IE INFORMATION NOTICE NO. 82-49: CORRECTION FOR SAMPLE CONDITIONS FOR AIR AND GAS MONITORING

Addressees:

All nuclear power plant facilities holding an operating license (OL) or construction permit (CP), research and test reactors, fuel facilities, and Priority I material licensees.

Purpose:

This information notice is provided as notification of errors in radioactive gaseous effluent monitoring. Regional surveys of equipment and practices at selected light water reactors (LWRs) revealed that a number of LWRs were not routinely correcting for pressure differentials between main vent effluent streams and associated offline sampling systems. Failure to correct for this pressure differential can introduce errors (both in direct-reading gas monitoring and in flow indication) in monitoring gaseous effluents with offline sampling systems. These sampling errors can cause a significant underestimation when quantifying effluent releases.

The potential also exists for systematic errors in occupational air monitoring programs. Failure to apply pressure correction factors for flow measuring devices when calibrating air samplers could lead to erroneous determinations of airborne radioactivity levels.

It is expected that recipients will review the information for applicability to their facilities. No specific action or response is required at this time.

Description of Circumstances:

A problem of pressure differentials in gas monitoring systems was identified by the licensee at the Diablo Canyon nuclear power plant. At Diablo Canyon the gas monitor takes suction through an isokinetic sampling head about 100 feet up the plant vent stack. In maintaining a flow of 10 cfm, necessary to ensure isokinetic sampling, it was found that the gas monitor chamber pressure was approximately 12 inches of Hg below atmospheric pressure (30 inches of Hg). This resulted in a reduction in the density of the sample chamber gas by approximately 40 percent.

The licensee has found that the reduced pressure phenomenon is most pronounced in systems with long sample lines and is less noticeable where sample lines are short. The licensee plans to incorporate pressure or ΔP gauges on the gas monitoring equipment and to include corrections for pressure variations in calculation of gaseous activity.

8208190267

As a result of this reported sampling deficiency, each Region conducted a survey of selected operating LWRs to determine whether licensees were making the necessary pressure differential corrections for effluent monitoring. Results of these Regional surveys indicate that a generic deficiency does exist. Twenty plants were surveyed and eleven facilities reported they made no pressure differential corrections.

Discussion:

Since calibration of normal range noble gas detectors (sensors) is usually done at atmospheric pressure using Kr-85 gas, it is essential that calibration and operational readouts be automatically corrected for the reduced pressure conditions encountered in system operation, or procedures specify the application of appropriate correction factors. Current models of effluent air monitoring systems provided by major vendors usually incorporate such correction factors.

Particulate and iodine effluent release determinations also are sensitive to sample flowrate which may be affected by system pressure variations. Errors in the order of 10 percent to 50 percent in the calculation of particulates and iodine can result if no compensation is provided for measurement of actual gas flow in the sampling system at reduced pressure.

One of the simplest and most commonly used gas flow measurement devices is the variable area flow meter, commonly known as the rotameter. A rotameter calibrated at atmospheric pressure will not read correctly at either higher or lower pressure, unless properly compensated. (D. K. Craig, See Attachment 1). Pressure correction factors for specific rotameters are available from the various manufacturers as part of the instruction manuals supplied with the equipment.

Operating variables such as the length of sample run, and variations in ΔP across a particulate filter can affect operating pressure. In addition to long sample runs, another significant factor is the increase in pressure drop across a particulate filter caused by dust loading. Craig cites an example involving dust buildup on a filter where ΔP increased from 5.9 inches of Hg to 10.7 inches of Hg while the rotameter float reading was kept constant. The initial flow rate was measured at 5.08 liters/minute and the end flow was 4.02 liters/minute.

Assuming linear change in flow rate, the true mean value would have been 4.55 liters/minute. A determination of total volume flow made on the assumption that the 5.08 liters/minute initial value prevailed over the entire sampling period would have been 11.7% too high, and air contaminant concentrations obtained using the initial flow rate would have been too low, by the same percentage.

Manufacturers of sampling/monitoring systems are aware of the flow-measurement discrepancies just discussed. Current systems provide built-in compensation of air flow rate indication for operation at less-than-atmospheric pressure through the use of pressure and temperature transducers and computer software algorithms. Older analog systems may require application of manual correction

factors for given conditions of ΔP and flow. Instruction manuals provided to licensees by the vendors of older sampling/monitoring systems describe the procedures for making the necessary corrections.

Independent verification of calibration of a flow rate measurement system can be accomplished by placing a calibrated rotameter in series at the sample intake end of the system and comparing readings of the system rotameter under various system pressure conditions with those of the calibrated rotameter. Since the verification rotameter operates at ambient pressure, the only corrections needed for the calibration procedure are the correction for ambient pressure (relative to standard) and a small correction for temperature (the latter is only necessary for high precision work--the error in assuming a standard condition of 70°F is less than 5% for the temperature range 24°F to 116°F which encompasses most plant effluent streams).

Existing NRC regulations require the control of radioactive releases from nuclear facilities and require measurements of radioactive materials in effluents. It is implicit in all requirements for effluent monitoring that these measurements be reasonably accurate. Licensees are expected to review their facility's effluent monitoring program to determine the applicability of the information provided in this notice.

No written response to this information notice is required. If you need additional information about this matter, please contact the Regional Administrator of the appropriate NRC Regional Office or this Office.

The Interpretation of Rotameter Air Flow Readings*

(*Received* 14 *September* 1970; *in revised form* 30 *November* 1970)

1. Introduction

VARIABLE area flow meters, commonly known as rotameters, are extensively used in industrial hygiene and health physics practice to measure the volume of air samples. The principles upon which the rotameter operates are simple and, provided certain elementary precautions are taken, flow rate readings accurate to within ±5% should be obtained. However, as LOVSEN[1] has pointed out in a recent paper on "Errors in measurement of working level," inaccuracies may arise due to incorrect calibration of the rotameter used.

The purpose of this note is to emphasize the considerable importance of a few of the factors involved in interpreting rotameter air flow readings. Some of these involve the flow meter calibration, others do not. For example, it is obvious that any leakage between a sampling device and the rotameter will result in error, as will incorrect recording of the sampling time.

What we are concerned with here are the errors that arise as a consequence of the rotameter operating at conditions of temperature and pressure other than standard. In air sampling applications, it is a general rule that the sampling device is placed upstream of the rotameter in order as far as possible to minimize sampling line losses and to prevent dust or corrosive substances from entering the rotameter. If there is any pressure drop across the sampling device, the rotameter is automatically operating at a pressure other than ambient. Seldom is any clear explanation given in the literature as to exactly what the effect of this will be.[2]

2. Theoretical

Very briefly, the mass of air flowing through a rotameter, which consists simply of a tapered glass tube containing a float of suitable shape (Fig. 1), is obtained by reading off the scale on the tube the position of the float and comparing the reading with the flow rate on the appropriate calibration curve. This position is that at which the downward gravitation force due to the weight of the float is exactly balanced by the upward forces due to the flow of the fluid through the annulus between the float and the tapered tube. The detailed theory of operation of the rotameter has been discussed by several authors[3–7] and may be summarized for the present purpose in the equation

SCHEMATIC OF ROTAMETER

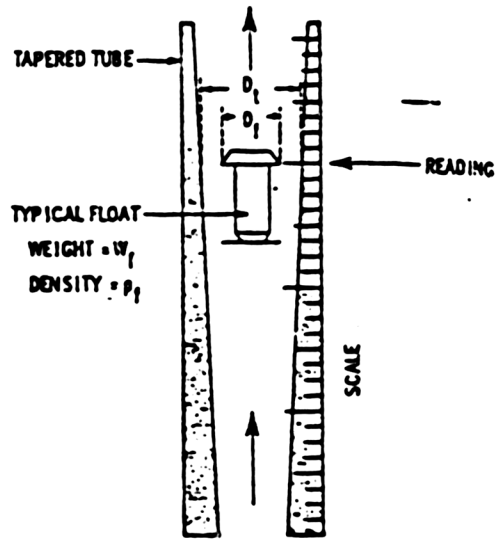

FIG. 1.

$$\frac{Q_o}{Q_s} = \frac{K_o}{K_s}\left(\frac{P_s}{P_o}\frac{T_o}{T_s}\right)^{1/2} \qquad (1)$$

where Q = volumetric flow rate (cu. ft/sec or cm³/sec)
K = flow parameter (ft^1/2/sec or cm^1/2/sec)
P = gas pressure (lb/in² or g/cm²)
T = absolute temperature

while the subscripts refer to operating conditions (0) and standard conditions (P_s = 29.92 inHg, T_s = 70°F = 530°R), respectively. K_s is a constant for a given rotameter reading (i.e., for a fixed value of D_t/D_f), but K_o is a function of the operating conditions which may be obtained experimentally or from a family of curves of K versus the viscous influence number N for various D_t/D_f values.[8]

FISHER and PORTER state in Catalog 10A1022:[7a] "Density correction factors alone cannot be used on ball floats ¼ in. size and smaller. . . For all corrections on ¼ in. and smaller floats, refer to Catalog Number 10A1025."[7b] This latter catalog was supposed to have been available December 1968, but does not yet appear to have been issued. Since most air sampling that is carried out for health physics, industrial

hygiene or inhalation toxicity evaluations is carried out at flow rates of less than 30 L/min, this is the region of major concern to us.

3. Experimental

All the work involved in these experiments was with either a Fisher and Porter triflat rotameter with tube No. FP-1/4-20-G-5/77 and $\frac{1}{8}$ in.-SS spherical float, the tube being graduated from 1 through 20 (D_t/D_f) corresponding to 18.3 L/min at 14.7 p.s.i.a. and 70°F, or a 0–2.4 L/min Brooks rotameter with tube No. 2-65B and a $\frac{1}{8}$ in. diameter sapphire float. A variety of other flow meters are also available, but the above two types are fairly representative. The wet test meter (W.T.M.) used to measure flow under standard conditions was checked and found to be accurate to within ±1%. The pressure/vacuum gauges used were checked against a mercury manometer.

In general, an experimental arrangement such as that shown in Fig. 2 was used for these calibrations. A typical series of results obtained on an FP triflat rotameter is presented in Fig. 3. W.T.M. readings were made at various fixed scale readings (D_t/D_f ratios) for S (Fig. 2) comprising varying numbers of filters from 0 through 10. It is seen that two sets of straight lines can be obtained, one for each number of in-line filters and another set for each rotameter scale reading. These results may also be plotted in a different way, as has been done in Fig. 4. Here, the scale reading under operating conditions has been plotted against the standard flow rate F_s for each value of the gauge-indicated pressure drop ΔP. Obviously, a similar set of lines exists on the other side of the $\Delta P = 0$ line for positive values of ΔP.

4. Discussion

In Fig. 4, straight lines have been drawn through the experimental points, even though some systematic deviation from linearity is apparent. The large error caused by drawing straight lines is of the order of +4%. The manufacturer's calibration curve for this rotameter under standard conditions is plotted as crosses and is seen to agree quite well with the $\Delta P = 0$ line. The actual values from which the graph was obtained are given in Table 1.

Figure 4 is obviously a fairly satisfactory set of calibration curves for this rotameter, i.e., by reading the scale value and the pressure drop across the sampling device, the flow under standard conditions can be obtained. However, it is clearly not a practical proposition to calibrate all one's rotameters in this way, nor is there a simple way of calculating the correct flow under standard conditions.

The importance of taking the actual pressure at the rotameter into account may be appreciated by examining Table 1. For a scale reading of 8, the manufacturer's calibration curve indicates an F_s value

ROTAMETER READING VERSUS AIR FLOW RATE UNDER STANDARD CONDITIONS FOR VARIOUS PRESSURE GAUGE READINGS AT ROTAMETER

of 6.05 L/min for $P = 29.92$ inHg and $T = 70°F$. The present work indicates that *the same scale reading* on the rotameter can give F_s values ranging from 5.85 L/min for $\Delta P = 0$ down to 1.15 L/min for $\Delta P = -24$ inHg, where the atmospheric pressure was 29.2 inHg.

The above is obviously an extreme example of what could happen, so we need to examine what is more likely to happen. Millipore HA or Gelman GA-6 filter paper, both having a mean pore size of 0.45 μm, are frequently used in air sampling situations, the 1 in. and 2 in. dia. being used among other sizes. For the 1 in. diameter paper, a scale indication of 8 gave $\Delta P = 5.9$ inHg and $F_s = 5.08$ L/min, compared with 5.85 L/min at $\Delta P = 29.2$ inHg and the manufacturer's value of 6.05 L/min at 29.92 inHg and 70°F (see Table 1). This means that, had the manufacturer's value been taken as the flow rate, this would have been in error by some 19%. Even for the 2 in. dia. paper, with a nearly five-fold larger effective area, $F_s = 5.55$ L/min and the error would have been 9%.

When sampling from dusty atmospheres, a further problem arises in that, as dust builds up on the filter paper, the pressure drop increases and, even if the flow reading is adjusted to a constant value, the meaning of that reading changes. For example, assume that ΔP increased from 5.9 inHg to 10.7 inHg while the rotameter reading was kept constant at 8 on the guage, for $\Delta P = 29.2$ inHg. The final value for F_s is 4.02 L/min. If we assume that the change in flow rate was constant with time, the true mean would have been

$$\frac{5.08 + 4.02}{2} = 4.55 \text{ L/min.}$$

The value of 6.05 L/min for $\Delta P = 0$ and $\Delta P = 29.92$ inHg exceeds this value by 33%, and even the value of 5.08 L/min obtained by calibration for conditions as they were at the start of sampling would yield a result that was 11.7% too high. The air contaminant concentrations obtained by using these values (6.05 or 5.08 L/min) could, therefore, have been LOW by corresponding amounts. Table 1 shows that substantial errors can arise, even when the rotameter reading is fairly small. If the temperature differs significantly from the standard calibration value of 70°F = 530°K, then corrections must be made for this. However, the error caused by using 70°F is less than 5% for the temperature range $24°F < T < 116°F$.

LOYSEN's analysis[1] of errors due to incorrect flowmeter calibration is confusing in that it does not make it very clear as to what flow rate is desired and, further, does not seem to take into account the effect of pressure changes on the operating characteristics of the rotameter. In addition, his equation (2) (p. 632) appears to be incorrect, containing a T_m in the denominator instead of P_m. Logically, all flow rates should be reduced to standard conditions of temperature and pressure, i.e., a fixed mass of air. This latter point cannot be over-emphasized, since it is widely ignored. For example, the author recently discovered that the manufacturer of a widely used

multistage sampling device gives the airflow and stage calibrations applicable to air at 4500 ft above sea level with no indication to the purchaser that this is the case.

5. Conclusions

The importance of calibrating rotameters under exactly the same conditions as those under which they will be used is discussed. Calibration data is presented to demonstrate the magnitude of the errors that can arise when using a rotameter downstream of a sampling device across which there is a pressure drop. It is clearly essential to always have a pressure gauge to measure the pressure at the flowmeter (on the same side of the valve as the rotameter float). Not only does this enable corrections to be applied, but it serves as a very good leak detector since, for a given sampling device and flow rate, the pressure drop should be roughly the same from one sample to another. It is also obviously desirable to use flow rates that will give as low a pressure drop as possible and meter readings at the upper end of the rotameter scale.
