model on 7/84.
  robert steinke converted the trac-pf1/mod1 input-data model with
  gocnvt to a trac-pf1/mod2 input-data model and added component-
  network diagrams on 9/90. marvin salazar added units labels to
  the control blocks and trips for si/english units i/o on 10/93.
  robert steinke replaced stgen components with htstr, pipe, and tee
  components on 2/96.  James lime upgraded the w3loop input-data model
  to be consistent with the current h.b.robinson plant model on 5/96.

 trac large edit

 problem time is 0.000000E+00 s, time-step size is  1.0000E-03 s, time-step number is      0, outer-iteration number is  0

 maximum convective power differance has been-0.1000000E+01   w    in component    0 at time-1.0000000E+00 s
 time-step size was limited by component   0 at cell   0 to 1.0000E+08 s
 average outer-iteration count over the last     0 time steps was    0.000
 last minimum number of outer iterations was  0 at time step     0 (limited by component   0 with fr.error of 0.0000E+00)
 last maximum number of outer iterations was  0 at time step     0 (limited by component   0 with fr.error of 0.0000E+00)
 total number of times that each component (id#) was the last to converge since the last short edit

inner-surface node-interval thermal conductivity is 2.77658E+00 w/m/k
outer-surface node-interval thermal conductivity is 1.64769E+01 w/m/k
effective r-direction wall thermal conductivity is 3.59039E+00 w/m/k
which have been axially averaged over all 6 average-power rod s

total inner surface area is 0.00000E+00 m2 and
total outer surface area is 3.96347E+03 m2 of all 6 average-power rod s

total power from the heat-structure inner surface is 0.00000E+00 w and outer surface is 2.29992E+09 w

 trac large edit
```

14

```
 problem time is 1.002189E+02 s, time-step size is  2.9771E-01 s, time-step number is  1046, outer-iteration number is  2

 maximum convective power differance has been 0.3176545E+08   w    in component  910 at time 7.7178549E+00 s
 time-step size was limited by component 200 at cell   1 to 9.0866E-03 s
 average outer-iteration count over the last 1051 time steps was   2.734
 last minimum number of outer iterations was  1 at time step  984 (limited by component  14 with fr.error of 9.8254E-05)
 last maximum number of outer iterations was  9 at time step  152 (limited by component 430 with fr.error of 7.4290E-08)
 total number of times that each component (id#) was the last to converge since the last short edit

total power to the component from all heat-transfer surfaces is -1.349176E+05   w
total power to the liquid is -1.349176E+05   w    and total power to the gas is  0.000000E+00   w

total convective energy transported to the fluid from component wall:  1.8153565E+08 w*s
total energy input into the component wall=  0.0000000E+00 w*s
                inside convective energy error: absolute=  3.18004E+07 w*s     effective=  2.40004E+06 w*s

pipe wall total power loss on the inner surface is  1.30279E+05   w    and on the outer surface is  0.00000E+00   w

pipe  component  total coolant mass is  2.15225E+03 kg , total coolant energy is  2.61094E+09 w*s, and
computed initial total coolant mass is  1.93238E+03 kg

total power to the vessel coolant from all heat surfaces is  9.05965E+07   w
total power to the liquid is  9.05965E+07   w    and total power to the gas is  0.00000E+00   w

vessel lower plenum
liquid volume is  2.33861E+01 m3 , liquid volume fraction is  1.00000E+00 and liquid mass is  1.78514E+04 kg
volume-averaged liquid temperature is  5.51505E+02 k and volume-averaged saturation temperature is  5.94173E+02 k

vessel reactor core
liquid volume fraction is  1.00000E+00 and liquid mass is  1.13440E+04 kg
volume-averaged liquid temperature is  5.52291E+02 k and volume-averaged saturation temperature is  5.93515E+02 k

vessel reactor core
inlet  liquid mass flow is  1.28725E+04  kg/s  and inlet  gas mass flow is  0.00000E+00  kg/s
outlet liquid mass flow is  1.28734E+04  kg/s  and outlet gas mass flow is  0.00000E+00  kg/s

vessel upper plenum
liquid volume fraction is  1.00000E+00 and liquid mass is  2.71485E+04 kg
volume-averaged liquid temperature is  5.52830E+02 k and volume-averaged saturation temperature is  5.93463E+02 k

vessel downcomer
liquid volume fraction is  0.00000E+00, liquid mass is  0.00000E+00 kg , volume-averaged pressure is  0.00000E+00  pa
volume-averaged liquid temperature is  0.00000E+00 k and volume-averaged saturation temperature is  0.00000E+00 k

vessel component total coolant mass is  7.19531E+04 kg , total coolant energy is  8.84089E+10 w*s, and
computed initial total coolant mass is  6.78684E+04 kg

inner-surface node-interval thermal conductivity is 5.13977E+00 w/m/k
outer-surface node-interval thermal conductivity is 1.59303E+01 w/m/k
effective r-direction wall thermal conductivity is 5.82666E+00 w/m/k
which have been axially averaged over all 6 average-power rod s

total inner surface area is 0.00000E+00 m2 and
total outer surface area is 3.96347E+03 m2 of all 6 average-power rod s

total power from the heat-structure inner surface is 0.00000E+00 w and outer surface is 8.79439E+07 w

average-power rod 4 has the peak surface temperature of 5.55202E+02 k
supplemental rod 10 has the peak surface temperature of 5.55713E+02 k

total mass of hydrogen (based on the average temperature of all average-power rod s) is 0.00000E+00 kg

 restart dump generated at problem time   200.068671 s after  1383 time steps
1
 trac large edit

 problem time is 2.004179E+02 s, time-step size is  3.4920E-01 s, time-step number is  1384, outer-iteration number is  2

 maximum convective power differance has been 0.3176545E+08   w    in component  910 at time 7.7178549E+00 s
 time-step size was limited by component 200 at cell   1 to 1.0489E-02 s
 average outer-iteration count over the last  338 time steps was   2.178
 last minimum number of outer iterations was  2 at time step 1383 (limited by component  32 with fr.error of 8.4807E-05)
 last maximum number of outer iterations was  4 at time step 1379 (limited by component 202 with fr.error of 6.9931E-07)
 total number of times that each component (id#) was the last to converge since the last short edit

total power to the vessel coolant from all heat surfaces is 6.69581E+07 w
total power to the liquid is 6.69581E+07 w and total power to the gas is 0.00000E+00 w

vessel lower plenum
liquid volume is 2.33861E+01 m3 , liquid volume fraction is 1.00000E+00 and liquid mass is 1.76658E+04 kg
volume-averaged liquid temperature is 5.54792E+02 k and volume-averaged saturation temperature is 5.87514E+02 k

vessel reactor core
liquid volume fraction is 1.00000E+00 and liquid mass is 1.12313E+04 kg
volume-averaged liquid temperature is 5.55366E+02 k and volume-averaged saturation temperature is 5.86816E+02 k

vessel reactor core
inlet liquid mass flow is 1.27426E+04 kg/s and inlet gas mass flow is 0.00000E+00 kg/s
outlet liquid mass flow is 1.27439E+04 kg/s and outlet gas mass flow is 0.00000E+00 kg/s

vessel upper plenum
liquid volume fraction is 1.00000E+00 and liquid mass is 2.69076E+04 kg
volume-averaged liquid temperature is 5.55491E+02 k and volume-averaged saturation temperature is 5.86762E+02 k

vessel downcomer
liquid volume fraction is 0.00000E+00, liquid mass is 0.00000E+00 kg , volume-averaged pressure is 0.00000E+00 pa
volume-averaged liquid temperature is 0.00000E+00 k and volume-averaged saturation temperature is 0.00000E+00 k

vessel component total coolant mass is 7.15196E+04 kg , total coolant energy is 8.86230E+10 w*s, and
computed initial total coolant mass is 6.78684E+04 kg

```

the heat-structure component type is a rod and the component number is 900

reactor-core power is 6.702719E+07 w and neutron multiplication constant keff is 0.966184

rod 1 plane (perpendicular to z direction) coupled to cells 0 (inner) and 1 (outer), peaking factor is 1.0000

inner-surface node-interval thermal conductivity is  5.15828E+00    w/m/k
outer-surface node-interval thermal conductivity is  1.59649E+01    w/m/k
effective  r-direction wall thermal conductivity is  5.84035E+00    w/m/k
which have been axially averaged over all   6 average-power rod s

total inner surface area is  0.00000E+00 m2  and
total outer surface area is  3.96347E+03 m2  of all   6 average-power rod s

total power from the heat-structure inner surface is  0.00000E+00   w    and outer surface is  6.70269E+07   w

average-power rod   4 has the peak surface temperature of  5.56260E+02 k
supplemental  rod  10 has the peak surface temperature of  5.56652E+02 k

total mass of hydrogen (based on the average temperature of all average-power rod s) is  0.00000E+00 kg

 trac large edit                                                    14

problem time is 3.006423E+02 s, time-step size is  3.1107E-01 s, time-step number is  1713, outer-iteration number is  2

maximum convective power differance has been 0.3176545E+08   w    in component  910 at time 7.7178549E+00 s
time-step size was limited by component 202 at cell  11 to 1.3429E-02 s
average outer-iteration count over the last  329 time steps was   2.331
last minimum number of outer iterations was  2 at time step 1712 (limited by component 410 with fr.error of 1.3930E-05)
last maximum number of outer iterations was  4 at time step 1685 (limited by component  32 with fr.error of 5.5398E-05)
total number of times that each component (id#) was the last to converge since the last short edit

total power to the component from all heat-transfer surfaces is -1.701109E+04 w
total power to the liquid is -1.701109E+04 w and total power to the gas is 0.000000E+00 w

total convective energy transported to the fluid from component wall: 1.5939968E+08 w*s
total energy input into the component wall= 0.0000000E+00 w*s
inside convective energy error: absolute= 7.52788E+07 w*s effective= 1.60642E+06 w*s

pipe wall total power loss on the inner surface is 1.64065E+04 w and on the outer surface is 0.00000E+00 w

pipe component total coolant mass is 2.11709E+03 kg , total coolant energy is 2.62663E+09 w*s, and
computed initial total coolant mass is 1.93238E+03 kg

total power to the vessel coolant from all heat surfaces is 5.93698E+07 w
total power to the liquid is 5.93698E+07 w and total power to the gas is 0.00000E+00 w

vessel lower plenum
liquid volume is 2.33861E+01 m3 , liquid volume fraction is 1.00000E+00 and liquid mass is 1.75771E+04 kg
volume-averaged liquid temperature is 5.55776E+02 k and volume-averaged saturation temperature is 5.78703E+02 k

vessel reactor core
liquid volume fraction is 1.00000E+00 and liquid mass is 1.11757E+04 kg
volume-averaged liquid temperature is 5.56308E+02 k and volume-averaged saturation temperature is 5.77940E+02 k

vessel reactor core
inlet liquid mass flow is 1.26791E+04 kg/s and inlet gas mass flow is 0.00000E+00 kg/s
outlet liquid mass flow is 1.26793E+04 kg/s and outlet gas mass flow is 0.00000E+00 kg/s

vessel upper plenum
liquid volume fraction is 1.00000E+00 and liquid mass is 2.67729E+04 kg
volume-averaged liquid temperature is 5.56450E+02 k and volume-averaged saturation temperature is 5.77880E+02 k

vessel downcomer
liquid volume fraction is 0.00000E+00, liquid mass is 0.00000E+00 kg , volume-averaged pressure is 0.00000E+00 pa
volume-averaged liquid temperature is 0.00000E+00 k and volume-averaged saturation temperature is 0.00000E+00 k

vessel component total coolant mass is 7.13036E+04 kg , total coolant energy is 8.86086E+10 w*s, and
computed initial total coolant mass is 6.78684E+04 kg

total power loss by 1-d comp.wall is -6.948410E+06 w*s on the inner surface and  9.426375E+05 w*s on the outer surface
                      system total coolant energy is  9.312153E+18 w*s
                       system total coolant mass is  4.544427E+13 kg
total coolant mass discharged by break components is -8.335128E+04 kg
   total coolant mass injected by fill components is  1.539893E+04 kg
       system computed initial total coolant mass is  4.544427E+13 kg

restart dump generated at problem time   400.081136 s after  2056 time steps
1
 trac large edit

problem time is 4.007157E+02 s, time-step size is  3.1679E-01 s, time-step number is  2058, outer-iteration number is  2

maximum convective power differance has been 0.3176545E+08   w    in component  910 at time 7.7178549E+00 s
time-step size was limited by component 200 at cell   1 to 1.3330E-02 s
average outer-iteration count over the last  345 time steps was   2.081
last minimum number of outer iterations was  2 at time step 2057 (limited by component 410 with fr.error of 5.0362E-06)
last maximum number of outer iterations was  4 at time step 1775 (limited by component  30 with fr.error of 3.5408E-07)
total number of times that each component (id#) was the last to converge since the last short edit

total power to the vessel coolant from all heat surfaces is  5.34273E+07   w
total power to the liquid is  5.34273E+07   w    and total power to the gas is  0.00000E+00   w

vessel lower plenum
liquid volume is  2.33861E+01 m3 , liquid volume fraction is  1.00000E+00 and liquid mass is  1.75485E+04 kg
volume-averaged liquid temperature is  5.56480E+02 k and volume-averaged saturation temperature is  5.79898E+02 k

vessel reactor core
liquid volume fraction is  1.00000E+00 and liquid mass is  1.11593E+04 kg
volume-averaged liquid temperature is  5.56951E+02 k and volume-averaged saturation temperature is  5.79146E+02 k

vessel reactor core
inlet  liquid mass flow is  1.26579E+04  kg/s  and inlet  gas mass flow is  0.00000E+00  kg/s
outlet liquid mass flow is  1.26582E+04  kg/s  and outlet gas mass flow is  0.00000E+00  kg/s

vessel upper plenum
liquid volume fraction is  1.00000E+00 and liquid mass is  2.67356E+04 kg
volume-averaged liquid temperature is  5.57067E+02 k and volume-averaged saturation temperature is  5.79088E+02 k

vessel downcomer
liquid volume fraction is  0.00000E+00, liquid mass is  0.00000E+00 kg , volume-averaged pressure is  0.00000E+00  pa
volume-averaged liquid temperature is  0.00000E+00 k and volume-averaged saturation temperature is  0.00000E+00 k

vessel component total coolant mass is  7.12687E+04 kg , total coolant energy is  8.86564E+10 w*s, and
computed initial total coolant mass is  6.78684E+04 kg

1005  0.00000E+00  2.73150E+02  3.96471E-05  5.78892E+02

inner-surface node-interval thermal conductivity is  5.17233E+00    w/m/k
outer-surface node-interval thermal conductivity is  1.59826E+01    w/m/k
effective  r-direction wall thermal conductivity is  5.85144E+00    w/m/k
which have been axially averaged over all   6 average-power rod s

total inner surface area is  0.00000E+00 m2  and
total outer surface area is  3.96347E+03 m2  of all   6 average-power rod s

total power from the heat-structure inner surface is  0.00000E+00   w    and outer surface is  5.38429E+07   w

average-power rod   4 has the peak surface temperature of  5.57907E+02 k
supplemental  rod  10 has the peak surface temperature of  5.58222E+02 k

total mass of hydrogen (based on the average temperature of all average-power rod s) is  0.00000E+00 kg

 trac large edit

problem time is 5.007272E+02 s, time-step size is  1.5974E-01 s, time-step number is  2449, outer-iteration number is  2

maximum convective power differance has been 0.3176545E+08   w    in component  910 at time 7.7178549E+00 s
time-step size was limited by component 200 at cell   1 to 1.3246E-02 s
average outer-iteration count over the last  394 time steps was   2.043
```

last minimum number of outer iterations was 1 at time step 2447 (limited by component 200 with fr.error of 5.3681E-05)
last maximum number of outer iterations was 4 at time step 2403 (limited by component 210 with fr.error of 1.2542E-07)
total number of times that each component (id#) was the last to converge since the last short edit

total power to the vessel coolant from all heat surfaces is 5.06226E+07 w
total power to the liquid is 5.06226E+07 w and total power to the gas is 0.00000E+00 w

vessel lower plenum
liquid volume is 2.33861E+01 m3 , liquid volume fraction is 1.00000E+00 and liquid mass is 1.75222E+04 kg
volume-averaged liquid temperature is 5.57080E+02 k and volume-averaged saturation temperature is 5.80516E+02 k

vessel reactor core
liquid volume fraction is 1.00000E+00 and liquid mass is 1.11433E+04 kg
volume-averaged liquid temperature is 5.57527E+02 k and volume-averaged saturation temperature is 5.79770E+02 k

vessel reactor core
inlet liquid mass flow is 1.26391E+04 kg/s and inlet gas mass flow is 0.00000E+00 kg/s
outlet liquid mass flow is 1.26393E+04 kg/s and outlet gas mass flow is 0.00000E+00 kg/s

vessel upper plenum
liquid volume fraction is 1.00000E+00 and liquid mass is 2.66978E+04 kg

volume-averaged liquid temperature is 5.57633E+02 k and volume-averaged saturation temperature is 5.79712E+02 k

vessel downcomer
liquid volume fraction is 0.00000E+00, liquid mass is 0.00000E+00 kg , volume-averaged pressure is 0.00000E+00 pa
volume-averaged liquid temperature is 0.00000E+00 k and volume-averaged saturation temperature is 0.00000E+00 k

vessel component total coolant mass is 7.12051E+04 kg , total coolant energy is 8.87096E+10 w*s, and
computed initial total coolant mass is 6.78684E+04 kg

which have been axially averaged over all   6 average-power rod s

total inner surface area is  0.00000E+00 m2  and
total outer surface area is  3.96347E+03 m2  of all   6 average-power rod s

total power from the heat-structure inner surface is  0.00000E+00   w    and outer surface is  5.09302E+07   w

average-power rod   4 has the peak surface temperature of  5.58399E+02 k
supplemental  rod  10 has the peak surface temperature of  5.58696E+02 k

total mass of hydrogen (based on the average temperature of all average-power rod s) is  0.00000E+00 kg

problem time is 6.000010E+02 s, time-step size is  3.4165E-01 s, time-step number is  2810, outer-iteration number is  2

maximum convective power differance has been 0.3176545E+08   w    in component  910 at time 7.7178549E+00 s
time-step size was limited by component 200 at cell   1 to 1.3376E-02 s
average outer-iteration count over the last  362 time steps was   2.039
last minimum number of outer iterations was  1 at time step 2613 (limited by component 200 with fr.error of 3.3585E-05)
last maximum number of outer iterations was  4 at time step 2686 (limited by component 190 with fr.error of 3.9531E-07)
total number of times that each component (id#) was the last to converge since the last short edit

inner-surface node-interval thermal conductivity is 5.17229E+00 w/m/k
outer-surface node-interval thermal conductivity is 1.59987E+01 w/m/k
effective r-direction wall thermal conductivity is 5.85008E+00 w/m/k
which have been axially averaged over all 6 average-power rod s

total inner surface area is 0.00000E+00 m2 and
total outer surface area is 3.96347E+03 m2 of all 6 average-power rod s

total power from the heat-structure inner surface is 0.00000E+00 w and outer surface is 4.88848E+07 w

average-power rod 4 has the peak surface temperature of 5.59270E+02 k
supplemental rod 10 has the peak surface temperature of 5.59556E+02 k

total mass of hydrogen (based on the average temperature of all average-power rod s) is 0.00000E+00 kg

total convective energy to the fluid during hydro solution:
                inside surface= -3.8689436E+08 w*s      outside surface=  3.4957199E+08 w*s
```

```
errors in conservation of convective energy at the wall between hydro and conduction solutions:
          inside convective energy error: absolute=  3.37628E+06 w*s     effective=  2.15886E+04 w*s
         outside convective energy error: absolute=  2.84561E+06 w*s     effective=  5.44516E+05 w*s

inner-surface node-interval thermal conductivity is  5.05525E+01    w/m/k
outer-surface node-interval thermal conductivity is  5.05117E+01    w/m/k
effective  r-direction wall thermal conductivity is  5.05320E+01    w/m/k
which have been axially averaged over all   3 average-power rod s

total inner surface area is  6.61197E+02 m2  and
total outer surface area is  6.62564E+02 m2  of all   3 average-power rod s

total power from the heat-structure inner surface is  4.48662E+06   w    and outer surface is -4.41542E+06   w

average-power rod   2 has the peak surface temperature of  5.56951E+02 k

total mass of hydrogen (based on the average temperature of all average-power rod s) is  0.00000E+00 kg

system results

total power loss by 1-d comp.wall is -3.483347E+06 w*s on the inner surface and  9.135330E+05 w*s on the outer surface

                     system total coolant energy is  9.312153E+18 w*s

                       system total coolant mass is  4.544427E+13 kg

total coolant mass discharged by break components is -8.335128E+04 kg

   total coolant mass injected by fill components is  3.672824E+04 kg

       system computed initial total coolant mass is  4.544427E+13 kg

                            end of problem

computative timing statistics
cpu time is 4.2924E+04 s
```
