1.0 PURPOSE

The purpose of this report is to document an area-by-area analysis of the Post-Fire Safe Shutdown (PFSSD) capability at Wolf Creek Nuclear Operating Corporation (WCNOC), Unit 1. This report provides objective evidence that Wolf Creek complies with applicable provisions in 10CFR50.48(a) and Wolf Creek commitments to 10CFR50, Appendix R, Section III.G, as they relate to protection of one train (or success path) of systems necessary to achieve and maintain safe shutdown.

The PFSSD analysis is part of the "Approved Fire Protection Program" at Wolf Creek. In accordance with operating license condition 2.C.(5)(b), changes to the approved fire protection program are allowed as long as the change does not impact the ability to achieve and maintain PFSSD. Technical changes to this document require review per AI 26A-003 and PSRC approval prior to implementing.

2.0 SCOPE

This document includes a detailed review of the PFSSD capability in all fire areas at Wolf Creek. Fire areas within the powerblock structures are listed in the fire hazards analysis and fire delineation drawings (A-1801 through A-1812).

The detailed review was performed in accordance with the methodology in Section 4.0. This includes reviewing each selected area using the new component list, cable list and logic diagrams contained in Calculation XX-E-013; E-15000 (SETROUTE); and, drawings E-1F9001 through E-1F9444.

3.0 BACKGROUND

On March 22, 1975 a fire occurred at the Browns Ferry Nuclear Power Plant that damaged over 1600 electrical cables and caused the temporary unavailability of some core cooling systems. Prior to the Browns Ferry fire, fire protection requirements were limited to the broad and generalized criteria contained in 10CFR50, Appendix A, General Design Criteria 3, *Fire Protection* as well as the Insurance guidelines of ANI. The fire at Browns Ferry caused the NRC to review the fire protection programs and requirements at all operating nuclear power plants. A special review group was formed to investigate the fire and provide recommendations for improving the fire protection programs at operating plants.

The special review group developed over 50 recommendations to improve the fire prevention and control at existing power plants. Based on these recommendations, the NRC developed guidelines that were issued by the NRC in Branch Technical Position Auxiliary and Power Conversion Systems Branch (BTP APCSB) 9.5-1, "Guidelines for Fire Protection for Nuclear Power Plants." These guidelines only applied to new plants that were not currently docketed. Guidelines for existing plants were contained in Appendix A to BTP APCSB 9.5-1.

In May, 1976 the NRC requested licensees review their fire protection program against the guidelines in BTP APCSB 9.5-1. In September, 1976 the licensees were also requested to prepare a fire hazard analysis that divided the plant into distinct fire areas and show that redundant systems required to achieve and maintain cold shutdown are adequately protected against damage by a fire. The licensees responded with a fire protection program evaluation and a fire hazard analysis that, in some cases, identified aspects of licensees' fire protection programs that did not conform to the NRC guidelines.

After a number of meetings and discussions with licensees to resolve differences, several unresolved issues remained. The NRC and licensees attempted to resolve the differences but, despite these efforts, could not come to common ground on some key recommendations. Since the recommendations in BTP APCSB 9.5-1 did not have the force of law, the NRC could do nothing to require the licensees to comply. Consequently, the NRC issued a proposed "Fire Protection Rule" (10CFR50.48) and Appendix R to 10CFR50, which was later adopted into law.

The fire protection rule (10CFR50.48) made it clear that Appendix R only applies to plants licensed to operate prior to January 1, 1979. Therefore, Wolf Creek is not an Appendix R plant by law. However, 10 CFR 50.48(e) states that plants licensed to operate after January 1, 1979 are required to complete all fire protection modifications needed to satisfy Criterion 3 of Appendix A to 10CFR50 in accordance with the provisions of their operating license. The Wolf Creek SER, dated April 1982, Section 9.5.1.7 states, in part:

> *Although this rule and its Appendix R are not directly applicable to Wolf Creek, the requirements set forth in Appendix R are being used as guidelines in licensing plants after January 1, 1979. ... The Staff will condition the operating license to require the applicant to meet the technical requirements of Appendix R to 10CFR50, or provide equivalent protection.*

Wolf Creek responded to this request by performing a comparison of the requirements in Appendix R with the Wolf Creek design. This comparison is contained in the Wolf Creek USAR, Appendix 9.5E. The Wolf Creek responses to the Appendix R requirements are considered license commitments.

Section III.G of Appendix R specifies the requirements for fire protection of safe shutdown capability. Wolf Creek's response to the requirements of Appendix R, Section III.G is as follows:

> *USAR Appendix 9.5B provides an area-by-area analysis of the power block that demonstrates that no single fire can prevent safe shutdown.*
>
> *Redundant trains of systems required to achieve and maintain hot standby are separated by 3-hour rated fire barriers, or the equivalent provided by III.G.2, or else a diverse means of providing the safe shutdown capability exists and is unaffected by the fire.*
>
> *For redundant trains of systems required to achieve and maintain cold shutdown that could potentially be affected by a single fire, repairs or local operator actions can be performed within 72 hours.*
>
> *As described in Appendix 9.5B and Section 7.4, an auxiliary shutdown panel is provided as a dedicated means of achieving and maintaining hot standby in the event that the control room is uninhabitable due to a fire.*
>
> *The ESW pumphouse also complies.*

The EFHA was the original evaluation that reviewed the capability to achieve and maintain safe shutdown after a fire. Following completion of the EFHA, a summary of the safe shutdown capability following a fire in each plant area was documented in the Wolf Creek USAR, Appendix 9.5B. In addition, a list of the minimum components needed to achieve and maintain safe shutdown following a fire was included in Table 9.5B-2 of the USAR. Wolf Creek document E-15000, Electrical Cable and Raceway List, identified cables and components necessary for post-fire safe shutdown with an (S.) designation in the appropriate field.

The EFHA was not a controlled document and did not have a Wolf Creek document number. Since the pertinent information from the EFHA was placed in the USAR and E-15000, control of the post-fire equipment and cable list fell under the design change and USAR change process.

During the 2005 NRC triennial fire protection inspection, the NRC team identified a non-cited violation for failure to maintain one train of equipment free of fire damage. The basis for this finding was that Wolf Creek credited manual actions in fire areas where physical separation and/or protection of redundant PFSSD equipment were not provided. Wolf Creek challenged the violation on the basis that the Wolf Creek operating license allows the use of 'diverse means' to achieve and maintain PFSSD where physical separation and/or protection are not provided. This is documented in the Wolf Creek USAR, Table 9.5E-1. The NRC replied by stating that the use

of manual actions outside the control room is not sufficient to demonstrate a diverse means of providing safe shutdown capability. In addition, the NRC argued that use of manual actions is an adverse change to the fire protection program due to the introduction of human error vulnerabilities. The NRC accepted the use of feasible manual actions as compensatory measures and re-classified the non-cited violation as an apparent violation with enforcement discretion. The crediting of manual actions as 'diverse means' is no longer applicable to Wolf Creek.

4.0 METHODOLOGY

The PFSSD capability in a given area is determined by evaluating all PFSSD related cables and components in the area and determining if redundant capability exists outside of the area and is unaffected by a fire. The minimum set of systems and components required for PFSSD are listed in Calculation XX-E-013. These systems and components are required to ensure hot standby and cold shutdown reactivity conditions can be achieved following a fire. System/component interactions, as well as component redundancy, is shown on the PFSSD logic diagrams (E-1F9001 through E-1F9444). The Wolf Creek electrical cable and raceway list (E-15000) identifies all required PFSSD components and cables, as well as associated circuits of concern.

The methodology for completing each fire area analysis is described in this section. Figure 4.1 is a flow chart showing the area analysis methodology.

The reactor building is divided into 11 distinct fire areas in other WCNOC documents such as the fire hazards analysis, the combustible loading calculation and the fire delineation drawings. However, for this report, the reactor building is combined into one analysis due to the physical characteristics of the building.

In some areas, conduit carrying PFSSD cables is embedded in the concrete walls and floors. If the concrete embedment meets minimum depth requirements, then fire damage to the cable does not have to be considered in the fire area assessment. If the embedment does not meet minimum requirements, then the PFSSD analysis needs to consider that the cable is located in the fire area that it passes. Attachment 2 provides an evaluation of the embedded raceway at Wolf Creek.

Instrumentation is credited to provide operators with diagnostic indication of system parameters. Instrument sensing lines are vulnerable to the effects of fires because the heat from a fire could affect the sensitivity of the instrument and provide false readings and/or cause spurious actuation of equipment. Attachment 3 provides an analysis of the effects of fire on PFSSD credited instrument sensing lines.

The methodology used to complete each area analysis is as follows:

1. Determine all PFSSD related cables and equipment located in the area of concern.

2. Determine worse-case PFSSD equipment failures that could occur due to a fire in the area of concern. The worse-case failures shall include multiple spurious operations (MSOs) that may occur due to the presence of cables and/or equipment in the fire area under consideration. The methodology for performing a MSO review is described in Section 4.2. The results of the MSO review are documented in Attachment 4.

3. Determine if redundant PFSSD capability exists outside the fire area of concern or if separation of redundant PFSSD components and circuits meets the requirements of 10CFR50, Appendix R, Section III.G.2.

4. Perform circuit analysis on the affected cable(s), if necessary, to determine the combinations of hot shorts, open circuits and/or shorts to ground necessary to cause the equipment to change to an undesired state and whether circuit failures could cause a spurious actuation. Circuit analysis should consider hot shorts through the ground plane, commonly known as ground fault equivalent hot shorts (GFEHS).

5. Determine if feasible and reliable manual actions exist using the guidance in NUREG-1852.

6. Document the analysis in a report.

Discussion of each methodology step is provided below.

4.1 DETERMINE ALL PFSSD RELATED CABLES AND EQUIPMENT

Equipment required to remain functional to safely shut down the plant and maintain it in a safe shutdown condition following a fire is listed in Calculation XX-E-013. The components listed in XX-E-013, as well as associated PFSSD cables, are designated as (S.) in the Wolf Creek electrical cable and raceway list (E-15000). "Associated circuits" are also designated as (S.). Using the computer database program SETROUTE (E-15000), generate a report of all S. cables and equipment in the area. The data on this report comprises the master list of cables and equipment to be analyzed in the area analysis. Only (S.) cables and equipment are evaluated in this report.

Tabulate the list of (S.) equipment in the area, along with a description of the equipment, its location (room number), and a reference to the evaluation section containing a detailed discussion about the component. Provide comments regarding the component, as necessary.

Tabulate the list of (S.) cables in the area, along with the cables location, primary PFSSD equipment associated with the cable, the cables function (Power, Control or Instrumentation), a reference to the report section containing a detailed discussion of the cable and comments.

4.2 DETERMINE WORSE-CASE PFSSD EQUIPMENT FAILURES THAT COULD OCCUR

All unprotected PFSSD cables and equipment in the area of concern are assumed to be damaged by the fire, regardless of fire loading and presence of automatic fire suppression. If a 20 foot combustible and fire hazard free zone exists within the area, as well as automatic suppression and detection per Wolf Creek's commitments to 10CFR50, Appendix R Section III.G.2.b, the fire is assumed to only affect cables and equipment on one side of the combustible and fire hazard free zone (Note: Evaluation of insitu combustibles within the 20 foot combustible and fire hazard free zone is documented in E-1F9905). Cables that are protected in accordance with Appendix R, Section III.G.2.a (3-hour fire barrier) or III.G.2.c (1-hour fire barrier with suppression and detection in the area) are assumed to be unaffected by a fire. Equipment associated with unprotected PFSSD cables running through the fire affected area of concern is assumed to move to its undesired position (i.e. valves fail closed when PFSSD requires them to be open). Detailed circuit analysis to determine the legitimate failures that can occur was not performed during this step.

Damage to cables associated with instruments (e.g., resistance temperature detectors, thermocouples, pressure transmitters, and flow transmitters) causes the instrument to fail upscale, midscale, or downscale, whichever is worse. An instrument performing a control function is assumed to provide an undesired signal to the control circuit.

Based on the assumption that equipment fails in its undesired state, perform an evaluation to determine if redundant capability exists, as described in Section 4.3 below. If redundant capability exists and is unaffected by the fire, no additional analysis, including circuit analysis, is required and the evaluation is documented in the appropriate section.

4.2.1 IDENTIFICATION AND TREATMENT OF MULTIPLE SPURIOUS OPERATIONS (MSOS)

Enforcement Guidance Memorandum (EGM) 09-002 was issued on May 14, 2009. This EGM describes the conditions limiting enforcement discretion during the resolution of fire protection concerns involving multiple spurious operations (MSOs). Based on the EGM, enforcement discretion is limited to three years from the date of issuance of Regulatory Guide (RG) 1.189, Revision 2 as follows: (1) six months following the issuance of RG 1.189, Rev. 2, licensees to identify non-compliances related to multiple fire induced circuit faults, place the non-compliances into their corrective action program and implement compensatory measures, and (2) three years following the issuance of RG 1.189, Rev. 2 for licensees to complete the corrective actions associated with noncompliant fire induced circuit faults. RG 1.189, Rev. 2 was issued on November 2, 2009.

The methodology to perform a MSO review is described in Nuclear Energy Institute (NEI) document 00-01, Chapter 4. This approach was accepted by the NRC in RG 1.189, Section 5.3.1.1. The basic steps in performing this review are described below. For a more detailed discussion, refer to NEI 00-01.

4.2.1.1 Industry Develop a Generic List of MSOs

Appendix G of NEI 00-01 provides a generic list of MSOs developed from an industry survey of all US nuclear power plants. The survey results were compiled into a table, and draft lists were developed for each reactor type (BWR and PWR). Comments on the draft lists were received from the industry and the final lists were published in NEI 00-01, Rev. 2 Appendix G.

4.2.1.2 Plant Specific Expert Panel Review of Generic MSO List

A plant specific expert panel review was performed to review the generic MSO list, determine applicability of each MSO scenario at the facility and to develop plant-specific scenarios that are not listed in the generic list. An expert panel was convened at Wolf Creek on February 17 and 18, 2009. The expert panel was made up of representatives from Operations, Fire Protection, Design Engineering, Systems Engineering and PRA groups.

The MSO expert panel meeting was led by Westinghouse PRA personnel as part of the Fire PRA development. Although the expert panel was conducted specifically for the Fire PRA, the conduct and scope of the meeting generally followed the methodology in a draft version of NEI 00-01, Rev. 2, since the final version was not released until after the Wolf Creek MSO expert panel meeting. There were no significant differences between the methodology and generic MSO list in the draft version of NEI 00-01, Rev. 2 and the final version.

As a result of the expert panel meeting, 13 plant specific scenarios were added and five of the 59 generic MSOs were screened out. Attachment 4 shows the Wolf Creek list of MSOs.

4.2.1.3 Review of Plant Specific MSO List for Impact on PFSSD

The Wolf Creek MSO list was reviewed to determine if any of the scenarios have the potential to adversely impact the ability to safely shutdown following a fire. The Wolf Creek PFSSD analysis (E-1F9910) was used to determine which fire areas, if any, the MSO scenario can occur in. This was determined by reviewing cable routing associated with each component identified in the scenario. If cables associated with the components identified in the scenario are located in the fire area, then the fire area is identified as applicable to the scenario.

After all MSO scenarios are reviewed, and applicable fire areas listed, the list is reviewed again to determine if PFSSD is potentially affected. The following was considered in determining potential PFSSD impact:

1. Are actions available in the main control room to mitigate the MSO.
2. Will cable damage actually cause the spurious actuation.

3. Does the thermal hydraulic analysis (WCNOC-CP-002) support a conclusion that the MSO will not adversely impact PFSSD.
4. Is redundant capability available to mitigate the effects of the MSO.
5. Is an approved feasible and reliable operator manual action available to mitigate the MSO.
6. Is a calculation available that supports a conclusion that the MSO will not adversely impact PFSSD.

If at least one of the conditions above is satisfied, then the results are documented in the fire area analysis for the area(s) under consideration. If none of the above conditions are satisfied, then a potential PFSSD concern is identified and placed in the corrective action program. The corrective action program then determines the corrective measures that are needed to resolve the MSO concern. Attachment 4 shows the results of the MSO evaluation.

4.3 DETERMINE IF REDUNDANT PFSSD CAPABILITY EXISTS OUTSIDE THE FIRE AREA OF CONCERN

The PFSSD Logic Diagrams (E-1F9001 through E-1F9444) show the combinations of equipment and redundancy necessary to achieve safe shutdown after a fire. Using the logic diagrams, redundant PFSSD capability in the area of concern was determined.

The list of equipment that is unavailable due to a fire in the area was compared against the logic diagrams to determine if redundant equipment remains available to achieve the PFSSD functions. If redundant equipment remains available and is unaffected by a fire in the area of concern such that all PFSSD functions can be achieved, then the PFSSD goals are satisfied for a fire in the area. The analysis is documented and PFSSD is assured. If redundant equipment is not available, then further analysis is necessary as described in the next section.

4.4 PERFORM CIRCUIT ANALYSIS

Where redundant PFSSD capability does not exist or is affected by the fire, a circuit analysis on the affected cable(s) is performed to determine if a single failure or combination of failures will result in the component moving to an undesired position. If the circuit analysis determines that no possible combinations of failures could occur that will result in the component moving to an undesired position, then the analysis is documented and PFSSD is assured. If the circuit analysis determines that the redundant component could spuriously operate to the undesired state, then an evaluation of manual actions is performed as described in the next section.

With few exceptions, the circuit analysis was performed using a conservative “any-and-all” approach. This approach assumes that any number of cable failures could occur at the same time to cause the component to fail in an undesired state, and is intended to bound any current and foreseeable regulatory positions on the matter of cable failures. The cable failures have to be credible, in that inter-cable hot shorts cannot occur between cables routed in different raceways, except in the case of ground fault equivalent hot shorts (GFEHS) discussed below. Also, for three-phase AC circuits, the probability of having a hot short in the proper sequence to cause spurious operation of a motor is implausible and does not require evaluation, except in cases involving high/low pressure interfaces.

The circuit analysis assumes that inter-cable (cable-to-cable) hot shorts involving thermoset cables can occur, even though current NRC guidance indicates that this failure mode is substantially less likely than other cable failure modes (RIS 2004-003, Rev 1). The circuit analysis also considers that, for DC control circuits, intra-cable (conductor-to-conductor) failures of the proper polarity are possible and that inter-cable failures of the proper polarity are possible, even between thermoset cables, if the cables are run in the same raceway. Finally, the analysis assumes that cable failure and subsequent equipment mal-operation occurs indefinitely and will not self-mitigate after a specified time period, even though RIS 2004-003, Rev. 1 states that

recent testing strongly suggests fire-induced hot shorts tend to self-mitigate (e.g. short to ground) in less than 20 minutes.

Ground fault equivalent hot shorts (GFEHS) were experienced during fire testing of DC circuits and reported in NUREG/CR-7100, Direct Current Electrical Shorting in Response to Exposure Fire (DESIREE-Fire) dated April, 2012. The test results were analyzed in draft NUREG-2128, Electrical Cable Test Results and Analysis during Fire Exposure (ELECTRA-FIRE). A GFEHS is a hot short from an energized source conductor in one cable that contacts the ground plane and energizes a target conductor in a different cable that has also come into contact with the ground plane. In this scenario, the ground plane becomes the conducting path from source to target conductors. A GFEHS only needs to be considered on ungrounded AC or DC circuits. This is because a short to ground on a grounded circuit would clear the circuit protective device and de-energize the circuit. At Wolf Creek, AC circuits credited for PFSSD are grounded. Therefore, the GFEHS scenario only applies to ungrounded DC circuits at Wolf Creek. Furthermore, the power source needs to be compatible. For example, an AC hot short on a DC circuit is not compatible. Also, the DC hot short source must be from the same power supply as the ungrounded polarity to ensure a complete flow path, otherwise no current will flow in the circuit. Another factor to consider is the relative location of the source and target cables. Fire testing reported in the test reports above showed GFEHS where the source and target cables were located in different raceway located adjacent to one another. No deterministic conclusion can be made where the raceways containing these cables are located a distance from one another. Therefore, it should be assumed that GFEHS can occur between cables located anywhere within the fire area under consideration.

Exceptions to the above approach are discussed in the individual area analyses on a case-by-case basis.

4.5 IDENTIFY MANUAL ACTIONS

If redundant PFSSD capability does not exist and circuit analysis shows that spurious actuation can occur such that PFSSD is not assured, determine if feasible and reliable manual actions are available to safely shut down the plant using the guidance in NUREG-1852. If feasible and reliable manual actions are available, document the feasibility and reliability analysis in E-1F9900 and submit a license amendment request to the NRC as applicable and initiate any additional compensatory measures as necessary until the license amendment is granted. If feasible and reliable manual actions are not available, initiate appropriate compensatory measures and document the condition in a condition report.

4.6 DOCUMENT THE ANALYSIS IN A REPORT

The area analysis is documented in a report that is divided into the following sections:

1. *General area description* - This section describes the rooms located in the area, a general description of the fire protection features provided, and a discussion of the 10CFR50, Appendix R, Section III.G.2 separation criteria used.

2. *Primary equipment used for PFSSD* - This section contains a table that identifies each required PFSSD system and a discussion of the availability of the system to perform its PFSSD functions. Additional summary is contained in Section 8.0 of this Fire Area Analysis Narrative section.

3. *Actions to achieve and maintain PFSSD* - This section describes those actions that are necessary to ensure Wolf Creek can achieve and maintain safe shutdown conditions following a fire in the area of concern. Actions required outside the control room are considered compensatory measures subject to enforcement discretion until permanent corrective actions are taken to resolve the condition. Actions required inside the control room are documented because of the potential failure of a redundant control room component. These actions are acceptable per the Wolf Creek licensing basis. Actions to

achieve and maintain cold shutdown are documented to identify potential repairs. Cold shutdown repairs are acceptable per the Wolf Creek licensing basis.

4. *Conclusion* - This section provides an overall summary of the PFSSD capability for a fire in the area of concern.

5. *Detailed analysis* - This section describes the detailed component and cable analysis for all PFSSD components and cables in the area. The first sub-section evaluates PFSSD equipment and associated cables that are physically located in the area of concern. The second sub-section evaluates all PFSSD cables run through the area.

5.0 ASSUMPTIONS

1. Inter-cable (cable-to-cable) hot shorts involving thermoset cables can occur.

2. For DC control circuits, intra-cable (conductor-to-conductor) failures of the proper polarity are possible and inter-cable failures of the proper polarity are possible if the cables are run in the same raceway.

3. Cable failure and subsequent equipment mal-operation occurs immediately, simultaneously, and last indefinitely and will not self-mitigate after a specified time period.

4. Whenever both RCP seal injection and thermal barrier cooling are lost, the RCPs are assumed to be tripped and a natural circulation cool down performed. When only one of the two seal cooling methods is lost, RCP operation will continue and the lost method will be re-established when available, per Wolf Creek procedures.

For a list of additional assumptions, see Calculation XX-E-013.

6.0 DEFINITIONS

Inter-Cable Hot Short - A term used to describe a cable failure whereby a short occurs between conductors within different cables.

Intra-Cable Hot Short - A term used to describe a cable failure whereby a short occurs within a multi-conductor cable.

8.0 SUMMARY OF AREA ANALYSES

This section provides a summary of the detailed analyses for each fire area. Each summary contains the following information:

- A description of the physical characteristics of the fire area including the presence or absence of 20 foot combustible and fire hazard free zones and fire protection features provided.
- The 'Train' of equipment primarily credited for post-fire safe shutdown (PFSSD).
- A summary of the reactivity control success path availability to achieve and maintain PFSSD.
- A summary of the reactor coolant makeup success path availability to achieve and maintain PFSSD.
- A summary of the decay heat removal success path availability to achieve and maintain PFSSD.

8.1 FIRE AREA A-1 (GENERAL AREAS 1974 AND 1988 ELEVATIONS)

There are no 20 foot combustible and fire hazard free zones in fire area A-1. Fire area A-1 is protected by automatic fire detection throughout the 1974'-0" elevation. There is no fire detection installed on the 1988'-0" elevation. An automatic pre-action sprinkler system is installed above cable tray concentrations. Some of the PFSSD circuits that run through area A-1 are wrapped with 1-hour fire rated material to protect the PFSSD function of the associated equipment. This configuration meets Wolf Creek's commitments to the requirements of 10CFR50, Appendix R, Section III.G.2.c.

PFSSD is assured using Train A safety related and non-safety related equipment.

Reactivity control is achieved by tripping the reactor from the control room. Boration is available using the Train A centrifugal charging pump (CCP) taking suction from the refueling water storage tank (RWST) and injecting borated water through the reactor coolant pump (RCP) seals and boron injection tank (BIT). Main steam isolation is accomplished by closing the main steam isolation valves (MSIVs) from the control room. Steam generator atmospheric relief valve (ARV) control is accomplished by controlling all four steam generator ARVs from the control room. Steam generator blowdown is isolated by closing all four blowdown valves from the control room. All four source range neutron flux monitors are available.

Reactor coolant makeup is achieved using the Train A CCP taking suction from the RWST and injecting water through the RCP seals and BIT. Pressurizer level reduction due to uncontrolled cool down through steam generator blowdown lines, steam generator atmospheric relief valves and main steam lines would not be caused by a fire in this area. A fire in this area could cause a loss of inventory through the letdown flow path until the letdown isolation valves can be failed closed. Both pressurizer spray valves could open until operator action is taken in the control room to close the valves. No other inventory reduction paths are affected by a fire in this area.

Decay heat removal is achieved using the turbine driven auxiliary feed water pump (TDAFP), taking suction from the condensate storage tank (CST), and supplying all four steam generators. All four steam generator ARVs are available to control reactor coolant system (RCS) temperature during hot standby. Both motor driven auxiliary feed water pumps (MDAFPs) could be affected. Main feed water is isolated by closing the main feed water isolation valves (MFIVs) from the control room. Diagnostic instrumentation is available to verify RCS temperature and pressure. Train A residual heat removal (RHR) system is available for transition from hot standby to cold shutdown, however RHR pump suction may have to be lined up locally.

A fire in this area will not prevent safe shutdown of the plant.

8.2 FIRE AREA A-2 (TRAIN A SAFETY RELATED PUMPS)

There are no 20 foot combustible and fire hazard free zones in fire area A-2. Fire area A-2 has automatic fire detection installed.

PFSSD is assured using Train B safety related and non-safety related equipment.

Reactivity control is achieved by tripping the reactor from the control room. Boration is available using Train B centrifugal charging pump (CCP) taking suction from the refueling water storage tank (RWST) and injecting borated water through the reactor coolant pump (RCP) seals and boron injection tank (BIT). Main steam isolation is accomplished by closing the main steam isolation valves (MSIVs) from the control room. Steam generator atmospheric relief valve (ARV) control is accomplished by controlling all four steam generator ARVs from the control room. Steam generator blowdown is isolated by closing all four blowdown valves from the control room. All four source range neutron flux monitors are available.

Reactor coolant makeup is achieved using Train B CCP taking suction from the RWST and injecting water through the RCP seals and BIT. Pressurizer level reduction due to uncontrolled cool down through steam generator blowdown lines, steam generator atmospheric relief valves and main steam lines would not be caused by a fire in this area. No inventory reduction paths are affected by a fire in this area.

Decay heat removal is achieved using Train B motor driven auxiliary feed water pump (MDAFP), taking suction from the condensate storage tank (CST), and supplying steam generators A and D. Steam generators A and D ARVs are available to control RCS temperature during hot standby. Main feed water is isolated by closing the main feed water isolation valves (MFIVs) from the control room. Diagnostic instrumentation is available to verify RCS temperature and pressure. Train B residual heat removal (RHR) system is available for transition from hot standby to cold shutdown, however RHR pump suction may have to be lined up locally.

A fire in this area will not prevent safe shutdown of the plant.

8.3 FIRE AREA A-3 (BORIC ACID TANK ROOM)

There are no 20 foot combustible and fire hazard free zones in fire area A-3. Fire area A-3 has automatic fire detection installed.

PFSSD is assured using Train B safety related and non-safety related equipment.

Reactivity control is achieved by tripping the reactor from the control room. Boration is available using Train B centrifugal charging pump (CCP) taking suction from the refueling water storage tank (RWST) and injecting borated water through the reactor coolant pump (RCP) seals and boron injection tank (BIT). Main steam isolation is accomplished by closing the main steam isolation valves (MSIVs) from the control room. Steam generator atmospheric relief valve (ARV) control is accomplished by controlling all four steam generator ARVs from the control room. Steam generator blowdown is isolated by closing all four blowdown valves from the control room. All four source range neutron flux monitors are available.

Reactor coolant makeup is achieved using Train B CCP taking suction from the RWST and injecting water through the RCP seals and BIT. Pressurizer level reduction due to uncontrolled cool down through steam generator blowdown lines, steam generator atmospheric relief valves and main steam lines would not be caused by a fire in this area. No inventory reduction paths are affected by a fire in this area.

Decay heat removal is achieved using either the Train A or Train B motor driven auxiliary feed water pumps (MDAFPs), taking suction from the condensate storage tank (CST), and supplying all four steam generators. All four steam generator ARVs are available to control RCS

temperature during hot standby. Main feed water is isolated by closing the main feed water isolation valves (MFIVs) from the control room. Diagnostic instrumentation is available to verify RCS temperature and pressure. Train B residual heat removal (RHR) system is available for transition from hot standby to cold shutdown.

A fire in this area will not prevent safe shutdown of the plant.

8.4 FIRE AREA A-4 (TRAIN B SAFETY RELATED PUMPS)

There are no 20 foot combustible and fire hazard free zones in fire area A-4. Fire area A-4 has automatic fire detection installed.

PFSSD is assured using Train A safety related and non-safety related equipment.

Reactivity control is achieved by tripping the reactor from the control room. Boration is available using Train A centrifugal charging pump (CCP) taking suction from the refueling water storage tank (RWST) and injecting borated water through the reactor coolant pump (RCP) seals and boron injection tank (BIT). Main steam isolation is accomplished by closing the main steam isolation valves (MSIVs) from the control room. Steam generator atmospheric relief valve (ARV) control is accomplished by controlling all four steam generator ARVs from the control room. Steam generator blowdown is isolated by closing all four blowdown valves from the control room. All four source range neutron flux monitors are available.

Reactor coolant makeup is achieved using Train A CCP taking suction from the RWST and injecting water through the RCP seals and BIT. Pressurizer level reduction due to uncontrolled cool down through steam generator blowdown lines, steam generator atmospheric relief valves and main steam lines would not be caused by a fire in this area. No inventory reduction paths are affected by a fire in this area.

Decay heat removal is achieved using all three auxiliary feed water pumps (AFPs), taking suction from the condensate storage tank (CST), and supplying all four steam generators. All four steam generator ARVs are available to control RCS temperature during hot standby. Main feed water is isolated by closing the main feed water isolation valves (MFIVs) from the control room. Diagnostic instrumentation is available to verify RCS temperature and pressure. Train A residual heat removal (RHR) system is available for transition from hot standby to cold shutdown, however RHR pump suction may have to be lined up locally.

A fire in this area will not prevent safe shutdown of the plant.

8.5 FIRE AREA A-5 (SOUTH STAIRWAY)

There are no 20 foot combustible and fire hazard free zones in fire area A-5. Fire area A-5 has automatic fire detection installed at the top of the stairway.

PFSSD is assured using either Train A or Train B safety related and non-safety related equipment.

Reactivity control is achieved by tripping the reactor from the control room. Boration is available using either Train A or Train B centrifugal charging pump (CCP) taking suction from the refueling water storage tank (RWST) and injecting borated water through the reactor coolant pump (RCP) seals and boron injection tank (BIT). Main steam isolation is accomplished by closing the main steam isolation valves (MSIVs) from the control room. Steam generator atmospheric relief valve (ARV) control is accomplished by controlling all four steam generator ARVs from the control room. Steam generator blowdown is isolated by closing all four blowdown valves from the control room. Source range neutron flux monitoring is available.

Reactor coolant makeup is achieved using either Train A or Train B CCP taking suction from the RWST and injecting water through the RCP seals and BIT. Pressurizer level reduction due to uncontrolled cool down through steam generator blowdown lines, steam generator atmospheric relief valves and main steam lines would not be caused by a fire in this area. No inventory reduction paths are affected by a fire in this area.

Decay heat removal is achieved using all three auxiliary feed water pumps taking suction from the condensate storage tank (CST), and supplying all four steam generators. All four steam generator ARVs are available to control RCS temperature during hot standby. Main feed water is isolated by closing the main feed water isolation valves (MFIVs) from the control room. Diagnostic instrumentation is available to verify RCS temperature and pressure. Train A and Train B residual heat removal (RHR) system is available for transition from hot standby to cold shutdown.

A fire in this area will not prevent safe shutdown of the plant.

8.6 FIRE AREA A-6 (NORTH STAIRWAY)

There are no 20 foot combustible and fire hazard free zones in fire area A-6. There is no fire suppression installed in area A-6. An automatic fire detector is installed at the top of the stairway.

PFSSD is assured using Train A safety related and non-safety related equipment.

Reactivity control is achieved by tripping the reactor from the control room. Boration is available using either Train A or Train B centrifugal charging pump (CCP) taking suction from the refueling water storage tank (RWST) and injecting borated water through the reactor coolant pump (RCP) seals and boron injection tank (BIT). Main steam isolation is accomplished by closing the main steam isolation valves (MSIVs) from the control room. Steam generator atmospheric relief valve (ARV) control is accomplished by controlling steam generator A, B and C ARVs from the control room and locally isolating steam generator D ARV. Steam generator blowdown is isolated by closing all four blowdown valves from radwaste control room panel BM157. All four source range neutron flux monitors are available.

Reactor coolant makeup is achieved using either Train A or Train B CCP taking suction from the RWST and injecting water through the RCP seals and BIT. Pressurizer level reduction could occur due to uncontrolled cool down through all four steam generator blowdown lines and one steam generator atmospheric relief valve until operator action is taken to isolate these flow paths. No other inventory reduction paths are affected by a fire in this area.

Decay heat removal is achieved using Train A motor driven auxiliary feed water pump (MDAFP), taking suction from the condensate storage tank (CST), and supplying steam generators B and C. Steam generators B and C ARVs are available to control RCS temperature during hot standby. Main feed water is isolated by closing the main feed water isolation valves (MFIVs) from the control room. Diagnostic instrumentation is available to verify RCS temperature and pressure. Both trains of residual heat removal (RHR) are available for transition from hot standby to cold shutdown.

A fire in this area will not prevent safe shutdown of the plant.

8.7 FIRE AREA A-7 (BORON INJECTION TANK ROOM)

There are no 20 foot combustible and fire hazard free zones in fire area A-7. Fire area A-7 has automatic fire detection installed but no suppression.

PFSSD is assured using either Train A or Train B safety related and non-safety related equipment.

Reactivity control is achieved by tripping the reactor from the control room. Boration is available using either Train A or Train B centrifugal charging pump (CCP) taking suction from the refueling water storage tank (RWST) and injecting borated water through the reactor coolant pump (RCP) seals. Main steam isolation is accomplished by closing the main steam isolation valves (MSIVs) from the control room. Steam generator atmospheric relief valve (ARV) control is accomplished by controlling all four steam generator ARVs from the control room. Steam generator blowdown is isolated by closing all four blowdown valves from the control room. All four source range neutron flux monitors are available.

Reactor coolant makeup is achieved using either Train A or Train B CCP taking suction from the RWST and injecting water through the RCP seals. If necessary, the boron injection tank (BIT) flow path will need to be manually aligned for transition from hot standby to cold shutdown. Pressurizer level reduction due to uncontrolled cool down through steam generator blowdown lines, steam generator atmospheric relief valves and main steam lines would not be caused by a fire in this area. No inventory reduction paths are affected by a fire in this area.

Decay heat removal is achieved using all three auxiliary feed water pumps taking suction from the condensate storage tank (CST), and supplying all four steam generators. All four steam generator ARVs are available to control RCS temperature during hot standby. Main feed water is isolated by closing the main feed water isolation valves (MFIVs) from the control room. Diagnostic instrumentation is available to verify RCS temperature and pressure. Train A and Train B residual heat removal (RHR) system is available for transition from hot standby to cold shutdown.

A fire in this area will not prevent safe shutdown of the plant.

8.8 FIRE AREA A-8 (GENERAL AREA 2000 ELEVATION)

There are no 20 foot combustible and fire hazard free zones in fire area A-8. Fire area A-8 is protected by automatic fire detection throughout areas containing more than negligible quantities of combustibles and an automatic pre-action sprinkler system above cable tray concentrations. Some of the PFSSD circuits that run through area A-8 are wrapped with 1-hour fire rated material to protect the PFSSD function of the associated equipment. This configuration meets Wolf Creek's commitments to the requirements of 10CFR50, Appendix R, Section III.G.2.c.

PFSSD is assured using Train B safety related and non-safety related equipment.

Reactivity control is achieved by tripping the reactor from the control room. Boration is available using Train B centrifugal charging pump (CCP) taking suction from the refueling water storage

tank (RWST) and injecting borated water through the reactor coolant pump (RCP) seals. The VCT can be isolated using both hand switches in the control room to ensure closure of at least one valve (See License Amendment 205). Main steam isolation is accomplished by closing the main steam isolation valves (MSIVs) from the control room. Steam generator atmospheric relief valve (ARV) control is accomplished by controlling steam generator B and D ARVs from the control room and locally isolating steam generators A and C ARVs. Steam generator blowdown is isolated by closing all four blowdown valves from the control room. Source range neutron flux monitoring is available.

Reactor coolant makeup is achieved using the Train B CCP taking suction from the RWST and injecting water through the RCP seals. If necessary, the boron injection tank (BIT) flow path will need to be manually aligned for transition from hot standby to cold shutdown. The VCT can be isolated using both hand switches in the control room to ensure closure of at least one valve (See License Amendment 205). Pressurizer level reduction could occur due to uncontrolled cool down through two steam generator atmospheric relief valves until operator action is taken to isolate these flow paths. A fire in this area could prevent isolation of letdown from the control room. However, letdown will automatically isolate when pressurizer level reaches 17%. Both pressurizer spray valves could open until operator action is taken in the control room to close the valves. One pressurizer PORV may spuriously open and its associated block valve may not close. If this occurs, operators can close the PORV using the hand switch in the control room. No other inventory reduction paths are affected by a fire in this area.

Decay heat removal is achieved using Train B motor driven auxiliary feed water pump (MDAFP), taking suction from the condensate storage tank (CST), and supplying steam generator D. Steam generator D ARV is available to control RCS temperature during hot standby. Steam generator A ARV control could be lost. Per Calculation WCNOC-CP-002, hot standby can be maintained using a single steam generator ARV. A spuriously opened ARV will not adversely impact safe shutdown. Main feed water is isolated by closing the main feed water isolation valves (MFIVs) from the control room. Diagnostic instrumentation is available to verify RCS temperature and pressure. Train B residual heat removal (RHR) is available for transition from hot standby to cold shutdown, however the Train B RHR pump suction may have to be lined up locally.

A fire in this area will not prevent safe shutdown of the plant.

8.9 FIRE AREA A-9 (TRAIN B RHR HEAT EXCHANGER ROOM)

There are no 20 foot combustible and fire hazard free zones in fire area A-9. There is no fire suppression or detection installed in area A-9.

PFSSD is assured using either Train A or Train B safety related and non-safety related equipment.

Reactivity control is achieved by tripping the reactor from the control room. Boration is available using either Train A or Train B centrifugal charging pump (CCP) taking suction from the refueling water storage tank (RWST) and injecting borated water through the reactor coolant pump (RCP) seals and boron injection tank (BIT). Main steam isolation is accomplished by closing the main steam isolation valves (MSIVs) from the control room. Steam generator atmospheric relief valve (ARV) control is accomplished by controlling all four steam generator ARVs from the control room. Steam generator blowdown is isolated by closing all four blowdown valves from the control room. All four source range neutron flux monitors are available.

Reactor coolant makeup is achieved using either Train A or Train B CCP taking suction from the RWST and injecting water through the RCP seals and BIT. Pressurizer level reduction due to uncontrolled cool down through steam generator blowdown lines, steam generator atmospheric relief valves and main steam lines would not be caused by a fire in this area. No inventory reduction paths are affected by a fire in this area.

Decay heat removal is achieved using all three auxiliary feed water pumps taking suction from the condensate storage tank (CST), and supplying all four steam generators. All four steam generator ARVs are available to control RCS temperature during hot standby. Main feed water is isolated by closing the main feed water isolation valves (MFIVs) from the control room. Diagnostic instrumentation is available to verify RCS temperature and pressure. Trains A and B residual heat removal (RHR) systems are available for transition from hot standby to cold shutdown.

A fire in this area will not prevent safe shutdown of the plant.

8.10 FIRE AREA A-10 (TRAIN A RHR HEAT EXCHANGER ROOM)

There are no 20 foot combustible and fire hazard free zones in fire area A-10. There is no fire suppression or detection installed in area A-10.

PFSSD is assured using either Train A or Train B safety related and non-safety related equipment.

Reactivity control is achieved by tripping the reactor from the control room. Boration is available using either Train A or Train B centrifugal charging pump (CCP) taking suction from the refueling water storage tank (RWST) and injecting borated water through the reactor coolant pump (RCP) seals and boron injection tank (BIT). Main steam isolation is accomplished by closing the main steam isolation valves (MSIVs) from the control room. Steam generator atmospheric relief valve (ARV) control is accomplished by controlling all four steam generator ARVs from the control room. Steam generator blowdown is isolated by closing all four blowdown valves from the control room. All four source range neutron flux monitors are available.

Reactor coolant makeup is achieved using either Train A or Train B CCP taking suction from the RWST and injecting water through the RCP seals and BIT. Pressurizer level reduction due to uncontrolled cool down through steam generator blowdown lines, steam generator atmospheric relief valves and main steam lines would not be caused by a fire in this area. No inventory reduction paths are affected by a fire in this area.

Decay heat removal is achieved using all three auxiliary feed water pumps taking suction from the condensate storage tank (CST), and supplying all four steam generators. All four steam generator ARVs are available to control RCS temperature during hot standby. Main feed water is isolated by closing the main feed water isolation valves (MFIVs) from the control room. Diagnostic instrumentation is available to verify RCS temperature and pressure. Train B residual heat removal (RHR) system is available for transition from hot standby to cold shutdown.

A fire in this area will not prevent safe shutdown of the plant.

8.11 FIRE AREA A-11 (NORTH ELECTRICAL CHASE)

There are no 20 foot combustible and fire hazard free zones in fire area A-11. Fire area A-11 has automatic fire detection and suppression installed.

PFSSD is assured using Train B safety related and non-safety related equipment.

Reactivity control is achieved by tripping the reactor from the control room. Boration is available using the Train B centrifugal charging pump (CCP) taking suction from the refueling water storage tank (RWST) and injecting borated water through the reactor coolant pump (RCP) seals and boron injection tank (BIT). Main steam isolation is accomplished by closing the main steam isolation valves (MSIVs) from the control room. Steam generator atmospheric relief valve (ARV) control is accomplished by controlling all four steam generator ARVs from the control room. Steam generator blowdown is isolated by closing all four blowdown valves from the control room. All four source range neutron flux monitors are available.

Reactor coolant makeup is achieved using the Train B CCP taking suction from the RWST and injecting water through the RCP seals and BIT. Pressurizer level reduction due to uncontrolled cool down through steam generator blowdown lines, steam generator atmospheric relief valves and main steam lines would not be caused by a fire in this area. A fire in this area could cause a loss of inventory through the letdown flow path until the letdown isolation valves can be failed closed. The pressurizer spray valves could open until the valves can be failed closed. One pressurizer PORV may spuriously open and its associated block valve may not close. If this occurs, operators can close the PORV using the hand switch in the control room. No other inventory reduction paths are affected by a fire in this area.

Decay heat removal is achieved using the turbine driven auxiliary feed water pump (TDAFP), taking suction from the condensate storage tank (CST), and supplying all four steam generators. All four steam generator ARVs are available to control RCS temperature during hot standby. In addition, the Train B motor driven auxiliary feed water pump (MDAFP) is available to supply auxiliary feed water to steam generators A and D. Main feed water is isolated by closing the main feed water isolation valves (MFIVs) from the control room. Diagnostic instrumentation is available to verify RCS temperature and pressure. Train B residual heat removal (RHR) system is available for transition from hot standby to cold shutdown, however RHR pump suction may have to be lined up locally.

A fire in this area will not prevent safe shutdown of the plant.

8.12 FIRE AREA A-12 (SOUTH ELECTRICAL CHASE)

There are no 20 foot combustible and fire hazard free zones in fire area A-12. Fire area A-12 has automatic fire detection and suppression installed.

PFSSD is assured using Train A safety related and non-safety related equipment.

Reactivity control is achieved by tripping the reactor from the control room. Boration is available using either the Train A or Train B centrifugal charging pump (CCP) taking suction from the refueling water storage tank (RWST) and injecting borated water through the reactor coolant pump (RCP) seals and boron injection tank (BIT). Main steam isolation is accomplished by closing the main steam isolation valves (MSIVs) from the control room. Steam generator atmospheric relief valve (ARV) control is accomplished by controlling all four steam generator ARVs from the control room. Steam generator blowdown is isolated by closing all four blowdown valves from the control room. All four source range neutron flux monitors are available.

Reactor coolant makeup is achieved using the Train A or Train B CCP taking suction from the RWST and injecting water through the RCP seals and BIT. Pressurizer level reduction due to uncontrolled cool down through steam generator blowdown lines, steam generator atmospheric relief valves and main steam lines would not be caused by a fire in this area. No inventory reduction paths are affected by a fire in this area.

Decay heat removal is achieved using all three auxiliary feed water pumps taking suction from the condensate storage tank (CST), and supplying all four steam generators. All four steam generator ARVs are available to control RCS temperature during hot standby. Main feed water is isolated by closing the main feed water isolation valves (MFIVs) from the control room. Diagnostic instrumentation is available to verify RCS temperature and pressure. Train A residual heat removal (RHR) system is available for transition from hot standby to cold shutdown, but one valve in the RHR system may need to be manually closed.

A fire in this area will not prevent safe shutdown of the plant.

8.13 FIRE AREA A-13 (TRAIN B MOTOR DRIVEN AUXILIARY FEEDWATER PUMP)

There are no 20 foot combustible and fire hazard free zones in fire area A-13. Fire area A-13 has automatic fire detection installed but no suppression.

PFSSD is assured using Train A safety related and non-safety related equipment.

Reactivity control is achieved by tripping the reactor from the control room. Boration is available using either Train A or Train B centrifugal charging pump (CCP) taking suction from the refueling water storage tank (RWST) and injecting borated water through the reactor coolant pump (RCP) seals and boron injection tank (BIT). Main steam isolation is accomplished by closing the main steam isolation valves (MSIVs) from the control room. Steam generator atmospheric relief valve (ARV) control is accomplished by controlling steam generators A, C and D ARVs from the control room and locally controlling steam generator B ARV using the local controller. Steam generators A and D ARVs may need to be controlled manually from the control room. Two steam generator blowdown valves can be isolated from the main control room while the other two may need to be isolated from radwaste control room panel BM157. All four source range neutron flux monitors are available.

Reactor coolant makeup is achieved using either Train A or Train B CCP taking suction from the RWST and injecting water through the RCP seals and BIT. Pressurizer level reduction could occur due to uncontrolled cool down through two steam generator blowdown lines and two steam generator atmospheric relief valve until operator action is taken to isolate these flow paths. No other inventory reduction paths are affected by a fire in this area.

Decay heat removal is achieved using Train A motor driven auxiliary feed water pump (MDAFP), taking suction from the condensate storage tank (CST), and supplying steam generator C. Steam generator C ARV is available to control RCS temperature during hot standby. Steam generator B ARV may need to be controlled locally. Per Calculation WCNOC-CP-002, hot standby can be maintained using a single steam generator ARV and a spuriously opened ARV will not adversely impact safe shutdown. Main feed water is isolated by closing the main feed water isolation valves (MFIVs) from the control room. Diagnostic instrumentation is available to verify RCS temperature and pressure. Both Trains of residual heat removal (RHR) are available for transition from hot standby to cold shutdown.

A fire in this area will not prevent safe shutdown of the plant.

8.14 FIRE AREA A-14 (TRAIN A MOTOR DRIVEN AUXILIARY FEEDWATER PUMP)

There are no 20 foot combustible and fire hazard free zones in fire area A-14. Fire area A-14 has automatic fire detection installed but no suppression.

PFSSD is assured using Train B safety related and non-safety related equipment.

Reactivity control is achieved by tripping the reactor from the control room. Boration is available using either Train A or Train B centrifugal charging pump (CCP) taking suction from the refueling water storage tank (RWST) and injecting borated water through the reactor coolant pump (RCP) seals and boron injection tank (BIT). Main steam isolation is accomplished by closing the main steam isolation valves (MSIVs) from the control room. Steam generator atmospheric relief valve (ARV) control is accomplished by controlling all four steam generators from the control room. Steam generator A ARV may need to be controlled manually from the control room. Steam generator blowdown is isolated by closing all four blowdown valves from the control room. All four source range neutron flux monitors are available.

Reactor coolant makeup is achieved using either Train A or Train B CCP taking suction from the RWST and injecting water through the RCP seals and BIT. Pressurizer level reduction due to uncontrolled cool down through steam generator blowdown lines, steam generator atmospheric

relief valves and main steam lines would not be caused by a fire in this area. No inventory reduction paths are affected by a fire in this area.

Decay heat removal is achieved using Train B motor driven auxiliary feed water pump (MDAFP), taking suction from the condensate storage tank (CST), and supplying steam generators A and D. In addition, the turbine driven auxiliary feed water pump (TDAFP) is available but may be limited to supplying only steam generators B and C using Train B ESW as the water source. All four steam generator ARVs are available to control RCS temperature during hot standby. Main feed water is isolated by closing the main feed water isolation valves (MFIVs) from the control room. Diagnostic instrumentation is available to verify RCS temperature and pressure. Both Trains of residual heat removal (RHR) are available for transition from hot standby to cold shutdown.

A fire in this area will not prevent safe shutdown of the plant.

8.15 FIRE AREA A-15 (TURBINE DRIVEN AUXILIARY FEEDWATER PUMP)

There are no 20 foot combustible and fire hazard free zones in fire area A-15. Fire area A-15 has automatic fire detection and a fixed manual fire suppression system installed.

PFSSD is assured using Train B safety related and non-safety related equipment.

Reactivity control is achieved by tripping the reactor from the control room. Boration is available using either Train A or Train B centrifugal charging pump (CCP) taking suction from the refueling water storage tank (RWST) and injecting borated water through the reactor coolant pump (RCP) seals and boron injection tank (BIT). Two of the four main steam isolation valves (MSIVs) may not close when control room hand switches are actuated. Main steam isolation is accomplished by closing valves downstream of the MSIVs using hand switches in the control room. Steam generators A, C and D atmospheric relief valve (ARV) control is accomplished using hand switches in the control room. Steam generator B ARV may need to be controlled using the local controller. Steam generator blowdown is isolated by closing all four blowdown valves from the control room, however two of the four steam generator blowdown valves may need to be isolated by disconnecting 125 VDC power to fail the valves closed. All four source range neutron flux monitors are available.

Reactor coolant makeup is achieved using either Train A or Train B CCP taking suction from the RWST and injecting water through the RCP seals and BIT. Pressurizer level reduction could occur due to uncontrolled cool down through two steam generator blowdown lines, one steam generator atmospheric relief valve and two main steam isolation valves until operator action is taken to isolate these flow paths. No other inventory reduction paths are affected by a fire in this area.

Decay heat removal is achieved using Train B motor driven auxiliary feed water pump (MDAFP), taking suction from the condensate storage tank (CST), and supplying steam generators A and D. Steam generators A and D ARVs are available to control RCS temperature during hot standby. Main feed water isolation valves (MFIVs) for steam generators A and D can be isolated from the control room. MFIVs for steam generators B and C may not close but flow diversion is prevented as long as steam generators A and D MFIVs are closed. Diagnostic instrumentation is available to verify RCS temperature and pressure. Both Trains of residual heat removal (RHR) are available for transition from hot standby to cold shutdown.

A fire in this area will not prevent safe shutdown of the plant.

8.16 FIRE AREA A-16 (GENERAL AREA 2026 ELEVATION)

Fire area A-16 is divided into two sections. The North section (A-16 North) starts from approximately 2'-0" South of column line A7 and ends at the North wall at column line A1. The South section (A-16 South) starts at column line A14 and runs North to approximately 2'-0" South of column line A8. Area A-16 South also includes room 1402.

The area between A-16 North and A-16 South is a minimum of 20'-0" in width and is considered an area free of combustibles and fire hazards. The 20'-0" wide combustible/fire hazard free zone extends from the East wall of fire area A-9 to the West containment wall. This area shall be maintained free of combustibles and fire hazards at all times, except as approved in the fire hazard analysis.

Fire area A-16 is provided with automatic fire detection throughout and an automatic pre-action sprinkler system installed above cable tray concentrations.

8.16.1 FIRE AREA A-16 NORTH

PFSSD is assured using primarily Train B safety related and non-safety related equipment, except that the Train B motor driven auxiliary feed water pump (MDAFP) could be affected.

Reactivity control is achieved by tripping the reactor from the control room. Boration is available using Train B centrifugal charging pump (CCP) taking suction from the refueling water storage tank (RWST) and injecting borated water through the reactor coolant pump (RCP) seals and boron injection tank (BIT). Main steam isolation is accomplished by closing the main steam isolation valves (MSIVs) from the control room. Steam generator A atmospheric relief valve (ARV) control is accomplished using the hand switch in the control room. Steam generators B and C ARVs may need to be controlled using the local controller. Steam generator D ARV may need to be closed locally. Steam generator blowdown is isolated by closing all four blowdown valves from radwaste control room panel BM157. Source range neutron flux monitoring is available.

Reactor coolant makeup is achieved using Train B CCP taking suction from the RWST and injecting water through the RCP seals and BIT. Pressurizer level reduction could occur due to uncontrolled cool down through all four steam generator blowdown lines and three steam generator atmospheric relief valves until operator action is taken to isolate these flow paths. Both pressurizer spray valves could open until operator action is taken in the control room to close the valves. Both pressurizer PORVs could open due to spurious high pressurizer pressure signals until action is taken in the control room to close the PORVs. No other inventory reduction paths are affected by a fire in this area.

Decay heat removal is achieved using Train A motor driven auxiliary feed water pump (MDAFP), taking suction from the condensate storage tank (CST), and supplying steam generators B and C, however steam generators B and C ARVs may need to be controlled using the local controllers. A spurious swap over to ESW could occur due to potential damage to two of three suction pressure transmitter circuits that initiate swap over on 2/3 low suction pressure signals. This is acceptable for PFSSD since the Train A ESW system is unaffected. Main feed water is isolated by closing the main feed water isolation valves (MFIVs) from the control room. Diagnostic instrumentation is available to verify RCS temperature and pressure. Train B residual heat removal (RHR) system is available for transition from hot standby to cold shutdown, however RHR pump suction may have to be lined up locally.

A fire in area A-16 North will not prevent safe shutdown of the plant.

8.16.2 FIRE AREA A-16 SOUTH

PFSSD is assured using Train A safety related and non-safety related equipment.

Reactivity control is achieved by tripping the reactor from the control room. Boration is available using Train A centrifugal charging pump (CCP) taking suction from the refueling water storage tank (RWST) and injecting borated water through the reactor coolant pump (RCP) seals and boron injection tank (BIT). Main steam isolation is accomplished by closing the main steam isolation valves (MSIVs) from the control room. Steam generator atmospheric relief valve (ARV) control is accomplished by controlling all four steam generator ARVs from the control room. Steam generator blowdown is isolated by closing all four blowdown valves from radwaste control room panel BM157. Source range neutron flux monitoring is available.

Reactor coolant makeup is achieved using Train A CCP taking suction from the RWST and injecting water through the RCP seals and BIT. Pressurizer level reduction could occur due to uncontrolled cool down through all four steam generator blowdown lines until operator action is taken to isolate these flow paths. One pressurizer PORV may spuriously open and its associated block valve may not close. If this occurs, operators can close the PORV using the hand switch in the control room. The RWST could drain to the containment sump due to spurious opening of the Train B containment sump isolation valve until operator action is taken to isolate this drain down path. No other inventory reduction paths are affected by a fire in this area.

Decay heat removal is achieved using either Train A or Train B motor driven auxiliary feed water pumps (MDAFPs) or the turbine driven auxiliary feed water pump (TDAFP), taking suction from the condensate storage tank (CST), and supplying all four steam generators. All four steam generator ARVs are available to control RCS temperature during hot standby. Main feed water is isolated by closing the main feed water isolation valves (MFIVs) from the control room. Diagnostic instrumentation is available to verify RCS temperature and pressure. Train A residual heat removal (RHR) system is available for transition from hot standby to cold shutdown, however RHR pump suction may have to be lined up locally.

A fire in area A-16 South will not prevent safe shutdown of the plant.

8.17 FIRE AREA A-17 (SOUTH ELECTRICAL PENETRATION ROOM)

There are no 20 foot combustible and fire hazard free zones in fire area A-17. Fire area A-17 has automatic fire detection and a fixed automatic Halon fire suppression system installed.

PFSSD is assured using primarily Train A safety related and non-safety related equipment.

Reactivity control is achieved by tripping the reactor from the control room. Boration is available using the Train A centrifugal charging pump (CCP) taking suction from the refueling water storage tank (RWST) and injecting borated water through the reactor coolant pump (RCP) seals and boron injection tank (BIT). Main steam isolation is accomplished by closing the main steam isolation valves (MSIVs) from the control room. Steam generator atmospheric relief valve (ARV) control is accomplished by controlling all four steam generator ARVs from the control room. Steam generator blowdown is isolated by closing all four blowdown valves from the control room. Source range neutron flux monitoring is available.

Reactor coolant makeup is achieved using the Train A CCP taking suction from the RWST and injecting water through the RCP seals and BIT. Pressurizer level reduction due to uncontrolled cool down through steam generator blowdown lines, steam generator atmospheric relief valves and main steam lines would not be caused by a fire in this area. One pressurizer PORV may spuriously open and its associated block valve may not close. If this occurs, operators can close the PORV using the hand switch in the control room. The Train B reactor head vent valves and Train B excess letdown valves could open, causing a loss of RCS inventory through these flow

paths. If this occurs, operators will need to increase charging flow to make up for the inventory loss. No other inventory reduction paths are affected by a fire in this area.

Decay heat removal is achieved using either Train A or Train B motor driven auxiliary feed water pumps (MDAFPs) or the turbine driven auxiliary feed water pump (TDAFP), taking suction from the condensate storage tank (CST), and supplying all four steam generators. All four steam generator ARVs are available to control RCS temperature during hot standby. Main feed water is isolated by closing the main feed water isolation valves (MFIVs) from the control room. Diagnostic instrumentation is available to verify RCS temperature and pressure. Train A residual heat removal (RHR) system is available for transition from hot standby to cold shutdown, however RHR pump suction may have to be lined up locally.

A fire in this area will not prevent safe shutdown of the plant.

8.18 FIRE AREA A-18 (NORTH ELECTRICAL PENETRATION ROOM)

There are no 20 foot combustible and fire hazard free zones in fire area A-18. Fire area A-18 has automatic fire detection and a fixed automatic Halon fire suppression system installed.

PFSSD is assured using Train B safety related and non-safety related equipment.

Reactivity control is achieved by tripping the reactor from the control room. Boration is available using Train B centrifugal charging pump (CCP) taking suction from the refueling water storage tank (RWST) and injecting borated water through the reactor coolant pump (RCP) seals and boron injection tank (BIT). Main steam isolation is accomplished by closing the main steam isolation valves (MSIVs) from the control room. Steam generators A, C and D atmospheric relief valve (ARV) control is accomplished using the hand switches in the control room. Steam generator B ARV may need to be closed locally. Steam generator blowdown is isolated by closing all four blowdown valves from the control room. Source range neutron flux monitoring is available.

Reactor coolant makeup is achieved using Train B CCP taking suction from the RWST and injecting water through the RCP seals and BIT. Pressurizer level reduction could occur due to uncontrolled cool down through one steam generator atmospheric relief valve until operator action is taken to isolate this flow path. A fire in this area could cause a loss of inventory through the letdown flow path until the letdown isolation valves can be failed closed. The pressurizer spray valves could open until the valves can be failed closed. One pressurizer PORV may spuriously open and its associated block valve may not close. If this occurs, operators can close the PORV using the hand switch in the control room. The Train A reactor head vent valves and Train A excess letdown valves could open, causing a loss of RCS inventory through these flow paths. If this occurs, operators will need to increase charging flow to make up for the inventory loss. No other inventory reduction paths are affected by a fire in this area.

Decay heat removal is achieved using Train B motor driven auxiliary feed water pump (MDAFP), taking suction from the condensate storage tank (CST), and supplying steam generators A and D. Steam generators A and D ARVs are available to control RCS temperature during hot standby. Main feed water is isolated by closing the main feed water isolation valves (MFIVs) from the control room. Diagnostic instrumentation is available to verify RCS temperature and pressure. Train B residual heat removal (RHR) system is available for transition from hot standby to cold shutdown, however RHR pump suction may have to be lined up locally.

A fire in this area will not prevent safe shutdown of the plant.

8.19 FIRE AREA A-19 (GENERAL AREA 2047 ELEVATION)

There are no 20 foot combustible and fire hazard free zones in fire area A-19. Fire area A-19 has automatic fire detection installed.

PFSSD is assured using primarily Train B safety related and non-safety related equipment.

Reactivity control is achieved by tripping the reactor from the control room. Boration is available using Train B centrifugal charging pump (CCP) taking suction from the refueling water storage tank (RWST) and injecting borated water through the reactor coolant pump (RCP) seals and boron injection tank (BIT). Main steam isolation is accomplished by closing the main steam isolation valves (MSIVs) from the control room. Steam generators B, C and D atmospheric relief valve (ARV) control is accomplished using the hand switches in the control room. Steam generator A ARV may need to be closed locally. Steam generator blowdown is isolated by closing all four blowdown valves from the control room. Source range neutron flux monitoring is available.

Reactor coolant makeup is achieved using Train B CCP taking suction from the RWST and injecting water through the RCP seals and BIT. Pressurizer level reduction could occur due to uncontrolled cool down through one steam generator atmospheric relief valve until operator action is taken to isolate this flow path. No other inventory reduction paths are affected by a fire in this area.

Decay heat removal is achieved using Train B motor driven auxiliary feed water pump (MDAFP), taking suction from the condensate storage tank (CST), and supplying steam generator D, and the turbine driven auxiliary feed water pump (TDAFP), taking suction from the Train B essential service water (ESW) system, and supplying steam generators B, C and D. Steam generators B, C and D ARVs are available to control RCS temperature during hot standby. Steam generator A ARV may need to be locally closed. Main feed water is isolated by closing the main feed water isolation valves (MFIVs) from the control room. Diagnostic instrumentation is available to verify RCS temperature and pressure. Train B residual heat removal (RHR) system is available for transition from hot standby to cold shutdown, however RHR pump suction may have to be lined up locally.

A fire in this area will not prevent safe shutdown of the plant.

8.20 FIRE AREA A-20 (CCW SURGE TANK AREA ELEVATION 2047)

There are no 20 foot combustible and fire hazard free zones in fire area A-20. Fire area A-20 has automatic fire detection installed near the elevator and near the containment personnel hatch.

PFSSD is assured using either Train A or Train B safety related and non-safety related equipment.

Reactivity control is achieved by tripping the reactor from the control room. Boration is available using either Train A or Train B centrifugal charging pump (CCP) taking suction from the refueling water storage tank (RWST) and injecting borated water through the reactor coolant pump (RCP) seals and boron injection tank (BIT). Main steam isolation is accomplished by closing the main steam isolation valves (MSIVs) from the control room. Steam generator atmospheric relief valve (ARV) control is accomplished by controlling all four steam generator ARVs from the control room. Steam generator blowdown is isolated by closing all four blowdown valves from the control room. Source range neutron flux monitoring is available.

Reactor coolant makeup is achieved using either Train A or Train B CCP taking suction from the RWST and injecting water through the RCP seals and BIT. Pressurizer level reduction due to uncontrolled cool down through steam generator blowdown lines, steam generator atmospheric

relief valves and main steam lines would not be caused by a fire in this area. No inventory reduction paths are affected by a fire in this area.

Decay heat removal is achieved using all three auxiliary feed water pumps taking suction from the condensate storage tank (CST), and supplying all four steam generators. All four steam generator ARVs are available to control RCS temperature during hot standby. Main feed water is isolated by closing the main feed water isolation valves (MFIVs) from the control room. Diagnostic instrumentation is available to verify RCS temperature and pressure. Train A and Train B residual heat removal (RHR) system is available for transition from hot standby to cold shutdown.

A fire in this area will not prevent safe shutdown of the plant.

8.21 FIRE AREA A-21 (TRAIN B CONTROL ROOM HVAC)

There are no 20 foot combustible and fire hazard free zones in fire area A-21. Fire area A-21 has automatic fire detection installed.

PFSSD is assured using primarily Train A safety related and non-safety related equipment.

Reactivity control is achieved by tripping the reactor from the control room. Boration is available using the Train A centrifugal charging pump (CCP) taking suction from the refueling water storage tank (RWST) and injecting borated water through the reactor coolant pump (RCP) seals and boron injection tank (BIT). Main steam isolation is accomplished by closing the main steam isolation valves (MSIVs) from the control room. Steam generators A, B and C atmospheric relief valve (ARV) control is accomplished using the hand switches in the control room. Steam generator D ARV may need to be closed locally. Steam generator blowdown is isolated by closing all four blowdown valves from radwaste control room panel BM157. Source range neutron flux monitoring is available.

Reactor coolant makeup is achieved using the Train A CCP taking suction from the RWST and injecting water through the RCP seals and BIT. Pressurizer level reduction could occur due to uncontrolled cool down through all four steam generator blowdown lines and one steam generator atmospheric relief valve until operator action is taken to isolate these flow paths. No other inventory reduction paths are affected by a fire in this area.

Decay heat removal is achieved using the Train A motor driven auxiliary feed water pump (MDAFP), taking suction from the condensate storage tank (CST), and supplying steam generators B and C, and the turbine driven auxiliary feed water pump (TDAFP), taking suction from the condensate storage tank (CST), and supplying steam generator A. Steam generators A, B and C ARVs are available to control RCS temperature during hot standby. Steam generator D ARV may need to be locally closed. Main feed water is isolated by closing the main feed water isolation valves (MFIVs) from the control room. Diagnostic instrumentation is available to verify RCS temperature and pressure. Train A residual heat removal (RHR) system is available for transition from hot standby to cold shutdown, however RHR pump suction may have to be lined up locally.

A fire in this area will not prevent a safe shutdown of the plant.

8.22 FIRE AREA A-22 (TRAIN A CONTROL ROOM HVAC)

There are no 20 foot combustible and fire hazard free zones in fire area A-22. Fire area A-22 has automatic fire detection installed.

PFSSD is assured using primarily Train B safety related and non-safety related equipment.

Reactivity control is achieved by tripping the reactor from the control room. Boration is available using Train B centrifugal charging pump (CCP) taking suction from the refueling water storage tank (RWST) and injecting borated water through the reactor coolant pump (RCP) seals and boron injection tank (BIT). Main steam isolation is accomplished by closing the main steam isolation valves (MSIVs) from the control room. Steam generators B, C and D atmospheric relief valve (ARV) control is accomplished using the hand switches in the control room. Steam generator A ARV may need to be closed locally. Steam generator blowdown is isolated by closing all four blowdown valves from the control room. All four source range neutron flux monitors are available.

Reactor coolant makeup is achieved using Train B CCP taking suction from the RWST and injecting water through the RCP seals and BIT. Pressurizer level reduction could occur due to uncontrolled cool down through one steam generator atmospheric relief valve until operator action is taken to isolate this flow path. No other inventory reduction paths are affected by a fire in this area.

Decay heat removal is achieved using Train B motor driven auxiliary feed water pump (MDAFP), taking suction from the condensate storage tank (CST), and supplying steam generator D, and the turbine driven auxiliary feed water pump (TDAFP), taking suction from the Train B essential service water (ESW) system, and supplying steam generators B, C and D. Steam generators B, C and D ARVs are available to control RCS temperature during hot standby. Steam generator A ARV may need to be locally closed. Main feed water is isolated by closing the main feed water isolation valves (MFIVs) from the control room. Diagnostic instrumentation is available to verify RCS temperature and pressure. Train B residual heat removal (RHR) system is available for transition from hot standby to cold shutdown.

A fire in this area will not prevent a safe shutdown of the plant.

8.23 FIRE AREA A-23 (MAIN STEAM AND FEEDWATER VALVE COMPARTMENT)

There are no 20 foot combustible and fire hazard free zones in fire area A-23. Fire area A-23 has automatic fire detection (flame detectors) installed. A 2-foot thick concrete barrier separates the west compartment from the east compartment. The west compartment consists of rooms 1411 and 1508 and the east compartment consists of rooms 1412 and 1509.

8.23.1 FIRE AREA A-23 EAST

PFSSD is assured using either Train A or Train B safety related and non-safety related equipment.

Reactivity control is achieved by tripping the reactor from the control room. Boration is available using either Train A or Train B centrifugal charging pump (CCP) taking suction from the refueling water storage tank (RWST) and injecting borated water through the reactor coolant pump (RCP) seals and boron injection tank (BIT). Main steam isolation is accomplished by closing valves downstream of the MSIVs using hand switches in the control room. Steam generators A and D atmospheric relief valves (ARVs) can be controlled from the control room. Steam generators B and C ARVs may need to be failed closed by disconnecting 120 VAC power to the controllers. Steam generator blowdown is isolated by closing all four blowdown valves from the control room, however two of the four steam generator blowdown

valves may need to be failed closed by disconnecting 125 VDC power to fail the valves closed. All four source range neutron flux monitors are available.

Reactor coolant makeup is achieved using either Train A or Train B CCP taking suction from the RWST and injecting water through the RCP seals and BIT. Pressurizer level reduction could occur due to uncontrolled cool down through two steam generator blowdown lines, two steam generator atmospheric relief valves and two main steam isolation valves until operator action is taken to isolate these flow paths. No other inventory reduction paths are affected by a fire in this area.

Decay heat removal is achieved using the Train B motor driven auxiliary feed water pump (MDAFP), taking suction from the condensate storage tank (CST), and supplying steam generators A and D. Steam generators A and D ARVs are available to control RCS temperature during hot standby. Two main feed water isolation valves (MFIVs) can be isolated from the control room. The remaining two MFIVs may not close but flow diversion is prevented as long as two of the valves are closed. Diagnostic instrumentation is available to verify RCS temperature and pressure. Both Trains of residual heat removal (RHR) are available for transition from hot standby to cold shutdown.

A fire in this area will not prevent safe shutdown of the plant.

8.23.2 FIRE AREA A-23 WEST

PFSSD is assured using either Train A or Train B safety related and non-safety related equipment.

Reactivity control is achieved by tripping the reactor from the control room. Boration is available using either Train A or Train B centrifugal charging pump (CCP) taking suction from the refueling water storage tank (RWST) and injecting borated water through the reactor coolant pump (RCP) seals and boron injection tank (BIT). Main steam isolation is accomplished by closing valves downstream of the MSIVs using hand switches in the control room. Steam generators B and C atmospheric relief valves (ARVs) can be controlled from the control room. Steam generators A and D ARVs may need to be failed closed by disconnecting 120 VAC power to the controllers. Steam generator blowdown is isolated by closing all four blowdown valves from the control room, however two of the four steam generator blowdown valves may need to be isolated by disconnecting 125 VDC power to fail the valves closed. All four source range neutron flux monitors are available.

Reactor coolant makeup is achieved using either Train A or Train B CCP taking suction from the RWST and injecting water through the RCP seals and BIT. Pressurizer level reduction could occur due to uncontrolled cool down through two steam generator blowdown lines, two steam generator atmospheric relief valves and two main steam isolation valves until operator action is taken to isolate these flow paths. No other inventory reduction paths are affected by a fire in this area.

Decay heat removal is achieved using the Train A motor driven auxiliary feed water pump (MDAFP) or the turbine driven auxiliary feed water pump (TDAFP), taking suction from the condensate storage tank (CST), and supplying steam generators B and C. Steam generators B and C ARVs are available to control RCS temperature during hot standby. Two main feed water isolation valves (MFIVs) can be isolated from the control room. The remaining two MFIVs may not close but flow diversion is prevented as long as two of the valves are closed. Diagnostic instrumentation is available to verify RCS temperature and pressure. Both Trains of residual heat removal (RHR) are available for transition from hot standby to cold shutdown.

A fire in this area will not prevent safe shutdown of the plant.

8.24 FIRE AREA A-24 (NORTH PIPE PENETRATION ROOM)

There are no 20 foot combustible and fire hazard free zones in fire area A-24. Fire area A-24 has automatic fire detection installed.

PFSSD is assured using Train B safety related and non-safety related equipment.

Reactivity control is achieved by tripping the reactor from the control room. Boration is available using the Train B centrifugal charging pump (CCP) taking suction from the refueling water storage tank (RWST) and injecting borated water through the reactor coolant pump (RCP) seals. Main steam isolation is accomplished by closing the main steam isolation valves (MSIVs) from the control room. Steam generators A, B and D atmospheric relief valve (ARV) control is accomplished using the hand switches in the control room. Steam generator C ARV may need to be closed locally. Steam generator blowdown is isolated by closing all four blowdown valves from the control room. All four source range neutron flux monitors are available.

Reactor coolant makeup is achieved using the Train B CCP taking suction from the RWST and injecting water through the RCP seals. If necessary, the boron injection tank (BIT) flow path will need to be manually aligned for transition from hot standby to cold shutdown. Pressurizer level reduction could occur due to uncontrolled cool down through one steam generator atmospheric relief valve until operator action is taken to isolate this flow path. No other inventory reduction paths are affected by a fire in this area.
Decay heat removal is achieved using Train B motor driven auxiliary feed water pump (MDAFP), taking suction from the condensate storage tank (CST), and supplying steam generators A and D. Steam generators A and D ARVs are available to control RCS temperature during hot standby. Main feed water is isolated by closing the main feed water isolation valves (MFIVs) from the control room. Diagnostic instrumentation is available to verify RCS temperature and pressure. Both residual heat removal (RHR) trains are available for transition from hot standby to cold shutdown.

A fire in this area will not prevent safe shutdown of the plant.

8.25 FIRE AREA A-25 (SOUTH PIPE PENETRATION ROOM)

There are no 20 foot combustible and fire hazard free zones in fire area A-25. Fire area A-25 has automatic fire detection installed.

PFSSD is assured using Train A and Train B safety related and non-safety related equipment.

Reactivity control is achieved by tripping the reactor from the control room. Boration is available using either Train A or Train B centrifugal charging pump (CCP) taking suction from the refueling water storage tank (RWST) and injecting borated water through the reactor coolant pump (RCP) seals and boron injection tank (BIT). Main steam isolation is accomplished by closing the main steam isolation valves (MSIVs) from the control room. Steam generator atmospheric relief valve (ARV) control is accomplished by controlling all four steam generator ARVs from the control room. Steam generator blowdown is isolated by closing all four blowdown valves from the control room. All four source range neutron flux monitors are available.

Reactor coolant makeup is achieved using either Train A or Train B CCP taking suction from the RWST and injecting water through the RCP seals and BIT. Pressurizer level reduction due to uncontrolled cool down through steam generator blowdown lines, steam generator atmospheric relief valves and main steam lines would not be caused by a fire in this area. No inventory reduction paths are affected by a fire in this area.

Decay heat removal is achieved using either the Train A or Train B motor driven auxiliary feed water pump (MDAFP) or the turbine driven auxiliary feed water pump (TDAFP), taking suction from the condensate storage tank (CST), and supplying all four steam generators. All four steam

generator atmospheric relief valves (ARVs) are available to control RCS temperature during hot standby. Main feed water is isolated by closing the main feed water isolation valves (MFIVs) from the control room. Diagnostic instrumentation is available to verify RCS temperature and pressure. Both Trains of residual heat removal (RHR) are available for transition from hot standby to cold shutdown, however RHR pump suction may have to be lined up locally.

A fire in this area will not prevent safe shutdown of the plant.

8.26 FIRE AREA A-26 (STORAGE AND I&C HOT TOOL SHOP 2026 ELEVATION)

There are no 20 foot combustible and fire hazard free zones in fire area A-26. Fire area A-26 has automatic fire detection installed.

PFSSD is assured using Train A safety related and non-safety related equipment.

Reactivity control is achieved by tripping the reactor from the control room. Boration is available using Train A centrifugal charging pump (CCP) taking suction from the refueling water storage tank (RWST) and injecting borated water through the reactor coolant pump (RCP) seals and boron injection tank (BIT). Main steam isolation is accomplished by closing the main steam isolation valves (MSIVs) from the control room. Steam generator atmospheric relief valve (ARV) control is accomplished by controlling all four steam generator ARVs from the control room. Steam generator blowdown is isolated by closing all four blowdown valves from the control room. All four source range neutron flux monitors are available.

Reactor coolant makeup is achieved using Train A CCP taking suction from the RWST and injecting water through the RCP seals and BIT. Pressurizer level reduction due to uncontrolled cool down through steam generator blowdown lines, steam generator atmospheric relief valves and main steam lines would not be caused by a fire in this area. No inventory reduction paths are affected by a fire in this area.

Decay heat removal is achieved using all three auxiliary feed water pumps (AFPs), taking suction from the condensate storage tank (CST), and supplying all four steam generators. All four steam generator ARVs are available to control RCS temperature during hot standby. Main feed water is isolated by closing the main feed water isolation valves (MFIVs) from the control room. Diagnostic instrumentation is available to verify RCS temperature and pressure. Train A residual heat removal (RHR) system is available for transition from hot standby to cold shutdown.

A fire in this area will not prevent a safe shutdown of the plant.

8.27 FIRE AREA A-27 (ROD DRIVE/MG SET ROOM)

There are no 20 foot combustible and fire hazard free zones in fire area A-27. Fire area A-27 has automatic fire detection and a fixed automatic Halon fire suppression system installed.

PFSSD is assured using primarily Train B safety related and non-safety related equipment. However, since this area contains cables and equipment for both trains, Train A equipment may also be used.

Reactivity control is achieved by de-energizing the rod drive motor generators from the control room because the reactor trip breakers may be affected by the fire. Boration is available using the Train B centrifugal charging pump (CCP) taking suction from the refueling water storage tank (RWST) and injecting borated water through the reactor coolant pump (RCP) seals and boron injection tank (BIT). Main steam isolation is accomplished by closing the main steam isolation valves (MSIVs) from the control room. Steam generators A and D atmospheric relief valve (ARV) control is accomplished using hand switches in the control room. Steam generators B and C ARVs may need to be controlled using the local controllers. Steam generator blowdown is

isolated by closing all four blowdown valves from radwaste control room panel BM157. Source range neutron flux monitoring is available.

Reactor coolant makeup is achieved using the Train B CCP taking suction from the RWST and injecting water through the RCP seals and BIT. Pressurizer level reduction could occur due to uncontrolled cool down through all four steam generator blowdown lines and two steam generator atmospheric relief valves until operator action is taken to isolate these flow paths. Both pressurizer spray valves could open until operator action is taken in the control room to close the valves. Both pressurizer PORVs may spuriously open. One pressurizer PORV block valve can be closed from the control room. Both PORVs can be closed using the hand switch in the control room. No other inventory reduction paths are affected by a fire in this area.

Decay heat removal is achieved using the Train B motor driven auxiliary feed water pump (MDAFP), taking suction from the condensate storage tank (CST), and supplying steam generators A and D. Steam generators A and D ARVs are available to control RCS temperature during hot standby. Main feed water is isolated by closing the main feed water isolation valves (MFIVs) from the control room. Diagnostic instrumentation is available to verify RCS temperature and pressure. Train B residual heat removal (RHR) is available for transition from hot standby to cold shutdown, however valves in the suction and discharge flow path may have to be lined up locally to support shutdown cooling.

A fire in this area will not prevent safe shutdown of the plant.

8.28 FIRE AREA A-28 (AUXILIARY SHUTDOWN PANEL ROOM)

There are no 20 foot combustible and fire hazard free zones in fire area A-28. Fire area A-28 has automatic fire detection installed.

This fire area consists of two rooms that are separated by a 3-hour fire rated barrier. The North room contains the Train A auxiliary shutdown panel and the South room contains the Train B auxiliary shutdown panel. A fire in one room could impact the ability to achieve safe shutdown on the associated train, but the redundant train will remain available.

8.28.1 FIRE AREA A-28 NORTH

PFSSD is assured using Train A and Train B safety related and non-safety related equipment.

Reactivity control is achieved by tripping the reactor from the control room. Boration is available using either Train A or Train B centrifugal charging pump (CCP) taking suction from the refueling water storage tank (RWST) and injecting borated water through the reactor coolant pump (RCP) seals and boron injection tank (BIT). Main steam isolation is accomplished by closing the main steam isolation valves (MSIVs) from the control room. Steam generators B and D atmospheric relief valve (ARV) control is accomplished using the hand switches in the control room. Steam generators A and C ARVs may need to be closed locally. Steam generator blowdown is isolated by closing all four blowdown valves from the control room. All four source range neutron flux monitors are available.

Reactor coolant makeup is achieved using either the Train A or Train B CCP taking suction from the RWST and injecting water through the RCP seals and BIT. Pressurizer level reduction could occur due to uncontrolled cool down through two steam generator ARVs until operator action is taken to isolate this flow path. A fire in this area could cause a loss of inventory through the letdown flow path. Letdown will automatically isolate when pressurizer level reaches 17%. No other inventory reduction paths are affected by a fire in this area.

Decay heat removal is achieved using the turbine driven auxiliary feed water pump (TDAFP), taking suction from the condensate storage tank (CST), and supplying steam generator B and the Train B MDAFP taking suction from the CST and supplying steam generator D. Steam

generators B and D ARVs are available to control RCS temperature during hot standby. Main feed water is isolated by closing the main feed water isolation valves (MFIVs) from the control room. Diagnostic instrumentation is available to verify RCS temperature and pressure. Both residual heat removal (RHR) trains are available for transition from hot standby to cold shutdown.

A fire in this area will not prevent safe shutdown of the plant.

8.28.2 FIRE AREA A-28 SOUTH

PFSSD is assured using Train A and Train B safety related and non-safety related equipment.

Reactivity control is achieved by tripping the reactor from the control room. Boration is available using either Train A or Train B centrifugal charging pump (CCP) taking suction from the refueling water storage tank (RWST) and injecting borated water through the reactor coolant pump (RCP) seals and boron injection tank (BIT). Main steam isolation is accomplished by closing the main steam isolation valves (MSIVs) from the control room. Steam generators A and C atmospheric relief valve (ARV) control is accomplished using the hand switches in the control room. Steam generators B and D ARVs may need to be closed locally. Steam generator blowdown is isolated by closing all four blowdown valves from the control room. All four source range neutron flux monitors are available.

Reactor coolant makeup is achieved using either the Train A or Train B CCP taking suction from the RWST and injecting water through the RCP seals and BIT. Pressurizer level reduction could occur due to uncontrolled cool down through two steam generator ARVs until operator action is taken to isolate these flow paths. No other inventory reduction paths are affected by a fire in this area.

Decay heat removal is achieved using the Train A MDAFP, taking suction from the condensate storage tank (CST), and supplying steam generator C. Steam generator C ARV is available to control RCS temperature during hot standby. Steam generator B ARV may need to be controlled locally. Per Calculation WCNOC-CP-002, hot standby can be maintained using a single steam generator ARV and a spuriously opened ARV will not adversely impact safe shutdown. Main feed water is isolated by closing the main feed water isolation valves (MFIVs) from the control room. Diagnostic instrumentation is available to verify RCS temperature and pressure. Both residual heat removal (RHR) trains are available for transition from hot standby to cold shutdown.

A fire in this area will not prevent safe shutdown of the plant.

8.29 FIRE AREA A-29 (TRAIN B AUX FEEDWATER VALVE COMPARTMENTS/ACCUMULATOR TANK)

There are no 20 foot combustible and fire hazard free zones in fire area A-29. Fire area A-29 has no automatic fire detection or suppression installed.

PFSSD is assured using Train A and Train B safety related and non-safety related equipment.

Reactivity control is achieved by tripping the reactor from the control room. Boration is available using either Train A or Train B centrifugal charging pump (CCP) taking suction from the refueling water storage tank (RWST) and injecting borated water through the reactor coolant pump (RCP) seals and boron injection tank (BIT). Steam generators A, B and D atmospheric relief valves (ARVs) can be controlled from the control room but the controller may have to be placed in manual. Steam generator C ARV may need to be controlled locally. Main steam isolation is accomplished by closing the main steam isolation valves (MSIVs) from the control room. Steam generator blowdown is isolated by closing all four blowdown valves from the control room. All four source range neutron flux monitors are available.

Reactor coolant makeup is achieved using either Train A or Train B CCP taking suction from the RWST and injecting water through the RCP seals and BIT. Pressurizer level reduction could occur due to uncontrolled cool down through all four steam generator ARVs until operator action is taken to isolate these flow paths. No other inventory reduction paths are affected by a fire in this area.

Decay heat removal is achieved using the Train A MDAFP, taking suction from the CST, and supplying steam generator B. Steam generator B ARV is available to control RCS temperature during hot standby. Steam generator C atmospheric relief valve (ARV) may need to be controlled locally. Per Calculation WCNOC-CP-002, hot standby can be maintained using a single steam generator ARV and a spuriously opened ARV will not adversely impact safe shutdown. Main feed water is isolated by closing the main feed water isolation valves (MFIVs) from the control room. Diagnostic instrumentation is available to verify RCS temperature and pressure. Train A and Train B residual heat removal (RHR) system is available for transition from hot standby to cold shutdown.

A fire in this area will not prevent safe shutdown of the plant.

8.30 FIRE AREA A-30 (TRAIN A AUX FEEDWATER VALVE COMPARTMENTS/ACCUMULATOR TANK)

There are no 20 foot combustible and fire hazard free zones in fire area A-30. Fire area A-30 has no automatic fire detection or suppression installed.

PFSSD is assured using Train A and Train B safety related and non-safety related equipment.

Reactivity control is achieved by tripping the reactor from the control room. Boration is available using either Train A or Train B centrifugal charging pump (CCP) taking suction from the refueling water storage tank (RWST) and injecting borated water through the reactor coolant pump (RCP) seals and boron injection tank (BIT). Steam generators A, B and D atmospheric relief valves (ARVs) can be controlled from the control room but the controllers may have to be placed in manual. Steam generator C ARV may need to be controlled locally. Main steam isolation is accomplished by closing the main steam isolation valves (MSIVs) from the control room. Steam generator blowdown is isolated by closing all four blowdown valves from the control room. All four source range neutron flux monitors are available.

Reactor coolant makeup is achieved using either Train A or Train B CCP taking suction from the RWST and injecting water through the RCP seals and BIT. Pressurizer level reduction could occur due to uncontrolled cool down through one steam generator ARV until operator action is taken to isolate this flow path. No other inventory reduction paths are affected by a fire in this area.

Decay heat removal is achieved using the Train B motor driven auxiliary feed water pump (MDAFP) and the turbine driven auxiliary feed water pump (TDAFP), taking suction from the condensate storage tank (CST), and supplying steam generators A and D. A spurious low auxiliary feed water (AFW) suction pressure signal could occur which would swap the AFW source to ESW. Steam generators A and D ARVs are available to control RCS temperature during hot standby. Main feed water is isolated by closing the main feed water isolation valves (MFIVs) from the control room. Diagnostic instrumentation is available to verify RCS temperature and pressure. Train A and Train B residual heat removal (RHR) system is available for transition from hot standby to cold shutdown.

A fire in this area will not prevent safe shutdown of the plant.

8.31 FIRE AREA A-31

Fire Area A-31 does not exist.

8.32 FIRE AREA A-32

Fire Area A-32 does not exist.

8.33 FIRE AREA A-33 (AUX FEEDWATER PIPE SPACE)

This area has a 20 foot combustible and fire hazard free zone between valves ALHV0032 and ALHV0033. In addition, where cables associated with ALHV0032 are run within 20 feet of redundant components, the cables are enclosed with a qualified 1-hour fire barrier. The horizontal separation and 1-hour fire barrier, along with automatic fire suppression and detection throughout the area meets Wolf Creek's commitments to 10CFR50, Appendix R, Section III.G.2.b.

PFSSD is assured using Train A or Train B safety related and non-safety related equipment.

Reactivity control is achieved by tripping the reactor from the control room. Boration is available using either Train A or Train B centrifugal charging pump (CCP) taking suction from the refueling water storage tank (RWST) and injecting borated water through the reactor coolant pump (RCP) seals and boron injection tank (BIT). All four steam generator atmospheric relief valves (ARVs) can be controlled from the control room. Main steam isolation is accomplished by closing the main steam isolation valves (MSIVs) from the control room. Steam generator blowdown is isolated by closing all four blowdown valves from the control room. All four source range neutron flux monitors are available.

Reactor coolant makeup is achieved using either Train A or Train B CCP taking suction from the RWST and injecting water through the RCP seals and BIT. Pressurizer level reduction due to uncontrolled cool down through steam generator blowdown lines, steam generator atmospheric relief valves and main steam lines would not be caused by a fire in this area. No inventory reduction paths are affected by a fire in this area.

Decay heat removal is achieved using the turbine driven auxiliary feed water pump (TDAFP), taking suction from the condensate storage tank (CST), and supplying steam generators A and D. A spurious low auxiliary feed water (AFW) suction pressure signal could occur which would swap the AFW source to ESW. Steam generators A and D ARVs are available to control RCS temperature during hot standby. Main feed water is isolated by closing the main feed water isolation valves (MFIVs) from the control room. Diagnostic instrumentation is available to verify RCS temperature and pressure. Train A and Train B residual heat removal (RHR) system is available for transition from hot standby to cold shutdown.

A fire in this area will not prevent safe shutdown of the plant.

8.34 FIRE AREA A-34 (SEAL WATER HEAT EXCHANGER ROOM)

There are no 20 foot combustible and fire hazard free zones in fire area A-34. Fire area A-34 has no automatic fire detection or suppression installed.

PFSSD is assured using Train A and Train B safety related and non-safety related equipment.

Reactivity control is achieved by tripping the reactor from the control room. Boration is available using either Train A or Train B centrifugal charging pump (CCP) taking suction from the refueling water storage tank (RWST) and injecting borated water through the reactor coolant pump (RCP) seals and boron injection tank (BIT). All four steam generator atmospheric relief valves (ARVs) can be controlled from the control room. Main steam isolation is accomplished by closing the main steam isolation valves (MSIVs) from the control room. Steam generator blowdown is isolated by closing all four blowdown valves from the control room. All four source range neutron flux monitors are available.

Reactor coolant makeup is achieved using either Train A or Train B CCP taking suction from the RWST and injecting water through the RCP seals and BIT. No inventory reduction paths are affected by a fire in this area.

Decay heat removal is achieved using all three auxiliary feed water pumps taking suction from the condensate storage tank (CST), and supplying all four steam generators. All four steam generator ARVs are available to control RCS temperature during hot standby. Main feed water is isolated by closing the main feed water isolation valves (MFIVs) from the control room. Diagnostic instrumentation is available to verify RCS temperature and pressure. Train A and Train B residual heat removal (RHR) system is available for transition from hot standby to cold shutdown.

A fire in this area will not prevent safe shutdown of the plant.

8.35 FIRE AREA AB-1 (AUXILIARY BOILER ROOM)

There are no PFSSD components or cables in this area. This area is separated from adjoining safe shutdown areas by a 3-hour-rated barrier. Consequently, a fire in area AB-1 will not prevent safe shutdown of the plant.

8.36 FIRE AREA C-1 (PIPE SPACE AND TANK AREA/STAIRWELL FROM ACCESS CONTROL)

Fire Area C-1 is divided into two sections, C-1 North and C-1 South. Redundant PFSSD components within fire areas C-1 North and C-1 South are divided by a 20 foot combustible and fire hazard free zone. This horizontal separation along with automatic fire suppression and detection meets Wolf Creek's commitments to 10CFR50, Appendix R, Section III.G.2.b.

8.36.1 FIRE AREA C-1 NORTH

PFSSD is assured using primarily Train B safety related and non-safety related equipment.

Reactivity control is achieved by tripping the reactor from the control room. Boration is available using Train B centrifugal charging pump (CCP) taking suction from the refueling water storage tank (RWST) and injecting borated water through the reactor coolant pump (RCP) seals and boron injection tank (BIT). Main steam isolation is accomplished by closing the main steam isolation valves (MSIVs) from the control room. All four steam generator atmospheric relief valves (ARVs) can be controlled from the control room. Steam generator blowdown is isolated by closing all four blowdown valves from the control room. All four source range neutron flux monitors are available.

Reactor coolant makeup is achieved using Train B CCP taking suction from the RWST and injecting water through the RCP seals and BIT. Pressurizer level reduction due to uncontrolled cool down through steam generator blowdown lines, steam generator atmospheric relief valves and main steam lines would not be caused by a fire in this area. No inventory reduction paths are affected by a fire in this area.

Decay heat removal is achieved using all three auxiliary feed water pumps (AFPs), taking suction from the condensate storage tank (CST), and supplying all four steam generators. All four steam generator ARVs are available to control RCS temperature during hot standby. Main feed water is isolated by closing the main feed water isolation valves (MFIVs) from the control room. Diagnostic instrumentation is available to verify RCS temperature and pressure. Train B residual heat removal (RHR) system is available for transition from hot standby to cold shutdown.

A fire in area C-1 North will not prevent safe shutdown of the plant.

8.36.2 FIRE AREA C-1 SOUTH

PFSSD is assured using primarily Train A safety related and non-safety related equipment.

Reactivity control is achieved by tripping the reactor from the control room. Boration is available using Train A centrifugal charging pump (CCP) taking suction from the refueling water storage tank (RWST) and injecting borated water through the reactor coolant pump (RCP) seals and boron injection tank (BIT). Main steam isolation is accomplished by closing the main steam isolation valves (MSIVs) from the control room. All four steam generator atmospheric relief valves (ARVs) can be controlled from the control room. Steam generator blowdown is isolated by closing all four blowdown valves from the control room. All four source range neutron flux monitors are available.

Reactor coolant makeup is achieved using Train A CCP taking suction from the RWST and injecting water through the RCP seals and BIT. Pressurizer level reduction due to uncontrolled cool down through steam generator blowdown lines, steam generator atmospheric relief valves and main steam lines would not be caused by a fire in this area. No inventory reduction paths are affected by a fire in this area.

Decay heat removal is achieved using all three auxiliary feed water pumps (AFPs), taking suction from the condensate storage tank (CST), and supplying all four steam generators. All four steam generator ARVs are available to control RCS temperature during hot standby. Main feed water is isolated by closing the main feed water isolation valves (MFIVs) from the control room. Diagnostic instrumentation is available to verify RCS temperature and pressure. Train A residual heat removal (RHR) system is available for transition from hot standby to cold shutdown.

A fire in area C-1 South will not prevent safe shutdown of the plant.

8.37 FIRE AREA C-2 (NORTH SMALL ELECTRICAL CHASE 1974 ELEVATION)

There are no safe shutdown circuits or equipment in this area. Consequently, a fire in area C-2 will not prevent safe shutdown of the plant.

8.38 FIRE AREA C-3 (SOUTH SMALL ELECTRICAL CHASE 1974 ELEVATION)

There are no safe shutdown circuits or equipment in this area. Consequently, a fire in area C-3 will not prevent safe shutdown of the plant.

8.39 FIRE AREA C-4

Fire Area C-4 does not exist.

8.40 FIRE AREA C-5 (ACCESS CONTROL NORTH)

There are no 20 foot combustible and fire hazard free zones in fire area C-5. Fire area C-5 has automatic fire detection and suppression installed.

PFSSD is assured using Train B safety related and non-safety related equipment.

Reactivity control is achieved by tripping the reactor from the control room. Boration is available using Train B centrifugal charging pump (CCP) taking suction from the refueling water storage tank (RWST) and injecting borated water through the reactor coolant pump (RCP) seals and boron injection tank (BIT). Main steam isolation is accomplished by closing the main steam isolation valves (MSIVs) from the control room. All four steam generator atmospheric relief valves (ARVs) can be controlled from the control room. Steam generator blowdown is isolated by closing all four blowdown valves from the control room. All four source range neutron flux monitors are available.

Reactor coolant makeup is achieved using Train B CCP taking suction from the RWST and injecting water through the RCP seals and BIT. Pressurizer level reduction due to uncontrolled cool down through steam generator blowdown lines, steam generator atmospheric relief valves and main steam lines would not be caused by a fire in this area. No inventory reduction paths are affected by a fire in this area.

Decay heat removal is achieved using Train B motor driven auxiliary feed water pump (MDAFP) or the turbine driven auxiliary feed water pump (TDAFP), taking suction from the condensate storage tank (CST), and supplying all four steam generators. All four steam generator ARVs are available to control RCS temperature during hot standby. Main feed water is isolated by closing the main feed water isolation valves (MFIVs) from the control room. Diagnostic instrumentation is available to verify RCS temperature and pressure. Train B residual heat removal (RHR) system is available for transition from hot standby to cold shutdown.

A fire in this area will not prevent safe shutdown of the plant.

8.41 FIRE AREA C-6 (ACCESS CONTROL SOUTH)

There are no 20 foot combustible and fire hazard free zones in fire area C-6. Fire area C-6 has automatic fire detection and suppression installed.

PFSSD is assured using Train A safety related and non-safety related equipment.

Reactivity control is achieved by tripping the reactor from the control room. Boration is available using Train A centrifugal charging pump (CCP) taking suction from the refueling water storage tank (RWST) and injecting borated water through the reactor coolant pump (RCP) seals and boron injection tank (BIT). Main steam isolation is accomplished by closing the main steam isolation valves (MSIVs) from the control room. All four steam generator atmospheric relief valves (ARVs) can be controlled from the control room. Steam generator blowdown is isolated by closing all four blowdown valves from the control room. All four source range neutron flux monitors are available.

Reactor coolant makeup is achieved using Train A CCP taking suction from the RWST and injecting water through the RCP seals and BIT. Pressurizer level reduction due to uncontrolled cool down through steam generator blowdown lines, steam generator atmospheric relief valves and main steam lines would not be caused by a fire in this area. No inventory reduction paths are affected by a fire in this area.

Decay heat removal is achieved using Train A motor driven auxiliary feed water pump (MDAFP) or the turbine driven auxiliary feed water pump (TDAFP), taking suction from the condensate storage tank (CST), and supplying all four steam generators. All four steam generator ARVs are available to control RCS temperature during hot standby. Main feed water is isolated by closing the main feed water isolation valves (MFIVs) from the control room. Diagnostic instrumentation is available to verify RCS temperature and pressure. Train A residual heat removal (RHR) system is available for transition from hot standby to cold shutdown.

A fire in this area will not prevent safe shutdown of the plant.

8.42 FIRE AREA C-7 (NORTH SMALL ELECTRICAL CHASE 1984 ELEVATION)

There are no 20 foot combustible and fire hazard free zones in fire area C-7. Fire area C-7 has automatic fire detection and suppression installed.

PFSSD is assured using either Train A or Train B safety related and non-safety related equipment.

Reactivity control is achieved by tripping the reactor from the control room. Boration is available using either Train A or Train B centrifugal charging pump (CCP) taking suction from the refueling water storage tank (RWST) and injecting borated water through the reactor coolant pump (RCP) seals and boron injection tank (BIT). All four steam generator atmospheric relief valves (ARVs) can be controlled from the control room. Main steam isolation is accomplished by closing the main steam isolation valves (MSIVs) from the control room. Steam generator blowdown is isolated by closing all four blowdown valves from the control room. All four source range neutron flux monitors are available.

Reactor coolant makeup is achieved using either Train A or Train B CCP taking suction from the RWST and injecting water through the RCP seals and BIT. Pressurizer level reduction due to uncontrolled cool down through steam generator blowdown lines, steam generator atmospheric relief valves and main steam lines would not be caused by a fire in this area. A fire in this area could cause a loss of inventory through the letdown flow path until the letdown isolation valves can be failed closed. The pressurizer spray valves could open until the valves can be failed closed. No other inventory reduction paths are affected by a fire in this area.

Decay heat removal is achieved using all three auxiliary feed water pumps (AFPs), taking suction from the condensate storage tank (CST), and supplying all four steam generators. All four steam generator ARVs are available to control RCS temperature during hot standby. Main feed water is isolated by closing the main feed water isolation valves (MFIVs) from the control room. Diagnostic instrumentation is available to verify RCS temperature and pressure. Train A and Train B residual heat removal (RHR) systems are available for transition from hot standby to cold shutdown.

A fire in this area will not prevent safe shutdown of the plant.

8.43 FIRE AREA C-8 (SOUTH SMALL ELECTRICAL CHASE 1984 ELEVATION)

There are no 20 foot combustible and fire hazard free zones in fire area C-8. Fire area C-8 has automatic fire detection and suppression installed.

PFSSD is assured using either Train A or Train B safety related and non-safety related equipment.

Reactivity control is achieved by tripping the reactor from the control room. Boration is available using either Train A or Train B centrifugal charging pump (CCP) taking suction from the refueling water storage tank (RWST) and injecting borated water through the reactor coolant pump (RCP) seals and boron injection tank (BIT). All four steam generator atmospheric relief valves (ARVs) can be controlled from the control room. Main steam isolation is accomplished by closing the main steam isolation valves (MSIVs) from the control room. Steam generator blowdown is isolated by closing all four blowdown valves from the control room. All four source range neutron flux monitors are available.

Reactor coolant makeup is achieved using either Train A or Train B CCP taking suction from the RWST and injecting water through the RCP seals and BIT. Pressurizer level reduction due to uncontrolled cool down through steam generator blowdown lines, steam generator atmospheric

relief valves and main steam lines would not be caused by a fire in this area. No inventory reduction paths are affected by a fire in this area.

Decay heat removal is achieved using all three auxiliary feed water pumps (AFPs), taking suction from the condensate storage tank (CST), and supplying all four steam generators. All four steam generator ARVs are available to control RCS temperature during hot standby. Main feed water is isolated by closing the main feed water isolation valves (MFIVs) from the control room. Diagnostic instrumentation is available to verify RCS temperature and pressure. Train A and Train B residual heat removal (RHR) systems are available for transition from hot standby to cold shutdown.

A fire in this area will not prevent safe shutdown of the plant.

8.44 FIRE AREA C-9 (TRAIN A ESF SWITCHGEAR ROOM)

There are no 20 foot combustible and fire hazard free zones in fire area C-9. Fire area C-9 has automatic fire detection and Halon fire suppression installed.

PFSSD is assured using Train B safety related and non-safety related equipment.

Reactivity control is achieved by tripping the reactor from the control room. Boration is available using Train B centrifugal charging pump (CCP) taking suction from the refueling water storage tank (RWST) and injecting borated water through the reactor coolant pump (RCP) seals and boron injection tank (BIT). Main steam isolation is accomplished by closing the main steam isolation valves (MSIVs) from the control room. All four steam generator atmospheric relief valves (ARVs) can be controlled from the control room. Steam generator blowdown is isolated by closing all four blowdown valves from the control room. All four source range neutron flux monitors are available.

Reactor coolant makeup is achieved using Train B CCP taking suction from the RWST and injecting water through the RCP seals and BIT. Pressurizer level reduction due to uncontrolled cool down through steam generator blowdown lines, steam generator atmospheric relief valves and main steam lines would not be caused by a fire in this area. No inventory reduction paths are affected by a fire in this area.

Decay heat removal is achieved using Train B motor driven auxiliary feed water pump (MDAFP), taking suction from the condensate storage tank (CST), and supplying steam generators A and D. Steam generators A and D ARVs are available to control RCS temperature during hot standby. Main feed water is isolated by closing the main feed water isolation valves (MFIVs) from the control room. Diagnostic instrumentation is available to verify RCS temperature and pressure. Train B residual heat removal (RHR) system is available for transition from hot standby to cold shutdown.

A fire in this area will not prevent safe shutdown of the plant.

8.45 FIRE AREA C-10 (TRAIN B ESF SWITCHGEAR ROOM)

There are no 20 foot combustible and fire hazard free zones in fire area C-10. Fire area C-10 has automatic fire detection and Halon fire suppression installed.

PFSSD is assured using Train A safety related and non-safety related equipment.

Reactivity control is achieved by tripping the reactor from the control room. Boration is available using Train A centrifugal charging pump (CCP) taking suction from the refueling water storage tank (RWST) and injecting borated water through the reactor coolant pump (RCP) seals and boron injection tank (BIT). Main steam isolation is accomplished by closing the main steam isolation valves (MSIVs) from the control room. Steam generators A and C atmospheric relief

valve (ARV) control is accomplished using hand switches in the control room. Steam generator B ARV may need to be controlled using the local controller. Steam generator D ARV may need to be locally closed. Steam generator blowdown is isolated by closing all four blowdown valves from the control room. All four source range neutron flux monitors are available.

Reactor coolant makeup is achieved using Train A CCP taking suction from the RWST and injecting water through the RCP seals and BIT. Pressurizer level reduction could occur due to uncontrolled cool down through two steam generator atmospheric relief valves until operator action is taken to isolate these flow paths. No other inventory reduction paths are affected by a fire in this area.

Decay heat removal is achieved using Train A motor driven auxiliary feed water pump (MDAFP), taking suction from the condensate storage tank (CST), and supplying steam generator C. Steam generator C ARV is available to control RCS temperature during hot standby. Steam generator B ARV may need to be controlled locally. Per Calculation WCNOC-CP-002, hot standby can be maintained using a single steam generator ARV and a spuriously opened ARV will not adversely impact safe shutdown. Main feed water is isolated by closing the main feed water isolation valves (MFIVs) from the control room. Diagnostic instrumentation is available to verify RCS temperature and pressure. Train A residual heat removal (RHR) system is available for transition from hot standby to cold shutdown.

A fire in this area will not affect safe shutdown of the plant.

8.46 FIRE AREA C-11 (SOUTH LARGE ELECTRICAL CHASE 2000 ELEVATION)

There are no 20 foot combustible and fire hazard free zones in fire area C-11. Fire area C-11 has automatic fire detection and suppression installed.

PFSSD is assured using Train A safety related and non-safety related equipment.

Reactivity control is achieved by tripping the reactor from the control room. Boration is available using Train A centrifugal charging pump (CCP) taking suction from the refueling water storage tank (RWST) and injecting borated water through the reactor coolant pump (RCP) seals and boron injection tank (BIT). Main steam isolation is accomplished by closing the main steam isolation valves (MSIVs) from the control room. Steam generators A, B and C atmospheric relief valve (ARV) control is accomplished using hand switches in the control room. Steam generator D ARV may need to be locally closed. Steam generator blowdown is isolated by closing all four blowdown valves from the control room. All four source range neutron flux monitors are available.

Reactor coolant makeup is achieved using Train A CCP taking suction from the RWST and injecting water through the RCP seals and BIT. Pressurizer level reduction could occur due to uncontrolled cool down through one steam generator atmospheric relief valves until operator action is taken to isolate this flow path. No other inventory reduction paths are affected by a fire in this area.

Decay heat removal is achieved using Train A motor driven auxiliary feed water pump (MDAFP), taking suction from the condensate storage tank (CST), and supplying steam generators B and C. Alternatively, the turbine driven auxiliary feed water pump is available to supply steam generators A, C and D. Steam generators A, B and C ARVs are available to control RCS temperature during hot standby. Main feed water is isolated by closing the main feed water isolation valves (MFIVs) from the control room. Diagnostic instrumentation is available to verify RCS temperature and pressure. Train A residual heat removal (RHR) system is available for transition from hot standby to cold shutdown.

A fire in this area will not affect safe shutdown of the plant.

8.47 FIRE AREA C-12 (NORTH LARGE ELECTRICAL CHASE 2000 ELEVATION)

There are no 20 foot combustible and fire hazard free zones in fire area C-12. Fire area C-12 has automatic fire detection and suppression installed.

PFSSD is assured using Train B safety related and non-safety related equipment.

Reactivity control is achieved by tripping the reactor from the control room. Boration is available using Train B centrifugal charging pump (CCP) taking suction from the refueling water storage tank (RWST) and injecting borated water through the reactor coolant pump (RCP) seals and boron injection tank (BIT). Main steam isolation is accomplished by closing the main steam isolation valves (MSIVs) from the control room. All four steam generator atmospheric relief valves (ARVs) can be controlled from the control room. Steam generator blowdown is isolated by closing all four blowdown valves from the control room. All four source range neutron flux monitors are available.

Reactor coolant makeup is achieved using Train B CCP taking suction from the RWST and injecting water through the RCP seals and BIT. Pressurizer level reduction due to uncontrolled cool down through steam generator blowdown lines, steam generator atmospheric relief valves and main steam lines would not be caused by a fire in this area. A fire in this area could cause a loss of inventory through the letdown flow path until the letdown isolation valves can be failed closed. The pressurizer spray valves could open until the valves can be failed closed. No other inventory reduction paths are affected by a fire in this area.

Decay heat removal is achieved using Train B motor driven auxiliary feed water pump (MDAFP) or the turbine driven auxiliary feed water pump (TDAFP), taking suction from the condensate storage tank (CST), and supplying all four steam generators. All four steam generator ARVs are available to control RCS temperature during hot standby. Main feed water is isolated by closing the main feed water isolation valves (MFIVs) from the control room. Diagnostic instrumentation is available to verify RCS temperature and pressure. Train B residual heat removal (RHR) system is available for transition from hot standby to cold shutdown.

A fire in this area will not prevent safe shutdown of the plant.

8.48 FIRE AREA C-13 (TRAIN B CLASS 1E ELECTRICAL EQUIPMENT ROOM COOLER)

There are no 20 foot combustible and fire hazard free zones in fire area C-13. Fire area C-13 has automatic fire detection installed.

PFSSD is assured using Train A safety related and non-safety related equipment.

Reactivity control is achieved by tripping the reactor from the control room. Boration is available using Train A centrifugal charging pump (CCP) taking suction from the refueling water storage tank (RWST) and injecting borated water through the reactor coolant pump (RCP) seals and boron injection tank (BIT). Main steam isolation is accomplished by closing the main steam isolation valves (MSIVs) from the control room. All four steam generator atmospheric relief valves (ARVs) can be controlled from the control room. Steam generator blowdown is isolated by closing all four blowdown valves from the control room. All four source range neutron flux monitors are available.

Reactor coolant makeup is achieved using Train A CCP taking suction from the RWST and injecting water through the RCP seals and BIT. Pressurizer level reduction due to uncontrolled cool down through steam generator blowdown lines, steam generator atmospheric relief valves and main steam lines would not be caused by a fire in this area. No inventory reduction paths are affected by a fire in this area.

Decay heat removal is achieved using the Train A motor driven auxiliary feed water pump (MDAFP) and the turbine driven auxiliary feed water pump (TDAFP), taking suction from the condensate storage tank (CST), and supplying all four steam generators. All four steam generator ARVs are available to control RCS temperature during hot standby. Main feed water is isolated by closing the main feed water isolation valves (MFIVs) from the control room. Diagnostic instrumentation is available to verify RCS temperature and pressure. Train A residual heat removal (RHR) system is available for transition from hot standby to cold shutdown.

A fire in this area will not prevent safe shutdown of the plant.

8.49 FIRE AREA C-14 (TRAIN A CLASS 1E ELECTRICAL EQUIPMENT ROOM COOLER)

There are no 20 foot combustible and fire hazard free zones in fire area C-14. Fire area C-14 has automatic fire detection installed.

PFSSD is assured using Train B safety related and non-safety related equipment.

Reactivity control is achieved by tripping the reactor from the control room. Boration is available using Train B centrifugal charging pump (CCP) taking suction from the refueling water storage tank (RWST) and injecting borated water through the reactor coolant pump (RCP) seals and boron injection tank (BIT). Main steam isolation is accomplished by closing the main steam isolation valves (MSIVs) from the control room. All four steam generator atmospheric relief valves (ARVs) can be controlled from the control room. Steam generator blowdown is isolated by closing all four blowdown valves from the control room. All four source range neutron flux monitors are available.

Reactor coolant makeup is achieved using Train B CCP taking suction from the RWST and injecting water through the RCP seals and BIT. Pressurizer level reduction due to uncontrolled cool down through steam generator blowdown lines, steam generator atmospheric relief valves and main steam lines would not be caused by a fire in this area. No inventory reduction paths are affected by a fire in this area.

Decay heat removal is achieved using the Train B motor driven auxiliary feed water pump (MDAFP) and the turbine driven auxiliary feed water pump (TDAFP), taking suction from the condensate storage tank (CST), and supplying all four steam generators. All four steam generator ARVs are available to control RCS temperature during hot standby. Main feed water is isolated by closing the main feed water isolation valves (MFIVs) from the control room. Diagnostic instrumentation is available to verify RCS temperature and pressure. Train A residual heat removal (RHR) system is available for transition from hot standby to cold shutdown.

A fire in this area will not prevent safe shutdown of the plant.

8.50 FIRE AREA C-15 (TRAIN B CLASS 1E/NON-CLASS 1E ELECTRICAL SWITCHGEAR AND BATTERY ROOMS)

There are no 20 foot combustible and fire hazard free zones in fire area C-15. Fire area C-15 has automatic fire detection and Halon fire suppression installed.

PFSSD is assured using Train A safety related and non-safety related equipment.

Reactivity control is achieved by tripping the reactor from the control room. Boration is available using Train A centrifugal charging pump (CCP) taking suction from the refueling water storage tank (RWST) and injecting borated water through the reactor coolant pump (RCP) seals and boron injection tank (BIT). Main steam isolation is accomplished by closing the main steam isolation valves (MSIVs) from the control room. Steam generators A and C atmospheric relief valve (ARV) control is accomplished using hand switches in the control room. Steam generators B and D ARVs may lose power and fail closed but will not need to be locally closed. Steam

generator blowdown is isolated by closing all four blowdown valves from the control room. Source range neutron flux monitoring is available.

Reactor coolant makeup is achieved using Train A CCP taking suction from the RWST and injecting water through the RCP seals and BIT. Pressurizer level reduction due to uncontrolled cool down through steam generator blowdown lines, steam generator atmospheric relief valves and main steam lines would not be caused by a fire in this area. No inventory reduction paths are affected by a fire in this area.

Decay heat removal is achieved using Train A motor driven auxiliary feed water pump (MDAFP), taking suction from the condensate storage tank (CST), and supplying steam generators B and C. However, only steam generators A and C ARVs are available to control RCS temperature during hot standby. Main feed water is isolated by closing the main feed water isolation valves (MFIVs) from the control room. Loops 1 and 2 hot leg temperature indication is available. Remaining RCS temperature instruments are unavailable. Pressurizer pressure indication is available using all four pressurizer pressure indicators. Train A residual heat removal (RHR) system is available for transition from hot standby to cold shutdown.

A fire in this area will not prevent safe shutdown of the plant.

8.51 FIRE AREA C-16 (TRAIN A CLASS 1E/NON-CLASS 1E ELECTRICAL SWITCHGEAR AND BATTERY ROOMS)

There are no 20 foot combustible and fire hazard free zones in fire area C-16. Fire area C-16 has automatic fire detection and Halon fire suppression installed.

PFSSD is assured using Train B safety related and non-safety related equipment.

Reactivity control is achieved by tripping the reactor from the control room. Boration is available using Train B centrifugal charging pump (CCP) taking suction from the refueling water storage tank (RWST) and injecting borated water through the reactor coolant pump (RCP) seals and boron injection tank (BIT). Main steam isolation is accomplished by closing the main steam isolation valves (MSIVs) from the control room. Steam generators B and D atmospheric relief valve (ARV) control is accomplished using hand switches in the control room. Steam generators A and C ARVs may lose power and fail closed but will not need to be locally closed. Steam generator blowdown is isolated by closing all four blowdown valves from the control room. Source range neutron flux monitoring is available.

Reactor coolant makeup is achieved using Train B CCP taking suction from the RWST and injecting water through the RCP seals and BIT. Pressurizer level reduction due to uncontrolled cool down through steam generator blowdown lines, steam generator atmospheric relief valves and main steam lines would not be caused by a fire in this area. No inventory reduction paths are affected by a fire in this area.

Decay heat removal is achieved using Train B motor driven auxiliary feed water pump (MDAFP), taking suction from the condensate storage tank (CST), and supplying steam generators A and D, and the turbine driven auxiliary feed water pump (TDAFP), taking suction from the condensate storage tank (CST), and supplying steam generators A, B, C and D. Steam generators B and D ARVs are available to control RCS temperature during hot standby. Main feed water is isolated by closing the main feed water isolation valves (MFIVs) from the control room. Hot leg temperature indication on loops 3 and 4 and cold leg temperature indication on loops 1 and 2 are available. Remaining RCS temperature instruments are unavailable. Pressurizer pressure indication is available using all four pressurizer pressure indicators. Train B residual heat removal (RHR) system is available for transition from hot standby to cold shutdown.

A fire in this area will not prevent safe shutdown of the plant.

8.52 FIRE AREA C-17 (SOUTH LARGE ELECTRICAL CHASE 2016 ELEVATION)

There are no 20 foot combustible and fire hazard free zones in fire area C-17. Fire area C-17 has automatic fire detection and suppression installed.

PFSSD is assured using Train A safety related and non-safety related equipment.

Reactivity control is achieved by tripping the reactor from the control room. Boration is available using Train A centrifugal charging pump (CCP) taking suction from the refueling water storage tank (RWST) and injecting borated water through the reactor coolant pump (RCP) seals and boron injection tank (BIT). Main steam isolation is accomplished by closing the main steam isolation valves (MSIVs) from the control room. Steam generators A, B and C atmospheric relief valve (ARV) control is accomplished using hand switches in the control room. Steam generator D ARV may need to be locally closed. Steam generator blowdown is isolated by closing all four blowdown valves from the control room. Source range neutron flux monitoring is available.

Reactor coolant makeup is achieved using Train A CCP taking suction from the RWST and injecting water through the RCP seals and BIT. Pressurizer level reduction could occur due to uncontrolled cool down through one steam generator atmospheric relief valve until operator action is taken to isolate this flow path. No other inventory reduction paths are affected by a fire in this area.

Decay heat removal is achieved using Train A motor driven auxiliary feed water pump (MDAFP), taking suction from the condensate storage tank (CST), and supplying steam generators B and C, and the turbine driven auxiliary feed water pump (TDAFP), taking suction from the condensate storage tank (CST), and supplying steam generator A. Steam generators A, B and C ARVs are available to control RCS temperature during hot standby. Steam generator D ARV may need to be closed locally. Main feed water is isolated by closing the main feed water isolation valves (MFIVs) from the control room. Diagnostic instrumentation is available to verify RCS temperature and pressure. Train A residual heat removal (RHR) system is available for transition from hot standby to cold shutdown.

A fire in this area will not prevent safe shutdown of the plant.

8.53 FIRE AREA C-18 (NORTH LARGE ELECTRICAL CHASE 2016 ELEVATION)

There are no 20 foot combustible and fire hazard free zones in fire area C-18. Fire area C-18 has automatic fire detection and suppression installed.

PFSSD is assured using Train B safety related and non-safety related equipment.

Reactivity control is achieved by tripping the reactor from the control room. Boration is available using Train B centrifugal charging pump (CCP) taking suction from the refueling water storage tank (RWST) and injecting borated water through the reactor coolant pump (RCP) seals and boron injection tank (BIT). Main steam isolation is accomplished by closing the main steam isolation valves (MSIVs) from the control room. Steam generators B, C and D atmospheric relief valve (ARV) control is accomplished using hand switches in the control room. Steam generator A ARV may need to be locally closed. Steam generator blowdown is isolated by closing all four blowdown valves from the control room. Source range neutron flux monitoring is available.

Reactor coolant makeup is achieved using Train B CCP taking suction from the RWST and injecting water through the RCP seals and BIT. Pressurizer level reduction could occur due to uncontrolled cool down through one steam generator atmospheric relief valve until operator action is taken to isolate this flow path. A fire in this area could cause a loss of inventory through the letdown flow path until the letdown isolation valves can be failed closed. The pressurizer spray valves could open until the valves can be failed closed. One pressurizer PORV may spuriously open and its associated block valve may not close. If this occurs, operators can close

the PORV using the hand switch in the control room. No other inventory reduction paths are affected by a fire in this area.

Decay heat removal is achieved using Train B motor driven auxiliary feed water pump (MDAFP), taking suction from the condensate storage tank (CST), and supplying steam generator D, and the turbine driven auxiliary feed water pump (TDAFP), taking suction from the condensate storage tank (CST), and supplying steam generators B and C. Steam generators B, C and D ARVs are available to control RCS temperature during hot standby. Steam generator A ARV may need to be closed locally. Main feed water is isolated by closing the main feed water isolation valves (MFIVs) from the control room. Diagnostic instrumentation is available to verify RCS temperature and pressure. Train A residual heat removal (RHR) system is available for transition from hot standby to cold shutdown.

A fire in this area will not prevent safe shutdown of the plant.

8.54 FIRE AREA C-19 (NORTH SMALL ELECTRICAL CHASE 2016 ELEVATION)

There are no 20 foot combustible and fire hazard free zones in fire area C-19. Fire area C-19 has automatic fire detection and suppression installed.

PFSSD is assured using either Train A or Train B safety related and non-safety related equipment.

Reactivity control is achieved by tripping the reactor from the control room. Boration is available using either Train A or Train B centrifugal charging pump (CCP) taking suction from the refueling water storage tank (RWST) and injecting borated water through the reactor coolant pump (RCP) seals and boron injection tank (BIT). Steam generators A, B and D atmospheric relief valves (ARVs) can be controlled from the control room. Steam generator C ARV may fail closed due to loss of power but will not spuriously open. Main steam isolation is accomplished by closing the main steam isolation valves (MSIVs) from the control room. Steam generator blowdown is isolated by closing all four blowdown valves from the control room. All four source range neutron flux monitors are available.

Reactor coolant makeup is achieved using either Train A or Train B CCP taking suction from the RWST and injecting water through the RCP seals and BIT. Pressurizer level reduction due to uncontrolled cool down through steam generator blowdown lines, steam generator atmospheric relief valves and main steam lines would not be caused by a fire in this area. No inventory reduction paths are affected by a fire in this area.

Decay heat removal is achieved using all three auxiliary feed water pumps (AFPs), taking suction from the condensate storage tank (CST), and supplying steam generators A, B and D. Steam generators A, B and D ARVs are available to control RCS temperature during hot standby. Main feed water is isolated by closing the main feed water isolation valves (MFIVs) from the control room. Diagnostic instrumentation is available to verify RCS temperature and pressure. Train A and Train B residual heat removal (RHR) systems are available for transition from hot standby to cold shutdown.

A fire in this area will not prevent safe shutdown of the plant.

8.55 FIRE AREA C-20 (SOUTH SMALL ELECTRICAL CHASE 2016 ELEVATION)

There are no 20 foot combustible and fire hazard free zones in fire area C-20. Fire area C-20 has automatic fire detection and suppression installed.

PFSSD is assured using either Train A or Train B safety related and non-safety related equipment.

Reactivity control is achieved by tripping the reactor from the control room. Boration is available using either Train A or Train B centrifugal charging pump (CCP) taking suction from the refueling water storage tank (RWST) and injecting borated water through the reactor coolant pump (RCP) seals and boron injection tank (BIT). Steam generators A, C and D atmospheric relief valves (ARVs) can be controlled from the control room. Steam generator B ARV may need to be closed locally. Main steam isolation is accomplished by closing the main steam isolation valves (MSIVs) from the control room. Steam generator blowdown is isolated by closing all four blowdown valves from the control room. Source range neutron flux monitoring is available.

Reactor coolant makeup is achieved using either Train A or Train B CCP taking suction from the RWST and injecting water through the RCP seals and BIT. Pressurizer level reduction could occur due to uncontrolled cool down through one steam generator atmospheric relief valve until operator action is taken to isolate this flow path. No other inventory reduction paths are affected by a fire in this area.

Decay heat removal is achieved using the Train B motor driven auxiliary feed water pump (MDAFP), taking suction from the condensate storage tank (CST), and supplying steam generators A and D, and the Train A motor driven auxiliary feed water pump (MDAFP), taking suction from the CST, and supplying steam generators B and C. Steam generators A, C and D ARVs are available to control RCS temperature during hot standby. Main feed water is isolated by closing the main feed water isolation valves (MFIVs) from the control room. Diagnostic instrumentation is available to verify RCS temperature and pressure. Train A and Train B residual heat removal (RHR) systems are available for transition from hot standby to cold shutdown.

A fire in this area will not prevent safe shutdown of the plant.

8.56 FIRE AREA C-21 (LOWER CABLE SPREADING ROOM)

There are no 20 foot combustible and fire hazard free zones in fire area C-21. Fire area C-21 has automatic fire detection and suppression installed.

PFSSD is assured using Train B safety related and non-safety related equipment.

Reactivity control is achieved by tripping the reactor from the control room. Boration is available using Train B centrifugal charging pump (CCP) taking suction from the refueling water storage tank (RWST) and injecting borated water through the reactor coolant pump (RCP) seals and boron injection tank (BIT). Main steam isolation is accomplished by closing the main steam isolation valves (MSIVs) from the control room. Steam generators B and D atmospheric relief valve (ARV) control is accomplished using hand switches in the control room. Steam generators A and C ARVs may need to be locally closed. Steam generator blowdown is isolated by closing all four blowdown valves from the control room. Source range neutron flux monitoring is available.

Reactor coolant makeup is achieved using Train B CCP taking suction from the RWST and injecting water through the RCP seals and BIT. Pressurizer level reduction could occur due to uncontrolled cool down through two steam generator atmospheric relief valves until operator action is taken to isolate this flow path. A fire in this area could cause a loss of inventory through

the letdown flow path until the letdown isolation valves can be failed closed. The pressurizer spray valves could open until the valves can be failed closed. One pressurizer PORV may spuriously open and its associated block valve may not close. If this occurs, operators can close the PORV using the hand switch in the control room. The containment spray pumps could operate and deplete inventory in the RWST until operator action is taken to stop the pumps. No other inventory reduction paths are affected by a fire in this area.

Decay heat removal is achieved using Train B motor driven auxiliary feed water pump (MDAFP), taking suction from the condensate storage tank (CST), and supplying steam generator D, and the turbine driven auxiliary feed water pump (TDAFP), taking suction from the condensate storage tank (CST), and supplying steam generator B. Steam generators B and D ARVs are available to control RCS temperature during hot standby. Steam generators A and C ARVs may need to be closed locally. Main feed water is isolated by closing the main feed water isolation valves (MFIVs) from the control room. Diagnostic instrumentation is available to verify RCS temperature and pressure. Train A residual heat removal (RHR) system is available for transition from hot standby to cold shutdown.

A fire in this area will not prevent safe shutdown of the plant.

8.57 FIRE AREA C-22 (UPPER CABLE SPREADING ROOM)

There are no 20 foot combustible and fire hazard free zones in fire area C-22. Fire area C-22 has automatic fire detection and suppression installed.

PFSSD is assured using Train A safety related and non-safety related equipment.

Reactivity control is achieved by tripping the reactor from the control room. Boration is available using Train A centrifugal charging pump (CCP) taking suction from the refueling water storage tank (RWST) and injecting borated water through the reactor coolant pump (RCP) seals and boron injection tank (BIT). Main steam isolation is accomplished by closing the main steam isolation valves (MSIVs) from the control room. Steam generators A and C atmospheric relief valve (ARV) control is accomplished using hand switches in the control room. Steam generators B and D ARVs may need to be locally closed or controlled. Steam generator blowdown is isolated by closing all four blowdown valves from radwaste control room panel BM157. Source range neutron flux monitoring is available.

Reactor coolant makeup is achieved using Train A CCP taking suction from the RWST and injecting water through the RCP seals and BIT. Pressurizer level reduction could occur due to uncontrolled cool down through all four steam generator blowdown lines and two steam generator atmospheric relief valves until operator action is taken to isolate these flow paths. One pressurizer PORV may spuriously open and its associated block valve may not close. If this occurs, operators can close the PORV using the hand switch in the control room. One containment spray pump could operate and deplete inventory in the RWST until operator action is taken to stop the pump. No other inventory reduction paths are affected by a fire in this area.

Decay heat removal is achieved using Train A motor driven auxiliary feed water pump (MDAFP), taking suction from the condensate storage tank (CST), and supplying steam generator C. Steam generator C ARV is available to control RCS temperature during hot standby. Per Calculation WCNOC-CP-002, hot standby can be maintained using a single steam generator ARV and a spuriously opened ARV will not adversely impact safe shutdown. Steam generator B ARV may need to be controlled locally or at the auxiliary shutdown panel. Main feed water is isolated by closing the main feed water isolation valves (MFIVs) from the control room. Diagnostic instrumentation is available to verify RCS temperature and pressure. Train A residual heat removal (RHR) system is available for transition from hot standby to cold shutdown, however RHR pump suction may have to be opened locally and RHR to SI hot leg loops 2 and 3 may have to be closed locally.

A fire in this area will not prevent safe shutdown of the plant.

8.58 FIRE AREA C-23 (SOUTH LARGE ELECTRICAL CHASE 2032 ELEVATION)

There are no 20 foot combustible and fire hazard free zones in fire area C-23. Fire area C-23 has automatic fire detection and suppression installed.

PFSSD is assured using Train A safety related and non-safety related equipment.

Reactivity control is achieved by tripping the reactor from the control room. Boration is available using Train A centrifugal charging pump (CCP) taking suction from the refueling water storage tank (RWST) and injecting borated water through the reactor coolant pump (RCP) seals and boron injection tank (BIT). Main steam isolation is accomplished by closing the main steam isolation valves (MSIVs) from the control room. Steam generators A, B and C atmospheric relief valve (ARV) control is accomplished using hand switches in the control room. Steam generator D ARV may need to be locally closed. Steam generator blowdown is isolated by closing all four blowdown valves from the control room. Source range neutron flux monitoring is available.

Reactor coolant makeup is achieved using Train A CCP taking suction from the RWST and injecting water through the RCP seals and BIT. Pressurizer level reduction could occur due to uncontrolled cool down through one steam generator atmospheric relief valve until operator action is taken to isolate this flow path. One pressurizer PORV may spuriously open and its associated block valve may not close. If this occurs, operators can close the PORV using the hand switch in the control room. No other inventory reduction paths are affected by a fire in this area.

Decay heat removal is achieved using Train A motor driven auxiliary feed water pump (MDAFP), taking suction from the condensate storage tank (CST), and supplying steam generators B and C, and the turbine driven auxiliary feed water pump (TDAFP), taking suction from the condensate storage tank (CST), and supplying steam generator A. Steam generators A, B and C ARVs are available to control RCS temperature during hot standby. Steam generator D ARV may need to be closed locally. Main feed water is isolated by closing the main feed water isolation valves (MFIVs) from the control room. Diagnostic instrumentation is available to verify RCS temperature and pressure. Train A residual heat removal (RHR) system is available for transition from hot standby to cold shutdown, however RHR pump suction may have to be lined up locally and RHR to SI hot leg injection loops 2 and 3 may need to be closed locally to support shutdown cooling.

A fire in this area will not prevent safe shutdown of the plant.

8.59 FIRE AREA C-24 (NORTH LARGE ELECTRICAL CHASE 2032 ELEVATION)

There are no 20 foot combustible and fire hazard free zones in fire area C-24. Fire area C-24 has automatic fire detection and suppression installed.

PFSSD is assured using Train B safety related and non-safety related equipment.

Reactivity control is achieved by tripping the reactor from the control room. Boration is available using Train B centrifugal charging pump (CCP) taking suction from the refueling water storage tank (RWST) and injecting borated water through the reactor coolant pump (RCP) seals and boron injection tank (BIT). Main steam isolation is accomplished by closing the main steam isolation valves (MSIVs) from the control room. Steam generators B, C and D atmospheric relief valve (ARV) control is accomplished using hand switches in the control room. Steam generator A ARV may need to be locally closed. Steam generator blowdown is isolated by closing all four blowdown valves from the control room. Source range neutron flux monitoring is available.

Reactor coolant makeup is achieved using Train B CCP taking suction from the RWST and injecting water through the RCP seals and BIT. Pressurizer level reduction could occur due to

uncontrolled cool down through one steam generator atmospheric relief valve until operator action is taken to isolate this flow path. A fire in this area could cause a loss of inventory through the letdown flow path until the letdown isolation valves can be failed closed. The pressurizer spray valves could open until the valves can be failed closed. One pressurizer PORV may spuriously open and its associated block valve may not close. If this occurs, operators can close the PORV using the hand switch in the control room. One containment spray pump could operate and deplete inventory in the RWST until operator action is taken to stop the pump. No other inventory reduction paths are affected by a fire in this area.

Decay heat removal is achieved using Train B motor driven auxiliary feed water pump (MDAFP), taking suction from the condensate storage tank (CST), and supplying steam generator D. The turbine driven auxiliary feed water pump (TDAFP) is also available but it may be limited to supplying only steam generators B and C. Steam generators B, C and D ARVs are available to control RCS temperature during hot standby. Steam generator A ARV may need to be closed locally. Main feed water is isolated by closing the main feed water isolation valves (MFIVs) from the control room. Diagnostic instrumentation is available to verify RCS temperature and pressure. Train B residual heat removal (RHR) system is available for transition from hot standby to cold shutdown, however RHR pump suction may have to be lined up locally.

A fire in this area will not prevent safe shutdown of the plant.

8.60 FIRE AREA C-25 (SOUTH SMALL ELECTRICAL CHASE 2032 ELEVATION)

There are no 20 foot combustible and fire hazard free zones in fire area C-25. Fire area C-25 has automatic fire detection and suppression installed.

PFSSD is assured using either Train A or Train B safety related and non-safety related equipment.

Reactivity control is achieved by tripping the reactor from the control room. Boration is available using either Train A or Train B centrifugal charging pump (CCP) taking suction from the refueling water storage tank (RWST) and injecting borated water through the reactor coolant pump (RCP) seals and boron injection tank (BIT). Steam generators A, C and D atmospheric relief valves (ARVs) can be controlled from the control room. Steam generator B ARV may need to be closed locally. Main steam isolation is accomplished by closing the main steam isolation valves (MSIVs) from the control room. Steam generator blowdown is isolated by closing all four blowdown valves from the control room. Source range neutron flux monitoring is available.

Reactor coolant makeup is achieved using either Train A or Train B CCP taking suction from the RWST and injecting water through the RCP seals and BIT. Pressurizer level reduction could occur due to uncontrolled cool down through one steam generator atmospheric relief valve until operator action is taken to isolate this flow path. One pressurizer PORV could spuriously open until operator action is taken in the control room to close the PORV. No other inventory reduction paths are affected by a fire in this area.

Decay heat removal is achieved using the Train B motor driven auxiliary feed water pump (MDAFP), taking suction from the condensate storage tank (CST), and supplying steam generators A and D, and the Train A motor driven auxiliary feed water pump (MDAFP), taking suction from the condensate storage tank (CST), and supplying steam generators B and C. Steam generators A, C and D ARVs are available to control RCS temperature during hot standby. Main feed water is isolated by closing the main feed water isolation valves (MFIVs) from the control room. Diagnostic instrumentation is available to verify RCS temperature and pressure. Train A and Train B residual heat removal (RHR) systems are available for transition from hot standby to cold shutdown.

A fire in this area will not prevent safe shutdown of the plant.

8.61 FIRE AREA C-26 (NORTH SMALL ELECTRICAL CHASE 2032 ELEVATION)

There are no 20 foot combustible and fire hazard free zones in fire area C-26. Fire area C-26 has automatic fire detection and suppression installed.

PFSSD is assured using either Train A or Train B safety related and non-safety related equipment.

Reactivity control is achieved by tripping the reactor from the control room. Boration is available using either Train A or Train B centrifugal charging pump (CCP) taking suction from the refueling water storage tank (RWST) and injecting borated water through the reactor coolant pump (RCP) seals and boron injection tank (BIT). Steam generators A, B and D atmospheric relief valves (ARVs) can be controlled from the control room. Steam generator C ARV may need to be locally closed. Main steam isolation is accomplished by closing the main steam isolation valves (MSIVs) from the control room. Steam generator blowdown is isolated by closing all four blowdown valves from the control room. All four source range neutron flux monitors are available.

Reactor coolant makeup is achieved using either Train A or Train B CCP taking suction from the RWST and injecting water through the RCP seals and BIT. Pressurizer level reduction due to uncontrolled cool down through steam generator blowdown lines, steam generator atmospheric relief valves and main steam lines would not be caused by a fire in this area. Both pressurizer spray valves could open until operator action is taken in the control room to close the valves. One pressurizer PORV could spuriously open until operator action is taken in the control room to close the PORV. No other inventory reduction paths are affected by a fire in this area.

Decay heat removal is achieved using all three auxiliary feed water pumps (AFPs), taking suction from the condensate storage tank (CST), and supplying steam generators A, B and D. Steam generators A, B and D ARVs are available to control RCS temperature during hot standby. Steam generator C ARV may need to be locally closed. Main feed water is isolated by closing the main feed water isolation valves (MFIVs) from the control room. Diagnostic instrumentation is available to verify RCS temperature and pressure. Train A and Train B residual heat removal (RHR) systems are available for transition from hot standby to cold shutdown.

A fire in this area will not prevent safe shutdown of the plant.

8.62 FIRE AREA C-27 (CONTROL ROOM)

There are no 20 foot combustible and fire hazard free zones in fire area C-27. Fire area C-27 has automatic fire detection installed. Automatic Halon fire suppression is installed in the cable trenches.

Document E-1F9915 provides the design basis for control room evacuation procedure OFN RP-017. In the event of a fire in the control room that requires evacuation and shutdown from outside the control room, OFN RP-017 will successfully shut down the plant based on the evaluation in E-1F9915.

Cold shutdown from outside the control room is achieved using procedure OFN RP-017A, Hot Standby to Cold Shutdown from Outside the Control Room due to Fire.

A fire in this area will not prevent safe shutdown of the plant.

8.63 FIRE AREA C-28 (SERVICE AREA BY CONTROL ROOM)

There are no 20 foot combustible and fire hazard free zones in fire area C-28. Fire area C-28 has automatic fire detection installed in the Pantry (Room 3602) and the Janitors Closet (Room 3608). No detection is installed in the toilet (Room 3607). This area is not equipped with automatic suppression.

PFSSD is assured using either Train A or Train B safety related and non-safety related equipment.

Reactivity control is achieved by tripping the reactor from the control room. Boration is available using either Train A or Train B centrifugal charging pump (CCP) taking suction from the refueling water storage tank (RWST) and injecting borated water through the reactor coolant pump (RCP) seals and boron injection tank (BIT). All four steam generator atmospheric relief valves (ARVs) can be controlled from the control room. Main steam isolation is accomplished by closing the main steam isolation valves (MSIVs) from the control room. Steam generator blowdown is isolated by closing all four blowdown valves from the control room. All four source range neutron flux monitors are available.

Reactor coolant makeup is achieved using either Train A or Train B CCP taking suction from the RWST and injecting water through the RCP seals and BIT. Pressurizer level reduction due to uncontrolled cool down through steam generator blowdown lines, steam generator atmospheric relief valves and main steam lines would not be caused by a fire in this area. No inventory reduction paths are affected by a fire in this area.

Decay heat removal is achieved using all three auxiliary feed water pumps (AFPs), taking suction from the condensate storage tank (CST), and supplying all four steam generators. All four steam generator ARVs are available to control RCS temperature during hot standby. Main feed water is isolated by closing the main feed water isolation valves (MFIVs) from the control room. Diagnostic instrumentation is available to verify RCS temperature and pressure. Train A and Train B residual heat removal (RHR) systems are available for transition from hot standby to cold shutdown.

A fire in this area will not prevent safe shutdown of the plant.

8.64 FIRE AREA C-29 (SAS ROOM)

There are no safe shutdown circuits or equipment in this area. Consequently, a fire in area C-29 will not prevent safe shutdown of the plant.

8.65 FIRE AREA C-30 (SOUTH LARGE ELECTRICAL CHASE 2047 ELEVATION)

There are no 20 foot combustible and fire hazard free zones in fire area C-30. Fire area C-30 has automatic fire detection and suppression installed.

PFSSD is assured using Train A safety related and non-safety related equipment.

Reactivity control is achieved by tripping the reactor from the control room. Boration is available using Train A centrifugal charging pump (CCP) taking suction from the refueling water storage tank (RWST) and injecting borated water through the reactor coolant pump (RCP) seals and boron injection tank (BIT). Main steam isolation is accomplished by closing the main steam isolation valves (MSIVs) from the control room. Steam generators A, B and C atmospheric relief valve (ARV) control is accomplished using hand switches in the control room. Steam generator D ARV may need to be locally closed. Steam generator blowdown is isolated by closing all four blowdown valves from radwaste control room panel BM157. Source range neutron flux monitoring is available.

Reactor coolant makeup is achieved using Train A CCP taking suction from the RWST and injecting water through the RCP seals and BIT. Pressurizer level reduction could occur due to uncontrolled cool down through all four steam generator blowdown lines and one steam generator atmospheric relief valve until operator action is taken to isolate these flow paths. One pressurizer PORV may spuriously open and its associated block valve may not close. If this occurs, operators can close the PORV using the hand switch in the control room. One containment spray pump could operate and deplete inventory in the RWST until operator action is taken to stop the pump. No other inventory reduction paths are affected by a fire in this area.

Decay heat removal is achieved using Train A motor driven auxiliary feed water pump (MDAFP), taking suction from the condensate storage tank (CST), and supplying steam generators B and C. Steam generators B and C ARVs are available to control RCS temperature during hot standby. Steam generator D ARV may need to be closed locally. Main feed water is isolated by closing the main feed water isolation valves (MFIVs) from the control room. Diagnostic instrumentation is available to verify RCS temperature and pressure. Train A residual heat removal (RHR) system is available for transition from hot standby to cold shutdown, however RHR pump suction may have to be lined up locally and RHR to SI hot leg injection loops 2 and 3 may need to be closed locally to support shutdown cooling.

A fire in this area will not prevent safe shutdown of the plant.

8.66 FIRE AREA C-31 (NORTH LARGE ELECTRICAL CHASE 2047 ELEVATION)

There are no 20 foot combustible and fire hazard free zones in fire area C-31. Fire area C-31 has automatic fire detection and suppression installed.

PFSSD is assured using Train B safety related and non-safety related equipment.

Reactivity control is achieved by tripping the reactor from the control room. Boration is available using Train B centrifugal charging pump (CCP) taking suction from the refueling water storage tank (RWST) and injecting borated water through the reactor coolant pump (RCP) seals and boron injection tank (BIT). Main steam isolation is accomplished by closing the main steam isolation valves (MSIVs) from the control room. Steam generators B, C and D atmospheric relief valve (ARV) control is accomplished using hand switches in the control room. Steam generator A ARV may need to be locally closed. Steam generator blowdown is isolated by closing all four blowdown valves from the control room. All four source range neutron flux monitors are available.

Reactor coolant makeup is achieved using Train B CCP taking suction from the RWST and injecting water through the RCP seals and BIT. Pressurizer level reduction could occur due to uncontrolled cool down through one steam generator atmospheric relief valve until operator action is taken to isolate this flow path. No other inventory reduction paths are affected by a fire in this area.

Decay heat removal is achieved using Train B motor driven auxiliary feed water pump (MDAFP), taking suction from the condensate storage tank (CST), and supplying steam generator D, and the turbine driven auxiliary feed water pump (TDAFP), taking suction from the condensate storage tank (CST), and supplying steam generators B, C and D. Steam generators B, C and D ARVs are available to control RCS temperature during hot standby. Steam generator A ARV may need to be closed locally. Main feed water is isolated by closing the main feed water isolation valves (MFIVs) from the control room. Diagnostic instrumentation is available to verify RCS temperature and pressure. Train B residual heat removal (RHR) system is available for transition from hot standby to cold shutdown.

A fire in this area will not prevent safe shutdown of the plant.

8.67 FIRE AREA C-32 (SOUTH SMALL ELECTRICAL CHASE 2047 ELEVATION)

There are no 20 foot combustible and fire hazard free zones in fire area C-32. Fire area C-32 has automatic fire detection and suppression installed.

PFSSD is assured using either Train A or Train B safety related and non-safety related equipment.

Reactivity control is achieved by tripping the reactor from the control room. Boration is available using either Train A or Train B centrifugal charging pump (CCP) taking suction from the refueling water storage tank (RWST) and injecting borated water through the reactor coolant pump (RCP) seals and boron injection tank (BIT). Steam generators A, C and D atmospheric relief valves (ARVs) can be controlled from the control room. Steam generator B ARV may need to be closed locally. Main steam isolation is accomplished by closing the main steam isolation valves (MSIVs) from the control room. Steam generator blowdown is isolated by closing all four blowdown valves from the control room. Source range neutron flux monitoring is available.

Reactor coolant makeup is achieved using either Train A or Train B CCP taking suction from the RWST and injecting water through the RCP seals and BIT. Pressurizer level reduction could occur due to uncontrolled cool down through one steam generator atmospheric relief valve until operator action is taken to isolate this flow path. One pressurizer PORV could spuriously open until operator action is taken in the control room to close the PORV. No other inventory reduction paths are affected by a fire in this area.

Decay heat removal is achieved using the Train B motor driven auxiliary feed water pump (MDAFP), taking suction from the condensate storage tank (CST), and supplying steam generators A and D, and the Train A motor driven auxiliary feed water pump (MDAFP), taking suction from the condensate storage tank (CST), and supplying steam generators B and C. Steam generators A, C and D ARVs are available to control RCS temperature during hot standby. Main feed water is isolated by closing the main feed water isolation valves (MFIVs) from the control room. Diagnostic instrumentation is available to verify RCS temperature and pressure. Train A and Train B residual heat removal (RHR) systems are available for transition from hot standby to cold shutdown.

A fire in this area will not prevent safe shutdown of the plant.

8.68 FIRE AREA C-33 (SOUTH LARGE ELECTRICAL CHASE 2073 ELEVATION)

There are no 20 foot combustible and fire hazard free zones in fire area C-33. Fire area C-33 has automatic fire detection and suppression installed.

PFSSD is assured using Train A safety related and non-safety related equipment.

Reactivity control is achieved by tripping the reactor from the control room. Boration is available using Train A centrifugal charging pump (CCP) taking suction from the refueling water storage tank (RWST) and injecting borated water through the reactor coolant pump (RCP) seals and boron injection tank (BIT). Main steam isolation is accomplished by closing the main steam isolation valves (MSIVs) from the control room. Steam generators A, B and C atmospheric relief valve (ARV) control is accomplished using hand switches in the control room. Steam generator D ARV may need to be locally closed. Steam generator blowdown is isolated by closing all four blowdown valves from radwaste control room panel BM157. Source range neutron flux monitoring is available.

Reactor coolant makeup is achieved using Train A CCP taking suction from the RWST and injecting water through the RCP seals and BIT. Pressurizer level reduction could occur due to uncontrolled cool down through all four steam generator blowdown lines and one steam generator atmospheric relief valve until operator action is taken to isolate these flow paths. One

pressurizer PORV may spuriously open and its associated block valve may not close. If this occurs, operators can close the PORV using the hand switch in the control room. No other inventory reduction paths are affected by a fire in this area.

Decay heat removal is achieved using Train A motor driven auxiliary feed water pump (MDAFP), taking suction from the condensate storage tank (CST), and supplying steam generators B and C. Steam generators B and C ARVs are available to control RCS temperature during hot standby. Steam generator D ARV may need to be closed locally. Main feed water is isolated by closing the main feed water isolation valves (MFIVs) from the control room. Diagnostic instrumentation is available to verify RCS temperature and pressure. Train A residual heat removal (RHR) system is available for transition from hot standby to cold shutdown, however RHR pump suction may have to be lined up locally and RHR to SI hot leg injection loops 2 and 3 may need to be closed locally to support shutdown cooling.

A fire in this area will not prevent safe shutdown of the plant.

8.69 FIRE AREA C-34 (SOUTH SMALL ELECTRICAL CHASE 2073 ELEVATION)

There are no 20 foot combustible and fire hazard free zones in fire area C-34. Fire area C-34 has automatic fire detection and suppression installed.

PFSSD is assured using either Train A or Train B safety related and non-safety related equipment.

Reactivity control is achieved by tripping the reactor from the control room. Boration is available using either Train A or Train B centrifugal charging pump (CCP) taking suction from the refueling water storage tank (RWST) and injecting borated water through the reactor coolant pump (RCP) seals and boron injection tank (BIT). Steam generators A, C and D atmospheric relief valves (ARVs) can be controlled from the control room. Steam generator B ARV may fail closed due to loss of power but will not spuriously open. Main steam isolation is accomplished by closing the main steam isolation valves (MSIVs) from the control room. Steam generator blowdown is isolated by closing all four blowdown valves from the control room. All four source range neutron flux monitors are available.

Reactor coolant makeup is achieved using either Train A or Train B CCP taking suction from the RWST and injecting water through the RCP seals and BIT. Pressurizer level reduction due to uncontrolled cool down through steam generator blowdown lines, steam generator atmospheric relief valves and main steam lines would not be caused by a fire in this area. No inventory reduction paths are affected by a fire in this area.

Decay heat removal is achieved using the Train B motor driven auxiliary feed water pump (MDAFP), taking suction from the condensate storage tank (CST), and supplying steam generators A and D, and the Train A motor driven auxiliary feed water pump (MDAFP), taking suction from the condensate storage tank (CST), and supplying steam generator C. Steam generators A, C and D ARVs are available to control RCS temperature during hot standby. Main feed water is isolated by closing the main feed water isolation valves (MFIVs) from the control room. Diagnostic instrumentation is available to verify RCS temperature and pressure. Train A and Train B residual heat removal (RHR) systems are available for transition from hot standby to cold shutdown.

A fire in this area will not prevent safe shutdown of the plant.

8.70 FIRE AREA C-35 (CORRIDOR 2016 ELEVATION)

There are no 20 foot combustible and fire hazard free zones in fire area C-35. Fire area C-35 has no automatic fire detection or suppression installed.

PFSSD is assured using either Train A or Train B safety related and non-safety related equipment. However, Train B Class 1E electrical equipment room cooling could be affected, potentially causing a loss of Train B Class 1E electrical equipment.

Reactivity control is achieved by tripping the reactor from the control room. Boration is available using Train A centrifugal charging pump (CCP) taking suction from the refueling water storage tank (RWST) and injecting borated water through the reactor coolant pump (RCP) seals and boron injection tank (BIT). Steam generators A and C atmospheric relief valves (ARVs) can be controlled from the control room. Main steam isolation is accomplished by closing the main steam isolation valves (MSIVs) from the control room. Steam generator blowdown is isolated by closing all four blowdown valves from the control room. All four source range neutron flux monitors are available.

Reactor coolant makeup is achieved using the Train A CCP taking suction from the RWST and injecting water through the RCP seals and BIT. Pressurizer level reduction due to uncontrolled cool down through steam generator blowdown lines, steam generator atmospheric relief valves and main steam lines would not be caused by a fire in this area. No inventory reduction paths are affected by a fire in this area.

Decay heat removal is achieved using the Train A motor driven auxiliary feed water pump (MDAFP), taking suction from the condensate storage tank (CST), and supplying steam generator C or the turbine driven auxiliary feed water pump (TDAFP), taking suction from the condensate storage tank (CST), and supplying steam generators A and C. Steam generators A and C ARVs are available to control RCS temperature during hot standby. Main feed water is isolated by closing the main feed water isolation valves (MFIVs) from the control room. Diagnostic instrumentation is available to verify RCS temperature and pressure. Train A residual heat removal (RHR) systems are available for transition from hot standby to cold shutdown.

A fire in this area will not prevent safe shutdown of the plant.

8.71 FIRE AREA C-36 (SOUTH SMALL ELECTRICAL CHASE 2000 ELEVATION)

There are no 20 foot combustible and fire hazard free zones in fire area C-36. Fire area C-36 has automatic suppression installed but no fire detection.

PFSSD is assured using either Train A or Train B safety related and non-safety related equipment.

Reactivity control is achieved by tripping the reactor from the control room. Boration is available using either Train A or Train B centrifugal charging pump (CCP) taking suction from the refueling water storage tank (RWST) and injecting borated water through the reactor coolant pump (RCP) seals and boron injection tank (BIT). Steam generators A, C and D atmospheric relief valves (ARVs) can be controlled from the control room. Steam generator B ARV may need to be closed locally. Main steam isolation is accomplished by closing the main steam isolation valves (MSIVs) from the control room. Steam generator blowdown is isolated by closing all four blowdown valves from the control room. All four source range neutron flux monitors are available.

Reactor coolant makeup is achieved using either Train A or Train B CCP taking suction from the RWST and injecting water through the RCP seals and BIT. Pressurizer level reduction due to uncontrolled cool down through steam generator blowdown lines, steam generator atmospheric

relief valves and main steam lines would not be caused by a fire in this area. No inventory reduction paths are affected by a fire in this area.

Decay heat removal is achieved using the Train B motor driven auxiliary feed water pump (MDAFP), taking suction from the condensate storage tank (CST), and supplying steam generators A and D, and the Train A motor driven auxiliary feed water pump (MDAFP), taking suction from the condensate storage tank (CST), and supplying steam generator C. Steam generators A, C and D ARVs are available to control RCS temperature during hot standby. Main feed water is isolated by closing the main feed water isolation valves (MFIVs) from the control room. Diagnostic instrumentation is available to verify RCS temperature and pressure. Train A and Train B residual heat removal (RHR) systems are available for transition from hot standby to cold shutdown.

A fire in this area will not prevent safe shutdown of the plant.

8.72 FIRE AREA C-37 (NORTH SMALL ELECTRICAL CHASE 2000 ELEVATION)

There are no 20 foot combustible and fire hazard free zones in fire area C-37. Fire area C-37 has automatic suppression installed but no fire detection.

PFSSD is assured using either Train A or Train B safety related and non-safety related equipment.

Reactivity control is achieved by tripping the reactor from the control room. Boration is available using either Train A or Train B centrifugal charging pump (CCP) taking suction from the refueling water storage tank (RWST) and injecting borated water through the reactor coolant pump (RCP) seals and boron injection tank (BIT). All four steam generator atmospheric relief valves (ARVs) can be controlled from the control room. Main steam isolation is accomplished by closing the main steam isolation valves (MSIVs) from the control room. Steam generator blowdown is isolated by closing all four blowdown valves from the control room. All four source range neutron flux monitors are available.

Reactor coolant makeup is achieved using either Train A or Train B CCP taking suction from the RWST and injecting water through the RCP seals and BIT. Pressurizer level reduction due to uncontrolled cool down through steam generator blowdown lines, steam generator atmospheric relief valves and main steam lines would not be caused by a fire in this area. No inventory reduction paths are affected by a fire in this area.

Decay heat removal is achieved using all three auxiliary feed water pumps (AFPs), taking suction from the condensate storage tank (CST), and supplying all four steam generators. All four steam generator ARVs are available to control RCS temperature during hot standby. Main feed water is isolated by closing the main feed water isolation valves (MFIVs) from the control room. Diagnostic instrumentation is available to verify RCS temperature and pressure. Train A and Train B residual heat removal (RHR) systems are available for transition from hot standby to cold shutdown.

A fire in this area will not prevent safe shutdown of the plant.

8.73 FIRE AREA CST (YARD AREA AROUND THE CST)

PFSSD is assured using either Train A or Train B safety related and non-safety related equipment.

Reactivity control is achieved by tripping the reactor from the control room. Boration is available using either Train A or Train B centrifugal charging pump (CCP) taking suction from the refueling water storage tank (RWST) and injecting borated water through the reactor coolant pump (RCP) seals and boron injection tank (BIT). All four steam generator atmospheric relief valves (ARVs) can be controlled from the control room. Main steam isolation is accomplished by closing the main steam isolation valves (MSIVs) from the control room. Steam generator blowdown is isolated by closing all four blowdown valves from the control room. All four source range neutron flux monitors are available.

Reactor coolant makeup is achieved using either Train A or Train B CCP taking suction from the RWST and injecting water through the RCP seals and BIT. Pressurizer level reduction due to uncontrolled cool down through steam generator blowdown lines, steam generator atmospheric relief valves and main steam lines would not be caused by a fire in this area. No inventory reduction paths are affected by a fire in this area.

Decay heat removal is achieved using all three auxiliary feed water pumps (AFPs), taking suction from the condensate storage tank (CST), and supplying all four steam generators. An exposure fire will not likely cause failure of the CST. All four steam generator ARVs are available to control RCS temperature during hot standby. Main feed water is isolated by closing the main feed water isolation valves (MFIVs) from the control room. Diagnostic instrumentation is available to verify RCS temperature and pressure. Train A and Train B residual heat removal (RHR) systems are available for transition from hot standby to cold shutdown.

A fire in this area will not prevent safe shutdown of the plant.

8.74 FIRE AREAS CC-1, T-1, T-2 AND TURB (COMMUNICATION CORRIDOR AND TURBINE BUILDING ALL ELEVATIONS EXCEPT FIRE AREAS T-4 AND T-10)

There are no 20 foot combustible and fire hazard free zones in fire areas CC-1, T-1, T-2 or TURB. Except for the Communication Corridor (CC-1), The South stairway (T-1), and the Turbine Building operating floor (El. 2065-0) these areas are protected with automatic fire suppression and detection. Fire area T-1 has an automatic smoke detector installed at the top of the stairway. Portions of the Communication Corridor are provided with automatic detection.

PFSSD is assured using either Train A or Train B safety related and non-safety related equipment.

Reactivity control is achieved by tripping the reactor from the control room. Boration is available using either Train A or Train B centrifugal charging pump (CCP) taking suction from the refueling water storage tank (RWST) and injecting borated water through the reactor coolant pump (RCP) seals and boron injection tank (BIT). All four steam generator atmospheric relief valves (ARVs) can be controlled from the control room. Main steam isolation is accomplished by closing the main steam isolation valves (MSIVs) from the control room. Steam generator blowdown is isolated by closing all four blowdown valves from the control room. All four source range neutron flux monitors are available.

Reactor coolant makeup is achieved using either Train A or Train B CCP taking suction from the RWST and injecting water through the RCP seals and BIT. Pressurizer level reduction due to uncontrolled cool down through steam generator blowdown lines, steam generator atmospheric relief valves and main steam lines would not be caused by a fire in this area. No inventory reduction paths are affected by a fire in this area.

Decay heat removal is achieved using all three auxiliary feed water pumps (AFPs), taking suction from the condensate storage tank (CST), and supplying all four steam generators. All four steam generator ARVs are available to control RCS temperature during hot standby. Main feed water is isolated by closing the main feed water isolation valves (MFIVs) from the control room. Diagnostic instrumentation is available to verify RCS temperature and pressure. Train A and Train B residual heat removal (RHR) systems are available for transition from hot standby to cold shutdown.

A fire in this area will not prevent safe shutdown of the plant.

8.75 FIRE AREA D-1 (TRAIN A DIESEL GENERATOR ROOM EAST)

There are no 20 foot combustible and fire hazard free zones in fire area D-1. Fire area D-1 has automatic fire detection and suppression installed in the Diesel Generator Room.

PFSSD is assured using Train B safety related and non-safety related equipment.

Reactivity control is achieved by tripping the reactor from the control room. Boration is available using Train B centrifugal charging pump (CCP) taking suction from the refueling water storage tank (RWST) and injecting borated water through the reactor coolant pump (RCP) seals and boron injection tank (BIT). All four steam generator atmospheric relief valves (ARVs) can be controlled from the control room initially. However, due to the potential loss of Train A power, only two of the four ARVs may be available after the nitrogen supply is depleted. Main steam isolation is accomplished by closing the main steam isolation valves (MSIVs) from the control room. Steam generator blowdown is isolated by closing all four blowdown valves from the control room. All four source range neutron flux monitors are available initially. However, only the Train B source range monitors may be available long term due to the potential loss of Train A power.

Reactor coolant makeup is achieved using Train B CCP taking suction from the RWST and injecting water through the RCP seals and BIT. Pressurizer level reduction due to uncontrolled cool down through steam generator blowdown lines, steam generator atmospheric relief valves and main steam lines would not be caused by a fire in this area. No inventory reduction paths are affected by a fire in this area.

Decay heat removal is achieved using the TDAFP or the Train B MDAFP, taking suction from the condensate storage tank (CST), and supplying all four steam generators. All four steam generator ARVs are available to control RCS temperature during hot standby. However, as stated above, only two ARVs may be available long term. Main feed water is isolated by closing the main feed water isolation valves (MFIVs) from the control room. Diagnostic instrumentation is available to verify RCS temperature and pressure. Train B residual heat removal (RHR) system is available for transition from hot standby to cold shutdown.

A fire in this area will not prevent safe shutdown of the plant.

8.76 FIRE AREA D-2 (TRAIN B DIESEL GENERATOR ROOM WEST)

There are no 20 foot combustible and fire hazard free zones in fire area D-2. Fire area D-2 has automatic fire detection and suppression installed in the Diesel Generator Room.

PFSSD is assured using Train A safety related and non-safety related equipment.

Reactivity control is achieved by tripping the reactor from the control room. Boration is available using Train A centrifugal charging pump (CCP) taking suction from the refueling water storage tank (RWST) and injecting borated water through the reactor coolant pump (RCP) seals and boron injection tank (BIT). All four steam generator atmospheric relief valves (ARVs) can be controlled from the control room. Main steam isolation is accomplished by closing the main

steam isolation valves (MSIVs) from the control room. Steam generator blowdown is isolated by closing all four blowdown valves from the control room. All four source range neutron flux monitors are available.

Reactor coolant makeup is achieved using Train A CCP taking suction from the RWST and injecting water through the RCP seals and BIT. Pressurizer level reduction due to uncontrolled cool down through steam generator blowdown lines, steam generator atmospheric relief valves and main steam lines would not be caused by a fire in this area. No inventory reduction paths are affected by a fire in this area.

Decay heat removal is achieved using the TDAFP or the Train A MDAFP, taking suction from the condensate storage tank (CST), and supplying all four steam generators. All four steam generator ARVs are available to control RCS temperature during hot standby. Main feed water is isolated by closing the main feed water isolation valves (MFIVs) from the control room. Diagnostic instrumentation is available to verify RCS temperature and pressure. Train B residual heat removal (RHR) system is available for transition from hot standby to cold shutdown.

A fire in this area will not prevent safe shutdown of the plant.

8.77 FIRE AREA ESWA (TRAIN A ESSENTIAL SERVICE WATER PUMPHOUSE, ELECTRICAL VAULTS AND DUCT BANKS)

There are no 20 foot combustible and fire hazard free zones in fire area ESWA. Fire area ESWA has automatic fire detection installed but no suppression.

PFSSD is assured using Train B safety related and non-safety related equipment.

Reactivity control is achieved by tripping the reactor from the control room. Boration is available using Train B centrifugal charging pump (CCP) taking suction from the refueling water storage tank (RWST) and injecting borated water through the reactor coolant pump (RCP) seals and boron injection tank (BIT). Main steam isolation is accomplished by closing the main steam isolation valves (MSIVs) from the control room. All four steam generator atmospheric relief valves (ARVs) can be controlled from the control room. Steam generator blowdown is isolated by closing all four blowdown valves from the control room. All four source range neutron flux monitors are available.

Reactor coolant makeup is achieved using Train B CCP taking suction from the RWST and injecting water through the RCP seals and BIT. Pressurizer level reduction due to uncontrolled cool down through steam generator blowdown lines, steam generator atmospheric relief valves and main steam lines would not be caused by a fire in this area. No inventory reduction paths are affected by a fire in this area.

Decay heat removal is achieved using Train B motor driven auxiliary feed water pump (MDAFP) or the turbine driven auxiliary feed water pump (TDAFP), taking suction from the condensate storage tank (CST), and supplying all four steam generators. All four steam generator ARVs are available to control RCS temperature during hot standby. Main feed water is isolated by closing the main feed water isolation valves (MFIVs) from the control room. Diagnostic instrumentation is available to verify RCS temperature and pressure. Train B residual heat removal (RHR) system is available for transition from hot standby to cold shutdown.

A fire in this area will not prevent safe shutdown of the plant.

8.78 FIRE AREA ESWB (TRAIN B ESSENTIAL SERVICE WATER PUMPHOUSE, ELECTRICAL VAULTS AND DUCT BANKS)

There are no 20 foot combustible and fire hazard free zones in fire area ESWB. Fire area ESWB has automatic fire detection installed but no suppression.

PFSSD is assured using Train A safety related and non-safety related equipment.

Reactivity control is achieved by tripping the reactor from the control room. Boration is available using Train A centrifugal charging pump (CCP) taking suction from the refueling water storage tank (RWST) and injecting borated water through the reactor coolant pump (RCP) seals and boron injection tank (BIT). Main steam isolation is accomplished by closing the main steam isolation valves (MSIVs) from the control room. All four steam generator atmospheric relief valves (ARVs) can be controlled from the control room. Steam generator blowdown is isolated by closing all four blowdown valves from the control room. All four source range neutron flux monitors are available.

Reactor coolant makeup is achieved using Train A CCP taking suction from the RWST and injecting water through the RCP seals and BIT. Pressurizer level reduction due to uncontrolled cool down through steam generator blowdown lines, steam generator atmospheric relief valves and main steam lines would not be caused by a fire in this area. No inventory reduction paths are affected by a fire in this area.

Decay heat removal is achieved using Train A motor driven auxiliary feed water pump (MDAFP) or the turbine driven auxiliary feed water pump (TDAFP), taking suction from the condensate storage tank (CST), and supplying all four steam generators. All four steam generator ARVs are available to control RCS temperature during hot standby. Main feed water is isolated by closing the main feed water isolation valves (MFIVs) from the control room. Diagnostic instrumentation is available to verify RCS temperature and pressure. Train A residual heat removal (RHR) system is available for transition from hot standby to cold shutdown.

A fire in this area will not prevent safe shutdown of the plant.

8.79 FIRE AREA ESWV (ESSENTIAL SERVICE WATER VAULTS)

There are no safe shutdown circuits or equipment in this area. Consequently, a fire in area ESWV will not prevent safe shutdown of the plant.

8.80 FIRE AREA F-1 (FUEL BUILDING GENERAL AREAS)

There are no 20 foot combustible and fire hazard free zones in fire area F-1. Fire area F-1 has automatic fire detection (flame detectors) installed on the operating floor. An automatic pre-action sprinkler system, actuated by heat detectors, is installed above the railroad bay.

PFSSD is assured using either Train A or Train B safety related and non-safety related equipment.

Reactivity control is achieved by tripping the reactor from the control room. Boration is available using either Train A or Train B centrifugal charging pump (CCP) taking suction from the refueling water storage tank (RWST) and injecting borated water through the reactor coolant pump (RCP) seals and boron injection tank (BIT). All four steam generator atmospheric relief valves (ARVs) can be controlled from the control room. Main steam isolation is accomplished by closing the main steam isolation valves (MSIVs) from the control room. Steam generator blowdown is isolated by closing all four blowdown valves from the control room. All four source range neutron flux monitors are available.

Reactor coolant makeup is achieved using either Train A or Train B CCP taking suction from the RWST and injecting water through the RCP seals and BIT. Pressurizer level reduction due to uncontrolled cool down through steam generator blowdown lines, steam generator atmospheric relief valves and main steam lines would not be caused by a fire in this area. No inventory reduction paths are affected by a fire in this area.

Decay heat removal is achieved using all three auxiliary feed water pumps (AFPs), taking suction from the condensate storage tank (CST), and supplying all four steam generators. All four steam generator ARVs are available to control RCS temperature during hot standby. Main feed water is isolated by closing the main feed water isolation valves (MFIVs) from the control room. Diagnostic instrumentation is available to verify RCS temperature and pressure. Train A and Train B residual heat removal (RHR) systems are available for transition from hot standby to cold shutdown.

A fire in this area will not prevent safe shutdown of the plant.

8.81 FIRE AREA F-2 (TRAIN B FUEL POOL COOLING HEAT EXCHANGER ROOM)

There are no 20 foot combustible and fire hazard free zones in fire area F-2. Fire area F-2 has automatic fire detection installed but no suppression.

PFSSD is assured using either Train A or Train B safety related and non-safety related equipment.

Reactivity control is achieved by tripping the reactor from the control room. Boration is available using either Train A or Train B centrifugal charging pump (CCP) taking suction from the refueling water storage tank (RWST) and injecting borated water through the reactor coolant pump (RCP) seals and boron injection tank (BIT). All four steam generator atmospheric relief valves (ARVs) can be controlled from the control room. Main steam isolation is accomplished by closing the main steam isolation valves (MSIVs) from the control room. Steam generator blowdown is isolated by closing all four blowdown valves from the control room. All four source range neutron flux monitors are available.

Reactor coolant makeup is achieved using either Train A or Train B CCP taking suction from the RWST and injecting water through the RCP seals and BIT. Pressurizer level reduction due to uncontrolled cool down through steam generator blowdown lines, steam generator atmospheric relief valves and main steam lines would not be caused by a fire in this area. No inventory reduction paths are affected by a fire in this area.

Decay heat removal is achieved using all three auxiliary feed water pumps (AFPs), taking suction from the condensate storage tank (CST), and supplying all four steam generators. All four steam generator ARVs are available to control RCS temperature during hot standby. Main feed water is isolated by closing the main feed water isolation valves (MFIVs) from the control room. Diagnostic instrumentation is available to verify RCS temperature and pressure. Train A and Train B residual heat removal (RHR) systems are available for transition from hot standby to cold shutdown.

A fire in this area will not prevent safe shutdown of the plant.

8.82 FIRE AREA F-3 (TRAIN A FUEL POOL COOLING HEAT EXCHANGER ROOM)

There are no safe shutdown circuits or equipment in this area. Consequently, a fire in area F-3 will not prevent safe shutdown of the plant.

8.83 FIRE AREA F-4 (FUEL BUILDING AIR HANDLING EQUIPMENT ROOM)

There are no 20 foot combustible and fire hazard free zones in fire area F-4. Fire area F-4 has automatic fire detection installed but no suppression.

PFSSD is assured using either Train A or Train B safety related and non-safety related equipment.

Reactivity control is achieved by tripping the reactor from the control room. Boration is available using either Train A or Train B centrifugal charging pump (CCP) taking suction from the refueling water storage tank (RWST) and injecting borated water through the reactor coolant pump (RCP) seals and boron injection tank (BIT). All four steam generator atmospheric relief valves (ARVs) can be controlled from the control room. Main steam isolation is accomplished by closing the main steam isolation valves (MSIVs) from the control room. Steam generator blowdown is isolated by closing all four blowdown valves from the control room. All four source range neutron flux monitors are available.

Reactor coolant makeup is achieved using either Train A or Train B CCP taking suction from the RWST and injecting water through the RCP seals and BIT. Pressurizer level reduction due to uncontrolled cool down through steam generator blowdown lines, steam generator atmospheric relief valves and main steam lines would not be caused by a fire in this area. No inventory reduction paths are affected by a fire in this area.

Decay heat removal is achieved using all three auxiliary feed water pumps (AFPs), taking suction from the condensate storage tank (CST), and supplying all four steam generators. All four steam generator ARVs are available to control RCS temperature during hot standby. Main feed water is isolated by closing the main feed water isolation valves (MFIVs) from the control room. Diagnostic instrumentation is available to verify RCS temperature and pressure. Train A and Train B residual heat removal (RHR) systems are available for transition from hot standby to cold shutdown.

A fire in this area will not prevent safe shutdown of the plant.

8.84 FIRE AREA F-5 (FUEL BUILDING ELECTRICAL EQUIPMENT ROOM)

There are no 20 foot combustible and fire hazard free zones in fire area F-5. Fire area F-5 has automatic fire detection installed but no suppression.

PFSSD is assured using either Train A or Train B safety related and non-safety related equipment.

Reactivity control is achieved by tripping the reactor from the control room. Boration is available using either Train A or Train B centrifugal charging pump (CCP) taking suction from the refueling water storage tank (RWST) and injecting borated water through the reactor coolant pump (RCP) seals and boron injection tank (BIT). All four steam generator atmospheric relief valves (ARVs) can be controlled from the control room. Main steam isolation is accomplished by closing the main steam isolation valves (MSIVs) from the control room. Steam generator blowdown is isolated by closing all four blowdown valves from the control room. All four source range neutron flux monitors are available.

Reactor coolant makeup is achieved using either Train A or Train B CCP taking suction from the RWST and injecting water through the RCP seals and BIT. Pressurizer level reduction due to uncontrolled cool down through steam generator blowdown lines, steam generator atmospheric relief valves and main steam lines would not be caused by a fire in this area. No inventory reduction paths are affected by a fire in this area.

Decay heat removal is achieved using all three auxiliary feed water pumps (AFPs), taking suction from the condensate storage tank (CST), and supplying all four steam generators. All four steam generator ARVs are available to control RCS temperature during hot standby. Main feed water is isolated by closing the main feed water isolation valves (MFIVs) from the control room. Diagnostic instrumentation is available to verify RCS temperature and pressure. Train A and Train B residual heat removal (RHR) systems are available for transition from hot standby to cold shutdown.

A fire in this area will not prevent safe shutdown of the plant.

8.85 FIRE AREA F-6 (FUEL BUILDING EMERGENCY EXHAUST EQUIPMENT ROOM EAST)

There are no safe shutdown circuits or equipment in this area. Consequently, a fire in area F-6 will not prevent safe shutdown of the plant.

8.86 FIRE AREA F-7 (FUEL BUILDING EMERGENCY EXHAUST EQUIPMENT ROOM WEST)

There are no 20 foot combustible and fire hazard free zones in fire area F-7. Fire area F-7 has automatic fire detection installed, but no suppression.

PFSSD is assured using either Train A or Train B safety related and non-safety related equipment.

Reactivity control is achieved by tripping the reactor from the control room. Boration is available using either Train A or Train B centrifugal charging pump (CCP) taking suction from the refueling water storage tank (RWST) and injecting borated water through the reactor coolant pump (RCP) seals and boron injection tank (BIT). All four steam generator atmospheric relief valves (ARVs) can be controlled from the control room. Main steam isolation is accomplished by closing the main steam isolation valves (MSIVs) from the control room. Steam generator blowdown is isolated by closing all four blowdown valves from the control room. All four source range neutron flux monitors are available.

Reactor coolant makeup is achieved using either Train A or Train B CCP taking suction from the RWST and injecting water through the RCP seals and BIT. Pressurizer level reduction due to uncontrolled cool down through steam generator blowdown lines, steam generator atmospheric relief valves and main steam lines would not be caused by a fire in this area. No inventory reduction paths are affected by a fire in this area.

Decay heat removal is achieved using all three auxiliary feed water pumps (AFPs), taking suction from the condensate storage tank (CST), and supplying all four steam generators. All four steam generator ARVs are available to control RCS temperature during hot standby. Main feed water is isolated by closing the main feed water isolation valves (MFIVs) from the control room. Diagnostic instrumentation is available to verify RCS temperature and pressure. Train A and Train B residual heat removal (RHR) systems are available for transition from hot standby to cold shutdown.

A fire in this area will not prevent safe shutdown of the plant.

8.87 FIRE AREA HMS-1 (HOT MACHINE SHOP)

There are no safe shutdown circuits or equipment in this area. Consequently, a fire in area HMS-1 will not prevent safe shutdown of the plant.

8.88 FIRE AREA RB (REACTOR BUILDING) (RB-1 THROUGH RB-11)

The reactor building is divided into 11 separate fire areas in the fire hazards analysis (RB-1 through RB-11). However, for the purposes of the PFSSD analysis, the reactor building is treated as one fire area, which is designated as fire area RB.

There are no designated 20 foot combustible and fire hazard free zones in fire area RB. During power operations, combustible loading is limited to that allowed by administrative procedures and is only allowed in designated areas, usually within metal containers. The reactor building is a locked high radiation area during power operations, so access is limited and combustible material quantities entering the building can be closely monitored. Fire detection using linear heat detection is installed on most cable trays in the building and above each reactor coolant pump. A manually charged fixed fire suppression system and linear heat detection is installed in each cable penetration area.

A number of redundant PFSSD components and associated circuits are located in the reactor building. Some circuits have fire wrap installed to meet the requirements of 10CFR50, Appendix R, Section III.G.2.f for a radiant energy shield. Other circuits are separated from their redundant counterpart by at least 20 feet of horizontal separation with limited or no combustibles and fire hazards.

PFSSD is assured using either Train A or Train B safety related and non-safety related equipment.

Reactivity control is achieved by tripping the reactor from the control room. Boration is available using either Train A or Train B centrifugal charging pump (CCP) taking suction from the refueling water storage tank (RWST) and injecting borated water through the reactor coolant pump (RCP) seals and boron injection tank (BIT). All four steam generator atmospheric relief valves (ARVs) can be controlled from the control room. Main steam isolation is accomplished by closing the main steam isolation valves (MSIVs) from the control room. Steam generator blowdown is isolated by closing all four blowdown valves from the control room. All four source range neutron flux monitors could be affected but at least one will be available because of spatial separation between monitors and cables.

Reactor coolant makeup is achieved using either Train A or Train B CCP taking suction from the RWST and injecting water through the RCP seals and BIT. Pressurizer level reduction due to uncontrolled cool down through steam generator blowdown lines, steam generator atmospheric relief valves and main steam lines would not be caused by a fire in this area. A fire in this area could cause a loss of inventory through the letdown and excess letdown flow paths until the letdown isolation valves and excess letdown isolation valves can be failed closed. The pressurizer spray valves could open until the valves can be failed closed. Both pressurizer PORVs may spuriously open and their associated block valves may not close. If this occurs, both PORVs can be closed from the control room. No other inventory reduction paths are affected by a fire in this area.

Decay heat removal is achieved using all three auxiliary feed water pumps (AFPs), taking suction from the condensate storage tank (CST), and supplying all four steam generators. All four steam generator ARVs are available to control RCS temperature during hot standby. Main feed water is isolated by closing the main feed water isolation valves (MFIVs) from the control room. Diagnostic instrumentation is available to verify RCS temperature and pressure. Train A and Train B residual heat removal (RHR) systems are available for transition from hot standby to cold shutdown, however RHR pump suction may have to be lined up locally.

A fire in this area will not prevent safe shutdown of the plant.

8.89 FIRE AREA RW (RADWASTE BUILDING) (RWA, RWB & RWC)

There are no 20 foot combustible and fire hazard free zones in fire area RW. Fire area RW has automatic fire detection installed and an automatic wet pipe sprinkler system in the dry waste compactor area.

PFSSD is assured using either Train A or Train B safety related and non-safety related equipment.

Reactivity control is achieved by tripping the reactor from the control room. Boration is available using either Train A or Train B centrifugal charging pump (CCP) taking suction from the refueling water storage tank (RWST) and injecting borated water through the reactor coolant pump (RCP) seals and boron injection tank (BIT). All four steam generator atmospheric relief valves (ARVs) can be controlled from the control room. Main steam isolation is accomplished by closing the main steam isolation valves (MSIVs) from the control room. Steam generator blowdown is isolated by closing all four blowdown valves from the control room. All four source range neutron flux monitors are available.

Reactor coolant makeup is achieved using either Train A or Train B CCP taking suction from the RWST and injecting water through the RCP seals and BIT. Pressurizer level reduction due to uncontrolled cool down through steam generator blowdown lines, steam generator atmospheric relief valves and main steam lines would not be caused by a fire in this area. No inventory reduction paths are affected by a fire in this area.

Decay heat removal is achieved using all three auxiliary feed water pumps (AFPs), taking suction from the condensate storage tank (CST), and supplying all four steam generators. All four steam generator ARVs are available to control RCS temperature during hot standby. Main feed water is isolated by closing the main feed water isolation valves (MFIVs) from the control room. Diagnostic instrumentation is available to verify RCS temperature and pressure. Train A and Train B residual heat removal (RHR) systems are available for transition from hot standby to cold shutdown.

A fire in this area will not prevent safe shutdown of the plant.

8.90 FIRE AREA RW-1 (RADWASTE TUNNEL)

This area consists of a radioactive tunnel and a non-radioactive personnel access tunnel. There are no 20 foot combustible and fire hazard free zones in fire area RW-1. Fire area RW-1 has automatic fire detection installed in the non-radioactive tunnel but no suppression. The radioactive tunnel has no detection or suppression installed.

PFSSD is assured using either Train A or Train B safety related and non-safety related equipment.

Reactivity control is achieved by tripping the reactor from the control room. Boration is available using either Train A or Train B centrifugal charging pump (CCP) taking suction from the refueling water storage tank (RWST) and injecting borated water through the reactor coolant pump (RCP) seals and boron injection tank (BIT). All four steam generator atmospheric relief valves (ARVs) can be controlled from the control room. Main steam isolation is accomplished by closing the main steam isolation valves (MSIVs) from the control room. Steam generator blowdown is isolated by closing all four blowdown valves from the control room. All four source range neutron flux monitors are available.

Reactor coolant makeup is achieved using either Train A or Train B CCP taking suction from the RWST and injecting water through the RCP seals and BIT. Pressurizer level reduction due to uncontrolled cool down through steam generator blowdown lines, steam generator atmospheric

relief valves and main steam lines would not be caused by a fire in this area. No inventory reduction paths are affected by a fire in this area.

Decay heat removal is achieved using all three auxiliary feed water pumps (AFPs), taking suction from the condensate storage tank (CST), and supplying all four steam generators. All four steam generator ARVs are available to control RCS temperature during hot standby. Main feed water is isolated by closing the main feed water isolation valves (MFIVs) from the control room. Diagnostic instrumentation is available to verify RCS temperature and pressure. Train A and Train B residual heat removal (RHR) systems are available for transition from hot standby to cold shutdown.

A fire in this area will not prevent safe shutdown of the plant.

8.91 FIRE AREA RWST (YARD AREA AROUND THE RWST)

PFSSD is assured using either Train A or Train B safety related and non-safety related equipment.

Reactivity control is achieved by tripping the reactor from the control room. Boration is available using either Train A or Train B centrifugal charging pump (CCP) taking suction from the refueling water storage tank (RWST) and injecting borated water through the reactor coolant pump (RCP) seals and boron injection tank (BIT). An exposure fire will not likely cause failure of the RWST. All four steam generator atmospheric relief valves (ARVs) can be controlled from the control room. Main steam isolation is accomplished by closing the main steam isolation valves (MSIVs) from the control room. Steam generator blowdown is isolated by closing all four blowdown valves from the control room. All four source range neutron flux monitors are available.

Reactor coolant makeup is achieved using either Train A or Train B CCP taking suction from the RWST and injecting water through the RCP seals and BIT. An exposure fire will not likely cause failure of the RWST. Pressurizer level reduction due to uncontrolled cool down through steam generator blowdown lines, steam generator atmospheric relief valves and main steam lines would not be caused by a fire in this area. No inventory reduction paths are affected by a fire in this area.

Decay heat removal is achieved using all three auxiliary feed water pumps (AFPs), taking suction from the condensate storage tank (CST), and supplying all four steam generators. All four steam generator ARVs are available to control RCS temperature during hot standby. Main feed water is isolated by closing the main feed water isolation valves (MFIVs) from the control room. Diagnostic instrumentation is available to verify RCS temperature and pressure. Train A and Train B residual heat removal (RHR) systems are available for transition from hot standby to cold shutdown.

A fire in this area will not prevent safe shutdown of the plant.

8.92 FIRE AREA T-4 (LUBE OIL STORAGE TANKS)

There are no safe shutdown circuits or equipment in this area. Consequently, a fire in area T-4 will not prevent safe shutdown of the plant.

8.93 FIRE AREA T-10 (LUBE OIL RESERVOIR ROOM)

There are no safe shutdown circuits or equipment in this area. Consequently, a fire in area T-10 will not prevent safe shutdown of the plant.

8.94 FIRE AREA YARD (GENERAL YARD AREAS)

PFSSD is assured using either Train A or Train B safety related and non-safety related equipment.

Reactivity control is achieved by tripping the reactor from the control room. Boration is available using either Train A or Train B centrifugal charging pump (CCP) taking suction from the refueling water storage tank (RWST) and injecting borated water through the reactor coolant pump (RCP) seals and boron injection tank (BIT). All four steam generator atmospheric relief valves (ARVs) can be controlled from the control room. Main steam isolation is accomplished by closing the main steam isolation valves (MSIVs) from the control room. Steam generator blowdown is isolated by closing all four blowdown valves from the control room. All four source range neutron flux monitors are available.

Reactor coolant makeup is achieved using either Train A or Train B CCP taking suction from the RWST and injecting water through the RCP seals and BIT. Pressurizer level reduction due to uncontrolled cool down through steam generator blowdown lines, steam generator atmospheric relief valves and main steam lines would not be caused by a fire in this area. No inventory reduction paths are affected by a fire in this area.

Decay heat removal is achieved using all three auxiliary feed water pumps (AFPs), taking suction from the condensate storage tank (CST), and supplying all four steam generators. All four steam generator ARVs are available to control RCS temperature during hot standby. Main feed water is isolated by closing the main feed water isolation valves (MFIVs) from the control room. Diagnostic instrumentation is available to verify RCS temperature and pressure. Train A and Train B residual heat removal (RHR) systems are available for transition from hot standby to cold shutdown.

A fire in this area will not prevent safe shutdown of the plant.

8.95 FIRE AREA YARD – ESF (YARD1 IN E-15000) (YARD AREA AROUND ESF TRANSFORMERS)

PFSSD is assured using either Train A or Train B safety related and non-safety related equipment.

Reactivity control is achieved by tripping the reactor from the control room. Boration is available using either Train A or Train B centrifugal charging pump (CCP) taking suction from the refueling water storage tank (RWST) and injecting borated water through the reactor coolant pump (RCP) seals and boron injection tank (BIT). All four steam generator atmospheric relief valves (ARVs) can be controlled from the control room. Main steam isolation is accomplished by closing the main steam isolation valves (MSIVs) from the control room. Steam generator blowdown is isolated by closing all four blowdown valves from the control room. All four source range neutron flux monitors are available.

Reactor coolant makeup is achieved using either Train A or Train B CCP taking suction from the RWST and injecting water through the RCP seals and BIT. Pressurizer level reduction due to uncontrolled cool down through steam generator blowdown lines, steam generator atmospheric relief valves and main steam lines would not be caused by a fire in this area. No inventory reduction paths are affected by a fire in this area.

Decay heat removal is achieved using all three auxiliary feed water pumps (AFPs), taking suction from the condensate storage tank (CST), and supplying all four steam generators. All four steam generator ARVs are available to control RCS temperature during hot standby. Main feed water is isolated by closing the main feed water isolation valves (MFIVs) from the control room. Diagnostic instrumentation is available to verify RCS temperature and pressure. Train A and

Train B residual heat removal (RHR) systems are available for transition from hot standby to cold shutdown.

A fire in this area will not prevent safe shutdown of the plant.

8.96 FIRE AREA YARD – MAIN (YARD2 IN E-15000) (YARD AREA AROUND MAIN TRANSFORMERS)

There are no safe shutdown circuits or equipment in this area. Consequently, a fire in area YARD – MAIN will not prevent safe shutdown of the plant.

8.97 FIRE AREA YARD – SU (YARD3 IN E-15000) (YARD AREA AROUND START UP TRANSFORMER)

PFSSD is assured using either Train A or Train B safety related and non-safety related equipment.

Reactivity control is achieved by tripping the reactor from the control room. Boration is available using either Train A or Train B centrifugal charging pump (CCP) taking suction from the refueling water storage tank (RWST) and injecting borated water through the reactor coolant pump (RCP) seals and boron injection tank (BIT). All four steam generator atmospheric relief valves (ARVs) can be controlled from the control room. Main steam isolation is accomplished by closing the main steam isolation valves (MSIVs) from the control room. Steam generator blowdown is isolated by closing all four blowdown valves from the control room. All four source range neutron flux monitors are available.

Reactor coolant makeup is achieved using either Train A or Train B CCP taking suction from the RWST and injecting water through the RCP seals and BIT. Pressurizer level reduction due to uncontrolled cool down through steam generator blowdown lines, steam generator atmospheric relief valves and main steam lines would not be caused by a fire in this area. No inventory reduction paths are affected by a fire in this area.

Decay heat removal is achieved using all three auxiliary feed water pumps (AFPs), taking suction from the condensate storage tank (CST), and supplying all four steam generators. All four steam generator ARVs are available to control RCS temperature during hot standby. Main feed water is isolated by closing the main feed water isolation valves (MFIVs) from the control room. Diagnostic instrumentation is available to verify RCS temperature and pressure. Train A and Train B residual heat removal (RHR) systems are available for transition from hot standby to cold shutdown.

A fire in this area will not prevent safe shutdown of the plant.

5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA A-1 10
5.2 PFSSD CABLE EVALUATION 17

1.0 GENERAL AREA DESCRIPTION

Fire area A-1 is located on the 1974 and 1988 elevations of the Auxiliary Building and includes the rooms listed in Table A-1-1.

Table A-1-1
Rooms Located in Fire Area A-1

ROOM #	DESCRIPTION
1101	General Floor Area (No. 1)
1102	Chiller & Surge Tanks Area
1103	Letdown Chiller Heat Exchanger Room
1104	Letdown Reheat Heat Exchanger Room
1105	Valve Compartment
1106	Moderating Heat Exchanger Room
1115	Normal Charging Pump Room
1120	General Floor Area (No. 2)
1121	Access Pit
1122	General Floor Area (No. 3)
1123	Passage
1124	Valve Compartment
1125	Letdown Heat Exchanger Room
1128	Unassigned Space
1129	Auxiliary Steam Condensate Recovery & Storage Tank
1130	North Corridor
1201	Vestibule
1202	Access Area (B) & Chiller Surge Tank
1203	Pipe Space (B)
1203A	South Electrical Chase
1204	Pipe Space (A)
1205	Access Area (A)

An automatic pre-action sprinkler system is installed over concentrations of cable in cable trays. Automatic fire detection is installed throughout the area. The automatic suppression and detection system meets the intent of 10CFR50, Appendix R Section III.G.2.c.

Where redundant circuits are run through area A-1, circuits associated with the protected components are wrapped with a raceway fire barrier material meeting the requirements for a 1-hour fire rating. This fire barrier, along with automatic suppression and detection installed in the area, provides reasonable assurance that PFSSD can be achieved.

2.0 PRIMARY EQUIPMENT USED FOR PFSSD

Table A-1-2 lists each system credited for post-fire safe shutdown and provides a discussion regarding the availability of the system to perform its Post Fire Safe Shutdown (PFSSD) function if a severe fire occurs in this area. For a summary of the area analysis results, see Section 8.0 of the Fire Area Analysis Narrative section.

Table A-1-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-1

System	System Name	PFSSD Function*	Comments
AB	Main Steam	R, M, H, P, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-1.
AC	Main Turbine	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-1.
AE	Main Feedwater	H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-1.
AL	Aux. Feedwater System	H, P	All PFSSD functions associated with the auxiliary feedwater system are satisfied. Both Motor Driven Auxiliary Feedwater Pumps could be inoperable. The Turbine Driven Auxiliary Feedwater Pump (TDAFP) is available to supply feedwater to the steam generators. Valves ALHV0009 and ALHV0011 may lose power, causing loss of control of AFW from Train A MDAFP to SGs B and C. The TDAFP is available to supply all four steam generators. Condensate Storage Tank (CST) level indication is available.
AP	Condensate Storage System	H	The condensate storage system is available to supply water to the TDAFP.
BB	Reactor Coolant System	R, M, H, P, S	All PFSSD functions associated with the reactor coolant system are satisfied. RCS pressure indication is available using BBPI0405. When transferring to RHR, valve BBPV8702A may need to be manually opened, or a cold shutdown repair performed, to provide a suction source from the RCS to RHR pump A. All four reactor coolant pumps may not stop using the control room hand switch. RCP seal injection and thermal barrier cooling remain available. Therefore, the inability to stop the RCPs will have no adverse impact on PFSSD. Pressurizer spray valves BBPCV0455B and BBPCV0455C could spuriously open. If this occurs, pressurizer spray can be stopped by closing KAFV0029 using KAHIS0029 in the main control room. Pressurizer pressure indication is available using BBPI0455A, BBPI0456, BBPI0457 or BBPI0458. Pressurizer level indication is available using BBLI0459A and BBLI0460A.
BG	Chemical and Volume Control System	R, M, S	PFSSD functions associated with the chemical and volume control system are satisfied. Train A Centrifugal Charging Pump (CCP) is available to provide charging flow from the RWST to the RCP seals. VCT to CCP valve BGLCV0112B will automatically close. Excess letdown isolation valves will remain closed. Letdown isolation valves BGLCV0459 and BGLCV0460 and letdown orifice isolation valves BGHV8149A, BGHV8149B, and BGHV8149C may need to be failed closed by closing valve KAFV0029 using KAHIS0029 in the main control room. RCP seal injection flow transmitters BGFT0215A and BGFT0215B could be affected. The component cooling water system is unaffected and RCP thermal barrier cooling remains available.

Table A-1-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-1

System	System Name	PFSSD Function*	Comments
BM	Steam Generator Blowdown System	R, M, H	All PFSSD functions associated with the steam generator blowdown system are satisfied. Steam generator blowdown is isolated by closing valves BMHV0001, BMHV0002, BMHV0003 and BMHV0004 using BMHIS0001A, BMHIS0002A, BMHIS0003A and BMHIS0004A, located on RL024 in the Main Control Room.
BN	Borated Refueling Water Storage System	R, M, H	The RWST is available to provide a suction source to Centrifugal Charging Pump A via valve BNLCV0112D. RWST level indication is available using all four level indicators. When initiating RHR, flow from the RWST to RHR pump A can be isolated using BNHV8812A.
EF	Essential Service Water System	H, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-1.
EG	Component Cooling Water System	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-1.
EJ	Residual Heat Removal System	M, H, P	All PFSSD functions associated with the Residual Heat Removal (RHR) system are satisfied. Loss of RCS inventory through the RHR flow path is prevented by maintaining valves EJHV8701A and EJHV8701B closed. RHR Train A is available via RCS suction valve EJHV8701A and discharge valves EJHCV0606 and EJHV8809A. RHR pump A mini-flow valve EJFCV0610 is available. RHR system flow diagnostic instrumentation is available using various available temperature indicators.
EM	High Pressure Coolant Injection	R, M	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-1.
EN	Containment Spray	R, M	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-1.
EP	Safety Injection Accumulators	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-1.
FB	Auxiliary Steam	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-1.
FC	Auxiliary Turbines	R, H, P	All PFSSD functions associated with the Auxiliary Turbines are satisfied. The TDAFP is used for a fire in area A-1.

Table A-1-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-1

System	System Name	PFSSD Function*	Comments
GD	ESW Pump House HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-1.
GF	AFW Pump Room Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-1.
GK	Control Room and Class 1E Switchgear Room Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-1.
GL	Auxiliary Building HVAC	S	The PFSSD Support function associated with the Auxiliary Building HVAC system is satisfied. Train A CCP room cooler SGL12A is available. Train A RHR pump room cooler SGL10A is available.
GM	Emergency Diesel Generator Room HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-1.
GN	Containment Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-1.
JE	Diesel Fuel Oil	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-1.
KA	Instrument Air	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-1.
KC	Fire Protection	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-1.
KH	Service Gas	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-1.
KJ	Standby Diesel Engine	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-1.
MA	Main Generation	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-1.
MR	Startup Transformer	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-1.
NB	4.16 kV System	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-1.
NE	Standby Diesel Generator	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-1.

Table A-1-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-1

System	System Name	PFSSD Function*	Comments
NF	Load Shed and Emergency Load Sequencing	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-1.
NG	480V Load Centers and MCCs	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-1.
NK	125VDC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-1.
NN	120VAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-1.
PA	13.8kV	S	Breakers PA0106 and PA0207 could trip. This will not affect PFSSD since redundant capability is available.
PB	4.16kV	H, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-1.
PG	480V Load Centers and MCCs	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-1.
PK	125VDC	S	Class 1E 480 VAC power to inverter PK24 could be disrupted. Battery rack PK14 is unaffected and is available to supply short-term 125 VDC power to bus PK04.
PL	Local Instrument Panels	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-1.
PN	120VAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-1.
QB	Standby AC Lighting	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-1.
QD	Emergency Lighting	S	Emergency lighting for PFSSD outside the control room is provided by self-contained 8-hour battery powered lights. Emergency lighting in the control room is provided by 125 VDC emergency lighting distribution switchboard NK051A. The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-1.
RL	Control Room MCB	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-1.
RP	Miscellaneous Control Panels	R, M, H, P, S	PFSSD functions associated with RP211 are affected by a fire in area A-1. Redundant capability exists in a separate area and is unaffected by a fire in area A-1.
SA	ESFAS	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-1.

Table A-1-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-1

System	System Name	PFSSD Function*	Comments
SB	Reactor Protection System	R, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-1.
SC	Reactor Instrumentation	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-1.
SE	Ex-Core Neutron Monitoring	R, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-1.
SY	Switchyard	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-1.
UU	Supervisory System	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-1.

* R - Reactivity Control; M - Reactor Coolant Makeup; H - Decay Heat Removal; P - Process Monitoring; S - Support Function

3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD

This section describes operator actions that may need to be performed inside or outside the control room to achieve and maintain hot standby if a fire occurs in area A-1. This section also describes cold shutdown repairs that may need to be made to achieve and maintain cold shutdown conditions. Operator actions are generally described in OFN KC-016.

3.1 ACTIONS OUTSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

None

3.2 ACTIONS INSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

3.2.1 Isolation of Letdown

A fire in area A-1 could prevent valves BGLCV0459, BGLCV0460, BGHV8149A, BGHV8149B, and BGHV8149C from being closed using their associated control room hand switches. If this occurs, the valves can be closed by isolating air to the valves. This can be accomplished by depressing the CLOSE push button on KAHIS0029 to close KAFV0029. KAHIS0029 is located on RL024. Pressurizer level indication is available using BBLI0459A and BBLI0460A.

3.2.2 Normal Pressurizer Spray

Pressurizer spray valves BBPCV0455B and BBPCV0455C could spuriously open. If this occurs, the spray can be stopped by isolating air to the valves. This can be accomplished by depressing the CLOSE push button on KAHIS0029 to close KAFV0029. KAHIS0029 is located on RL024. Pressurizer pressure indication is available using BBPI0455A, BBPI0456, BBPI0457 or BBPI0458.

3.3 ACTIONS TO ACHIEVE AND MAINTAIN COLD SHUTDOWN

3.3.1 RHR

If valve BBPV8702A fails to respond when initiating RHR for cold shutdown, make a containment entry to manually open the valve or perform a cold shutdown repair to fix the damaged circuit.

4.0 CONCLUSION

With some exceptions, redundant Post-Fire Safe Shutdown capability exists if a severe fire occurs in this area. For those exceptions, feasible manual actions are available and are unaffected by the fire. Manual actions are documented in Section 3.0.

5.0 DETAILED ANALYSIS

This section describes the detailed component-by-component and cable-by-cable analysis for a fire in area A-1.

5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA A-1

PFSSD components (S. in E-15000) located in fire area A-1 are shown in Table A-1-3. An evaluation of each component and associated cables is provided in the sections that follow. The applicable evaluation section is listed in Table A-1-3.

Table A-1-3
PFSSD Equipment Located in Fire Area A-1

Room #	PFSSD Equipment	Description	Evaluation Section	Comments
1101	RP211	Auxiliary Relay Rack	5.1.1	
1101	NG100B	CVCS Heat Trace Isolation Fuses	5.1.7	
1101	QJS0001	CVCS Heat Trace Power Transfer Switch	5.1.7	
1115	BG8402B	Charging pump discharge to the regenerative heat exchanger (Manual Valve)	5.1.2	
1115	BGV0017	Charging pump discharge to the regenerative heat exchanger bypass valve (Manual Valve)	5.1.2	
1202	BBPT403	Wide range reactor coolant pressure transmitter	5.1.5	
1202	BBPT406	Wide range reactor coolant pressure transmitter	5.1.5	
1202	BGFT0215A	Reactor coolant pump seal total flow transmitter	5.1.3	
1202	BGFT0215B	Reactor coolant pump seal total flow transmitter	5.1.3	
1203	EJHV8811B	Containment Recirc. Sump to RHR Pump B isolation valve	5.1.6	
1203	EJZS8811B	Position switch on Containment Recirc. Sump to RHR Pump B isolation valve	5.1.6	
1203	TB12403	RWST to RHR B Suction Valve Control Circuit Terminal Box	5.2.3	
1204	EJHV8811A	Containment Recirc. Sump to RHR Pump A isolation valve	5.1.4	
1204	EJZS8811A	Position switch on Containment Recirc. Sump to RHR Pump A isolation valve	5.1.4	

5.1.1 Auxiliary Relay Rack RP211

RP211 is an auxiliary relay rack located in room 1101. Power to this panel is supplied by the PK5129 distribution panel through cable 15RPK09EA. Loss of power to the relay panel will result in loss of power to relay 3XBM46, which will prevent closing the blowdown isolation valves.

Calculation XX-E-013 identifies relay 3XBM46 as the only PFSSD related relay located in this enclosure. The function of this relay is to close valves BMHV0001, BMHV0002, BMHV0003, and BMHV0004 if a blowdown and sample process isolation signal is received. Under normal conditions the relay is de-energized, the auxiliary contacts are closed, and valves BMHV0001, BMHV0002, BMHV0003, and BMHV0004 are open.

The PFSSD position of BMHV0001, BMHV0002, BMHV0003, and BMHV0004 is closed. Cables associated with relay 3XBM46 for all four valves run through room 1101. These cables are identified in Table A-1-4.

Table A-1-4
Cables Associated With Relay 3XBM46 in Fire Area A-1

BMHV0001	BMHV0002	BMHV0003	BMHV0004
15BMK06AA	15BMK06BA	15BMK06CA	15BMK06DA
15BMK06AB	15BMK06BB	15BMK06CB	15BMK06DB
15BMK06AC	15BMK06BC	15BMK06CC	15BMK06DC

A fire in area A-1 will damage the above listed cables, resulting in loss of valve position indication on the BM157 panel (room 7209) and loss of the ability to close BMHV0001, BMHV0002, BMHV0003, and BMHV0004 from the Steam Generator Blowdown Control Panel (BM157) in the Radwaste Control Room (Room 7209). Redundant circuits associated with valves BMHV0001, BMHV0002, BMHV0003, and BMHV0004 are located in fire area A-16 and are unaffected by a fire in area A-1. These redundant circuits allow control of valves BMHV0001, BMHV0002, BMHV0003, and BMHV0004 from the Main Control Room. In addition, valve position indication on the RL024 panel in the Main Control Room is unaffected by a fire in area A-1.

Damage to Auxiliary Relay Rack RP211, relay 3XBM46 and associated cables will not prevent achieving and maintaining safe shutdown following a fire in area A-1.

5.1.2 Charging Pump Discharge to Regenerative Heat Exchanger Isolation Valves

Valves BG8402B and BGV0017 are manual isolation valves located in room 1115 on the charging pump discharge to the regenerative heat exchanger. The PFSSD position of these valves is closed to direct charging flow (boration flow) through the RCP seals. The valve is used as a redundant means of isolating the regenerative heat exchanger flow path in the event that either BGHV8105 or BGHV8106 are unable to be closed from the control room.

Cables for BGHV8105 (Scheme 4BGG11A) are unaffected by a fire in area A-1. Therefore, BGHV8105 can be closed from the control room in the event of a fire in area A-1. Damage to valve BG8402B and BGV0017, or the inability to access these valves during a fire in area A-1 will not impact the ability to achieve and maintain PFSSD.

References: E-15000, XX-E-013, E-13BG11A, E-1F9102, M-12BG01, M-12BG03.

5.1.3 Centrifugal Charging Pump (CCP) Flow to RCP Seals

Seal injection, using either BGHV8357A (for seal injection using PBG05A) or BGHV8357B (for seal injection using PBG05B), is included in the PFSSD methodology for a fire outside the control room. The PFSSD methodology also requires that either BGHV8110 (if using the BGHV8357A flow path) or BGHV8111 (if using the BGHV8357B flow path) be open. Power, control and indication cables for both sets of redundant valves run through fire area A-1. These cables are listed in Table A-1-5.

Table A-1-5
Cables Associated With BGHV8110, BGHV8111, BGHV8357A and BGHV8357B in Fire Area A-1

BGHV8110	BGHV8111	BGHV8357A	BGHV8357B
11BGG11CA	14BGG11DA	11BGG52AA	14BGG52BA
11BGG11CB	14BGG11DB	11BGG52AB	14BGG52BB

Change Package 011038 installed 1-hour fire wrap around raceways carrying cables for Train A CCP valves BGHV8357A and BGHV8110, as shown in Table A-1-6. In addition, automatic fire suppression and detection is installed in the area. This configuration meets the Wolf Creek commitment to 10CFR50, Appendix R section III.G.2.c for protection of one redundant train of equipment. Therefore, a fire in area A-1 will not impact the ability to open valves BGHV8110 and BGHV8357A from the control room and provide seal injection using CCP PBG05A.

Table A-1-6
1-Hour Protected Raceways Associated With BGHV8110 and BGHV8357A in Fire Area A-1

BGHV8110		BGHV8357A	
CABLE	**RACEWAY(S)**	**CABLE**	**RACEWAY(S)**
11BGG11CA	111U1J3A, 111UJ002	11BGG52AA	111U1318, 111U1J9U, 111UJ062
11BGG11CB	111U1J3B, 111UJ002	11BGG52AB	111U1363, 111U1J3R, 111UJ062

Flow transmitters BGFT0215A and BGFT0215B measure the total seal injection flow. These flow transmitters are included in the PFSSD design to evaluate loss of charging flow to the RCP seals. A fire in area A-1 could damage the flow transmitters and associated cables, preventing diagnosis of a loss of seal injection in the event the operating charging pump is lost. RCP seal cooling remains available using thermal barrier cooling provided by the CCW system. Both trains of CCW are unaffected by a fire in this area and the thermal barrier flow path valves will remain in their normally open position. Loss of charging would be indicated by a drop in pressurizer level measured by BBLI0459A or BBLI0460A.

Based on the above discussion, RCP seal injection is available but could be momentarily lost until Train A CCP is lined up. Thermal barrier cooling remains available.

5.1.4 Containment Recirculation Sump to RHR Pump A Isolation Valve

EJHV8811A is the Containment Recirculation Sump to RHR Pump A isolation valve. The valve is required to be closed during hot standby and cold shutdown to prevent draining the RCS and the RWST to the containment sump. EJZS8811A is a position switch that provides an interlock to valve EJHV8701A (RCS to RHR Pump Suction). The interlock prevents the simultaneous opening of EJHV8811A and EJHV8701A.

Cables that run through area A-1 associated with the above equipment are listed in Table A-1-7.

Table A-1-7
Cables Associated With EJHV8811A and EJZS8811A in Fire Area A-1

EJHV8811A		EJZS8811A	
CABLE	**DESCRIPTION**	**CABLE**	**DESCRIPTION**
11EJG06AA	Valve EJHV8811A power	11EJG05AK	EJZS8811A to MCC
11EJG06AB	Valve EJHV8811A control	11EJG05AH	EJZS8811A to MCC
11EJG06AU	BNHV8812A interlock circuit		
11EJG06AJ	Valve EJHV8811A power		
11EJG06AK	Valve EJHV8811A control		

Cable 11EJG06AU is a 2-conductor cable connected to the position switch on BNHV8812A (RWST to RHR Pump A Suction). The position switch is in the open circuit on EJHV8811A. With BNHV8812A in the open position, the position switch contacts are open, thereby preventing EJHV8811A from opening. A short circuit in this cable will provide a permissive for valve EJHV8811A to open. However, the valve will not open because ARA contacts installed on both sides of the position switch contact will prevent the valve from opening. Therefore, damage to cable 11EJG06AU will not cause valve EJHV8811A to spuriously open.

Cables 11EJG06AA and 11EJG06AJ are 3-phase power cables that provide AC power to the motor operator for valve EJHV8811A and are run in Room 1204. This valve is not considered a High/Low pressure interface. Therefore, consideration of a 3-phase cable-to-cable hot short that could spuriously open the valve is not postulated per the assumption in calculation XX-E-013. Consequently, damage to the cables will not cause valve EJHV8811A to spuriously open.

Cables 11EJG06AB and 11EJG06AK are control cables for valve EJHV8811A and are routed in fire area A-1 (Room 1204). Spurious signals on these cables will not cause valve EJHV8811A to open but could cause a loss of valve position indication in the control room. Loss of indication will not impact the ability to achieve and maintain PFSSD since the valve is unaffected by a fire in A-1.

Cables 11EJG05AH and 11EJG05AK could be affected by a fire in area A-1 (Room 1204). A fire-induced short across the conductors in each cable will provide the permissive for valve EJHV8701A to open. If this occurs, hand switch EJHIS8701A will prevent valve EJHV8701A from spuriously opening because the circuit for hand switch EJHIS8701A is unaffected by a fire in area A-1.

Based on the above discussion, there is reasonable assurance that valve EJHV8811A will not spuriously open if a fire occurs in this area. Therefore, the RWST will not drain to the containment sump via the Train A flowpath.

References: E-15000, XX-E-013, E-13BB12A, E-13BN03, E-13EJ05A, E-13EJ06A, E-1F9102, E-1F9205, M-12BB01, M-12BN01, M-12EJ01

5.1.5 Reactor Coolant System (RCS) Pressure Indication

The PFSSD design requires RCS pressure indication to be available. RCS pressure indication is provided in the control room using BBPI0405 or BBPI0406 on RL022.

Pressure transmitter BBPT0403 is a wide range reactor coolant pressure transmitter located in room 1202. Cable 12BBI15NA associated with BBPT0403 is run through area A-1. This transmitter is used in the cold shutdown mode for PFSSD. The transmitter provides RCS pressure indication to the BBPV8702A(B) valve interlocks. On High-1 RCS pressure signal, valves BBPV8702A(B) cannot be opened. The cold shutdown PFSSD mode requires that one train of RHR be operable. A spurious signal due to a fire in area A-1 could cause a false High-1 pressure indication on BBPT403 and the inability to open valves BBPV8702A(B) from the control room.

During cold shutdown following a fire, repairs are allowed, per 10CFR50 Appendix R section III.G.1.b, as long as the repair can be made within 72 hours. If a spurious signal from BBPT403 causes valves BBPV8702A(B) to remain closed, a cold shutdown repair can be made by installing a jumper across terminals 1 and 2 on TB715 in SB032D or across terminals 3 and 21 on NG02BCF2. Alternatively, a containment entry could be made to manually operate the required valve.

BBPT0406 is a wide range reactor coolant pressure transmitter located in room 1202. This transmitter is used in the hot shutdown mode for PFSSD to provide RCS pressure indication in the Control Room. The cable associated with BBPT0406 located in area A-1 is 14BBI16BA. A fire in area A-1 could cause BBPT0406 to malfunction. The redundant PFSSD transmitter, BBPT0405, is located in room 1320 (Fire Area A-8) and is unaffected by a fire in area A-1. RCS pressure indication will, therefore, be available using BBPI0405.

References: E-15000, XX-E-013, E-13BB12A, E-13BB12B, E-13BB15, E-13BB16, E-1F9205, E-1F9201, M-12BB01, M-12BB04, M-761-00043, M-761-00101, M-767-00186.

5.1.6 Containment Recirculation Sump to RHR Pump B Isolation Valve

EJHV8811B is the Containment Recirculation Sump to RHR Pump B isolation valve. The valve is required to be closed during hot standby and cold shutdown to prevent draining the RCS and the RWST to the containment sump. EJZS8811B is a position switch that provides an interlock to valve EJHV8701B (RCS to RHR Pump Suction). The interlock prevents the simultaneous opening of EJHV8811B and EJHV8701B.

Cables that run through area A-1 associated with the above equipment are listed in Table A-1-8.

Table A-1-8 Cables Associated With EJHV8811B and EJZS8811B in Fire Area A-1			
EJHV8811B		**EJZS8811B**	
CABLE	**DESCRIPTION**	**CABLE**	**DESCRIPTION**
14EJG06BA	Valve EJHV8811B power	11EJG05BK	EJZS8811B to MCC
14EJG06BB	Valve EJHV8811B control		
14EJG06BF	BNHV8812B Interlock Circuit		
14EJG06BJ	Valve EJHV8811B power		
14EJG06BK	Valve EJHV8811B control		

Cable 14EJG06BF is a 2-conductor cable connected to the position switch on BNHV8812B (RWST to RHR Pump B Suction). The position switch is in the open circuit on EJHV8811B. With BNHV8812B in the open position, the position switch contacts are open, thereby preventing EJHV8811B from opening. A fire in area A-1 could cause a short across the contacts, which would provide the permissive for valve EJHV8811B to open. However, the valve will not open because ARA contacts installed on both sides of the position switch contact will prevent the valve from opening. Therefore, damage to cable 14EJG06BF will not cause valve EJHV8811B to spuriously open.

Cables 14EJG06BA and 14EJG06BJ are 3-phase power cables (3/C #6 AWG) that provide AC power to the motor operator for valve EJHV8811B and are routed in fire area A-1 (Room 1203). Valve EJHV8811B is not considered a High/Low pressure interface. Therefore, consideration of a 3-phase cable-to-cable hot short that could spuriously open the valve is not postulated per the assumption in calculation XX-E-013. Consequently, damage to the cables will not cause valve EJHV8811B to spuriously open.

Cables 14EJG06BB and 14EJG06BK are control cables (7/C #14 AWG) for valve EJHV8811B and are routed in fire area A-1 (Room 1203). Spurious signals on these cables will not cause valve EJHV8811B to open but could cause valve position indication to be lost. Loss of indication will not impact the ability to achieve and maintain PFSSD since the valve is unaffected by a fire in A-1.

Cable 11EJG05BK could be affected by a fire in A-1. A fire-induced short across the conductors will provide the permissive for valve EJHV8701B to open even though valve EJHV8811B may be open. If this occurs, valve EJHV8701B will not spuriously open because the circuit for hand switch EJHIS8701B is unaffected by a fire in area A-1 and would ensure valve EJHV8701B remains closed.

Based on the above discussion, there is reasonable assurance that valve EJHV8811B will not spuriously open if a fire occurs in this area. Therefore, the RWST will not drain to the containment sump via the Train B flowpath.

5.1.7 CVCS Heat Tracing

Heat tracing has been installed to maintain the emergency borate line and other fluid lines above the solidification temperature in the Train A SI pump room. Both safety trains can power the heat tracing; an automatic transfer switch (QJS0001) switches from Train A (primary source) to Train B (alternate source) on loss of A Train.

Fire area A-1 contains cables and components associated with the CVCS heat tracing system. Components of the heat tracing system located in this area are QJS0001 and NG100B. Cables 14NGY13BA, 16QJY07KB and 16QJY07KC are also located in this area.

Per Calculation XX-E-013, the emergency borate line and heat tracing is credited for long term boration after a control room fire. The heat tracing system is not credited for PFSSD where the fire is outside the control room. Although a fire in area A-1 could affect operation of the heat tracing system, the system is not required for a fire in area A-1. Loss of these components and cables will not adversely impact PFSSD. Therefore, the configuration is acceptable.

5.2.1 Auxiliary Feedwater

The PFSSD design requires the use of one auxiliary feedwater pump supplying water to at least two steam generators. The turbine driven auxiliary feedwater pump (TDAFP) is normally aligned to supply all four steam generators. The Train A motor driven auxiliary feedwater pump (MDAFP) is aligned to supply steam generators B and C. The Train B MDAFP is aligned to supply steam generators A and D.

The normal source of water to the AFPs is the condensate storage tank (CST). The emergency supply is from the essential service water (ESW) system. For commercial concerns, the CST is the preferred source and contains sufficient volume to supply the entire AFW demand to achieve cold shutdown.

Motor operated valves (MOVs) in the system allow operators to line up the auxiliary feedwater system as required to achieve and maintain safe shutdown. Damage to the MOV circuits due to a fire could prevent operators from lining up the system from the control room.

Cable 11ALB01AA is the power cable for the Train A MDAFP. Cable 14ALB01BA is the power cable for the Train B MDAFP. Damage these cables due to a fire in this area will prevent operation of MDAFPs PAL01A and PAL01B.

Cable 11ALY09CE is a power cable associated with the Modutronic controller on valve ALHV0009 (Train A MDAFP to Steam Generator B). Damage to this cable could disable power to the controller and prevent flow control from the Train A MDAFP to SG B. As stated above, the Train A MDAFP may not be available, therefore valve ALHV0009 is not required if a fire occurs in this area.

Cable 11ALY09DE is a power cable associated with the Modutronic controller on valve ALHV0011 (Train A MDAFP to Steam Generator C). Damage to this cable could disable power to the controller and prevent flow control from the Train A MDAFP to SG C. As stated above, the Train A MDAFP may not be available, therefore valve ALHV0011 is not required if a fire occurs in this area.

Cables associated with the turbine driven auxiliary feedwater pump (TDAFP) are located in a separate fire area and are unaffected by a fire in area A-1. The TDAFP is redundant to both motor driven auxiliary feedwater pumps and is unaffected by a fire in area A-1. Therefore, the TDAFWP is available to provide feedwater to the steam generators in the event of a fire in A-1.

Based on the above discussion, both motor driven auxiliary feedwater pumps may be unavailable if a fire occurs in this area but the turbine driven auxiliary feedwater pump is unaffected and is available to supply all four steam generators.

5.2.2 VCT and RWST to Charging Pump Suction Valves

The reactivity control and makeup functions of PFSSD require charging pumps taking suction from the RWST and isolation of at least one of the VCT outlet valves. A fire in area A-1 uses CCP A, so RWST to CCP A suction valve BNLCV0112D is required to be open and either VCT outlet valve BGLCV0112B or BGLCV0112C is required to be closed.

Cable 11BGG12AD is the close permissive interlock circuit that closes the Volume Control Tank (VCT) to Charging Pump suction valve (BGLCV0112B) when the RWST to CCP A valve (BNLCV0112D) is fully open.

Cable 11BNG01AA is the power cable for BNLCV0112D. Cable 11BNG01AB is a control cable for BNLCV0112D. Damage to either of these cables will prevent opening BNLCV0112D.

Change Package 011038 installed 1-hour fire wrap around raceways carrying cables for BGLCV0112B and BNLCV0112D as shown in Table A-1-10.

Table A-1-10
1-Hour Protected Raceways Associated With BGLCV0112B and BNLVC112D in Fire Area A-1

BGLCV0112B		BNLCV0112D	
CABLE	**RACEWAY(S)**	**CABLE**	**RACEWAY(S)**
11BGG12AD	111U1J3B, 111UJ002	11BNG01AA	111U1J3A, 111UJ002
		11BNG01AB	111U1J3B, 111UJ002

In addition, automatic fire suppression and detection is installed in the area. This configuration meets the Wolf Creek commitment to 10CFR50, Appendix R section III.G.2.c for protection of one redundant train of equipment. Therefore, a fire in area A-1 will not impact the ability for valve BGLCV0112B to automatically close on Low VCT level and will not prevent opening valve BNLCV0112D from the control room.

Cable 14BGG12BD is the close permissive interlock circuit that closes the Volume Control Tank (VCT) to Charging Pump suction valve (BGLCV0112C) when the RWST to CCP B valve (BNLCV0112E) is fully open. Cable 14BNG01BA is the power cable for BNLCV0112E. Cable 14BNG01BB is a control cable for BNLCV112E. Damage to either of these cables will prevent the opening of BNLCV0112E. However, as stated above, CCP B is not used for a fire in area A-1 so valve BNLCV0112E is not required to be open.

A fire in area A-1 will not prevent a suction source from the RWST to CCP A from being achieved. A fire in area A-1 will also not prevent isolating the VCT to CCP suction flow path.

References: E-15000, XX-E-013, DCP 011038, E-13BG12, E-13BN01

5.2.3 Refueling Water Storage Tank (RWST) and Containment Sump Isolation Valves

Cable 11BNG03AA is the power cable for the BNHV8812A valve motor. Cable 11BNG03AB is a control cable for the BNHV8812A valve. The PFSSD lineup requires that either BNHV8812A or EJHV8811A be shut to prevent draining down the RWST to the containment sump.

As discussed in Section 5.1.4 above, a fire in area A-1 will not cause valve EJHV8811A to spuriously open. In addition, Change Package 011038 installed 1-hour fire wrap around raceways carrying cables for BNHV8812A as shown in Table A-1-11.

Table A-1-11
1-Hour Protected Raceways Associated With BNHV8812A in Fire Area A-1

CABLE	RACEWAY(S)
11BNG03AA	111U1F2B, 111UJ001
11BNG03AB	111U1F2A, 111UJ001

In addition, automatic fire suppression and detection is installed in the area. This configuration meets the Wolf Creek commitment to 10CFR50, Appendix R section III.G.2.c for protection of

one redundant train of equipment. Therefore, a fire in area A-1 will not impact the ability to close valve BNHV8812A from the control room.

Cable 11BNG03AE is a control cable for valve BNHV8812A. An open circuit involving this cable could prevent automatic closure of valve BNHV8812A if valve EJHV8811A opens, causing the RWST to drain to the containment sump. A short to ground involving this cable could prevent operation of the valve from the control room. As stated previously, EJHV8811A will not spuriously open if a fire occurs in this area, so damage to this cable will have no adverse impact on PFSSD.

Cable 14BNG03BA is the power cable for the BNHV8812B valve motor. Cables 14BNG03BB, 14BNG03BK and 14BNG03BL are control cables for the BNHV8812B valve. Terminal box TB12402 is the connection for control cables 14BNG03BK and 14BNG03BL. The PFSSD lineup requires that either BNHV8812B or EJHV8811B be shut to prevent draining down the RWST to the containment sump. Damage to these cables could prevent closing BNHV8812B. As discussed in Section 5.1.6, valve EJHV8811B will not spuriously open if a fire occurs in this area.

Based on the above discussion, draindown of the RWST to the containment sump will not occur due to a fire in area A-1.

References: E-15000, XX-E-013, DCP 011038, E-13BN03

5.2.4 RHR Loop 1 Inlet Isolation Valves

Either RHR Loop 1 inlet isolation valve BBPV8702A or EJHV8701A is required to be closed during hot standby. Both valves BBPV8702A and EJHV8701A are required to be open when operating RHR Pump A for cold shutdown. A fire in area A-1 uses RHR pump A for cold shutdown.

Cable 11EJG05AG is the open permissive circuit that allows EJHV8701A to open only when RWST to RHR suction valve BNHV8812A is closed.

Change Package 011038 installed 1-hour fire wrap around raceways 111U1F2A and 111UJ001 which carry cable 11EJG05AG for EJHV8701A in area A-1. In addition, automatic fire suppression and detection is installed in the area. This configuration meets the Wolf Creek commitment to 10CFR50, Appendix R section III.G.2.c for protection of one redundant train of equipment. Therefore, there is reasonable assurance that damage to cable 11EJG05AG due to a fire in area A-1 will not occur and valve EJHV8701A can be controlled from the control room.

Cable 14BBG12AD is the open permissive circuit that allows BBPV8702A to open only when BNHV8812A is closed. Cable 14BBG12AE is the open permissive circuit that allows BBPV8702A to open only when EJHV8811A is closed.

Cable 14BBG12AD is routed in fire area A-1 (Room 1101). A fire in this area could cause a hot short across conductors 22 and 32 which would provide the open permissive signal for valve BBPV8702A to open even if valve BNHV8812A is open. A fire in area A-1 (Rooms 1203 and 1204) could also cause a hot short across conductors 12 and 22 in cable 14BBG12AE which would provide the open permissive signal for valve BBPV8702A to open even if valve EJHV8811A is open. However, even though the permissives may be satisfied, hand switch BBHIS8702A located on RL017 in the main control room is unaffected by the fire and is available to ensure valve BBPV8702A remains closed.

An open circuit on either conductor in cables 14BBG12AD and 14BBG12AE will prevent opening valve BBPV8702A from the control room. Since the valve is required to be open when transitioning to cold shutdown, a cold shutdown repair can be made by installing a jumper

across terminals TB19 and TB20 in NG02BCF2 to repair an open in cable 14BBG12AD and terminals TB18 and TB19 in NG02BCF2 to repair an open in cable 14BBG12AE.

A fire in area A-1 will not impact the ability to maintain the RCS to RHR pump A flow path closed during hot standby. The fire could impact the ability to open this flow path when transitioning to RHR for cold shutdown. In this case, a cold shutdown repair can be made or a containment entry made to open the valves.

References: E-15000, XX-E-013, E-13BB12A, E-13EJ05A, DCP 011038

5.2.5 RHR Loop 2 Inlet Isolation Valves

Either RHR Loop 2 inlet isolation valve BBPV8702A or EJHV8701A is required to be closed during hot standby. Since a fire in area A-1 uses RHR pump A for cold shutdown, either valve is required to be closed during cold shutdown.

Cable 11EJG05BF is the open permissive circuit that allows RHR loop 2 inlet isolation valve EJHV8701B to open only when SI Pump inlet isolation valve EJHV8804B is closed. Cable 11EJG05BG is the open permissive circuit that allows valve EJHV8701B to open only when RWST to RHR pump B suction valve BNHV8812B is closed.

Hand switch EJHIS8701B located on RL017 in the main control room is unaffected by a fire in A-1 and is available to ensure valve EJHV8701B remains closed during hot standby and cold shutdown.

Cable 11EJG05BG is routed in area A-1 (Room 1101) in conduit 111U1F2A and junction box 111UJ001. DCP 011038 added 1-hour rated fire wrap around conduit 111U1F2A and junction box 111UJ001. This fire wrap, in combination with automatic fire suppression and detection in the area, provides reasonable assurance that the cable will not be damaged during a fire in area A-1.

Cable 14BBG12BC is the open permissive circuit that allows BBPV8702B to open only when EJHV8804B is closed. Cable 14BBG12BD is the open permissive circuit that allows BBPV8702B to open only when BNHV8812B is closed. Cables 14BBG12BE and 14BBG12BK are part of the open permissive that allows BBPV8702B to open only when EJHV8811B is closed.

If a fire causes damage to these cables that allows the permissives to be satisfied, hand switch BBHIS8702B located on RL017 in the main control room is available to ensure valve BBPV8702B remains closed. Circuits for BBHIS8702B are unaffected by a fire in area A-1.

A fire in area A-1 will not cause either valve BBPV8702B or EJHV8701B to spuriously open as long as hand switches BBHIS8702B or EJHIS8701B are in the close position.

References: E-15000, XX-E-013, DCP 011038, E-13BB12B, E-13EJ05B

5.2.6 RHR Pump Mini-Flow Valves

The RHR pump mini-flow path is required when the RHR system is operating, to prevent damage to the RHR pump during low flow in the RHR system. The RHR mini-flow path consists of the mini-flow valve, flow indicating switch, pipe and fittings. With flow at or below the desired setting, the flow indicating switch low-flow contacts close, sending an “open” signal to the mini-flow valve and thus allowing recirculating flow through the mini-flow path. When flow exceeds the desired setting, the flow indicating switch high-flow contacts close, sending a “close” signal to the mini-flow valve and thus preventing recirculating flow through the mini-flow path.

Control cables associated with the B Train mini-flow indicating switch EJFIS0611 are located in Fire Area A-1, as shown in Table A-1-9. Damage to the cable could prevent the B Train RHR mini-flow sub-system from performing its intended function.

Cable 11EJG08AB is the control cable for RHR pump A mini-flow valve EJFCV0610. Cable 11EJG08AE is the power cable for valve EJFCV0610. Valve EJFCV0610 is installed on the recirculation line of the ‘A’ RHR pump and controls recirc flow to protect the pump during low flow conditions. The valve is required to be open during RHR pump A operation (cold shutdown). The valve is not required during hot standby.

Cable 14EJG08BB is the control cable for RHR pump B mini-flow valve EJFCV0611. 14EJG08BE is the power cable for valve EJFCV0611. Valve EJFCV0611 is installed on the recirculation line of the ‘B’ RHR pump and controls recirc flow to protect the pump during low flow conditions. The valve is required to be open during RHR pump B operation (cold shutdown). The valve is not required during hot standby.

Change Package 011038 installed 1-hour fire wrap around raceways carrying cables for EJFCV0610 as shown in Table A-1-12. In addition, automatic fire suppression and detection is installed in the area. This configuration meets the Wolf Creek commitment to 10CFR50, Appendix R section III.G.2.c for protection of one redundant train of equipment. Therefore, a fire in area A-1 will not impact the ability to control valve EJFCV0610.

Table A-1-12
1-Hour Protected Raceways Associated With EJFCV0610 in Fire Area A-1

CABLE	RACEWAY(S)
11EJG08AB 11EJG08AE	111U1F2C, 111UJ001

Based on the above discussion, damage to cables and components associated with the Train B RHR system will not adversely affect PFSSD since Train A RHR is available.

References: E-15000, XX-E-013, E-13EJ08, E-13EJ08A, E-1F9205, E-1R1124, M-12EJ01, CR 25002, CP 13615, CP 11038

5.2.7 Boron Injection Tank Flowpath

The Boron Injection Tank (BIT) flowpath is credited for reactivity control and reactor coolant makeup. For reactivity control, the BIT flowpath is credited as an alternate source of boration in the event RCP seal injection is unavailable. Based on Calculation XX-E-013, RCP seal injection will provide sufficient boration to achieve and maintain cold shutdown reactivity conditions. Therefore, the BIT flowpath is not required for reactivity control if RCP seal injection is available. Since RCP seal injection is limited to 5 gpm per seal or 20 gpm total injection to the RCS, an additional RCS charging flowpath is required for adequate RCS makeup during plant transition from hot standby to cold shutdown. The BIT injection path was selected as the additional RCS charging flowpath.

A fire in area A-1 uses CCP A since circuits for CCP B may be affected by the fire. Also, a fire in area A-1 has the possibility to cause a momentary loss of inventory through the letdown flow path until the letdown isolation valves can be failed closed. Therefore, charging through the BIT flow path may be required for hot standby. In addition, as discussed above, the BIT flowpath is required for transition to cold shutdown.

Valve EMHV8803A is a normally closed valve that controls charging flow from Train A CCP to the Boron Injection Tank (BIT). This valve is required to be open for PFSSD since a fire in area A-1 uses Train A CCP. Valve EMHV8882 is an isolation valve for the boron injection downstream test line. The PFSSD position of this valve is closed to prevent flow diversion through this flow path.

Cable 11EMG02AA is the power cable for EMHV8803A motor operator. Cable 11EMG02AB is the control cable for EMHV8803A.

Cable 15EMK05EA is a control cable for EMHV8882. A +125 VDC external cable hot short in contact with conductor 2 in cable 15EMK05EA will energize the solenoid and open valve EMHV8882. The cable is routed in raceways with cables carrying the proper voltage and polarity. The hot short would bypass the control room hand switch (EMHIS8882) on RL018 and control of this valve from the control room would be lost. Normally closed valve EMHV8871 is unaffected by a fire in area A-1 and will remain closed to prevent flow of water through the SIS test line.

Change package 011656 installed 1-hour fire wrap around raceway carrying cables for EMHV8803A as shown in Table A-1-13. In addition, automatic fire suppression and detection is installed in the area. This configuration meets the Wolf Creek commitment to 10CFR50, Appendix R section III.G.2.c for protection of one redundant train of equipment. Therefore, a fire in area A-1 will not impact EMHV8803A.

Table A-1-13
1-Hour Protected Raceways Associated With EMHV8803A in Fire Area A-1

CABLE	RACEWAY
11EMG02AA 11EMG02AB	111U3E1A

Based on the above discussion, the BIT flowpath is available for boration and inventory control.

5.2.8 Centrifugal Charging Pump (CCP) and Residual Heat Removal (RHR) Pump Room Coolers

A fire in area A-1 uses CCP A for boration and makeup and RHR pump A to achieve cold shutdown. Therefore, each pumps room cooler is required to be operable to support operation of the respective pump. Cables associated with both Trains of RHR pump room coolers are run in area A-1 (Room 1101).

Cable 11GLG05AA is the power cable to the ‘A’ RHR pump room cooler (DSGL10A). Cable 11GLG05GA is the power cable to the ‘A’ CCP pump room cooler (DSGL12A).

Cable 14GLG05BA is the power cable to the ‘B’ RHR pump room cooler (DSGL10B). Cable 14GLG05HA is the power cable to the ‘B’ CCP pump room cooler (DSGL12B).

Change Package 011038 installed 1-hour fire wrap around raceways carrying cables for DSGL10A and DSGL12A as shown in Table A-1-14. In addition, automatic fire suppression and detection is installed in the area. This configuration meets the Wolf Creek commitment to 10CFR50, Appendix R section III.G.2.c for protection of one redundant train of equipment. Therefore, a fire in area A-1 will not impact DSGL10A and DSGL12A.

Table A-1-14
1-Hour Protected Raceways Associated With DSGL10A and DSGL12A in Fire Area A-1

DSGL10A		DSGL12A	
CABLE	**RACEWAY(S)**	**CABLE**	**RACEWAY(S)**

5.2.9 RHR Pump B to Safety Injection Pump Isolation Valve

Valve EJHV8804B is the RHR pump B to Safety Injection pump isolation valve. The PFSSD position of this valve is closed during RHR Train B operation. A fire in area A-1 uses RHR Train A.

Cable 14EJG04BA is the power cable for valve EJHV8804B. Cable 14EJG04BB is a control cable for valve EJHV8804B. Valve EJHV8804B is normally closed.

The only possible failure mode that would cause valve EJHV8804B to spuriously open would be a three-phase external (inter-cable) cable-to-cable hot short across the conductors in cable 14EJG04BA. However, the assumptions section in Calculation XX-E-013 states that the probability of a three-phase hot short in the proper sequence is extremely low and does not require evaluation, except in cases of high-low pressure interfaces. Valve EJHV8804B is not a high-low pressure interface.

Therefore, there is reasonable assurance that a fire in area A-1 will not cause the spurious opening of valve EJHV8804B. In the unlikely event valve EJHV8804B spuriously opens, PFSSD is assured since RHR pump A is available for a fire in area A-1.

References: E-15000, XX-E-013, E-13EJ04B

5.2.10 Letdown Isolation Valves

Valves BGLCV0459 and BGLCV0460 are isolation valves installed in series on the inlet side of the regenerative heat exchanger. PFSSD requires that either of these valves be closed. Cables 15BGK10AA and 15BGK10AD are power/control cables for the BGLCV0459 solenoid valve (BGHY0459). Air supplied by an open (energized) solenoid valve will open valve BGLCV0459. A closed (de-energized) solenoid valve will cause loss of air pressure and closure of valve BGLCV0459.

Cables 15BGK10BA and 15BGK10BD are power/control cables for the BGLCV0460 solenoid valve (BGHY0460). Air supplied by an open (energized) solenoid valve will open valve BGLCV0460. A closed (de-energized) solenoid valve will cause loss of air pressure and closure of valve BGLCV0460.

Either BGLCV0459 or BGLCV0460 must be closed or letdown orifice isolation valves BGHV8149A, BGHV8149B, and BGHV8149C must be closed. The cables for BGLCV0459 or BGLCV0460 are routed in a common enclosure in cable trays. A hot short on the cables could cause the valves to open. A hot short on 15BGK10AA and 15BGK10BA prevents closing

BGLCV0459 and BGLCV0460 from the control room. Other cables routed in the cable trays have the proper voltage for hot shorts. The hot shorts bypass MCB hand switches for BGLCV0459 and BGLCV0460. BGLCV0459 and BGLCV0460 constitute a high/low pressure interface. Therefore multiple simultaneous hot shorts must be considered.

Letdown orifice isolation valves BGHV8149A, BGHV8149B, and BGHV8149C are listed as PFSSD components because of the interlock between these valves and BGLCV0459 and BGLCV0460. The interlock prevents closure of the letdown valves when any one or more orifice isolation valves are open. Cables associated with all three letdown orifice isolation valves are located in this fire area. Damage to these cables could prevent closure of the valves from the control room. Therefore, a fire in area A-1 will prevent closure of all three letdown orifice isolation valves (BGHV8149A, BGHV8149B, and BGHV8149C) as well as the two letdown isolation valves (BGLCV0459 and BGLCV0460).

BGHV8152 is located in the low-pressure piping rated for only 600 psi pressure down stream of BGLCV0459 and BGLCV0460. Isolating BGHV8152 with the reactor pressure above 600 psi will cause relief valve BGV8117 to open to protect the pipe, and discharge the water to the PRT. A maximum of 195 gpm can be passed through the three orifice isolation valves if they are all open. The centrifugal charging pump capacity is 150-gpm. Therefore approximately 45-gpm could be potentially lost while BGLCV0459 and BGLCV0460 remain open.

Valves BGLCV0459, BGLCV0460, BGHV8149A, BGHV8149B, and BGHV8149C are air operated and fail in the closed position. The valves are located in containment. Instrument air to containment is controlled by valve KAFV0029, which is unaffected by a fire in area A-1. Hand switch KAHIS0029 can be used to close the valve from the control room and isolate instrument air to containment. Pressurizer level indication is available using BBLI0459A and BBLI0460A.

Based on the above discussion, letdown valves BGLCV0459 and BGLCV0460 and letdown orifice valves BGHV8149A, BGHV8149B, and BGHV8149C can be closed from the control room if a fire occurs in area A-1.

References: E-15000, XX-E-013, E-13BG10, E-13BG35, E-13KA02, M-12KA01

5.2.11 Steam Generator Blowdown Panel BM157

The PFSSD function of BM157 is to provide a redundant means to isolate blowdown isolation valves BMHV0001, BMHV0002, BMHV0003 and BMHV0004 using solenoid valves BMHY0001C, BMHY0002C, BMHY0003C, and BMY0004C, respectively. This panel is located in Room 7209 in the Radwaste Control Room.

Cable 15BMK16AA is the power cable for BM157. A fire in area A-1 could cause a loss of power to BM157 which would close the blowdown isolation valves. If the blowdown isolation valves fail to close, then solenoids BMHY0001A, BMHY0002A, BMHY0003A, and BMY0004A controlled from BMHIS0001A, BMHIS0002A, BMHIS0003A and BMHIS0004A, respectively located on RL024 in the main control room are available and are unaffected by a fire in area A-1.

Therefore, damage to cable 15BMK16AA will not impact the ability to close the blowdown isolation valves.

References: E-15000, XX-E-013, E-13BM16

5.2.12 Non-Class 1E 125 VDC Battery Charger PK22

Cable 16PKG11BA is the 480 VAC power cable from NG0409 to 125 VDC battery charger PK22. Damage to this cable could result in a loss of the PK22 power feed to 125 VDC bus PK02. PK02 supplies 125 VDC power to essential PFSSD loads on the Train B system.

Redundant power feed to the PK02 bus is unaffected by a fire in area A-1. This power feed originates from 125 VDC battery group PK12, and is normally aligned to feed power to PK02 in the event PK22 is lost.

Based on the above discussion, a fire in area A-1 could result in a loss of power to PK22 but redundant power source PK02 is available and is unaffected by the fire.

References: E-15000, XX-E-013, E-11NG02, E-11PK02, E-13PK11, E-1F9422C

5.2.13 Reactor Coolant Pumps

The reactor coolant pumps are not credited in the PFSSD analysis. However, the capability to stop the pumps from the control room in the event of a loss of all seal cooling or spuriously open pressurizer spray is credited. Westinghouse Technical Bulletin TB-04-22, Rev. 1 recommends that if all seal cooling is lost (RCP seal injection and thermal barrier heat exchanger flow), operators need to stop the pumps before a seal LOCA occurs. Calculation WCNOC-CP-002 shows that if pressurizer spray spuriously actuates, the spray flow needs to be stopped within 50 minutes.

Two control cables associated with each reactor coolant pump are run in fire area A-1. Damage to these cables in the event of a fire could prevent operators from stopping the RCPs from the control room. However, a fire in A-1 will not cause a loss of all seal cooling. Both trains of CCW are available to provide cooling to the RCP thermal barriers and the Train A CCP is available for seal injection. As discussed in Section 5.2.14, if pressurizer spray spuriously operates, operators can stop the spray by isolating air to the valve from the control room. Therefore, tripping the RCPs is not required to mitigate spurious pressurizer spray.

Based on the above discussion, the inability to trip the RCPs from the control room will have no adverse impact on PFSSD. If pressurizer spray spuriously actuates, the valves can be closed by isolating air to the valves from the control room. In addition, seal injection is unaffected by a fire in area A-1. Therefore, the RCPs do not have to be tripped in the event of a fire in area A-1.

References: E-15000, XX-E-013, E-13BB01, Westinghouse TB-04-22 Rev. 1, CR 25002

5.2.14 Normal Pressurizer Spray

The normal pressurizer spray valves are included in the PFSSD design because spurious operation of pressurizer sprays can cause a decrease in pressure which can lead to boiling in the core. The pressurizer spray valves are part of the pressurizer pressure control system.

The pressurizer normal spray valves (BBPCV0455B and BBPCV0455C) operate off a signal from the Ovation pressurizer pressure control system. The operation of the pressure control system is discussed in Calculation XX-E-013.

Cable 15BBI19AA associated with pressurizer spray valve BBPCV0455B, and cable 15BBI19BA associated with pressurizer spray valve BBPCV0455C are run in this area. Damage to these cables could cause the spurious opening of the spray valves.

The pressurizer spray valves are electro/pneumatic operated and loss of air pressure will close the valves. The air supply comes from the compressed air system. Closing valve KAFV0029 using KAHIS0029 on RL024 will isolate compressed air to containment which will cause the pressurizer spray valves to close or prevent them from opening. Based on WCNOC-CP-002, spray flow needs to be stopped within 50 minutes. Since this is a control room action, this can be completed well within 50 minutes. Historical performance of STS KJ-001A, which isolates instrument air to the Reactor Building, reveals that BBPCV0455B and BBPCV0455C will fail closed in approximately 12 minutes following isolation of instrument air.

Based on the above discussion, the pressurizer spray valves could spuriously open if a fire occurs in this area. Pressurizer spray can be stopped by closing valve KAFV0029 from the main control room. Pressurizer pressure indication is available using BBPI0455A, BBPI0456, BBPI0457 or BBPI0458.

References: E-15000, XX-E-013, E-13BB19, E-13KA02, M-744-00028, WCNOC-CP-002, CR 25002, M-761A-0019 Sh. 2, DCP 013324.

5.2.15 Load Center Feeder Breakers PA0106 and PA0207

Load center feeder breakers PA0106 and PA0207 are credited for PFSSD because they supply power to credited non-safety related loads. Cables 15PGA10BA, associated with PA0106, and 16PGA11AC, associated with PA0207, run in this area. A fire induced short circuit in these cables will trip the associated breaker.

Breaker PA0106 supplies power to the following PFSSD components:

- PG19GCR217 – MCB Misc. Power Circuits RL023
- PG19GFR3 – Instr. Bus Transformer Alt. Feed XPN07D

Loss of power to these components will not adversely impact PFSSD

PFSSD components supplied power from PG19GCR217 are associated with MSIV downstream components. The MSIVs are unaffected by a fire in this area and can be closed from the control room. Therefore, the MSIV downstream components are not required if a fire occurs in this area.

PG19GFR3 is credited as one source of power to PN07. The redundant source of power from NG01BEF4 is unaffected by a fire in this area.

Based on the above discussion, loss of breaker PA0106 will not adversely affect PFSSD if a fire occurs in this area.

Breaker PA0207 supplies power to the following PFSSD components:

- PG20GBR217 – MCB Misc. Power Circuits RL023
- PG20GER5 – Instr. Bus Transformer Alt. Feed XPN08D

PFSSD components powered from PG20GBR217 are associated with MSIV downstream components. The MSIVs are unaffected by a fire in this area and can be closed from the control room. Therefore, the MSIV downstream components are not required if a fire occurs in this area.

PG20GER5 is credited as one source of power to PN08. The redundant source of power from NG02BBF1 is unaffected by a fire in this area.

Based on the above discussion, loss of breaker PA0207 will not adversely affect PFSSD if a fire occurs in this area.

Damage to cables 15PGA10BA and 16PGA11AC due to a fire in this area will not adversely impact the ability to achieve and maintain PFSSD due to the availability of redundant components that are unaffected by a fire in this area.

5.2.16 Non-Class 1E 125 VDC Battery Charger PK24

Cable 16PKG13AA is the 480 VAC power cable from NG0410 to 125 VDC battery charger PK24. Damage to this cable could result in a loss of the PK24 power feed to 125 VDC bus PK04. PK04 supplies 125 VDC power to 10 kVA inverter PN04, which supplies backup 120 VAC power to RP043 and primary 120 VAC power to RP047.

Redundant power feed to the PK04 bus is unaffected by a fire in area A-1. This power feed originates from 125 VDC battery group PK14 and is normally aligned to feed power to PK04 in the event PK24 is lost.

Based on the above discussion, a fire in area A-1 could result in a loss of power to PK24 but redundant power source PK14 is available and is unaffected by the fire. In addition, redundant power to panels RP043 and RP047 is available from PN310. Therefore, 120 VAC power to panels RP043 and RP047 is available if a fire occurs in fire area A-1.

1.0 GENERAL AREA DESCRIPTION

Fire area A-2 is located on the 1974 elevation of the Auxiliary Building and includes the rooms listed in Table A-2-1.

Table A-2-1
Rooms Located in Fire Area A-2

ROOM #	DESCRIPTION
1111	Train A RHR Pump Room
1112	Train A Containment Spray Pump Room
1113	Train A Safety Injection Pump Room
1114	Train A Centrifugal Charging Pump Room

Fire area A-2 is protected with automatic fire detection throughout. In addition, the area is bounded on all sides by minimum 3-hour fire resistance rated construction.

2.0 PRIMARY EQUIPMENT USED FOR PFSSD

Table A-2-2 lists each system credited for post-fire safe shutdown and provides a discussion regarding the availability of the system to perform its Post Fire Safe Shutdown (PFSSD) function if a severe fire occurs in this area. For a summary of the area analysis results, see Section 8.0 of the Fire Area Analysis Narrative section.

Table A-2-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-2

System	System Name	PFSSD Function*	Comments
AB	Main Steam	R, M, H, P, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-2.
AC	Main Turbine	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-2.
AE	Main Feedwater	H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-2.
AL	Aux. Feedwater System	H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-2.
AP	Condensate Storage System	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-2.
BB	Reactor Coolant System	R, M, H, P, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-2.
BG	Chemical and Volume Control System	R, M, S	Train A CVCS components could be affected. Train B CVCS is unaffected. A cable associated with VCT isolation valve BGLCV0112B may be affected. This will not prevent closing the valve from the control room using BGHIS0112B. VCT isolation valve BGLCV0112C is unaffected.
BM	Steam Generator Blowdown System	R, M, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-2.
BN	Borated Refueling Water Storage System	R, M, H	Valve BNHV8812A may be affected, preventing the valve from closing either automatically when EJHV8811A opens or manually from the control room. Valve EJHV8811A will remain closed to prevent the RWST from draining to the containment sump.
EF	Essential Service Water System	H, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-2.
EG	Component Cooling Water System	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-2.
EJ	Residual Heat Removal System	M, H, P	All PFSSD functions associated with the Residual Heat Removal (RHR) system are satisfied. The Train A RHR system may be affected. The Train B RHR system is unaffected. If valve EJHV8701B fails to respond when initiating RHR for cold shutdown, make a containment entry to manually open the valve or perform a cold shutdown repair to fix the damaged circuit.
EM	High Pressure Coolant Injection	R, M	Train A safety injection pump PEM01A could be affected. The fire will not cause the pump to spuriously start. The Train B safety injection pump is unaffected.

Table A-2-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-2

System	System Name	PFSSD Function*	Comments
EN	Containment Spray	R, M	Train A containment spray pump PEN01A could be affected. The fire will not cause the pump to spuriously start. The Train B containment spray pump is unaffected.
EP	Safety Injection Accumulators	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-2.
FB	Auxiliary Steam	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-2.
FC	Auxiliary Turbines	R, H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-2.
GD	ESW Pump House HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-2.
GF	AFW Pump Room Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-2.
GK	Control Room and Class 1E Switchgear Room Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-2.
GL	Auxiliary Building HVAC	S	The PFSSD function associated with the Auxiliary Building HVAC System is satisfied. The Train A RHR pump room cooler motor DSGL10A and Train A CCP pump room cooler motor DSGL12A may be affected. Train B room coolers/motors are available.
GM	Emergency Diesel Generator Room HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-2.
GN	Containment Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-2.
JE	Diesel Fuel Oil	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-2.
KA	Instrument Air	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-2.
KC	Fire Protection	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-2.
KH	Service Gas	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-2.
KJ	Standby Diesel Engine	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-2.

Table A-2-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-2

System	System Name	PFSSD Function*	Comments
MA	Main Generation	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-2.
MR	Startup Transformer	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-2.
NB	4.16 kV System	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-2.
NE	Standby Diesel Generator	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-2.
NF	Load Shed and Emergency Load Sequencing	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-2.
NG	480V Load Centers and MCCs	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-2.
NK	125VDC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-2.
NN	120VAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-2.
PA	13.8kV	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-2.
PB	4.16kV	H, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-2.
PG	480V Load Centers and MCCs	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-2.
PK	125VDC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-2.
PL	Local Instrument Panels	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-2.
PN	120VAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-2.
QB	Standby AC Lighting	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-2.
QD	Emergency Lighting	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-2.

3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD

This section describes operator actions that may need to be performed inside or outside the control room to achieve and maintain hot standby if a fire occurs in area A-2. This section also describes cold shutdown repairs that may need to be made to achieve and maintain cold shutdown conditions. Operator actions are proceduralized in OFN KC-016.

3.1 ACTIONS OUTSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

None

3.2 ACTIONS INSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

None

3.3 ACTIONS TO ACHIEVE AND MAINTAIN COLD SHUTDOWN

3.3.1 RHR

If valve EJHV8701B fails to respond when initiating RHR for cold shutdown, make a containment entry to manually open the valve or perform a cold shutdown repair to fix the damaged circuit.

4.0 CONCLUSION

Post Fire Safe Shutdown is assured if a fire occurs in fire area A-2.

5.0 DETAILED ANALYSIS

This section describes the detailed component-by-component and cable-by-cable analysis for a fire in area A-2.

5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA A-2

PFSSD components (S. in E-15000) located in fire area A-2 are shown in Table A-2-3. An evaluation of each component and associated cables is provided in the sections that follow. The applicable evaluation section is listed in Table A-2-3.

Table A-2-3
PFSSD Equipment Located in Fire Area A-2

Room #	PFSSD Equipment	Description	Evaluation Section	Comments
1113	BGHV8104	Immediate Borate to Charging Pump Suction	5.1.1	
1114	BGHV8110	CCP A Miniflow Isolation Valve	5.1.1

5.1.1 Chemical and Volume Control System (CVCS)

A number of cables and components associated with Train A CVCS could be affected, as identified in Table A-2-3. In addition, RCP seal injection using Train A charging pump could be affected due to damage to valve BGHV8357A and associated cables. Damage to these cables and components could prevent operation of Train A CVCS. Train B CVCS and seal injection using Train B charging pump is unaffected by a fire in area A-2.

The Train A CCP pump room cooler motor DSGL12A could be affected by a fire in this area. Damage to the cooler motor or associated power cable will prevent operation of the room cooler. Train B CCP room cooler motor DSGL12B is unaffected by a fire in area A-2.

Valve BGHV8104 is included in the PFSSD design for cold shutdown after a control room fire. The valve is used in OFN RP-017A to establish long term boration for cold shutdown. The valve is not credited for hot standby. Cables associated with the valve are not included in the PFSSD design because the valve can be de-energized and manually opened if needed. A fire in this area that affects valve BGHV8104 will not adversely impact PFSSD.

Based on the above discussion, the Train B CVCS is available if a fire occurs in this area.

References: E-15000, XX-E-013, E-13BG01, E-13BG11B, E-13BG13, E-13BG52, E-13BN01, E-13GL05, E-13NB01, E-13NB13, E-1F9102, E-1F9205, E-1F9302, E-1F9401A, E-1F9444, M-12BG03, M-12BG05, M-12BN01, M-12GL01, OFN RP-017A

5.1.2 RWST to Containment Sump

Either valve BNHV8812A or valve EJHV8811A is required to be closed for PFSSD to prevent the RWST from draining to the containment sump. Valve BNHV8812A is normally open and valve EJHV8811A is normally closed. Valve BNHV8812A and associated power and control cables are run in fire area A-2. Damage to these cables could prevent closing the valve from the control room.

One cable (11EJG06AU) associated with valve EJHV8811A is run in fire area A-2. A hot short within this cable will send an open permissive to valve EJHV8811A. However, the valve will not open because ARA contacts installed on both sides of the position switch contact will prevent the valve from opening. Based on the above discussion, a fire in area A-2 will not cause the RWST to drain to the containment sump.

References: E-15000, XX-E-013, E-13BN03, E-13EJ06A, E-1F9102, E-1F9205, M-12BN01, M-12EJ01

5.1.3 Residual Heat Removal System

The power cable associated with Train A RHR pump motor DPEJ01A is run through area A-2. Damage to this cable will prevent operation of the pump. Cables associated with Train B RHR pump motor DPEJ01B are unaffected by a fire in area A-2.

Power and control cables associated with Train A RHR pump miniflow valve EJFCV0610 are run in area A-2. Damage to these cables could prevent operation of the valve and cause damage to the Train A RHR pump, if it is operating. Train B RHR miniflow valve EJFCV0611 is unaffected by a fire in area A-2.

The power cable associated with Train A RHR pump room cooler motor DSGL10A is run in area A-2. Damage to this cable will prevent operation of the room cooler. Train B RHR room cooler motor DSGL10B circuits are unaffected by a fire in area A-2.

RCS Loop 1 to Train A RHR pump inlet isolation valve BBPV8702A is required to remain closed during normal operation and hot standby and is required to be open when using Train A RHR for shutdown cooling. As discussed above, Train A RHR could be affected by a fire in this area, so Train A RHR is not credited.

Limit switch BNZS8812AA is located on valve BNHV8812A to provide an OPEN permissive to valve BBPV8702A when valve BNHV8812A is fully closed. This is one of several coincident permissives that need to be satisfied before the control room HIS can be enabled to initiate an open signal. Damage to cable 14BBG12AD could provide a false open signal but since the other permissives will not be satisfied, and since BBPV8702A is normally de-energized, the valve will remain closed. For these same reasons, damage to cable 11EJG05AG will not cause redundant valve EJHV8701A to open.

For shutdown cooling, an operable flowpath from the RCS to the operating RHR pump needs to be established. Since Train A RHR could be affected, the Train B RCS to RHR flow path is required. This involves opening valves BBPV8702B and EJHV8701B. Valve BBPV8702B is unaffected by a fire in area A-2. Damage to cable 11EJG05BG could prevent opening EJHV8701B when needed. A cold shutdown repair or local manual operation of EJHV8701B may be required prior to shutdown cooling.

Based on the above discussion, Train B RHR pump motor DPEJ01B and all associated components with the exception of EJHV8701B are unaffected by a fire in area A-2 and will be used to provide decay heat removal during cold shutdown. When lining up the RCS to the Train B RHR pump, it may be necessary to perform a cold shutdown repair or manually open EJHV8701B locally.

5.1.4 Safety Injection Pumps

The safety injection pumps are not required for PFSSD, but are included to evaluate the impact of a spuriously operating pump. Similarly, the power cables are not included because they are not required for PFSSD. The control cables, however, are included in the PFSSD analysis to evaluate whether damage will cause a spurious pump start.

Control cables associated with safety injection pump PEM01A are not run in fire area A-2. Therefore, a fire in area A-2 will not cause a spurious start of PEM01A. Damage to the pump will have no adverse impact on PFSSD.

References: XX-E-013, E-15000, E-13EM01, E-1F9102, E-1F9302, M-12EM01

5.1.5 Containment Spray Pumps

The containment spray pumps are not required for PFSSD, but are included to evaluate the impact of a spuriously operating pump. Similarly, the power cables are not included because they are not required for PFSSD. The control cables, however, are included in the PFSSD analysis to evaluate whether damage will cause a spurious pump start.

Control cables associated with containment spray pump PEN01A are not run in fire area A-2. Therefore, a fire in area A-2 will not cause a spurious start of PEN01A. Damage to the pump will have no adverse impact on PFSSD.

References: XX-E-013, E-15000, E-13EN01, E-1F9102, E-1F9302, M-12EN01

5.1.6 CVCS Heat Tracing

Heat tracing has been installed to maintain the emergency borate line and other fluid lines above the solidification temperature in the Train A SI pump room. Both safety trains can power the heat tracing; an automatic transfer switch (QJS0001) switches from Train A (primary source) to Train B (alternate source) on loss of A Train.

Fire area A-2 contains cables and components associated with the CVCS heat tracing system. Components of the heat tracing system located in this area are QJTS6251, QJTE6244A and TB11207. Cable 16QJY07KC is also located in this area.

Per Calculation XX-E-013, the emergency borate line and heat tracing is credited for long term boration after a control room fire. The heat tracing system is not credited for PFSSD where the fire is outside the control room. Although a fire in area A-2 could affect operation of the heat tracing system, the system is not required for a fire in area A-2. Loss of these components and cables will not adversely impact PFSSD. Therefore, the configuration is acceptable.

5.2.1 Volume Control Tank (VCT) Outlet Valves

Either VCT isolation valve BGLCV0112B or BGLCV0112C needs to be closed for PFSSD to prevent hydrogen gas intrusion into the operating charging pump suction.

One control cable (11BGG12AD) associated with VCT valve BGLCV0112B runs through fire area A-2. Damage to this cable alone will not prevent closing BGLCV0112B from the control room. An intra-cable short within this cable will provide a permissive for valve BGLCV0112B to close. However, valve BGLCV0112B will close only upon presence of either a SIS or a VCT low-low level signal, coincident with an intra-cable short in cable 11BGG12AD. A fire in area A-2 will not cause a spurious SIS or VCT low-low level signal. An actual SIS is not required to be postulated. An actual VCT low-low level is possible because makeup to the VCT from letdown could be lost. However, a low-low VCT level signal will alert operators to swap to RWST before the VCT drains.

A short to ground on conductor 31 in cable 11BBG12AD coincident with a SIS or VCT low-low level signal will blow the control power fuse and prevent operation of valve BGLCV0112B. As stated above, a fire in area A-2 will not cause a spurious SIS or VCT low-low level signal. Therefore, there is reasonable assurance that valve BGLCV0112B can be operated from the control room prior to an actual low-low VCT level signal in the event of a fire in this area.

Cables for redundant VCT valve BGLCV0112C are run in a separate fire area and are unaffected by a fire in area A-2. Therefore, in the unlikely event valve BGLCV0112B cannot be operated, valve BGLCV0112C is available.

Based on the above discussion, there is reasonable assurance that either VCT outlet valve BGLCV0112B or BGLCV0112C can be isolated from the control room if a fire occurs in this area.

4.0 CONCLUSION 8
5.0 DETAILED ANALYSIS 8
5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA A-3 8
5.2 PFSSD CABLE EVALUATION 8

1.0 GENERAL AREA DESCRIPTION

Fire area A-3 is located on the 1974 and 2026 elevations of the Auxiliary Building and includes the rooms listed in Table A-3-1.

Table A-3-1
Rooms Located in Fire Area A-3

ROOM #	DESCRIPTION
1116	Boric Acid Tank Room B
1117	Boric Acid Tank Room A
1407	Boric Acid Batching Tank Area

Fire area A-3 is protected with automatic fire detection throughout. In addition, the area is bounded on all sides by minimum 3-hour fire resistance rated construction.

2.0 PRIMARY EQUIPMENT USED FOR PFSSD

Table A-3-2 lists each system credited for post-fire safe shutdown and provides a discussion regarding the availability of the system to perform its Post Fire Safe Shutdown (PFSSD) function if a severe fire occurs in this area. For a summary of the area analysis results, see Section 8.0 of the Fire Area Analysis Narrative section.

Table A-3-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-3

System	System Name	PFSSD Function*	Comments
AB	Main Steam	R, M, H, P, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-3.
AC	Main Turbine	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-3.
AE	Main Feedwater	H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-3.
AL	Aux. Feedwater System	H, P	The turbine driven auxiliary feedwater pump may not be available (See FC system discussion). The Train A and Train B motor driven auxiliary feedwater pumps are available.
AP	Condensate Storage System	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-3.
BB	Reactor Coolant System	R, M, H, P, S	All PFSSD functions associated with the reactor coolant system are satisfied. Valve BBHV8002A may be affected. Loss of inventory through the head vent valves is prevented by maintaining valves BBHV8001A and either BBHV8001B or BBHV8002B closed.
BG	Chemical and Volume Control System	R, M, S	All PFSSD functions associated with the chemical and volume control system are satisfied. The Train A centrifugal charging pump (CCP) may not be available due to the potential loss of CCW to the oil cooler. The Train B CCP is unaffected. Valve BGHV8153A may be affected. Loss of inventory through the excess letdown flowpath is prevented by maintaining valves BGHV8154A and either BGHV8153B or BGHV8154B closed.
BM	Steam Generator Blowdown System	R, M, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-3.
BN	Borated Refueling Water Storage System	R, M, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-3.
EF	Essential Service Water System	H, S	The Train B ESW system is unaffected by a fire in this area. Cables asociated with valves EFHV0051 and EFHV0059 could be affected. Damage will not result in the valves spuriously operating. If Train A CCW is operating at the time of the fire, the valves will be in the required operating position and will not spuriously operate. The remaining portions of the Train A ESW system are unaffected.
EG	Component Cooling Water System	S	The Train B CCW system is unaffected by a fire in this area. Temperature control valve EGTV0029 could fail closed. This will not prevent operation of the Train A CCW system.

Table A-3-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-3

System	System Name	PFSSD Function*	Comments
EJ	Residual Heat Removal System	M, H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-3.
EM	High Pressure Coolant Injection	R, M	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-3.
EN	Containment Spray	R, M	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-3.
EP	Safety Injection Accumulators	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-3.
FB	Auxiliary Steam	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-3.
FC	Auxiliary Turbines	R, H, P	Valves FCHV0312 and FCFV0313 may be affected by the fire, preventing steam flow to the turbine driven auxiliary feedwater pump turbine. The Train A and B motor driven auxiliary feedwater pumps are unaffected.
GD	ESW Pump House HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-3.
GF	AFW Pump Room Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-3.
GK	Control Room and Class 1E Switchgear Room Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-3.
GL	Auxiliary Building HVAC	S	Dampers GLHZ0080 and GLHZ0081 associated with the Train A CCW pump room cooler could be affected. This will not result in immediate inoperability of the Train A CCW pumps. The Train B CCW pump room cooler is unaffected.
GM	Emergency Diesel Generator Room HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-3.
GN	Containment Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-3.
JE	Diesel Fuel Oil	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-3.
KA	Instrument Air	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-3.

3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD

This section describes operator actions that may need to be performed inside or outside the control room to achieve and maintain hot standby if a fire occurs in area A-3. This section also describes cold shutdown repairs that may need to be made to achieve and maintain cold shutdown conditions. Operator actions are proceduralized in OFN KC-016.

3.1 ACTIONS OUTSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

None

3.2 ACTIONS INSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

None

3.3 ACTIONS TO ACHIEVE AND MAINTAIN COLD SHUTDOWN

None

4.0 CONCLUSION

Post Fire Safe Shutdown is assured if a fire occurs in fire area A-3.

5.0 DETAILED ANALYSIS

This section describes the detailed component-by-component and cable-by-cable analysis for a fire in area A-3.

5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA A-3

There are no PFSSD components located in area A-3. This fire area only contains cables associated with PFSSD equipment located in other areas.

5.2 PFSSD CABLE EVALUATION

Table A-3-3 lists all the PFSSD cables (S. in E-15000) located in fire area A-3. The applicable evaluation section is also listed in Table A-3-3.

Table A-3-3
PFSSD Cables Located in Fire Area A-3

Cable #	Location	Primary PFSSD Equipment	Cable Function (P) Power (C) Control (I) Instrumentation	Evaluation Section	Comments
11BBK30CA	1407	BBHV8002A	C	5.2.1	Reactor Vessel Head Vent Valve

5.2.1 Reactor Head Vent Valves

PFSSD requires that one of the two reactor vessel head vent valves on each flow path (2 flow paths total) be closed to prevent uncontrolled depressurization of the RCS. A cable (11BBK30CA) associated with one of the four head vent valves (BBHV8002A) runs through area A-3.

Cables for remaining head vent valves BBHV8001A, BBHV8001B and BBHV8002B are not run through A-3 and are unaffected by the fire. Therefore, at least one valve on each flow path can be controlled, and damage to the cable associated with BBHV8002A will have no adverse impact on PFSSD.

References: E-15000, XX-E-013, E-13BB30, E-1F9301, M-12BB04

5.2.2 Excess Letdown Isolation Valves

PFSSD requires the excess letdown path be isolated to prevent uncontrolled depressurization of the RCS. To accomplish this, either normally closed valve BGHV8153A or BGHV8154A must be maintained closed and either normally closed valve BGHV8153B or BGHV8154B must be maintained closed.

One cable (11BGK48CB) associated with BGHV8153A runs through fire area A-3. Cables for the remaining excess letdown flowpath valves are unaffected by a fire in this area. Therefore, the excess letdown flowpath will remain closed if a fire occurs in this area.

References: E-15000, XX-E-013, E-13BG48, E-1F9301, M-12BG01

5.2.3 Component Cooling Water

For PFSSD, the component cooling water (CCW) system is used to provide cooling to the centrifugal charging pump (CCP) oil cooler, seal water heat exchanger, the RHR heat exchanger and the RHR pump seal cooler. In addition, the CCW system provides cooling to the RCP thermal barriers and is credited as a backup to RCP seal injection for maintaining seal cooling.

Valve EFHV0051 is the Essential Service Water (ESW) Train A to Component Cooling Water (CCW) Train A heat exchanger supply isolation valve and is required to be open when using Train A for PFSSD. Valve EFHV0059 is the return isolation valve from CCW Train A heat exchanger to the Ultimate Heat Sink (UHS). PFSSD requires that EFHV0059 be closed when using Train A CCW for plant shutdown following a fire and that valve EFV0058 be maintained in a locked throttled position to provide the minimum required ESW water flow. If valve EFHV0059 were to spuriously open when operating Train A ESW, flow imbalance could occur, which will result in flow depletion and inoperability of essential PFSSD components.

Power and control cables associated with EFHV0051 (11EFG05AA and 11EFG05AB) and EFHV0059 (11EFG04AA and 11EFG04AB) run in area A-3. Damage to these cables would not result in the valves spuriously operating. If Train A CCW is operating at the time of the fire, these valves would be in their required operating position and will not spuriously operate. Therefore, a fire in area A-3 would not result in a loss of control of ESW flow to Train A CCW.

Cables associated with Train B ESW to/from CCW valves are run in a different fire area and are unaffected by a fire in area A-3. Therefore, Train B ESW is available to supply the necessary cooling flow to the CCW Train B heat exchanger.

Cable 11EGK16AA is associated with Train A CCW heat exchanger outlet temperature control valve EGTV0029. Damage to this cable will either de-energize or partially energize the associated solenoid valve, causing the valve to fail closed. This will not prevent operation of

the Train A CCW system. Train B CCW Heat Exchanger Bypass Valve EGTV0030 is unaffected by a fire in this area.

Power and control cables associated with Train A CCW Pump Room cooler SGL11A exhaust dampers GLHZ0080 and GLHZ0081 are run in area A-3. Damage to these cables could prevent operation of the dampers. This is acceptable based on PIR 2000-2646 and Calculation GL-M-006. CCW train B room coolers will provide sufficient cooling for continued operation of Train A pumps. Cables associated with the Train B CCW pump room coolers SGL17B and SGL11B are unaffected by a fire in area A-3.

Based on the above discussion, Train A and Train B CCW are available if a fire occurs in this area.

References: E-15000, XX-E-013, E-13EF04, E-13EF05, E-13EG16, E-13GL27, E-1F9401A, E-1F9403, E-1F9444, M-12EF02, M-12EG02, M-12GL01, Calculation GL-M-006

5.2.4 Turbine Driven Auxiliary Feedwater Pump

The PFSSD design requires the use of one auxiliary feedwater pump supplying water to at least two steam generators. The turbine driven auxiliary feedwater pump (TDAFP) is normally aligned to supply all four steam generators. The Train A motor driven auxiliary feedwater pump (MDAFP) is aligned to supply steam generators B and C. The Train B MDAFP is aligned to supply steam generators A and D.

Cable 12FCK23AX is a control cable associated with valves FCHV0312 and FCHV0313. One conductor within this five conductor cable is used in the close circuit of valve FCHV0312 and the remaining four cables are used in the control circuit of valve FCFV0313. Damage to this cable could prevent operation of valves FCHV0312 and FCFV0313.

In the event valves FCHV0312 and FCFV0313 fail due to damage to this cable, the Train A and Train B Motor Driven Auxiliary Feedwater Pumps (MDAFPs) are available to supply auxiliary feedwater to steam generators A, B, C and D.

5.2 PFSSD CABLE EVALUATION 12

1.0 GENERAL AREA DESCRIPTION

Fire area A-4 is located on the 1974 elevation of the Auxiliary Building and includes the rooms listed in Table A-4-1.

Table A-4-1
Rooms Located in Fire Area A-4

ROOM #	DESCRIPTION
1107	Train B Centrifugal Charging Pump Room
1108	Train B Safety Injection Pump Room
1109	Train B RHR Pump Room
1110	Train B Containment Spray Pump Room

Fire area A-4 is protected with automatic fire detection throughout. In addition, the area is bounded on all sides by minimum 3-hour fire resistance rated construction.

2.0 PRIMARY EQUIPMENT USED FOR PFSSD

Table A-4-2 lists each system credited for post-fire safe shutdown and provides a discussion regarding the availability of the system to perform its Post Fire Safe Shutdown (PFSSD) function if a severe fire occurs in this area. For a summary of the area analysis results, see Section 8.0 of the Fire Area Analysis Narrative section.

Table A-4-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-4

System	System Name	PFSSD Function*	Comments
AB	Main Steam	R, M, H, P, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-4.
AC	Main Turbine	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-4.
AE	Main Feedwater	H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-4.
AL	Aux. Feedwater System	H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-4.
AP	Condensate Storage System	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-4.
BB	Reactor Coolant System	R, M, H, P, S	All PFSSD functions associated with the reactor coolant system are satisfied. When transferring to RHR, valve BBPV8702A may need to be manually opened, or a cold shutdown repair performed, to provide a suction source from the RCS to RHR pump A.
BG	Chemical and Volume Control System	R, M, S	Train B CVCS components could be affected. Train A CVCS is unaffected. VCT isolation valve BGLCV0112C may be affected. VCT isolation valve BGLCV0112B is unaffected.
BM	Steam Generator Blowdown System	R, M, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-4.
BN	Borated Refueling Water Storage System	R, M, H	Valve BNHV8812B may be affected, preventing the valve from closing either automatically when EJHV8811B opens or manually from the control room. Valve EJHV8811B will remain closed to prevent the RWST from draining to the containment sump.
EF	Essential Service Water System	H, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-4.
EG	Component Cooling Water System	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-4.
EJ	Residual Heat Removal System	M, H, P	The Train B RHR system may be affected. The Train A RHR system is unaffected.
EM	High Pressure Coolant Injection	R, M	Train B safety injection pump PEM01B could be affected. The fire will not cause the pump to spuriously start. The Train A safety injection pump is unaffected.
EN	Containment Spray	R, M	Train B containment spray pump PEN01B could be affected. The fire will not cause the pump to spuriously start. The Train A containment spray pump is unaffected.

Table A-4-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-4

System	System Name	PFSSD Function*	Comments
EP	Safety Injection Accumulators	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-4.
FB	Auxiliary Steam	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-4.
FC	Auxiliary Turbines	R, H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-4.
GD	ESW Pump House HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-4.
GF	AFW Pump Room Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-4.
GK	Control Room and Class 1E Switchgear Room Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-4.
GL	Auxiliary Building HVAC	S	The PFSSD function associated with the Auxiliary Building HVAC System is satisfied. The Train B RHR pump room cooler SGL10B and CCP pump room cooler SGL12B may be affected. Train A room coolers are available.
GM	Emergency Diesel Generator Room HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-4.
GN	Containment Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-4.
JE	Diesel Fuel Oil	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-4.
KA	Instrument Air	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-4.
KC	Fire Protection	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-4.
KH	Service Gas	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-4.
KJ	Standby Diesel Engine	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-4.
MA	Main Generation	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-4.

Table A-4-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-4

System	System Name	PFSSD Function*	Comments
MR	Startup Transformer	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-4.

3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD

This section describes operator actions that may need to be performed inside or outside the control room to achieve and maintain hot standby if a fire occurs in area A-4. This section also describes cold shutdown repairs that may need to be made to achieve and maintain cold shutdown conditions. Operator actions are proceduralized in OFN KC-016.

3.1 ACTIONS OUTSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

None

3.2 ACTIONS INSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

None

3.3 ACTIONS TO ACHIEVE AND MAINTAIN COLD SHUTDOWN

3.3.1 RHR

If valve BBPV8702A fails to respond when initiating RHR for cold shutdown, make a containment entry to manually open the valve or perform a cold shutdown repair to fix the damaged circuit.

4.0 CONCLUSION

Post Fire Safe Shutdown is assured if a fire occurs in fire area A-4.

5.0 DETAILED ANALYSIS

This section describes the detailed component-by-component and cable-by-cable analysis for a fire in area A-4.

5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA A-4

PFSSD components (S. in E-15000) located in fire area A-4 are shown in Table A-4-3. An evaluation of each component and associated cables is provided in the sections that follow. The applicable evaluation section is listed in Table A-4-3.

Table A-4-3
PFSSD Equipment Located in Fire Area A-4

Room #	PFSSD Equipment	Description	Evaluation Section	Comments
1107	BGHV8111	CCP B Miniflow Isolation Valve	5.1.1	
1107	BGHV8357B	CCP B Discharge To RCP Seals Valve	5.1.1	
1109	BNHV8812B	RWST To RHR Pump B Suction Valve	5.1.2	
1107	BNLCV0112E	Charging Pump B RWST Suction Valve	5.1.1	
1109	BNZS8812BA	RWST To RHR Pump B Suction Valve Limit Switch	5.1.3	
1107	DPBG05B	Centrifugal Charging Pump B Motor	5.1.1	
1109	DPEJ01B	Residual Heat Removal Pump B Motor	5.1.3	
1108	DPEM01B	Safety Injection Pump B Motor	5.1.4	
1110	DPEN01B	Containment Spray Pump B Motor	5.1.5	
1109	DSGL10B	RHR Pump Room B Cooler Motor	5.1.3	
1107	DSGL12B	Centrifugal Charging Pump Room B Cooler Motor	5.1.1	
1107	EJFIS0611	Train B RHR Mini Flow Indicating Switch	5.1.3	
1108	EJHV8804B	RHR B to SI Pump B Isolation Valve	5.1.3	
1109	EJFCV0611	RHR Mini Flow Isolation Valve Loop B	5.1.3	
1108	EJZS8804BB	RHR B To SI Pump Iso Valve Limit Switch	5.1.3	

5.1.1 Chemical and Volume Control System (CVCS)

A number of cables and components associated with Train B CVCS could be affected, as identified in Table A-4-3. In addition, RCP seal injection using Train B charging pump could be affected due to damage to valve BGHV8357B and associated cables. Damage to these cables and components could prevent operation of Train B CVCS.

The Train B centrifugal charging pump (CCP) room cooler and associated power cable is located in this area. Damage to the motor and/or cable will prevent operation of the room cooler. Loss of the room cooler could prevent proper operation of the Train B CCP.

Train A CVCS and seal injection using Train A charging pump is unaffected by a fire in area A-4. Cables associated with Train A CVCS are located in a separate fire area and are unaffected by a fire in this area.

References: E-15000, XX-E-013, E-13BG01A, E-13BG11C, E-13BG52, E-13BN01A, E-13GL05, E-1F9102, E-1F9302, E-1F9401A, E-1F9444, M-12BG03, M-12BN01, M-12GL02

5.1.2 RWST to Containment Sump

Either valve BNHV8812B or valve EJHV8811B is required to be closed for PFSSD to prevent the RWST from draining to the containment sump. Valve BNHV8812B is normally open and valve EJHV8811B is normally closed. Valve BNHV8812B and associated power and control cables are run in fire area A-4. Damage to these cables could prevent closing the valve from the control room.

One cable (14EJG06BF) associated with valve EJHV8811B is run in fire area A-4. A hot short within this cable will send an OPEN permissive to valve EJHV8811B. However, the valve will not open because ARA contacts installed on both sides of the position switch contact will prevent the valve from opening.

Based on the above discussion, a fire in area A-4 will not cause the RWST to drain to the containment sump.

References: E-15000, XX-E-013, E-13BN03A, E-13EJ06B, E-1F9102, E-1F9205, M-12BN01, M-12EJ01

5.1.3 Residual Heat Removal System

The decay heat removal function requires an available RHR flowpath taking suction from the RCS and discharging cooled water back to the RCS. During normal operation and hot standby, the RHR system is not required and the RCS to RHR suction isolation valves must remain closed.

The power cable associated with Train B RHR pump motor DPEJ01B is run through area A-4. Damage to this cable will prevent operation of the pump. Cables associated with Train A RHR pump motor DPEJ01A are unaffected by a fire in area A-4.

Power and control cables associated with Train B RHR pump miniflow valve EJFCV0611 are run in area A-4. Damage to these cables could prevent operation of the valve and cause damage to the Train B RHR pump, if it is operating. Train A RHR miniflow valve EJFCV0610 is unaffected by a fire in area A-4.

The power cable associated with Train B RHR pump room cooler SGL10B is run in area A-4. Damage to this cable will prevent operation of the room cooler. Train A RHR pomp room cooler SGL10A circuits are unaffected by a fire in area A-4.

RCS Loop 1 to Train A RHR pump inlet isolation valves BBPV8702A and EJHV8701A are required to remain closed during normal operation and hot standby and are required to be open when using Train A RHR for shutdown cooling. RCS Loop 4 to Train B RHR pump inlet isolation valves BBPV8702B and EJHV8701B are required to remain closed during normal operation and hot standby and are required to be open when using Train B RHR for shutdown cooling. All four valves are normally closed with the breaker de-energized to prevent accidental opening of the valves. Power cables for these valves are not run in fire area A-4.

Cables 11EJG05BF and 11EJG05BG are associated with open permissives on valve EJHV8701B control circuit. Cable 11EJG05BF is tied to limit switch EJZS8804BB on valve EJHV8804B. Cable 11EJG05BG is tied to limit switch BNZS8812BA on valve BNHV8812B. Damage to these cables or limit switch could provide a false open permissive or could prevent the valve from being open when needed. The false open permissive will not cause the valve to open because the MOV is normally de-energized. As stated above, other Train B RHR components could be affected, so Train B RHR is not credited for shutdown cooling.

Valve EJHV8804B is the RHR pump B to Safety Injection pump isolation valve. Cable 14EJG04BA is the power cable for valve EJHV8804B. Cable 14EJG04BB is a control cable for valve EJHV8804B. Valve EJHV8804B is normally closed and is required to remain closed during RHR Train B operation. As stated throughout this section, the Train A RHR pump is credited if a fire occurs in this area. Therefore, spurious opening of this valve will not adversely impact PFSSD.

Cable 14BBG12AD is associated with an open permissive on valve BBPV8702A. Damage to this cable could provide a false open permissive or could prevent the valve from being open when needed. The false open permissive will not cause the valve to open because the MOV is normally de-energized. Since Train A RHR is credited for shutdown cooling if a fire occurs in this area, valve BBPV8702A is required to be open when lining up RHR. An open circuit or short to ground in this cable will prevent opening the valve when needed. Therefore, a containment entry to open the valve or cold shutdown repair may be necessary prior to establishing shutdown cooling.

Cables 14BBG12BC and 14BBG12BD are associated with open permissives on valve BBPV8702B. Damage to these cables could provide a false open permissive or could prevent the valve from being open when needed. The false open permissive will not cause the valve to

open because power is normally de-energized. As stated above, other Train B RHR components could be affected, so Train B RHR is not credited for shutdown cooling.

Based on the above discussion, Train A RHR pump PEJ01A and associated components are unaffected by a fire in area A-4 and will be used to provide decay heat removal during cold shutdown. When lining up the RCS to the Train A RHR pump, it may be necessary to perform a cold shutdown repair or manually open BBPV8702A locally.

References: XX-E-013, E-15000, E-13BB12A, E-13BB12B, E-13EJ01, E-13EJ04B, E-13EJ05B, E-13EJ08, E-13EJ08A, E-13GL05, E-1F9205, E-1F9301, E-1F9401A, E-1F9444, M-12BB01, M-12EJ01, M-12GL02

5.1.4 Safety Injection Pumps

The safety injection pumps are not required for PFSSD, but are included to evaluate the impact of a spuriously operating pump. The power cables are not included because they are not required for PFSSD. The control cables, however, are included in the PFSSD analysis to evaluate whether damage will cause a spurious pump start.

Control cables associated with safety injection pump PEM01B are not run in fire area A-4. Therefore, a fire in area A-4 will not cause a spurious start of PEM01B. Damage to the pump will have no adverse impact on PFSSD.

References: XX-E-013, E-15000, M-12EM01

5.1.5 Containment Spray Pumps

The containment spray pumps are not required for PFSSD, but are included to evaluate the impact of a spuriously operating pump. The power cables are not included because they are not required for PFSSD. The control cables, however, are included in the PFSSD analysis to evaluate whether damage will cause a spurious pump start.

Control cables associated with containment spray pump PEN01B are not run in fire area A-4. Therefore, a fire in area A-4 will not cause a spurious start of PEN01B. Damage to the pump will have no adverse impact on PFSSD.

5.2.1 Volume Control Tank (VCT) Isolation Valve (BGLCV0112B)

One control cable associated with VCT valve BGLCV0112C runs through fire area A-4. Cables for redundant VCT valve BGLCV0112B are run in a separate fire area and are unaffected by a fire in area A-4. The PFSSD position of these valves is at least one closed. Therefore, PFSSD can be accomplished by isolation of BGLCV0112B.

Damage to cable 14BGG12BD could provide a permissive for valve BGLCV0112C to close. If this occurs prior to establishing suction from the RWST, damage to the operating charging pump could occur due to loss of suction. Valve BGLCV0112C will close only upon presence of either a SIS or a VCT low-low level signal, coincident with postulated cable 14BGG12BD damage. A fire in area A-4 will not cause a spurious SIS or VCT low-low level signal. Therefore, valve BGLCV0112C will not spuriously close.

Based on the above discussion, the ability to achieve and maintain PFSSD is unaffected by a fire in area A-4, which affects VCT valve BGLCV0112C. Therefore, the configuration is acceptable.

1.0 GENERAL AREA DESCRIPTION

Fire area A-5 is located on the South side of the Auxiliary Building and includes the rooms listed in Table A-5-1.

Table A-5-1
Rooms Located in Fire Area A-5

ROOM #	DESCRIPTION
1119	Aux Building South Stairway 1974 to 2062 Elevation
1601	Elevator Machine Room

Fire area A-5 has no installed automatic fire suppression system. An automatic fire detector is installed at the top of the stairway at the 2047 foot elevation.

2.0 PRIMARY EQUIPMENT USED FOR PFSSD

Table A-5-2 lists each system credited for post-fire safe shutdown and provides a discussion regarding the availability of the system to perform its Post Fire Safe Shutdown (PFSSD) function if a severe fire occurs in this area. For a summary of the area analysis results, see Section 8.0 of the Fire Area Analysis Narrative section.

Table A-5-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-5

System	System Name	PFSSD Function*	Comments
AB	Main Steam	R, M, H, P, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-5.

3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD

This section describes operator actions that may need to be performed inside or outside the control room to achieve and maintain hot standby if a fire occurs in area A-5. This section also describes cold shutdown repairs that may need to be made to achieve and maintain cold shutdown conditions. Operator actions are proceduralized in OFN KC-016.

3.1 ACTIONS OUTSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

None

3.2 ACTIONS INSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

None

3.3 ACTIONS TO ACHIEVE AND MAINTAIN COLD SHUTDOWN

None

4.0 CONCLUSION

Post-Fire Safe Shutdown capability is assured if a severe fire occurs in this area.

5.0 DETAILED ANALYSIS

This section describes the detailed component-by-component and cable-by-cable analysis for a fire in area A-5.

5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA A-5

There are no PFSSD components located in area A-5. This fire area only contains cables associated with PFSSD equipment located in other areas.

5.2 PFSSD CABLE EVALUATION

Table A-5-3 lists all the PFSSD cables (S. in E-15000) located in fire area A-5. The applicable evaluation section is also listed in Table A-5-3.

Table A-5-3
PFSSD Cables Located in Fire Area A-5

Cable #	Location	Primary PFSSD Equipment	Cable Function (P) Power (C) Control (I) Instrumentation	Evaluation Section	Comments
15PGA10AA	1119	PA0105	C	5.2.1	Load Centers PG11, PG13 and PG25 Fdr Bkr
16PGA10CA	1119	PA0206	C	5.2.1	Load Centers PG12, PG16 and PG26 Fdr Bkr

5.2.1 Load Center Feeder Breakers PA0105 and PA0206

Load center feeder breakers PA0105 and PA0206 are credited for PFSSD because they supply power to credited non-safety related loads. Cables associated with these breakers run in this area. PFSSD impact due to damage to these cables is discussed below.

Cable 15PGA10AA is a control cable associated with breaker PA0105 and runs in fire area A-5. An intra-cable hot short in this cable will trip PA0105. Breaker PA0105 supplies power to the following PFSSD components:

- PG11JFR2 – Main Steam Supply to 2nd Stage Reheat Valve ABHV0031
- PG11KBR3 – Auxiliary Steam System Control Valve FBHV0081

PG11JFR2 and PG11KBR3 supply power to components downstream of the MSIVs. The MSIVs are unaffected by a fire in this area and can be closed from the control room using hand switch ABHS0079 or ABHS0080. Therefore, the MSIV downstream components are not required if a fire occurs in this area.

The cable note in Setroute for cable 15PGA10AA states that the cable is located within a heat affected zone per M-663-00017A and requires further fire protection review if credited for PFSSD. The heat affected zone evaluation is discussed in M-663-00017A, Appendix B13, pages B-13-64 through B-13-69 and occurs where the cable passes between fire areas A-5 (Roomn 1119) and A-16 South (Room 1408). Since the cable traverses both fire areas and is not credited for a fire in either area, there will be no adverse impact on PFSSD if a fire occurs in areas A-5 or A-16 South.

Cable 16PGA10CA is a control cable associated with breaker PA0206 and runs in fire area A-5. An intra-cable hot short in this cable will trip PA0206. Breaker PA0206 supplies power to the following PFSSD components:

- PG12KAF4 – Main Steam Supply to 2nd Stage Reheat Valve ABHV0032
- PG12KAF5 – Main Steam Supply to Steam Seals Valve ABHV0046
- PG12KEF3 – Auxiliary Steam System Control Valve FBHV0080

PG12KAF4, PG12KAF5 and PG12KEF3 supply power to components downstream of the MSIVs. The MSIVs are unaffected by a fire in this area and can be closed from the control room using hand switch ABHS0079 or ABHS0080. Therefore, the MSIV downstream components are not required if a fire occurs in this area.

Based on the above discussion, loss of breakers PA0105 and PA0206 will have no adverse impact on PFSSD.

5.2 PFSSD CABLE EVALUATION 11

1.0 GENERAL AREA DESCRIPTION

Fire area A-6 comprises stairway A-2 located on the North side of the Auxiliary Building and includes the rooms listed in Table A-6-1.

Table A-6-1
Rooms Located in Fire Area A-6

ROOM #	DESCRIPTION
1127	Aux Building North Stairway 1974 to 2047 Elevation

Fire area A-6 has no installed automatic fire suppression system. An automatic fire detector is installed at the top of the stairway at the 2047 foot elevation.

Circuits associated with redundant success paths are run through this area. In some cases, one success path is protected with a raceway fire barrier material meeting the requirements for a 3-hour fire rating. The 3-hour electrical raceway fire wrap meets Wolf Creek's commitments to 10CFR50, Appendix R Section III.G.2(a). This fire barrier provides reasonable assurance that circuits enclosed within the barrier will be unaffected by a fire in area A-6.

2.0 PRIMARY EQUIPMENT USED FOR PFSSD

Table A-6-2 lists each system credited for post-fire safe shutdown and provides a discussion regarding the availability of the system to perform its Post Fire Safe Shutdown (PFSSD) function if a severe fire occurs in this area. For a summary of the area analysis results, see Section 8.0 of the Fire Area Analysis Narrative section.

Table A-6-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-6

System	System Name	PFSSD Function*	Comments
AB	Main Steam	R, M, H, P, S	ABHS0080 is available to close the MSIVs. Steam generator ARV ABPV0004 may spuriously open. Steam generator ARVs ABPV0001, ABPV0002 and ABPV0003 are unaffected.
AC	Main Turbine	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-6.
AE	Main Feedwater	H, P	All PFSSD functions associated with the main feedwater system are satisfied. All four main feedwater isolation valves can be isolated using hand switch AEHS0080.
AL	Aux. Feedwater System	H, P	All PFSSD functions associated with the auxiliary feedwater system are satisfied. The Train A motor driven AFW pump is available to supply feedwater to steam generators B and C using appropriate Train A valves. Several Train B components could be affected by the fire. The turbine driven AFW pump may be unavailable.
AP	Condensate Storage System	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-6.
BB	Reactor Coolant System	R, M, H, P, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-6.
BG	Chemical and Volume Control System	R, M, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-6.
BM	Steam Generator Blowdown System	R, M, H	All PFSSD functions associated with the steam generator blowdown system are satisfied. Steam generator blowdown is isolated by closing valves BMHV0001, BMHV0002, BMHV0003 and BMHV0004 using BMHIS0001C, BMHIS0002C, BMHIS0003C and BMHIS0004C, located on the BM157 panel in the radwaste control room.
BN	Borated Refueling Water Storage System	R, M, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-6.
EF	Essential Service Water System	H, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-6.
EG	Component Cooling Water System	S	Valve EGHV0062 could spuriously close due to a spurious high CCW flow condition due to damage to EGFT0062. Bypass valve EGHV0132 is unaffected. RCP seal injection is unaffected. CCW flow indicators EGFI0128 and EGFI0129 are unaffected.

Table A-6-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-6

System	System Name	PFSSD Function*	Comments
EJ	Residual Heat Removal System	M, H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-6.
EM	High Pressure Coolant Injection	R, M	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-6.
EN	Containment Spray	R, M	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-6.
EP	Safety Injection Accumulators	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-6.
FB	Auxiliary Steam	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-6.
FC	Auxiliary Turbines	R, H, P	Valves FCHV0312 and FCFV0313 may be affected by the fire, preventing steam flow to the turbine driven auxiliary feedwater pump turbine. The Train A motor driven auxiliary feedwater pump is unaffected.
GD	ESW Pump House HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-6.
GF	AFW Pump Room Coolers	S	The PFSSD Support function associated with the AFW Pump Room Coolers is satisfied. The Train A Motor Driven AFW Pump is used for a fire in area A-6. Auxiliary Feedwater Pump A room cooler SGF02A is available. ESW Train A is available to supply the room cooler.
GK	Control Room and Class 1E Switchgear Room Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-6.
GL	Auxiliary Building HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-6.
GM	Emergency Diesel Generator Room HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-6.
GN	Containment Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-6.
JE	Diesel Fuel Oil	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-6.
KA	Instrument Air	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-6.

3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD

This section describes operator actions that may need to be performed inside or outside the control room to achieve and maintain hot standby if a fire occurs in area A-6. This section also describes cold shutdown repairs that may need to be made to achieve and maintain cold shutdown conditions. Operator actions are proceduralized in OFN KC-016.

3.1 ACTIONS OUTSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

Operator Manual Actions (OMAs) are those actions outside the main control room required to achieve and maintain hot standby. OMAs are identified in E-1F9900 and were determined from thermal hydraulic analysis WCNOC-CP-002. Applicable E-1F9900 OMAs are annotated herein. All other actions outside the control room are desirable for plant control in support of hot standby but not required to achieve and maintain hot standby.

3.1.1 Steam Generator ARVs

It may be necessary to fail close ABPV0004 by isolating the air and nitrogen supply, then venting air from the regulators. This action can be performed by an operator in fire area A-23. Access to area A-23 would need to be made through the emergency escape hatch from the Turbine Building 2015 elevation. The operator performing this action may need a flashlight in the escape hatch area but the main area of A-23 is provided with emergency lights.

3.1.2 Steam Generator Blowdown to Blowdown Flash Tank Isolation

If a fire occurs in area A-6, cables for BMHIS0001A, BMHIS0002A, BMHIS0003A and BMHIS0004A may be damaged by the fire. Therefore, use BMHIS0001C, BMHIS0002C, BMHIS0003C and BMHIS0004C located on the BM157 panel in the Radwaste Control room to close valves BMHV0001, BMHV0002, BMHV0003, and BMHV0004.

3.2 ACTIONS INSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

3.2.1 Main Steam Isolation Valves and MSIV Bypass Valves

Hand switch ABHS0079 may not be effective in closing the MSIVs and ensuring the MSIV bypass valves remain closed. ABHS0080 is unaffected by the fire and should be used to close the MSIVs and bypass valves.

3.2.2 Main Feedwater Isolation Valves

Cables for hand switch AEHS0081 may be damaged. Cables for redundant hand switch AEHS0080 are unaffected. Therefore, use AEHS0080 to close the MFIVs.

3.2.3 Thermal Barrier Cooling

RCP Thermal Barrier Cooling valve EGHV0062 could spuriously close. Operators can diagnose this condition using flow indicators EGFI0128 and EGFI0129. If necessary, bypass valve EGHV0132 can be opened. RCP seal injection is unaffected.

3.3 ACTIONS TO ACHIEVE AND MAINTAIN COLD SHUTDOWN

None specific to PFSSD

4.0 CONCLUSION

With some exceptions, redundant Post-Fire Safe Shutdown capability exists if a severe fire occurs in this area. For those exceptions, feasible manual actions are available and are unaffected by the fire. Manual actions are documented in Section 3.0.

5.0 DETAILED ANALYSIS

This section describes the detailed component-by-component and cable-by-cable analysis for a fire in area A-6.

5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA A-6

PFSSD components (S. in E-15000) located in fire area A-6 are shown in Table A-6-3. An evaluation of each component and associated cables is provided in the sections that follow. The applicable evaluation section is listed in Table A-6-3.

Table A-6-3 PFSSD Components Located in Fire Area A-6				
Room #	**PFSSD Component**	**Component Description**	**Evaluation Section**	**Comments**
1127	EGFT0062	RCP Thermal Barrier Outlet Flow	5.1.1	

5.1.1 CCW Flow From RCP Thermal Barriers

For PFSSD, the component cooling water (CCW) system is used to provide cooling to the centrifugal charging pump (CCP) oil cooler, the RHR heat exchanger and the RHR pump seal cooler. In addition, the CCW system provides cooling to the RCP thermal barriers and is credited as a backup to RCP seal injection for maintaining seal cooling.

Flow transmitter EGFT0062 and cable 14EGI15AA are located in this fire area. The flow transmitter monitors CCW outlet flow from the thermal barriers and automatically shuts valve EGHV0062 on a high flow signal. A fire could damage the flow transmitter and/or cable, causing a spurious high flow signal and close the valve. If this occurs, CCW flow to the thermal barriers would be lost until operators open bypass valve EGHV0132 from the control room.

Spurious closure of EGHV0062 would be indicated in the control room as a reduction in flow on flow indicators EGFI0128 and EGFI0129.

A fire in area A-6 will not cause a loss of RCP seal injection. Therefore, loss of thermal barrier cooling will have no adverse impact on PFSSD.

5.2.1 Steam Generator Atmospheric Relief Valves

Post fire safe shutdown (PFSSD) requires an operable auxiliary feedwater supply to at least two steam generators and control of the two associated steam generator atmospheric relief valves (SGARVs). In addition, the SGARVs on the other two steam generators are required to be closed. Cables associated with SGARVs ABPV0001 and ABPV0004 run through area A-6.

Cable 11ABI20EA is an instrument cable that runs from pressure transmitter ABPT0001, in Area 5 of the Auxiliary Building, to panel RP053AC in the control room. Pressure transmitter ABPT0001 monitors steamline pressure on loop 1. High steamline pressure (1125 psig or greater) sensed by ABPT0001 will send a signal to open ABPV0001. A spurious high pressure signal due to damage to the cable could open the ARV. The cable is run in tray 111J1L01, which has been wrapped with a 3-hour fire rated barrier. The 3-hour fire barrier provides reasonable assurance that damage to cable 11ABI20EA will not occur. Therefore, SGARV ABPV0001 is unaffected by a fire in area A-6.

Cable 14ABI20HE is an instrument cable that runs from panel RP147B in the Train B ESF switchgear room to pressure transducer ABPY0004 in Area 5 of the Auxiliary Building. Cable 14ABI20HH is an instrument cable that runs from pressure transmitter ABPT0004 in Area 5 of the Auxiliary Building to panel RP147B. High steamline pressure (1125 psig or greater) sensed by ABPT0004 will send a signal to open ABPV0004. Damage to either of these cables could prevent control of the ARV from the control room and auxiliary shutdown panel, and could cause the spurious opening of the ARV.

Spurious opening of ARV ABPV0004 will not impact PFSSD and is bounded by the main steamline break analysis. Access to the steam tunnel is available through the emergency escape hatch, which is accessible from the Turbine Building 2015 elevation south. If ARV ABPV0004 spuriously opens, an operator can enter the steam tunnel through the escape hatch and isolate air and nitrogen to the ARV to close the valve. Off-site power is not lost if a fire occurs in area A-6, based on Calculation XX-E-013. However, normal lighting in the steam tunnel may be lost due to routing of the lighting cables in area A-6. Emergency lighting is provided in the steam tunnel but not in the area of the hatch opening. Operators should carry a flashlight if it becomes necessary to perform this action.

Up to three ARVs can fail closed or open without impacting ability to achieve and maintain hot standby according to thermal hydraulic analysis WCNOC-CP-002. With at least one ARV unaffected, no E-1F9900 OMA is required to address ARV closure or control. Reference Attachment 4, MSO Evaluation Scenario ID PWROG 23.

References: E-15000, XX-E-013, E-13AB20A, E-13AB20B, E-1F9101

5.2.2 Safety Injection and Containment Spray

A spurious safety injection signal (SIS) could cause the safety injection pumps to operate. A spurious containment spray actuation signal (CSAS) could cause the containment spray pumps to operate, depleting inventory in the RWST. These conditions are not desirable for PFSSD at Wolf Creek.

Safety injection (SI) is initiated automatically by any of the following conditions:

1. Two out of three high containment pressures monitored by pressure transmitters GNPT0934, GNPT0935 and GNPT0936.
2. Two out of four low pressurizer pressures monitored by pressure transmitters BBPT0455, BBPT0456, BBPT0457 and BBPT0458.
3. Two out of three low steam line pressures on any steam generator monitored by ABPT0514, ABPT0515 and ABPT0516 on SG A; ABPT0524, ABPT0525 and

ABPT0526 on SG B; ABPT0534, ABPT0535 and ABPT0536 on SG C; and, ABPT0544, ABPT0545 and ABPT0546 on SG D. Two out of three logic must be satisfied on a single steam generator line. Low pressure on a single pressure transmitter co-incident with low pressure on another pressure transmitter on a different steam generator line will not initiate SIS.

Containment spray (CS) is initiated automatically by two out of four high containment pressures monitored by pressure transmitters GNPT0934, GNPT0935, GNPT0936 and GNPT0937.

Cables associated with steam line pressure transmitters ABPT0514, ABPT0516, ABPT0524, ABPT0534, ABPT0544 and ABPT0546 are run in area A-6. Cables associated with ABPT0514, ABPT0524, ABPT0534 and ABPT0544 are run in cable tray that has been wrapped with a 3-hour fire rated material. Therefore, there is reasonable assurance that these cables will be unaffected if a fire occurs in area A-6. Consequently, the two out of three logic for low steam line pressure initiation of SIS cannot be satisfied if a fire occurs in area A-6.

Based on the above discussion, a spurious SIS or CSAS is not credible if a fire occurs in area A-6.

References: E-15000, XX-E-013, E-1F9431, E-1F9432, E-1F9433, E-13AB21, E-13BB16, E-13EM01, E-13GN05

5.2.3 Steam Generator Main Steam Isolation Valves (MSIVs) and Bypass Valves

PFSSD requires the MSIVs and bypass valves be closed to prevent reactivity addition due to uncontrolled cooldown. The MSIVs and bypass valves are closed from the control room using all close hand switches ABHS0079 or ABHS0080. The bypass valves are normally closed.

Each MSIV is designed to utilize system fluid (main steam) as the motive force to open and close. The valve actuation (open or close) is accomplished through positioning a series of six electric solenoid pilot valves to either direct the system fluid to the Upper Piston Chamber (UPC) and/or the Lower Piston Chamber (LPC), or vent either or both piston chambers. The six solenoid pilot valves are divided into two trains (3 per train) that are independently powered and controlled. Either train can independently perform the PFSSD function to close the valve and isolate main steam. This is done by actuating either all close hand switch ABHS0079 (separation group 4) or ABHS0080 (separation group 1) to de-energize the associated solenoid valves.

The following table identifies the solenoids and associated control cables for each hand switch.

MSIV	ABHS0079 (Sep Group 4)		ABHS0080 (Sep Group 1)	
	Solenoids	Cable	Solenoids	Cable
ABHV0011	MV2, MV4, MV6	14ABK28BH	MV1, MV3, MV5	11ABK29BH
ABHV0014	MV2, MV4, MV6	14ABK29AH	MV1, MV3, MV5	11ABK28AH
ABHV0017	MV2, MV4, MV6	14ABK28AH	MV1, MV3, MV5	11ABK29AH
ABHV0020	MV2, MV4, MV6	14ABK29BH	MV1, MV3, MV5	11ABK28BH

All 8 cables associated with the 24 solenoid valves are run in area A-6. Cable damage due to a fire will likely result in disruption of power to the solenoids, which will close the valves. The four separation group 1 cables associated with hand switch ABHS0080 are run in tray that has been wrapped with a 3-hour fire rated material. The 3-hour fire wrap provides reasonable assurance that hand switch ABHS0080 will be available to close the four MSIVs.

Each MSIV bypass valve is normally closed and is required to remain closed for PFSSD. Two (2) redundant solenoid valves (one on each train) are installed on the air supply line and control air to the pneumatic actuator. The valves are normally closed with the solenoid valves

de-energized. Actuation of either hand switch will de-energize power to the solenoids to ensure they remain closed.

Cables associated with all 8 solenoids associated with the four bypass valves are run in area A-6. The four cables associated with separation group 1 (Train A) solenoids are run in tray that has been wrapped with a 3-hour fire rated material. The 3-hour fire wrap provides reasonable assurance that hand switch ABHS0080 will be available to close the four MSIV bypass valves if they are open at the time of the fire.

Based on the above discussion, hand switch ABHS0080 is available to close the MSIVs and bypass valves in the event of a fire in area A-6.

References: E-15000, XX-E-013, E-13AB23A, E-13AB23B, E-13AB26, E-13AB27, E-13AB28, E-13AB29, E-1F9101, M-12AB02

5.2.4 Steam Generator Main Feedwater Isolation Valves

PFSSD requires that either the main feedwater isolation valves (MFIVs) be closed or the main feedwater pumps be stopped to prevent overfilling the steam generators. Flow diversion from auxiliary feedwater (AFW) to the main feedwater system piping is prevented by check valves AEV0420, AEV0421, AEV0422 and AEV0423. Closure of the main feedwater isolation valves is not required to prevent AFW flow diversion.

Each MFIV is designed to utilize system fluid (feedwater) as the motive force to open and close. The valve actuation (open or close) is accomplished through positioning a series of six electric solenoid pilot valves to either direct the system fluid to the Upper Piston Chamber (UPC) and/or the Lower Piston Chamber (LPC), or vent either or both piston chambers. The six solenoid pilot valves are divided into two trains (3 per train) that are independently powered and controlled. Either train can independently perform the PFSSD function to close the valve and isolate main feedwater. This is done by actuating either all close hand switch AEHS0080 (separation group 1) or AEHS0081 (separation group 4) to de-energize the associated solenoid valves.

The following table identifies the solenoids and associated control cables for each hand switch.

MFIV	AEHS0080 (Sep Group 1)		AEHS0081 (Sep Group 4)	
	Solenoids	Cable	Solenoids	Cable
AEFV0039	MV1, MV3, MV5	11AEK16AH	MV2, MV4, MV6	14AEK17AH
AEFV0040	MV1, MV3, MV5	11AEK17AH	MV2, MV4, MV6	14AEK16AH
AEFV0041	MV1, MV3, MV5	11AEK16BH	MV2, MV4, MV6	14AEK17BH
AEFV0042	MV1, MV3, MV5	11AEK17BH	MV2, MV4, MV6	14AEK16BH

All 8 cables associated with the 24 solenoid valves are run in area A-6. Cable damage due to a fire will likely result in disruption of power to the solenoids, which will close the valves. The four separation group 1 cables associated with hand switch AEHS0080 are run in tray that has been wrapped with a 3-hour fire rated material. The 3-hour fire wrap provides reasonable assurance that hand switch AEHS0080 will be available to close the four MFIVs.

Based on the above discussion, MFIV isolation is assured using hand switch AEHS0080.

References: E-15000, XX-E-013, E-13AE14, E-13AE15, E-13AE16, E-13AE17, E-1F9201, M-12AE02

5.2.5 Auxiliary Feedwater

Several cables associated with both trains of auxiliary feedwater (AFW) are run in area A-6. Cables associated with Train A AFW components are run in cable tray (111J1L01 and 111U1K01) that has been wrapped with a 3-hour fire rated barrier. The 3-hour fire barrier provides reasonable assurance that the enclosed cables will be unaffected by a fire in area A-6.

Cables associated with Train B AFW components are not protected and could be damaged by the fire. Therefore, Train B AFW cannot be relied on to supply water to steam generators A and D.

One cable (12FCK23AX) associated with the TDAFP trip and throttle valve FCHV0312 and TDAFP speed governing valve FCFV0313 is run in area A-6. This cable is run in conduit with no other cables. Damage to the cable due to a fire could prevent operation of one or both valves. Therefore, the TDAFP may not be available to supply AFW to the steam generators if a fire occurs in area A-6.

Cables associated with two of the three CST pressure transmitters run in the area. The pressure transmitters (ALPT0037, ALPT0038 and ALPT0039) initiate swapover to ESW in the event the CST reaches low level. Low pressure on two out of three pressure transmitters initiates the swapover. Cable 11ALI08AA associated with ALPT0037 is run in tray that has been wrapped with a 3-hour fire rated material. The 3-hour fire wrap provides reasonable assurance that pressure transmitter ALPT0037 will not malfunction if a fire occurs in area A-6. Cables associated with ALPT0038 are not run in area A-6. Therefore, spurious AFW swapover to the ESW system will not occur.

Cables associated with Train A and Train B AFW pump room coolers SGF02A and SGF02B are run in area A-6. Damage to these cables will prevent operation of the associated cooler, which will prevent prolonged operation of the motor driven auxiliary feedwater pump. Cables associated with Train A AFP room cooler SGF02A are run in tray that has been wrapped with a 3-hour fire barrier. The 3-hour fire wrap provides reasonable assurance that the cables will be unaffected by a fire and that the cooler will be operable. Cables associated with SGF02B are not protected and may be damaged by a fire.

Based on the above discussion, the Train A AFW system is available to supply AFW to steam generators B and C.

5.2.6 Steam Generator Blowdown to Blowdown Flash Tank

The reactivity control function requires the steam generator blowdown to blowdown flash tank valves (BMHV0001, BMHV0002, BMHV0003, and BMHV0004) be closed to prevent reactivity addition from uncontrolled cooldown. The valves are normally open air operated and are controlled by three solenoid valves. All three solenoid valves are required to be energized to open the valve. If any one solenoid is de-energized, the associated valve will close. Only two of the three solenoids for each valve are considered in the PFSSD analysis, so the third solenoid is assumed energized throughout the event. Cables run in area A-6 associated with these valves are listed in Table A-6-4.

A hot short within cables 14BMK06AA, 14BMK06BA, 14BMK06CA and 14BMK06DA will not cause the valves to spuriously open due to the absence of a +125 VDC source conductor. However, the cables are run in raceway that could contain other cables carrying 125 VDC that,

if an inter-cable hot short occurs, could spuriously open the valves and prevent them from being closed using hand switches BMHIS0001A, BMHIS0002A, BMHIS0003A and BMHIS0004A. Although this is unlikely due to the use of thermoset cables, it is postulated to occur for the purpose of this analysis.

Separation group 1 cables run in area A-6 associated with these blowdown valves are run in tray that has been wrapped with a 3-hour fire rated material. These cables are connected to a limit switch contact on each blowdown valve that is open when the valve is in its normally open position. With the limit switch contact open, the associated auxiliary relay is de-energized, which closes the seal-in contact on the solenoid valve associated with the handswitch on the BM157 panel in the Radwaste Building control room. With the seal-in contact closed, the associated solenoid valve remains energized. To de-energize the solenoid valve, the handswitch at the BM157 panel would have to be used. The 3-hour fire wrap provides reasonable assurance that these cables will be unaffected by the fire and that the handswitch at the BM157 panel will work.

Based on the above discussion, a fire in area A-6 will not prevent closing steam generator blowdown valves BMHV0001, BMHV0002, BMHV0003 and BMHV0004.

Thermal hydraulic analysis WCNOC-CP-002 shows insignificant impact on SG inventory even with all four blowdown valves open. Therefore, no E-1F9900 OMA is required to close blowdown valves to achieve and maintain hot standby. Reference Attachment 4, MSO Evaluation Scenario ID PWROG 34.

5.2.7 TDAFP Drain Trap Isolation Valve

Valve FCFV0310 is an isolation valve on the 1-inch steam trap line associated with the TDAFP. Solenoid valve FCFY0310 controls the position of valve FCFV0310. PFSSD requires this valve to be closed to prevent uncontrolled loss of steam through this flow path.

Cable 14FCK21AA is a control cable associated with valve FCFV0310. Inter or intra-cable hot shorts could cause the valve to spuriously open. There are no energized 125 VDC cables in the same conduit as cable 14FCK21AA, so inter-cable hot shorts causing the valve to open are not possible. An intra-cable hot short from conductor 2 to conductor 1 will energize the solenoid and open the valve. This can be mitigated by depressing the close pushbutton on hand switch FCHIS0310. However, since this is a momantary contact switch, the operator would have to maintain the the button in the depressed position.

Uncontrolled blowdown through this 1-inch line is bounded by the main steam line break analysis and loss of steam through this line will not result in uncontrolled cooldown. Therefore, if the valve remains open, PFSSD is assured.

1.0 GENERAL AREA DESCRIPTION

Fire area A-7 is located on the 1974 elevation of the Auxiliary Building and includes the rooms listed in Table A-7-1.

Table A-7-1
Rooms Located in Fire Area A-7

ROOM #	DESCRIPTION
1126	Boron Injection Tank Room

Fire area A-7 is protected with automatic fire detection throughout. There is no automatic suppression installed in this area.

2.0 PRIMARY EQUIPMENT USED FOR PFSSD

Table A-7-2 lists each system credited for post-fire safe shutdown and provides a discussion regarding the availability of the system to perform its Post Fire Safe Shutdown (PFSSD) function if a severe fire occurs in this area. For a summary of the area analysis results, see Section 8.0 of the Fire Area Analysis Narrative section.

Table A-7-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-7

System	System Name	PFSSD Function*	Comments
AB	Main Steam	R, M, H, P, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-7.
AC	Main Turbine	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-7.
AE	Main Feedwater	H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-7.
AL	Aux. Feedwater System	H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-7.
AP	Condensate Storage System	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-7.
BB	Reactor Coolant System	R, M, H, P, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-7.
BG	Chemical and Volume Control System	R, M, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-7.
BM	Steam Generator Blowdown System	R, M, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-7.
BN	Borated Refueling Water Storage System	R, M, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-7.
EF	Essential Service Water System	H, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-7.
EG	Component Cooling Water System	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-7.
EJ	Residual Heat Removal System	M, H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-7.
EM	High Pressure Coolant Injection	R, M	BIT inlet valves EMHV8803A and EMHV8803B may be affected. Reactor coolant pump seal injection is available for boration and inventory control. For transition to cold shutdown, valve EMHV8803A or EMHV8803B may need to be manually opened to provide additional makeup, depending on the charging train being used.

3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD

This section describes operator actions that may need to be performed inside or outside the control room to achieve and maintain hot standby if a fire occurs in area A-7. This section also describes cold shutdown repairs that may need to be made to achieve and maintain cold shutdown conditions. Operator actions are proceduralized in OFN KC-016.

3.1 ACTIONS OUTSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

None

3.2 ACTIONS INSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

None

3.3 ACTIONS TO ACHIEVE AND MAINTAIN COLD SHUTDOWN

3.3.1 Boron Injection Tank Flowpath

It may be necessary to manually open EMHV8803A or EMHV8803B, or perform a cold shutdown repair to open the valves in order to establish a BIT flowpath. This action can be taken after the fire is out and the smoke has cleared the room.

4.0 CONCLUSION

Post-fire safe shutdown is assured if a fire occurs in this area.

5.0 DETAILED ANALYSIS

This section describes the detailed component-by-component and cable-by-cable analysis for a fire in area A-7.

5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA A-7

PFSSD components (S. in E-15000) located in fire area A-7 are shown in Table A-7-3. An evaluation of each component and associated cables is provided in the sections that follow. The applicable evaluation section is listed in Table A-7-3.

Table A-7-3
PFSSD Equipment Located in Fire Area A-7

Room #	PFSSD Equipment	Description	Evaluation Section	Comments
1126	EMHV8803A	Boron Injection Tank Inlet Valve	5.1.1	
1126	EMHV8803B	Boron Injection Tank Inlet Valve	5.1.1	

5.1.1 Boron Injection Tank Flowpath

The Boron Injection Tank (BIT) flowpath is credited for reactivity control and reactor coolant makeup. For reactivity control, the BIT flowpath is credited as an alternate source of boration in the event RCP seal injection is unavailable. Based on Calculation XX-E-013, RCP seal injection will provide sufficient boration to achieve and maintain cold shutdown reactivity conditions. Therefore, the BIT flowpath is not required for reactivity control if RCP seal injection is available. Since RCP seal injection is limited to 5 gpm per seal or 20 gpm total injection to the RCS, an additional RCS charging flowpath is required for adequate RCS makeup during plant transition from hot standby to cold shutdown. The BIT injection path was selected as the additional RCS charging flowpath.

Normally closed boron injection tank (BIT) inlet valves EMHV8803A and EMHV8803B, and associated power and control cables, are located in fire area A-7. When charging through the BIT, the valve (EMHV8803A or EMHV8803B) on the operating charging train is required to be open. Damage to the valves and/or cables could prevent opening, or could cause the spurious opening, of the valves.

A fire in fire area A-7 will not cause a loss of seal injection or a loss of inventory. Therefore, the BIT flowpath is not required for boration and inventory control during hot standby. If the valves spuriously open, flow is prevented by maintaining BIT outlet valves EMHV8801A and EMHV8801B closed. BIT outlet valves EMHV8801A and EMHV8801B are unaffected by a fire in fire area A-7.

If a fire in this area requires the plant be taken to cold shutdown, it may be necessary to manually open EMHV8803A or EMHV8803B to establish a BIT flowpath. This action can be taken after the fire is out and the smoke has cleared the room.

Based on the above discussion, damage to valves EMHV8803A and/or EMHV8803B due to a fire in area A-7 will have no adverse impact on safe shutdown.

1315	Containment Spray Additive Tank Area
1318	Valve Compartment
1319	Demineralizer Compartments
1320	Corridor No. 4
1321	Exit Vestibule

An automatic pre-action sprinkler system is installed over concentrations of cable in cable trays. Automatic fire detection is installed throughout the area, except in rooms containing negligible quantities of combustible materials. The automatic suppression and detection system meets the intent of 10CFR50, Appendix R Section III.G.2.c.

2.0 PRIMARY EQUIPMENT USED FOR PFSSD

Table A-8-2 lists each system credited for post-fire safe shutdown and provides a discussion regarding the availability of the system to perform its Post Fire Safe Shutdown (PFSSD) function if a severe fire occurs in this area. For a summary of the area analysis results, see Section 8.0 of the Fire Area Analysis Narrative section.

Table A-8-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-8

System	System Name	PFSSD Function*	Comments
AB	Main Steam	R, M, H, P, S	Steam generators A and C ARVs may be affected. Steam generators B and D ARVs are unaffected but only Aux Feedwater Pump B may be available to supply steam generators A and D. Calculation WCNOC-CP-002 demonstrates the ability to maintain hot standby using only one steam generator. Hand switch ABHS0079 is available to close the MSIVs. Steam generator pressure indication is available using ABPI0515A, ABPI0516A, ABPI0525A, ABPI0535A, ABPI0545A and ABPI0546A. A spurious safety injection signal (SIS) due to low steam line pressure on two out of three steam line pressure transmitters can occur.
AC	Main Turbine	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-8.
AE	Main Feedwater	H, P	All PFSSD functions associated with the main feedwater system are satisfied. Isolate all four main feedwater isolation valves using hand switch AEHS0081. Steam generator A narrow range level indicators AELI0517, AELI0518, and AELI0519 are available. Steam Generator D wide range level indicator AELI0504 and Steam Generator D narrow range level indicators AELI0547, AELI0548, and AELI0549 are available.
AL	Aux. Feedwater System	H, P	All PFSSD functions associated with the auxiliary feedwater system are satisfied. Train B MDAFP is available to supply S/Gs A and D. ALFT0007 and ALFT0001 are available to provide auxiliary feedwater flow indication from MDAFP B to SGs A and D, respectively. Condensate Storage Tank (CST) pressure indication is available using pressure transmitters/indicators ALPT0038/ALPI0038A and ALPT0039/ALPI0039A.
AP	Condensate Storage System	H	The condensate storage tank is available to supply water to Train B MDAFP.

Table A-8-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-8

System	System Name	PFSSD Function*	Comments
BB	Reactor Coolant System	R, M, H, P, S	RCP thermal barrier cooling could be affected due to spurious closure of BBHV0013, BBHV0014, BBHV0015 and BBHV0016. RCP seal injection is available but the charging flowpath from the RWST to the RCP seals may need to be lined up from the control room. Pressurizer level indication is available using BBLI0460A. RCS Loop 1 Wide Range Cold Leg Temperature Element BBTE413B and RCS Loop 4 Wide Range Hot Leg Temperature Element BBTE443A are available. RCS pressure indication is available using BBPI0406 on RL002. Pressurizer pressure indication is available using BBPI0456, BBPI0457 and BBPI0458 on RL002. Pressurizer PORV BBPCV0455A may open and block valve BBHV8000A may not close. The PORV can be closed by placing BBHIS0455A in the Close position. During hot standby, maintain the RCS to RHR flow path valves BBPV8702A and BBPV8702B closed by ensuring hand indicating switches BBHIS8702A and BBHIS8702B are in the closed position. Some open permissives may be affected by the fire. Loss of inventory through the head vent valves is prevented by maintaining valves BBHV8002A and either BBHV8001B or BBHV8002B closed. For cold shutdown, it may be necessary to manually open BBPV8702B when operating Train B RHR.
BG	Chemical and Volume Control System	R, M, S	All PFSSD functions associated with the chemical and volume control system are satisfied. Train B Centrifugal Charging Pump (CCP) is available to provide charging flow from the RWST to the RCP seals. Isolate the VCT using both hand switches BGHIS0112B and BGHIS0112C to close valves BGLCV0112B and/or C. Valves BGHV8153A and either BGHV8153B or BGHV8154B are maintained closed to isolate excess letdown. BGHV8105 is available to isolate normal charging using BGHIS8105. Letdown isolation valves BGLCV0459 and BGLCV0460 and letdown orifice isolation valves BGHV8149A, BGHV8149B, and BGHV8149C may not respond to a close signal from the control room. Valve BGLCV0460 will automatically close when pressurizer level reaches 17%. VCT level indication is available using BGLI0185. Level indicator BGLI0112 could be affected. RCP seal flow indication is available using BGFI0215B. RCP seal flow indicator BGFI0215A may be affected.

Table A-8-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-8

System	System Name	PFSSD Function*	Comments
BM	Steam Generator Blowdown System	R, M, H	All PFSSD functions associated with the steam generator blowdown system are satisfied. Steam generator blowdown is isolated by closing valves BMHV0001, BMHV0002, BMHV0003 and BMHV0004 using BMHIS0001A, BMHIS0002A, BMHIS0003A and BMHIS0004A, located on the RL024 panel in the main control room.
BN	Borated Refueling Water Storage System	R, M, H	The RWST is available to provide a suction source to Centrifugal Charging Pump B via valve BNLCV0112E. RWST to RHR suction valve BNHV8812A could spuriously close. If this occurs coincident with a SIS, the Train A RHR pump would be damaged. RWST to RHR suction valve BNHV8812B will not spuriously close as the BNHV8812B control circuit is protected with fire resistive cable 14BNG03BK in fire area A-8.
EF	Essential Service Water System	H, S	All PFSSD functions associated with the Essential Service Water (ESW) system are satisfied. Train B ESW is available to supply cooling water to Auxiliary Feedwater Pump room cooler SGF02B, Train B Component Cooling Water (CCW) Heat Exchanger, CCW B pump room cooler SGL11B, CCP B room cooler SGL12B, RHR B room cooler SGL10B, and Containment Air Coolers SGN01B and SGN01D.
EG	Component Cooling Water System	S	All PFSSD functions associated with the Component Cooling Water (CCW) system are satisfied. Train B CCW is available to provide cooling water to the RHR B heat exchanger, the CCP B oil cooler, the seal water heat exchanger and the RHR pump B seal cooler. Either CCW pumps PEG01B or PEG01D are available. Valve EGHV0015 may not close when swapping to Train B CCW. This is acceptable based on Calculation M-EG-24. CCW flow to all four RCP thermal barriers could be affected as discussed in the BB System comments. CCW to RCP flow indicators EGFI0128 and EGFI0129 could be affected. Valve EGHV0101 could be affected. Valve EGHV0102 is unaffected.
EJ	Residual Heat Removal System	M, H, P	Train A RHR could be affected by a spurious SIS coincident with damage to EJFIS0610 or spurious closure of BNHV8812A, which could cause the Train A RHR pump to start and overheat. Train B RHR system is unaffected by this scenario because EJFIS0611 and BNHV8812B are unaffected by a fire in area A-8. RHR Train B discharge valves EJHCV0607 and EJHV8809B are available. RCS to RHR isolation valve EJHV8701B may have to be manually opened for cold shutdown when operating RHR Train B. Valve EJHV8809A could be affected but valve EJHV8809B is unaffected. RHR system flow diagnostic instrumentation is available using various available temperature indicators.

Table A-8-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-8

System	System Name	PFSSD Function*	Comments
EM	High Pressure Coolant Injection	R, M	A spurious SIS due to two out of three low steamline pressures can occur. The spurious SIS can be terminated by entering EMG E-0. Boron injection tank (BIT) isolation valves EMHV8801A, EMHV8803A and EMHV8803B could be affected. Reactor coolant pump seal injection is available for boration and inventory control. For transition to cold shutdown, valve EMHV8803B may need to be manually opened to provide additional makeup using Train B CCP.
EN	Containment Spray	R, M	Train A containment spray isolation valve ENHV0006 could spuriously open. A spurious CSAS is not credible for a fire in this area and the Train A containment spray pump will not spuriously start. Therefore, spurious opening of ENHV0006 will not result in an actual containment spray.
EP	Safety Injection Accumulators	H	A containment entry may be required to close SI Accumulator injection valves EPHV8808A and EPHV8808C if these valves are unresponsive from the control room. The SI accumulators need to be isolated during cold shutdown, prior to the RCS reaching 1000 psig.
FB	Auxiliary Steam	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-8.
FC	Auxiliary Turbines	R, H, P	The Turbine Driven Auxiliary Feedwater Pump is not available for a fire in area A-8. One cable associated with FCHV0312 and FCHV0313 runs in this area and could cause the valves to close, isolating steam supply to the TDAFP.
GD	ESW Pump House HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-8.
GF	AFW Pump Room Coolers	S	AFW Pump B room cooler is unaffected by a fire in area A-8.
GK	Control Room and Class 1E Switchgear Room Coolers	S	Train B Class 1E switchgear room cooler SGK05B is available.
GL	Auxiliary Building HVAC	S	Train B Auxiliary Building HVAC is available.
GM	Emergency Diesel Generator Room HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-8.

Table A-8-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-8

System	System Name	PFSSD Function*	Comments
GN	Containment Coolers	S	Train A Containment Air Coolers SGN01A and SGN01C may be affected. Train B Containment Air Coolers SGN01B and SGN01D are available. Containment pressure indicators GNPI0934, GNPI0935 and GNPI0936 are available.
JE	Diesel Fuel Oil	S	The Train A EDG Fuel Oil Transfer Pump PJE01A could be affected. The Train B EDG Fuel Oil Transfer Pump PJE01B is unaffected.
KA	Instrument Air	S	Valve KAFV0029 could be affected by a fire in this area. This will have no adverse impact on PFSSD.
KC	Fire Protection	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-8.
KH	Service Gas	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-8.
KJ	Standby Diesel Engine	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-8.
MA	Main Generation	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-8.
MR	Startup Transformer	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-8.
NB	4.16 kV System	S	The PFSSD Support function associated with the 4.16 kV system is satisfied. Offsite and onsite power to NB02 is unaffected. Offsite and onsite power to NB01 could be lost.
NE	Standby Diesel Generator	S	The Train A EDG may not be available. The Train B EDG is unaffected.
NF	Load Shed and Emergency Load Sequencing	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-8.
NG	480V Load Centers and MCCs	S	Train B MCCs NG02B, NG02T and NG04T are not affected by a fire in area A-8.
NK	125VDC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-8.
NN	120VAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-8.
PA	13.8kV	S	Breakers PA0105, PA0106 and PA0206 could be affected by a fire in area A-8. Redundant capability is available.
PB	4.16kV	H, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-8.

Table A-8-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-8

System	System Name	PFSSD Function*	Comments
PG	480V Load Centers and MCCs	S	Load centers PG11, PG12, PG13 and PG19 may be lost. Redundant capability is unaffected.
PK	125VDC	S	Battery charger PK22 may be lost. Redundant power feed to the PK02 bus is available from 125 VDC battery group PK12. Class 1E 480 VAC power to inverter PK24 could be disrupted. Battery rack PK14 is unaffected and is available to supply short-term 125 VDC power to bus PK04.
PL	Local Instrument Panels	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-8.
PN	120VAC	S	The normal and alternate power feeds to PN07 are affected. PN08 remains available to supply power to its respective PFSSD loads.
QB	Standby AC Lighting	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-8.
QD	Emergency Lighting	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-8.
RL	Control Room MCB	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-8.
RP	Miscellaneous Control Panels	R, M, H, P, S	Auxiliary relay rack RP209 may be lost. Redundant relay rack RP210 is available.
SA	ESFAS	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-8.
SB	Reactor Protection System	R, S	SB102A may be lost. SB102B is unaffected.
SC	Reactor Instrumentation	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-8.
SE	Ex-Core Neutron Monitoring	R, P	Source range monitoring is available for a fire in area A-8 using SR monitors SENE0031, SENE0032, and SENY061A/B.
SY	Switchyard	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-8.
UU	Supervisory System	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-8.

3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD

This section describes operator actions that may need to be performed inside or outside the control room to achieve and maintain hot standby if a fire occurs in area A-8. This section also describes cold shutdown repairs that may need to be made to achieve and maintain cold shutdown conditions. Operator actions are generally described in OFN KC-016.

3.1 ACTIONS OUTSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

Operator Manual Actions (OMAs) are those actions outside the main control room required to achieve and maintain hot standby. OMAs are identified in E-1F9900 and were determined from thermal hydraulic analysis WCNOC-CP-002. Applicable E-1F9900 OMAs are annotated herein. All other actions outside the control room are desirable for plant control in support of hot standby but not required to achieve and maintain hot standby.

3.1.1 Steam Generator Atmospheric Relief Valves

A fire in the North corridor (Rooms 1301 and 1320) can cause the spurious operation or maloperation of steam generator ARVs ABPV0001 and/or ABPV0003. The Train A Motor Driven Auxiliary Feedwater Pump (MDAFP) and the Turbine Driven Auxiliary Feedwater Pump may be affected by the fire. The Train B MDAFP is available to supply steam generators A and D. Calculation WCNOC-CP-002 shows that no manual operator actions outside the control room are required in this case. Operators should continue operating the Train B MDAFP and supply auxiliary feedwater to steam generators A and D and operate ARV ABPV0004 as necessary.

If it is desired to close the failed ARVs, Operators can close ABPV0001 by isolating air and nitrogen to the valve using KAV1435 (air) and KAV1364 (nitrogen) then venting air from the regulator. Operators can close ABPV0003 using local controller ABFHC0003. These components are located in fire area A-23 and emergency lighting is available.

3.2 ACTIONS INSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

3.2.1 Pressurizer PORV/Block Valve

Pressurizer PORV BBPCV0455A could spuriously open and block valve BBHV8000A may not close. If this occurs, operators can close the PORV by placing BBHIS0455A in the CLOSE position. Pressurizer pressure indication is available using BBPI0456, BBPI0457 and BBPI0458 located on RL002.

3.2.2 Main Steam Isolation Valves (MSIVs) and MSIV Bypass Valves

Cables for hand switch ABHS0080 may be damaged by the fire. Cables for redundant hand switch ABHS0079 are unaffected. Use ABHS0079 to close the MSIVs and MSIV bypass valves.

3.2.3 Main Feedwater Isolation Valves (MFIVs)

Cables for hand switch AEHS0080 may be damaged. Cables for redundant hand switch AEHS0081 are unaffected. Use AEHS0081 to close the MFIVs.

3.2.4 RWST to Charging Pump B Suction

Cables associated with valve BNLCV0112D may be damaged by the fire. Automatic swapover due to low-low level in the VCT will occur since BGLT0185 is protected. If one or both VCT outlet valves close without the VCT being at the low-low level setpoint, automatic swapover will

not occur. In this case operators can open BNLCV0112E using BNHIS0112E on RL001 to provide a suction path from the RWST to Train B CCP.

3.2.5 Charging to Regenerative Heat Exchanger

A fire in area A-8 could prevent closure of valve BGHV8106 using BGHIS8106. Valve BGHV8105 can be closed using BGHIS8105 located on RL001 in the main control room.

3.2.6 Spurious SI

If a fire-induced spurious SI signal is received, enter EMG E-0 and terminate the SI. Pump PBG05B should be stopped immediately using hand switch BGHIS0002A because of the possibility of hydrogen gas binding. The pump can be re-started after action 3.1.3 is completed. Indication of Train A and Train B SI pump operation is available using the indicating lights on EMHIS0004 (Train A pump) and EMHIS0005 (Train B pump).

3.2.7 Component Cooling Water

Train A CCW could be affected by a fire in this area. If this occurs, swap to Train B CCW using normal operating procedures if Train B CCW is not already running.

3.2.8 Reactor Coolant Pump Seal Cooling

Thermal barrier cooling could be affected due to spurious closure of BBHV0013, BBHV0014, BBHV0015 and/or BBHV0016. RCP seal injection could temporarily be disrupted until the Train B CCP is lined up. To restore RCP seal injection, operators should line up the Train B CCP after isolating the VCT. Operators should closely monitor RCP seal total flow indicator BGFI0215B and take prompt action to restore seal injection if flow is lost.

3.2.9 Volume Control Tank (VCT) Isolation

To ensure VCT isolation, close both VCT isolation valves BGLCV0112B and BGLCV0112C using hand switches BGHIS0112B and BGLCV0112C in the control room. This action ensures at least one valve will close. VCT level indication is available using BGLI0185.

3.3 ACTIONS TO ACHIEVE AND MAINTAIN COLD SHUTDOWN

3.3.1 RHR

If operating the Train A RHR system for cold shutdown, it may be necessary to manually align EJHCV0606 due to possible damage to the associated circuits. Train B RHR discharge valve EJHCV0607 is unaffected by a fire in area A-8.

Depending on the RHR Train used for shutdown cooling, either valves BBPV8702A and EJHV8701A or valves BBPV8702B and EJHV8701B may need to be manually opened, or a cold shutdown repair made, when initiating RHR for cold shutdown.

3.3.2 SI Accumulators

A fire in area A-8 may require a containment entry to close SI Accumulator injection valves EPHV8808A and EPHV8808C if these valves are unresponsive from the control room. The SI accumulators need to be isolated during cold shutdown, prior to the RCS reaching 1000 psig.

3.3.3 Steam Generator Atmospheric Relief Valves

In order to regain control of ARV ABPV0001 in the control room, it may be necessary to perform a cold shutdown repair. This action will mitigate a spurious hot short on cable

11ABI20EC and transfer control back to ABPIC0001A. It may also be necessary to re-open air and nitrogen supply to the ARV by re-opening KAV1435 (air) and KAV1364 (nitrogen), if these valves were previously closed.

3.3.4 Boron Injection Tank Flowpath

It may be necessary to manually open EMHV8803B in order to establish a BIT flowpath using Train B CCP.

4.0 CONCLUSION

With some exceptions, redundant Post-Fire Safe Shutdown capability exists if a severe fire occurs in this area. For those exceptions, feasible manual actions are available and are unaffected by the fire. Manual actions are documented in Section 3.0.

5.0 DETAILED ANALYSIS

This section describes the detailed component-by-component and cable-by-cable analysis for a fire in area A-8.

5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA A-8

PFSSD components (S. in E-15000) located in fire area A-8 are shown in Table A-8-3. An evaluation of each component and associated cables is provided in the sections that follow. The applicable evaluation section is listed in Table A-8-3.

Table A-8-3
PFSSD Equipment Located in Fire Area A-8

Room #	PFSSD Equipment	Description	Evaluation Section	Comments
1301	EJFIS0610	RHR Pump A Mini Flow Indicating Switch	5.1.1

1320	EGFT0129	CCW to RCPs Flow Transmitter	5.2.19	

5.1.1 RHR Pumps A and B Mini-Flow

The RHR pump mini-flow path is required when the RHR system is operating to prevent damage to the RHR pump during low-flow in the RHR system. The RHR mini-flow path consists of the mini-flow valve, flow indicating switch, pipe and fittings. With flow at or below the desired setting, the flow indicating switch low-flow contacts close, sending an open signal to the mini-flow valve and thus allowing re-circulating flow through the mini-flow path. When flow exceeds the desired setting, the flow indicating switch high-flow contacts close, sending a close signal to the mini-flow valve and thus preventing re-circulating flow through the mini-flow path.

Mini-flow indicating switch EJFIS0610 and control cable associated with Train A RHR mini flow valve EJFCV0610 is located in Fire Area A-8 (Room 1301). Power and control cables associated with Train A mini-flow valve EJFCV0610 are located in Fire Area A-8. Damage to the switches or cables could prevent the Train A RHR mini-flow sub-system from performing its intended function. The Train B RHR mini-flow sub-system is unaffected by a fire in this area.

Based on the above discussion, damage to the Train A RHR mini-flow indicating switch, valve and/or associated circuits will not prevent the safe shutdown of the plant after a fire. The Train B RHR mini-flow system is unaffected by a fire in area A-8.

5.1.2 480V Non-Class 1E Electrical Distribution (PG19)

480V Non-Class 1E load center (PG19) supplies power to Motor Control Center (MCC) PG19G, which supplies power to the following PFSSD loads:

1. MCB Misc. Power Circuits (RL023)
2. Instrument Bus Transformer - Alt. Feed (XPN07D)

Several cables associated with PG19 are run in this area. Damage to these cables could disrupt power to PG19 and associated PFSSD equipment. The following paragraphs discuss the PFSSD impact on loss of PG19.

Load center PG19 transformer XPG19 steps 13.8kV down to 480 VAC prior to entering PG19. A fire in area A-8 could result in a loss of PG19 and associated PFSSD loads.

Loss of power to PG19 will cause a loss of power to PG19GCR217, which supplies MCB RL023/RL024 miscellaneous circuits. Several loads are supplied by this power supply, but only seven are PFSSD components. These are ABLV0051, ABLV0053, ABFV0023, ABFV0025, ABFV0027, ABFV0029 and ABHIS0032 which are components downstream of the Main Steam Isolation Valves (MSIVs). Loss of power to ABLV0051, ABLV0053, ABFV0023, ABFV0025, ABFV0027 and ABFV0029 will fail the valves open, which is not desired for PFSSD. Loss of power to ABHIS0032 will cause a loss of hand switch indicator lights. However, as described in Section 5.2, a fire in area A-8 does not affect the ability to close the MSIVs and MSIV bypass valves using hand switch ABHS0079 in the main control room. Therefore, the MSIV downstream components can fail in an undesired position without any consequence on PFSSD.

Loss of power to PG19 will cause a loss of power to PG19GFR3, which supplies power to XPN07D (Instrument Bus Transformer - Alt. Feed to PN07). The normal source of power to PN07 is from XPN07A. Cable 11PNG01AE runs from NG001BEF4 to NG001ABF1, through area A-8. Damage to this cable could cause a loss of power to XPN07A. Therefore, both the normal and alternate power feeds to PN07 could be lost if a fire occurs in area A-8.

The PFSSD function of panel PN07 is to supply power from PN0736 to Train A RHR Heat Exchanger Discharge Control Valve EJHCV0606 via RL017/RL018. Panel PN07 also supplies power from PN0738 to temperature recorder BBTR0423 via RL021/RL022. Loss of power to PN07 will disrupt power to these PFSSD components.

Panel PN08 is unaffected by a fire in area A-8 and is available to supply power to redundant Train B components. Therefore, loss of power to PN07 will have no adverse impact on PFSSD.

Valve EJHCV0606 is a normally open/fail open valve, so loss of power will fail the valve in the open position, which is the desired PFSSD state. In the event that EJHCV0606 control is lost, redundant Train B RHR heat exchanger discharge control valve EJHCV0607 is available and is unaffected by a fire in area A-8. In addition, a cold shutdown repair or manual action can be performed to restore the required valve to its desired position.

Based on the above discussion, loss of load center PG19 will have no adverse impact on PFSSD.

5.1.3 Volume Control Tank (VCT) Outlet Valves to Charging Pumps

The reactivity control and reactor coolant makeup functions of PFSSD require charging flow to the RCP seals taking suction from the Refueling Water Storage Tank (RWST). To ensure adequate suction pressure to the operating charging pump, either VCT outlet valve BGLCV0112B or BGLCV0112C needs to be closed. This will prevent hydrogen cover gas intrusion into the suction of the charging pump and prevent possible cavitation and failure of the pump. However, the valves need to remain open as long as the VCT is the only suction source to the charging pump. Inadvertent closure of either valve can cause damage to the operating charging pump.

The VCT provides surge protection and a suction source to the Chemical and Volume Control System (CVCS). Hydrogen cover gas is used in the VCT at a pressure of 30 – 35 psig to scavenge oxygen from the water. If the VCT remains the suction source for charging with insufficient or no makeup to the VCT, (see sections 5.1.4 and 5.2.21 for discussions on the VCT level transmitters and the normal letdown valves) the VCT could empty and H_2 could be introduced into the charging pump suction. This will damage the operating charging pump and make it inoperable. Inadvertent closure of either VCT outlet valve with no alternate suction source will damage the operating charging pump due to inadequate suction head. Assumption 3-A-22 in Calculation XX-E-013 states: “Systems and components are in their normal operating position or status prior to the fire....” The Normal Charging Pump is the normally operated pump in the CVCS. Therefore, if either VCT outlet valve inadvertently closes due to the fire, or the valves remain open such that Hydrogen is introduced into the charging pump suction header, both Trains of Centrifugal Charging Pumps (CCPs) will remain available, provided the fire does not cause damage to circuits associated with the CCPs. However, since the power cables for the NCP pass through fire area A-8 the NCP could trip. If this occurs, operations would not start another charging pump until suction lineup from the RWST has been confirmed.

Both VCT outlet valves (BGLCV0112B and BGLCV0112C) are located in fire area A-8 (Room 1318) within a few feet of each other. Power and control cables associated with BGLCV0112B are run in rooms 1301, 1313 and 1318. Power and control cables associated with BGLCV0112C are run in rooms 1318 and 1320. Cables for BGLCV0112C located in room 1320 are wrapped with a 1-hour fire rated material which will prevent damage to the cables in

the event of a fire in room 1320. Damage to cables in the remaining rooms could prevent closure of either valve and, in the absence of makeup to the VCT, could cause draindown of the VCT and possible hydrogen intrusion into the pump suction.

License Amendment 205 was issued on August 23, 2013 and approves the configuration of the VCT outlet valves, given the fire protection features present in fire area A-8. The fire protection features provide reasonable assurance that at least one VCT outlet valve will close upon a signal from the control room hand switches. Level indication is available in the control room using BGLI0185, which is protected from a fire in area A-8. Indication of a fire in area A-8 along with a reducing level in the VCT would prompt operators to isolate the VCT by actuating both hand switches BGHIS0112B and BGHIS0112C. These actions provide reasonable assurance that at least one VCT outlet valve will close and prevent hydrogen from entering the charging pump suction.

Based on the above discussion, a fire in area A-8 will not impact the ability to isolate VCT to charging pumps. If one of the VCT valves spuriously closes prior to lining up the RWST supply, then the Normal Charging Pump could be damaged due to loss of suction, but the train B CCP will be available.

5.1.4 VCT Level Indication

Volume Control Tank (VCT) level transmitter BGLT0112 is included in the PFSSD design because it initiates refueling water sequence upon sensing low-low water level in the VCT. The transmitter also provides VCT level indication in the control room. BGLT0112 uses sealed capillary tubing as instrument lines. Sealed capillary tubing can be affected by the heat generated by a fire. Therefore, the instrument tubing for this instrument is also considered to be damaged by a fire.

Damage to the VCT level transmitter, the instrument tubing or associated circuits could cause one or more of the following to occur:

1. Loss of VCT level indication in the Control Room
2. False low-low level in the VCT, initiating swap-over to the RWST
3. Inability to sense low-low level in the VCT, resulting in a loss of suction to the CCPs.

Redundant VCT level transmitter BGLT0185 is located in a separate fire area and is unaffected by a fire in area A-8. However, cable 14BGI51DA is located in fire area A-8 but has been protected with a 1-hour fire rated electrical raceway fire barrier system (ERFBS). The ERFBS along with automatic fire suppression and detection provides reasonable assurance that the cable will be unaffected by a fire in area A-8 and meets Wolf Creek commitments to 10 CFR 50, Appendix R. Therefore, VCT level indication remains available in the event of a fire in this area.

A sporadic low-low VCT level signal caused by damage to BGLT0112 and/or associated cable will start the RWST sequence, which is the desired PFSSD lineup. Therefore, this will not prevent PFSSD in the event of a fire in this area.

If transmitter BGLT0112 and associated cable is damaged, redundant VCT level transmitter BGLT0185 remains available to initiate RWST sequence upon low-low level in the VCT.

Based on the above discussion, damage to BGLT0112 and/or associated circuits will not prevent safe shutdown in the event of a fire in area A-8.

References: E-15000, XX-E-013, E-13BG12, E-13BG12A, E-13BG51, E-1F9102, E-1F9302, E-1R1323B, E-1R1323D, E-1R1323E, M-12BG03

5.1.5 Reactor Coolant System (RCS) Pressure Indication

The PFSSD design requires RCS pressure indication to be available. RCS pressure indication is provided in the control room using BBPI0405 or BBPI0406 on RL022. Pressure transmitter BBPT0405 is located in fire area A-8 (Room 1320) and could be damaged by a fire in this area. Cables associated with BBPT0405 (11BBI15EA and 11BBI15EB) are also run through fire area A-8 and could be damaged by a fire.

Redundant RCS pressure transmitter BBPT0406 is located in Fire Area A-1 (Room 1202) and is unaffected by a fire in area A-8. Cables associated with BBPT0406 do not run through area A-8. Therefore, RCS pressure indication is available if a fire occurs in area A-8 using BBPI0406.

Based on the above discussion, RCS pressure indication is available in the control room using BBPI0406 if a fire occurs in area A-8.

References: E-15000, XX-E-013, E-13BB15, E-13BB16, E-1F9201, E-1R1343A, M-12BB04

5.1.6 Auxiliary Relay Rack RP209

Auxiliary relay rack RP209 is located in Fire Area A-8 (Room 1320) and houses the following PFSSD relays:

1. 3XBM13 - Steam Generator Blowdown to Blowdown Flash Tank Isolation Valve BMHV0001
2. 3XBM14 - Steam Generator Blowdown to Blowdown Flash Tank Isolation Valve BMHV0002
3. 3XBM15 - Steam Generator Blowdown to Blowdown Flash Tank Isolation Valve BMHV0003
4. 3XBM16 - Steam Generator Blowdown to Blowdown Flash Tank Isolation Valve BMHV0004
5. 94XAB5 - MSIV Bypass Valve Auxiliary Relay

Redundant relay rack RP210 is located in a different fire area (A-16) and is unaffected by a fire in area A-8.

Power to RP209 is supplied from NK5113 via cable 11RPK09CA. This cable (11RPK09CA) runs through area A-8 and could be damaged by a fire, resulting in a loss of power to RP209. Loss of power to the relays will result in a fail closed position on the associated valves, which is the desired PFSSD position.

Auxiliary relays 3XBM13, 3XBM14, 3XBM15 and 3XBM16 are associated with one of the three solenoid circuits. These relays are part of the seal-in circuit that closes the seal-in contact when the BMHV valve is open (relay de-energized) and opens the seal-in contact when the BMHV valve is closed (relay energized). In order to re-open the BMHV valves, an operator needs to operate the associated hand indicating switch on the BM157 panel, provided the remaining two solenoids are energized. Damage or loss of power to these relays will not prevent safe shutdown due to redundant panel RP210 located in a different fire area.

Auxiliary relay 94XAB5 is associated with the separation group 1 MSIV bypass valve circuit. With the auxiliary relay energized, one of the two solenoid valves associated with each MSIV bypass valve is energized. With the auxiliary relay de-energized, the solenoid valve is de-

energized and the bypass valve closes. Damage or loss of power to this relay will not prevent safe shutdown due to redundant panel RP210 located in a different fire area.

Cables associated with the steam generator blowdown valves and the MSIV bypass valves are listed in Table A-8-4 and are evaluated in this section.

PFSSD requires that the MSIV bypass valves be closed to control cooldown. Cables 11ABK23AA, 11ABK23AB, 11ABK23AC, 11ABK23AD, 11ABK23AF and 11ABK23AG are associated with MSIV bypass valves ABHV0012, ABHV0015, ABHV0018 and ABHV0021. The bypass valves are normally closed, which is the desired PFSSD position. In order for the valves to spuriously open, both solenoids on the air line need to be energized. An external cable hot short on cables 11ABK23AA, 11ABK23AB, 11ABK23AC, 11ABK23AD or 11ABK23AG could energize one or more of the solenoids but the Train B solenoids are unaffected by a fire in area A-8. In addition, hand switch ABHS0079 is available to ensure the bypass valves are closed. Therefore, a fire in area A-8 will not affect the ability to isolate the MSIV bypass valves.

Cable 11ABK23AE is associated with steam line isolation signal relay K627. Upon receipt of a steam line isolation signal, the relay contact opens and the bypass valves close. An open circuit in one of the two conductors will produce the same result as a steam line isolation signal, which is desired for PFSSD. A hot short between the conductors will bypass the contact and prevent a steam line isolation signal from closing the valves. As stated earlier, redundant means are available to ensure the MSIV bypass valves are closed using separation group 4 solenoid valves and fast-close hand switch ABHS0079.

An open or hot short on cables 11BMK06EA, 11BMK06FA, 11BMK06GA or 11BMK06HA will have no adverse effect on the BMHV valves.

The reactivity control function requires the steam generator blowdown to blowdown flash tank valves (BMHV0001, BMHV0002, BMHV0003, and BMHV0004) be closed to prevent reactivity addition from uncontrolled cooldown. Cables 15BMK06AB, 15BMK06AC, 15BMK06BB, 15BMK06BC, 15BMK06CB, 15BMK06CC, 15BMK06DB and 15BMK06DC are associated with the BM157 panel mounted hand switches for each of the BMHV valves. Cable 15BMK16AA is a DC power feed for BM157. Damage to these cables could impact the ability to close the valves from BM157 in the Radwaste Control Room. However, the normal means of closing these valves using the RL024 mounted hand switches in the Main Control Room remains available. Therefore, a fire in area A-8 will not prevent the closure of valves BMHV0001, BMHV0002, BMHV0003, and BMHV0004.

Based on the above discussion, a fire in area A-8 that damages RP209 and associated PFSSD relays and cables will not prevent safe shutdown of the plant due to the availability of redundant capability located in a different fire area.

References: E-15000, XX-E-013, E-093-00048, E-093-00026, E-13AB23A, E-13AB23B, E-13AB26, E-13BM06A, E-13BM06C, E-13BM06D, E-13RP09, E-1F9101, M-12AB02, M-12BM01

5.1.7 Reverse Isolation Relay Rack RP330

Relay rack RP330 houses PFSSD relays 3XEG20 and 95XGK07. Other relays located in this panel are not credited in the PFSSD design except that relays 27XQB1 and 27XQB2 are associated with the control room emergency lights are evaluated in Section 5.2.27.

Relay 3XEG20 is associated with Train A CCW heat exchanger temperature control valve EGTV0029. EGTV0029 is an air operated valve using solenoid valve EGTY0029A to control air flow into the valve. With solenoid valve EGTY0029A energized (normal state), valve

EGTV0029 is automatically modulated to maintain required CCW heat exchanger outlet temperature. Loss of power to the solenoid will fail valve EGTV0029 closed, which is the desired PFSSD position.

Cables 11EGK16AA and 11EGK16AC are associated with valve EGTV0029. Damage to either of these cables will close the valve or allow it to modulate. Both scenarios are acceptable for PFSSD.

Cable 15RPK09NA is the power cable from PK5126 to separation group 5 relays in RP330 and runs through fire area A-8. Damage to this cable could cause a loss of power to relay 95XGK07 and shut down SGK05A.

Relay 95XGK07 is the fire signal isolation relay for Class 1E Electrical Equipment A/C unit SGK05A. This relay controls automatic shutdown of SGK05A prior to Halon actuation in the event of a fire in the Train A Class 1E switchgear rooms (Rooms 3301, 3408 and 3414). Damage to this relay could cause the SGK05A A/C unit to shut down.

Cables 11GKG13AE and 11GKG13AF are control cables for SGK05A and run to relay panel RP330 in area A-8. Damage to these cables could prevent automatic operation of SGK05A.

Cable 15GKK31CA is a control cable for fire signal isolation of SGK05A and runs to panel RP330 in area A-8. An open in cable 15GKK31CA will initiate a false fire isolation signal and shut down SGK05A.

Redundant Train B relay rack RP331 is located in fire area A-16 and is unaffected by a fire in area A-8. Relay rack RP331 houses relay 3XEG08 associated with the Train B CCW heat exchanger temperature control valve EGTV0030. Cables associated with valve EGTV0030 are not run in fire area A-8. Therefore, Train B CCW heat exchanger temperature control valve EGTV0030 is unaffected by a fire in area A-8.

Relay rack RP331 also houses relay 95XGK08 associated with the Train B Class 1E Electrical Equipment A/C unit SGK05B. Cables associated with SGK05B are not run in area A-8. Therefore, SGK05B will remain available to supply cooling to the Train B Class 1E electrical equipment.

Based on the above discussion, a fire in area A-8 that damages RP330 and associated PFSSD relays and cables will not prevent safe shutdown of the plant due to the availability of redundant capability located in a different fire area.

5.1.8 Auxiliary Relay Rack RP332

RP332 is an Auxiliary Relay Rack located in area A-8 room 1320. This relay rack houses PFSSD relay 62TDENB01, Degraded Voltage Trip Block Relay. PFSSD requires that either this relay or relay K617 in panel SB029C be available to ensure off-site power is available to NB01. Panel SB029C is located in fire area C-27 (room 3605) and is unaffected by a fire in area A-16.

Cable 11NBB12AD is a control cable that runs from NB0112 to RP332 and provides control power to relay 62TDENB01. This cable runs through area A-8 and could be damaged by a fire. Damage to this cable could cause a spurious degraded voltage signal which could result in a loss of off-site power to bus NB01.

Based on Calculation XX-E-013, Appendix 2, off-site power is available using NB02 for a fire in area A-8. Therefore, loss of off-site power to NB01 will not impact the ability to achieve and maintain PFSSD.

References: E-15000, XX-E-013, E-1F9425, E-13NB12

5.1.9 RCP Seal Injection

Valves BGV0101 and BGV0105 are manual valves used to isolate RCP seal injection. At least one of these valves is normally open and will remain open in the event of a fire. There are no electrical cables or components associated with these valves. The valves were added to the PFSSD component list in change package 12081 to provide a reliable means to isolate seal injection in the event of a fire in the control room and subsequent shutdown per OFN RP-017.

5.2.1 Steam Generator Atmospheric Relief Valves

PFSSD requires at least two steam generator atmospheric relief valves (ARV) be controlled and the other two closed. The ARVs are pneumatically operated using air from the compressed air system (KA) or nitrogen from the nitrogen accumulators. The valves open by pneumatic pressure and close by spring action. The valves are automatically controlled by a pressure input signal from a transmitter installed on the outlet side of the steam generator. Alternatively, each valve can be controlled manually from the control room or the auxiliary shutdown panel by placing the pressure indicating controller (PIC) in manual.

A fire in area A-8 could damage cables and equipment associated with both the Train A Motor Driven Auxiliary Feedwater Pump (MDAFP) and the Turbine Driven Auxiliary Feedwater Pump (TDAFP). The Train B MDAFP is unaffected by a fire in area A-8 and will be used to supply auxiliary feedwater to Steam Generators A and D. Therefore, it will be necessary to control steam release using ARVs on steam generators A (ABPV0001) and D (ABPV0004) and isolate the ARVs for steam generators B (ABPV0002) and C (ABPV0003).

Cable 11ABI20EA is the instrument cable for pressure transmitter ABPT0001. Damage to this cable could prevent ARV ABPV0001 on SG A from operating automatically. If this occurs, operators can override the pressure transmitter input signal and operate the ARV manually using the pressure indicating controller (ABPIC0001A) in the control room. However, as discussed below, other cable damage due to the same fire could prevent operating ABPV0001 from the control room.

Cables 11ABI20EC and 11ABI20ED are associated with ARV ABPV0001 pressure indicating controller at remote shutdown panel RP118A. Cable 11ABI20EC is associated with hand switch ABHS0001 located on RP118A, and is used to transfer control of ABPV0001 to ABPIC0001B on RP118A. Cable 11ABI20ED connects ABPIC0001B on RP118A to instrument rack RP053AC. A fire-induced short circuit in cable 11ABI20EC could cause a spurious transfer of control to ABPIC0001B on RP118A, which would prevent manual operation of ARV ABPV0001 from the control room. In addition, concurrent damage to cable 11ABI20ED could cause a loss of control of ABPV0001 from RP118A. Therefore, control of ARV ABPV0001, using any available means, could be lost. To prevent uncontrolled cooldown due to a spuriously opened ARV ABPV0001, operators may need to fail it closed by isolating air and nitrogen to the valve using KAV1435 (air) and KAV1364 (nitrogen), then venting air from the regulator. These valves are located in area A-23 and emergency lighting is available.

Cable 13ABI20GA is the instrument cable for pressure transmitter ABPT0003. Damage to this cable could prevent ARV ABPV0003 from operating automatically. If this occurs, operators can override the pressure transmitter input signal and operate the ARV manually using the pressure indicating controller (ABPIC0003A) in the control room.

Cables 13ABI20GC and 13ABI20GD are associated with ARV ABPV0003 pressure indicating controller at remote shutdown panel RP118A. Cable 13ABI20GC is associated with hand switch ABHS0003 located on RP118A, and is used to transfer control of ABPV0003 to ABPIC0003B on RP118A. Cable 13ABI20GD connects ABPIC0003B on RP118A to instrument rack RP053DC. A fire-induced short circuit in cable 13ABI20GC could cause a spurious transfer of control to ABPIC0003B on RP118A, which would prevent manual operation of ARV ABPV0003 from the control room. In addition, concurrent damage to cable 13ABI20GD could cause the ARV to spuriously open. If this occurs, local controller ABFHC0003, in room 1509, can be used to isolate the valve. Emergency lighting is available.

Cable 13ABI20GE is associated with ABPV0003 electro-pneumatic transducer ABPY0003. Damage to this cable could result in the inability of ABPV0003 to operate automatically or manually from the control room or remote shutdown panel. However, as discussed previously,

ABPV0003 can be isolated using ABFHC0003 in room 1509 or by closing associated air and nitrogen supply lines.

Cables associated with ARVs ABPV0002 (SG B) and ABPV0004 (SG D) do not run through fire area A-8. Therefore, ABPV0002 can be isolated and ABPV0004 can be controlled from the control room if a fire occurs in area A-8. Calculation WCNOC-CP-002 demonstrates the ability to cool down with all four steam generator ARVs closed and with auxiliary feedwater supplying two steam generators. In this case, the SG safety valves open to release steam. This bounds the case where one of the ARVs that is receiving AFW is available to be controlled from the control room. Calculation WCNOC-CP-002 also evaluates the case where two ARVs spuriously open and only one of the ARVs can receive AFW. In this case, the steam generator not receiving AFW will boil dry due to the open safety valves while heat transfer in the other steam generator can be maintained using AFW and the available ARV.

Based on the above discussion and the results of Calculation WCNOC-CP-002, there is reasonable assurance that damage to the steam generator ARVs as described above will not adversely impact the ability to achieve and maintain safe shutdown if a fire occurs in area A-8.

Up to three ARVs can fail closed or open without impacting ability to achieve and maintain hot standby according to thermal hydraulic analysis WCNOC-CP-002. With at least one ARV unaffected, no E-1F9900 OMA is required to address ARV closure or control. Reference Attachment 4, MSO Evaluation Scenario ID PWROG 23.

5.2.2 Safety Injection and Containment Spray

Calculation XX-E-013, Appendix 1 (PFSSD Support Section) provides a detailed discussion about the potential PFSSD impact of a spurious safety injection signal (SIS) and spurious containment spray actuation signal (CSAS). This section discusses the specific PFSSD impact if a fire occurs in this area.

Cables associated with steam line pressure transmitters ABPT0514, ABPT0524, ABPT0526, ABPT0534, ABPT0536 and ABPT0544 are run in area A-8. Consequently, the two out of three logic for low steam line pressure initiation of SIS can be satisfied on steam generators B and C if a fire occurs in area A-8.

Cables associated with BBPT0455 are run in area A-8. Cables associated with BBPT0456, BBPT0457 and BBPT0458 are not run in area A-8. Consequently, a fire in area A-8 cannot cause a spurious SIS due to low pressurizer pressure.

Containment pressure transmitter GNPT0937 and associated cables are located in area A-8. Cables for pressure transmitters GNPT0934, GNPT0935 and GNPT0936 are not run in area A-8. Consequently, a spurious CSAS due to high containment pressure cannot occur if a fire occurs in area A-8.

Control cables associated with Train A containment spray isolation valve ENHV0006 are run in fire area A-8. Damage to these cables could cause the valve to spuriously open. However, as stated in the previous paragraph, a spurious CSAS is not credible if a fire occurs in this area. In addition, control cables associated with the Train A containment spray pump are located outside fire area A-8. Therefore, the Train A containment spray pump will not spuriously start if a fire occurs in area A-8.

A spurious SIS starts the charging sequence which starts the CCPs and opens the BIT flowpath valves. For a fire in this area, three of the BIT flowpath valves (EMHV8801A, EMHV8803A and EMHV8803B) could be affected. These valves could remain closed if affected by a fire concurrent with the SIS, which would prevent CCP discharge flow through this path. RWST valve BNLCV0112E is unaffected and would open on a SIS, providing an assured suction source to the CCPs. The Train A CCP mini flow valve could be affected but the Train B CCP miniflow valve is unaffected. Train B CCW flow to the seal water heat exchanger is unaffected, and will ensure cooling of the recirc flow and RCP seal return. Also, Train B CCW flow is available for the Train B CCP oil cooler. Therefore, the Train B charging pump will not be affected by a spurious SIS caused by a fire in this area.

Both VCT outlet valves are located in this area. License Amendment 205 provides reasonable assurance that at least one of the VCT outlet valves will close in response to the SIS and RWST valves opening. See Section 5.1.3.

A start of the credited CCW system (Train B) will not adversely impact the system. The Train B ESW system is unaffected and will start on a spurious SIS, providing necessary cooling water to the CCW heat exchanger.

A start of the AFW pumps will not adversely impact PFSSD. The Train B AFW pump is credited for a fire in this area. Suction from the CST to the Train B AFW pump is unaffected. Discharge flow will either return to the CST or flow to the steam generators through the discharge control valves. Therefore, the Train B AFW pump is unaffected by a spurious SIS caused by a fire in this area.

A start of the RHR pumps due to a spurious SIS could damage both RHR pumps. A spurious low RWST level signal is not credible if a fire occurs in this area. However, cables 11BNG03AE (BNHV8812A) and 14BNG03BK (BNHV8812B) are run in this area. Damage to the 11BNG03AE cable could cause BNHV8812A to close. If this occurs with the A RHR pump running, then the A RHR pump would be damaged. Cable 14BNG03BK for the B RHR valve BNHV8812B is a fire resistive control cable and will prevent spurious operation of BNHV8812B. Therefore, the B RHR pump would not be damaged.

Based on the above discussion, a fire in area A-8 could cause a spurious SIS due to low steamline pressure. The spurious SIS will not cause damage to credited hot standby equipment. Train A of RHR could be affected but Train B is unaffected. Therefore, PFSSD hot standby and cold shutdown are assured.

5.2.3 Steam Generator Main Steam Isolation Valves (MSIVs)

PFSSD requires the MSIVs be closed to prevent reactivity addition due to uncontrolled cooldown. The MSIVs are closed from the control room using all close hand switches ABHS0079 or ABHS0080.

Each MSIV is designed to utilize system fluid (main steam) as the motive force to open and close. The valve actuation (open or close) is accomplished through positioning a series of six electric solenoid pilot valves to either direct the system fluid to the Upper Piston Chamber (UPC) and/or the Lower Piston Chamber (LPC), or vent either or both piston chambers. The six solenoid pilot valves are divided into two trains (3 per train) that are independently powered and controlled. Either train can independently perform the PFSSD function to close the valve and isolate main steam. This is done by actuating either all close hand switch ABHS0079

(separation group 4) or ABHS0080 (separation group 1) to de-energize the associated solenoid valves.
The following table identifies the solenoids and associated control cables for each hand switch.

MSIV	ABHS0079 (Sep Group 4)		ABHS0080 (Sep Group 1)	
	Solenoids	Cable	Solenoids	Cable
ABHV0011	MV2, MV4, MV6	14ABK28BH	MV1, MV3, MV5	11ABK29BH
ABHV0014	MV2, MV4, MV6	14ABK29AH	MV1, MV3, MV5	11ABK28AH
ABHV0017	MV2, MV4, MV6	14ABK28AH	MV1, MV3, MV5	11ABK29AH
ABHV0020	MV2, MV4, MV6	14ABK29BH	MV1, MV3, MV5	11ABK28BH

All 4 cables associated with the 12 separation group 1 solenoid valves are run in area A-8. Cable damage due to a fire will likely result in disruption of power to the solenoids, which will close the valves. The four separation group 4 cables associated with hand switch ABHS0079 are unaffected by a fire in area A-8. Therefore, hand switch ABHS0079 is available to close the four MSIVs.

Based on the above discussion, hand switch ABHS0079 is available to close the MSIVs in the event of a fire in area A-8.

References: E-15000, XX-E-013, E-13AB23A, E-13AB23B, E-13AB26, E-13AB27, E-13AB28, E-13AB29, E-1F9101, M-12AB02

5.2.4 Steam Generator Level Indication

The decay heat removal function for PFSSD requires the use of two RCS loops and two Steam Generators. Steam generator (SG) level indication is required to support this function. A fire in area A-8 uses MDAFP B, which is normally aligned to supply SGs A and D.

Cables 11AEI08BB and 11AEI08CB are associated with SGs B and C level transmitters AELT0529 (NR) and AELT0539 (NR). Damage to these cables due to a fire will not adversely impact PFSSD because SGs A and D are credited for a fire in this area. Furthermore, the remaining level transmitters on SGs B and C are unaffected by a fire in area A-8.

Cable 11AEI08AB, associated with SG A wide range level transmitter AELT0501, and cable 11AEI12AB, associated with SG A narrow range level transmitter AELT0551, run through area A-8. Cables for SG A narrow range level transmitters AELT0517, AELT0518, and AELT0519 run in a different fire area and are unaffected by a fire in this area. Therefore, level indication for SG A is available if a fire occurs in area A-8.

Cable 11AEI12DB, associated with SG D narrow range level transmitter AELT0554, runs through this fire area. Cables for SG D wide range level transmitter AELT0504 and SG D narrow range level transmitters AELT0547, AELT0548, and AELT0549 run in a different fire area and are unaffected by a fire in area A-8. Therefore, level indication for SG D is available if a fire occurs in area A-8.

Based on the above discussion, steam generator A and D level indication is assured if a fire occurs in area A-8.

References: E-15000, XX-E-013, E-1F9203, E-13AE08, M-12AE02

5.2.5 Steam Generator Main Feedwater Isolation Valves

PFSSD requires that either the main feedwater isolation valves (MFIVs) be closed or the main feedwater pumps be stopped to prevent overfilling the steam generators. Flow diversion from auxiliary feedwater (AFW) to the main feedwater system piping is prevented by check valves AEV0420, AEV0421, AEV0422 and AEV0423. Closure of the main feedwater isolation valves is not required to prevent AFW flow diversion.

Each MFIV is designed to utilize system fluid (feedwater) as the motive force to open and close. The valve actuation (open or close) is accomplished through positioning a series of six electric solenoid pilot valves to either direct the system fluid to the Upper Piston Chamber (UPC) and/or the Lower Piston Chamber (LPC), or vent either or both piston chambers. The six solenoid pilot valves are divided into two trains (3 per train) that are independently powered and controlled. Either train can independently perform the PFSSD function to close the valve and isolate main feedwater. This is done by actuating either all close hand switch AEHS0080 (separation group 1) or AEHS0081 (separation group 4) to de-energize the associated solenoid valves.

The following table identifies the solenoids and associated control cables for each hand switch.

MFIV	AEHS0080 (Sep Group 1)		AEHS0081 (Sep Group 4)	
	Solenoids	Cable	Solenoids	Cable
AEFV0039	MV1, MV3, MV5	11AEK16AH	MV2, MV4, MV6	14AEK17AH
AEFV0040	MV1, MV3, MV5	11AEK17AH	MV2, MV4, MV6	14AEK16AH
AEFV0041	MV1, MV3, MV5	11AEK16BH	MV2, MV4, MV6	14AEK17BH
AEFV0042	MV1, MV3, MV5	11AEK17BH	MV2, MV4, MV6	14AEK16BH

All 4 cables associated with the 12 separation group 1 solenoid valves are run in area A-8. Cable damage due to a fire will likely result in disruption of power to the solenoids, which will close the valves. The four separation group 4 cables associated with hand switch AEHS0081 are unaffected by a fire in area A-8. Therefore, hand switch AEHS0081 is available to close the four MFIVs.

Based on the above discussion, MFIV isolation is assured using hand switch AEHS0081.

References: E-15000, XX-E-013, E-13AE14, E-13AE15, E-13AE16, E-13AE17, E-1F9201, M-12AE02

5.2.6 Auxiliary Feedwater

The PFSSD design requires the use of one auxiliary feedwater pump supplying water to at least two steam generators. The turbine driven auxiliary feedwater pump (TDAFP) is normally aligned to supply all four steam generators. The Train A motor driven auxiliary feedwater pump (MDAFP) is aligned to supply steam generators B and C. The Train B MDAFP is aligned to supply steam generators A and D.

The normal source of water to the AFPs is the condensate storage tank (CST). The emergency supply is from the essential service water (ESW) system. For commercial concerns, the CST is the preferred source and contains sufficient volume to supply the entire AFW demand to achieve cold shutdown.

Motor operated valves (MOVs) in the system allow operators to line up the auxiliary feedwater system as required to achieve and maintain safe shutdown. Damage to the MOV circuits due to a fire could prevent operators from lining up the system from the control room.

Several PFSSD cables associated with various components of the auxiliary feedwater system (AL) run through fire area A-8. These cables are identified in Table A-8-4. All cables are associated with Train A (separation group 1). There are no Train B (separation group 4) cables associated with the AFW system running through area A-8.

Damage to the Train A cables listed in Table A-8-4 could prevent operation of Train A MDAFP and the TDAFP. However, Train B MDAFP and associated components are unaffected by a fire in area A-8.

Condensate storage tank pressure transmitters ALPT0037, ALPT0038 and ALPT0039 are included in the PFSSD design because they initiate swapover to ESW upon 2/3 low CST pressure indications. A spurious low CST pressure due to fire damage to cables associated with two of these pressure transmitters will swap the water source to ESW. As stated earlier, this is a commercial concern and should be prevented if possible.

Cables associated with ALPT0037 are run through area A-8. Cables associated with the remaining two pressure transmitters are not run in A-8. Therefore, a swapover to ESW due to spurious low CST pressure is not feasible if a fire occurs in area A-8.

PFSSD is assured for a fire in area A-8 using Train B MDAFP supplying auxiliary feedwater to steam generators A and D.

References: E-15000, XX-E-013, E-13AL01A, E-13AL01B, E-13AL02A, E-13AL02B, E-13AL03A, E-13AL03B, E-13AL04A, E-13AL04B, E-13AL05A, E-13AL05B, E-13FC23, E-13FC24, E-1F9204, M-12AL01

5.2.7 Pressurizer Power Operated Relief Valves and Associated Block Valves

PFSSD requires that either the pressurizer power operated relief valve (PORV) or its associated block valve be closed. Cables associated with PORV BBPCV0455A and associated block valve BBHV8000A are run through area A-8. Cables associated with PORV BBPCV0456A and associated block valve BBHV8000B are not located in area A-8.

A fire in area A-8 could cause PORV BBPCV0455A to spuriously open due to a cable to cable proper polarity hot short. The hot short would need to involve a positive 125 VDC source conductor in contact with conductor 22 in cable 11BBK40AK. This cable is run in cable tray with other 125 VDC sources, so this failure mode is postulated to occur. Therefore, pressurizer PORV BBPCV0455A could spuriously open in the event of a fire in area A-8. In addition, block valve BBHV8000A is also affected by a fire in this area and may not close.

In the event a fire causes BBPCV0455A to open and damages BBHV8000A cables, Operators can close BBPCV0455A by placing hand switch BBHIS0455A, located on RL021, in the close position. Pressurizer level and RCS pressure indication are available to diagnose a failed open PORV using BBLI0460A and BBPI0406, respectively. In addition, pressurizer pressure indication is available using BBPI0456, BBPI0457 and BBPI0458.

An instrument cable (11BBI16KB) associated with pressurizer pressure transmitter BBPT0455 is run in fire area A-8. Damage to this cable could send a spurious high-pressure signal to the pressurizer master controller. However, as discussed in Calculation XX-E-013, Appendix 1, damage to a single pressure channel will not cause the spurious operation of the pressurizer PORVs.

Based on the above discussion, pressurizer PORV BBPCV0455A could spuriously open due to damage to the PORV control cable. Block valve BBHV8000A may not close due to cable damage. If this occurs, the PORV can be closed using hand switch BBHIS0455A in the main control room.

References: E-15000, XX-E-013, E-13BB16, E-13BB39, E-13BB40, E-1F9301, M-12BB02, M-744-00028, OFN KC-016, CR 13079, DCP 12944 DCP 13324.

5.2.8 RCS Hot and Cold Leg Temperature Elements

PFSSD requires RCS hot and cold leg temperature indication on at least one loop to verify flow through the steam generators. The temperature elements used for this purpose are listed in Table A-8-5.

As identified in Table A-8-4, cables associated with RCS temperature elements BBTE0413A, BBTE0423A, BBTE0433B and BBTE0443B are run in area A-8. These cables are run in the same raceway through fire area A-8. A fire could damage these cables and cause temperature indication on these four temperature elements to be unavailable. Consequently, temperature indication on at least one leg on each loop could be lost, which is not in accordance with the PFSSD methodology at Wolf Creek.

Table A-8-5
RCS Hot and Cold Leg Temperature Elements Used for PFSSD

COMPONENT	FUNCTION
BBTE0413A	RCS Hot Leg Temperature Element (WR) Loop 1
BBTE0413B	RCS Cold Leg Temperature Element (WR) Loop 1
BBTE0423A	RCS Hot Leg Temperature Element (WR) Loop 2
BBTE0423B	RCS Cold Leg Temperature Element (WR) Loop 2
BBTE0433A	RCS Hot Leg Temperature Element (WR) Loop 3
BBTE0433B	RCS Cold Leg Temperature Element (WR) Loop 3
BBTE0443A	RCS Hot Leg Temperature Element (WR) Loop 4
BBTE0443B	RCS Cold Leg Temperature Element (WR) Loop 4

EMG ES-04 provides alternate indication that may be used. One of these methods verifies that steam generator pressure is stable or decreasing. S/G “A” and S/G “D” pressure instruments ABPT516 and ABPT546 are unaffected by a fire in A-8 and can be used per EMG ES-04 to verify heat removal in loops 1 and 4.

The configuration is acceptable because, in the event of fire in fire area A-8, cooldown will be performed using RCS loops 1 and 4. RCS wide range hot and cold leg temperature elements (BBTE413B and BBTE443A) as well as ABPT516 and ABPT546 will provide indication.

References: E-15000, XX-E-013, E-1F9201, E-13BB15, M-12AB01, M-12BB01, EMG ES-04

5.2.9 Pressurizer Level Transmitters

PFSSD requires pressurizer level indication to be available. Pressurizer level indication is provided by level transmitters BBLT0459 and BBLT0460. A cable associated with level transmitter BBLT0459 is run in this fire area. Consequently, pressurizer level may not be available on level indicator BBLI0459.

Cables associated with pressurizer level transmitter BBLT0460 do not run through fire area A-8. Therefore, level indication is available using level indicator BBLI0460.

References: E-15000, XX-E-013, E-13BB16, E-1F9301

5.2.10 Reactor Head Vent Valves

PFSSD requires that one of the two reactor vessel head vent valves on each flow path (2 flow paths total) be closed to prevent uncontrolled depressurization of the RCS. Either BBHV8001A or BBHV8002A and either BBHV8001B or BBHV8002B needs to be closed.

Only one cable associated with head vent valve BBHV8001A is run through A-8. An external (+) 125VDC hot short across conductor 2 in this cable is the only failure that will spuriously open this valve. Since this cable is run in tray with other cables carrying the proper voltage and polarity, this failure is possible.

Cables for the remaining three head vent valves are not run through area A-8 and are unaffected by a fire in A-8. Therefore, the spurious opening of BBHV8001A is mitigated by maintaining valve BBHV8002A closed. The second flow path is isolated using either head vent valve BBHV8001B or BBHV8002B.

Based on this discussion, both head vent valve flow paths can be isolated.

References: E-15000, XX-E-013, E-1F9301, E-13BB30, M-12BB04

5.2.11 Charging Flow to Regenerative Heat Exchanger Isolation Valves

PFSSD requires charging flow to be directed to RCP seals. To ensure adequate flow to RCP seals, flow diversion to the regenerative heat exchanger needs to be prevented. Valves BGHV8105 and BGHV8106 are included in the PFSSD design to accomplish this task. Manual valve BG8402B is also included to provide an alternate means of closing this flow path if either BGHV8105 or BGHV8106 are unavailable, and is also used during alternate safe shutdown per OFN RP-017.

Cables associated with BGHV8106 are run in area A-8 and could be damaged by a fire, preventing valve BGHV8106 from being closed from the control room.

Cables 14BGG11AA and 14BGG11AB are power and control cables, respectively, associated with BGHV8105 and are run in conduit 114U3D5R (room 1320). This conduit is wrapped with Thermo-Lag fire barrier material that was upgraded to a 1-hour fire resistance rating by Change Package 011888. In addition, automatic fire suppression and detection is installed in the area. This configuration meets the Wolf Creek commitment to 10CFR50, Appendix R section III.G.2.c for protection of one redundant train of equipment. Therefore, a fire in area A-8 will not impact the ability to ensure valve BGHV8105 can be closed using BGHIS8105 in the control room.

Based on the above discussion, there is reasonable assurance that valve BGHV8105 can be closed from the control room using BGHIS8105. This configuration meets Wolf Creek's commitments to 10CFR50, Appendix R Section III.G.2 and is, therefore, acceptable.

References: E-15000, XX-E-013, E-1F9102, E-1F9302, E-13BG11A, E-1R1343B, E-1R8900, M-12BG03, E-097, PIR 2005-2355, DCP 011888

5.2.12 Reactor Coolant Pump Seal Injection

PFSSD requires RCP seal injection to provide a boron injection path, provide makeup to the RCS and provide cooling to the RCP seals. The redundant boron injection and makeup path is through the boron injection tank (BIT). The redundant seal cooling method uses thermal barrier cooling.

Seal injection is accomplished by opening either BGHV8357A (for seal injection using PBG05A) or BGHV8357B (for seal injection using PBG05B). The PFSSD design also requires that either BGHV8110 (if using the BGHV8357A flow path) or BGHV8111 (if using the BGHV8357B flow path) be open to prevent the operating CCP from overheating due to low-flow.

Power and control cables for BGHV8110 run through fire area A-8 and could be damaged by a fire. In addition, cables associated with the CCP A room cooler SGL12A run through area A-8 and could be damaged, preventing operation of the room cooler. Also, a number of components associated with Train A component cooling water (CCW) may be inoperable due to damage to associated cables. Therefore, operation of the Train A CCP cannot be credited for a fire in area A-8.

Cables and components associated with the Train B CCP (PBG05B), as well as required PFSSD support functions, are unaffected by a fire in area A-8. Therefore, a fire in area A-8 will use the Train B CCP to achieve reactivity control and reactor coolant makeup goals.

A fire in area A-8 will not impact the ability to provide charging flow through the RCP seals using Train B charging pump. However, seal injection could temporarily be interrupted since the VCT outlet valves could spuriously close and automatic swapover to the RWST may not occur. Also, the normal charging pump is assumed to fail since it is not analyzed. As discussed in Section 5.2.2 a spurious SIS could occur, causing an automatic start of the CCPs. This will also cause valve BNLCV0112E to open, ensuring a suction source to the Train B CCP. If an SIS does not occur, it may be necessary for operators to line up Train B CCP from the control room. If RCP seal injection is not lined up within 12 minutes, operators should stop the RCPs, isolate seal injection and use natural circulation for cooldown.

Cable 11BGI51AA is associated with RCP seal total flow transmitter BGFT0215A. Damage to this cable could prevent operation of the flow transmitter and could prevent operators from determining total RCP seal flow using flow indicator BGFI0215A. Flow indicator BGFI0215B is unaffected by a fire in area A-8 and can be used by operators to determine if seal flow is functioning.

As discussed in Section 5.2.19, RCP thermal barrier cooling (TBC) could be affected by a fire in this area. Therefore, TBC may be unavailable to provide redundant seal cooling.

Based on the above discussion, RCP seal injection is available to provide boration, inventory control and RCP seal cooling. However, suction to the CCP may temporarily be lost causing a loss of charging until the RWST can be lined up. The RWST can be lined up from the control room as discussed in Section 5.2.14, so RCP seal injection will be available. RCP seal flow is available using BGFI0215B.

References: E-15000, XX-E-013, E-13BG11, E-13BG51, E-1F9102, E-1F9302, M-12BG03

5.2.13 Excess Letdown

PFSSD requires the excess letdown path be isolated to prevent uncontrolled depressurization of the RCS. To accomplish this, either normally closed valve BGHV8153A or BGHV8154A must be maintained closed and either normally closed valve BGHV8153B or BGHV8154B must be maintained closed. Cables associated with these valves are listed in Table A-8-4.

Only circuits associated with BGHV8154A run through fire area A-8. Therefore, the remaining valves are unaffected by a fire in area A-8 and will remain closed, and thereby achieving the PFSSD goals for this system.

References: E-15000, XX-E-013, E-1F9301, E-13BG48, M-12BG01

5.2.14 Refueling Water Storage Tank (RWST) to Charging Pumps Suction Isolation Valves

As stated earlier, the Train A CCP may not be available due to a fire in area A-8. Therefore, the Train B CCP is used, taking suction from the RWST. Cables associated with valve BNLCV0112E are unaffected by a fire in area A-8. Therefore, BNLCV0112E can be opened from the control room to provide the necessary suction from the RWST to the Train B CCP.

Cables associated with BNLCV0112D are run through fire area A-8. Damage to these cables will have no adverse impact on PFSSD due to the availability of BNLCV0112E.

A fire in area A-8 will use CCP B taking suction from the RWST through valve BNLCV0112E.

References: E-15000, XX-E-013, E-13BN01, E-1F9102, E-1F9302, M-12BG03, M-12BN01

5.2.15 Refueling Water Storage Tank (RWST) and Containment Sump Isolation Valves

To prevent draindown of the RWST into the containment sump, PFSSD requires that either valve BNHV8812A or valve EJHV8811A and valve BNHV8812B or valve EJHV8811B be closed during hot standby. For cold shutdown, the operating train containment sump valve (EJHV8811A or EJHV8811B) must be maintained closed to prevent flow diversion from the RCS to the containment sump. Valves BNHV8812A and BNHV8812B are normally open and valves EJHV8811A and EJHV8811B are normally closed.

Power and control cables for valve BNHV8812A run through fire area A-8. Damage to these cables could prevent closing this valve from the control room and could prevent the valve from automatically closing if valve EJHV8811A reaches full open position.

Power and control cables for valve EJHV8811A are also run through fire area A-8. Damage to these cables will not cause the valve to spuriously open unless valve BNHV8812A is fully closed at the time of the fire. In this case, draindown will not occur because BNHV8812A is closed. With BNHV8812A in the normally open position, there are no credible combinations of hot shorts, open circuits or shorts to ground sufficient to cause valve EJHV8811A to spuriously open. Therefore, valve EJHV8811A will remain closed and draindown of the RWST to the containment sump through this flowpath is not credible if a fire occurs in this area.

Only one control cable (14BNG03BK) for valve BNHV8812B runs through area A-8. This cable is a fire resistive cable and is protected against failure due to a fire in this area. Therefore, valve BNHV8812B can be operated from the control room if a fire occurs in the area (A-8).

Three cables (14EJG06BF, 14EJG06BJ and 14EJG06BK) associated with EJHV8811B run through area A-8. Damage to three phase power cable 14EJG06BJ will not cause the valve to spuriously open. Damage to control cable 14EJG06BK will not cause the valve to spuriously open. An intra-cable hot short within cable 14EJG06BF will not cause valve EJHV8811B to

open. An intra-cable hot short in cable 14EJG06BF combined with an inter-cable 120 VAC hot short on either conductor within 14EJG06BF will not cause the valve to open because ARA contacts are installed on both sides of the position switch contact. The ARA contacts prevent spurious operation of EJHV8811B if a fire occurs in this area.

Based on the above discussion, draindown of the RWST into the containment sump will not occur as a consequence of a fire in this area.

References: E-15000, XX-E-013, E-1F9205, E-13BN03, E-13BN03A, E-13EJ06A, E-13EJ06B, M-12BN01, M-12EJ01, M-10BN, DCP 13613, DCP 14325

5.2.16 Residual Heat Removal (RHR)

Note: For a discussion of the RHR mini-flow valves (EJFCV0610 and EJFCV0611), see Section 5.1.1. For a discussion of the RHR heat exchanger discharge control valves (EJHCV0606 and EJHCV0607), see Section 5.1.2. For a discussion of valves EJHV8804(A/B), see Section 5.2.20.

Cold shutdown mode of PFSSD requires RHR taking suction from the RCS. RHR pump suction from the RCS is controlled by valves BBPV8702A and EJHV8701A (Train A) and BBPV8702B and EJHV8701B (Train B). Both valves on the operating train must be open during cold shutdown.

Prior to transitioning to cold shutdown, either valve BBPV8702A or EJHV8701A and either BBPV8702B or EJHV8701B must be closed.

Hot Standby Evaluation

Cables associated with the safety interlocks on valves BBPV8702A and BBPV8702B are located in fire area A-8. These interlocks prevent premature opening of the BBPV valves when other valves are not in the closed position.

A fire-induced multiple simultaneous short within each cable will provide a false permissive that the associated valve is closed, and complete that portion of the open circuit. Relay K734 (low pressure permissive) contact is normally open in hot standby, which will ensure the valve will not open when RCS pressure is too high. However, as discussed in Section 5.1.5, pressure transmitter BBPT0405 and associated circuits are located in area A-8 and could send a false low RCS pressure and close the contact on relay K734. Therefore, operators should ensure the control room switches (BBHIS8702A and BBHIS8702B) are maintained in the closed position. Cables associated with the hand indicating switch (BBHIS8702A and BBHIS8702B) are not located in area A-8. Therefore, valves BBPV8702A and BBPV8702B will remain closed prior to transitioning to cold shutdown.

Cables associated with valves EJHV8701A and EJHV8701B are located in area A-8 and could be damaged in a manner that would cause the valves to open. However, since valves BBPV8702A and BBPV8702B can be maintained closed from the control room, the spurious opening of valves EJHV8701A and EJHV8701B is not a concern for PFSSD.

Cold Shutdown Evaluation

A fire in area A-8 could cause a loss of Train A CCW and the inability to operate Train A RHR. Therefore, Train B RHR is credited for a fire in area A-8.

Damage to any of the cables associated with BBPV8702A and BBPV8702B listed in Table A-8-4 could prevent opening the associated valve from the control room. Damage to cable 12BBI15NA associated with pressure transmitter BBPT0403 could send a false High-1 RCS

pressure signal and open the contacts on relay K734, which would prevent remote opening of valves BBPV8702A and BBPV8702B. Therefore, a fire in area A-8 may require a cold shutdown repair to be made within 72 hours per 10CFR50, Appendix R or a containment entry to manually open BBPV8702B when using RHR Train B.

Damage to any of the cables associated with EJHV8701A or EJHV8701B listed in Table A-8-4 could prevent opening the associated valve from the control room. Therefore, a fire in area A-8 may require a cold shutdown repair to be made within 72 hours per 10CFR50, Appendix R or a containment entry to manually open EJHV8701B when using RHR Train B.

The RHR pump discharge to RCS cold leg isolation valve (EJHV8809A or EJHV8809B) needs to be open on the operating train. Damage to cables 11EJG09CC and 11EJG09CD would likely result in valve EJHV8809A remaining in its as-is normally open position, which is the preferred PFSSD position. However, two proper intra-cable hot shorts in cable 11EJG09CD or one intra-cable hot short in cable 11EJG09CD combined with a short to ground on conductor 31 would spuriously close the valve.

Cable 11GLG05AA is the power cable for the RHR A room cooler SGL10A. Damage to this cable will prevent the RHR A room cooler from operating, and could impair the Train A RHR system. The B Train RHR room cooler is unaffected by a fire in area A-8.

Based on the above discussion, the Train A RHR system could be affected but the Train B RHR system is available in the event of a fire in area A-8. However, a cold shutdown repair or containment entry may be required to line up the RHR suction path from the RCS prior to initiating shutdown cooling.

5.2.17 Essential Service Water (ESW)

Essential Service Water provides various support functions to ensure PFSSD. Cables associated with Train A ESW are run through area A-8.

Power and control cables for normally closed valve EFHV0059 (CCW A to UHS return) are run through area A-8. This valve is required to remain closed for PFSSD. Locked and throttled valve EFV0058 bypasses valve EFHV0059 and is adjusted to provide the necessary flow for PFSSD. The power and control cables that run through area A-8 associated with EFHV0059 have no possible failures that could cause the valve to open. Therefore, there is reasonable assurance that valve EFHV0059 will not spuriously open due to a fire in area A-8.

Valves EFHV0031, EFHV0033, EFHV0045 and EFHV0049 are required to be open to ensure Train A ESW flow to the containment coolers. Control cables associated with these valves are run in area A-8. Damage to the cables could cause the spurious closure of the valves.

Cables associated with Train B ESW components are not run in area A-8 and are unaffected by a fire in A-8. Therefore, Train B ESW will be used for a fire in area A-8.

References: E-15000, XX-E-013, E-13EF04, E-13EF07, E-13EF08, E-13EF09, E-1F9403

5.2.18 Component Cooling Water (CCW)

Note: For a discussion of EGTV0029, see Section 5.1.7.

For PFSSD, the component cooling water (CCW) system is used to provide cooling to the centrifugal charging pump (CCP) oil cooler, seal water heat exchanger, the RHR heat exchanger and the RHR pump seal cooler. In addition, the CCW system provides cooling to the RCP thermal barriers and is credited as a backup to RCP seal injection for maintaining seal cooling.

Power and control cables (11EGG05AA, 11EGG05AB, 11EGG05CA and 11EGG05CB) for CCW A common header return isolation valve EGHV0015 and CCW A to nuclear auxiliary components valve EGHV0053 are run through area A-8. Hot shorts, open circuits and shorts to ground involving these cables will not cause the valves to spuriously operate. Damage to these cables could prevent operating these valves from the control room. If the Train A CCW system is operating at the time of the fire, the valves will be in the open position. If Train A off-site and on-site power is lost, it will be necessary to swap to Train B CCW and close EGHV0015 to prevent flow diversion from Train B CCW to Train A CCW.

Calculation M-EG-24 determines the amount of inventory lost from one train of CCW to the other train given a single failure of EGHV0015, EGHV0016, EGHV0053 or EGHV0054. The calculation also evaluates the impact on CCW pump NPSH given these failures. Based on the results of the calculation, there is no adverse impact on NPSH if a single failure occurs. In the case where both valves remain open, PFSSD is assured because, if EGHV0053 is open, check valve EGV0036 will prevent flow diversion from Train B to Train A CCW.

GLHZ0080 and GLHZ0081 are exhaust dampers on the Train A CCW pump room cooler (SGL11A). Cables 11GLY27AB and 11GLY27AD are associated with GLHZ0080 and GLHZ0081, respectively and are run in area A-8. Damage to these cables will prevent the CCW Train A room cooler dampers from functioning. This is acceptable based on PIR 2000-2646 and Calculation GL-M-006. CCW train B room coolers will provide sufficient cooling for continued operation of Train A pumps, or operations can switch to Train B pumps.

Based on the above discussion, Train B CCW is available to supply cooling water to Train B components if a fire occurs in area A-8.

References: E-15000, XX-E-013, E-13EG01A, E-13EG01B, E-13EG05A, E-13EG05B, E-13EG07, E-13GL27, E-1F9401A, M-12EG01, M-12EG02, Calculation GL-M-006, Calculation M-EG-24

5.2.19 Thermal Barrier Cooling

The Wolf Creek plant design provides two redundant methods of cooling the RCP seals, thermal barrier cooling using CCW and seal injection using the CCP. The PFSSD methodology at Wolf Creek requires tripping the RCPs and performing a natural circulation cooldown upon loss of both thermal barrier cooling (TBC) and seal injection. If only one method is lost, continued operation of the RCP is allowed by present established procedures until the other method can be re-established.

Valves EGHV0058, EGHV0071, EGHV0126 and EGHV0127 are used to control CCW flow to the RCPs. Valves EGHV0058 and EGHV0071 are normally open and valves EGHV0126 and EGHV0127 are normally closed. Cables 11EGG09AC and 11EGG09AD, associated with valve EGHV0058, are run in this area. Damage to these cables could cause the spurious closure of EGHV0058. If this occurs, bypass valve EGHV0127 can be opened from the control room to restore CCW flow to the RCPs. However, as stated below, CCW flow to the RCP thermal barriers may be affected by damage to other cables.

Power cable 14EGG09CA associated with valve EGHV0071 runs through area A-8. There is no feasible damage mechanism to this cable that can cause valve EGHV0071 to close. Control cable 14EGG09CB associated with valve EGHV0071 also runs through area A-8. Based on a circuit analysis, there is no feasible damage mechanism to this cable that can cause valve EGHV0071 to close.

Valves EGHV0061, EGHV0062, EGHV0132 and EGHV0133 are used to control thermal barrier cooling return flow at the exit from containment. Valves EGHV0061 and EGHV0062 are normally open and valves EGHV0132 and EGHV0133 are normally closed.

Power cable 11EGG09DA associated with valve EGHV0061 runs through area A-8. There is no feasible damage mechanism to this cable that can cause valve EGHV0061 to close. Control cable 11EGG09DB associated with valve EGHV0061 also runs through area A-8. Based on a circuit analysis, there is no feasible damage mechanism to this cable that can cause valve EGHV0061 to close. Valve EGHV0062 is unaffected by a fire in area A-8.

Valves BBHV0013, BBHV0014, BBHV0015 and BBHV0016 are located on the CCW return line from the RCP thermal barriers for RCPs A, B, C and D, respectively. Flow transmitters BBFT0017, BBFT0018, BBFT0019 and BBFT0020 are associated with valves BBHV0013, BBHV0014, BBHV0015 and BBHV0016, respectively. The flow transmitters monitor flow in the CCW piping and shut the valves on high CCW flow. Cables associated with these valves and flow transmitters are run in this area. Damage to the cables associated with the valves will not cause the valves to spuriously close. However, damage to the cables associated with the flow transmitter could cause a spurious high CCW flow signal and close the valves. Damage to the valve cables could prevent re-opening the valves. Therefore, thermal barrier cooling could be lost if a fire occurs in area A-8.

Cables 11EGI19AB and 14EGI19BB and associated flow transmitters EGFT0128 and EGFT0129, respectively, are located in fire area A-8. Damage to these cables and components could prevent operators from diagnosing a loss of CCW flow to the RCP thermal barriers. Operators should monitor BGFI0215B to ensure seal injection remains functional and take prompt action to start the credited charging pump if the operating charging pump fails.

Based on the above discussion, RCP thermal barrier cooling may be affected if a fire occurs in this area. RCP seal injection remains available.

References: E-15000, XX-E-013, E-13BB03, E-13BB28, E-13EG09, E-13EG09A, E-13EG10, E-13EG17A, E-13EG18A, E-13EG19, E-1F9303, M-12BB03, M-12EG03

5.2.20 Residual Heat Removal

PFSSD requires one train of residual heat removal (RHR) to be available for shutdown cooling. The RHR system is not used for hot standby.

Valve EGHV0101 is the Train A CCW to RHR Heat Exchanger control valve. Valve EGHV0102 is the Train B CCW to RHR Heat Exchanger control valve. These valves are normally closed during power operation. PFSSD requires that the valve on the operating train of CCW be closed until shutdown cooling mode is entered, at which time the valve on the operating train of RHR needs to be open. As stated in Section 5.2.18, the Train A CCW system may not be available to supply cooling water to the Train A RHR heat exchanger. Cables 11EGG07AA and 11EGG07AB associated with EGHV0101 are run in this area. Damage to these cables would not cause the spurious opening of the valve but could prevent opening the valve from the control room when needed. Valve EGHV0102 is unaffected by a fire in this area.

Normally closed valves EJHV8804A and EJHV8804B are located on the RHR heat exchanger discharge line and isolate flow to the suction side of the CCPs. During hot standby, these valves can fail in any position and not affect PFSSD, since the RHR system will not be operating. For cold shutdown, the valve on the operating RHR train must be closed to provide the proper permissives to open valves EJHV8701(A/B) and BBPV8702(A/B).

As stated previously, Train B RHR is credited for a fire in area A-8. Valve interlocks in the RHR system are discussed in Section 5.2.16. Other than the interlock circuit between EJHV8804B and EJHV8701B / BBPV8702B, there are no other circuits for valve EJHV8804B in area A-8. Therefore, valve EJHV8804B cannot spuriously open.

Cables 11EJG04AA and 11EJG04AB are associated with valve EJHV8804A. Damage to cable 11EJG04AA will not cause the valve to spuriously open. Since this is not a high-low interface boundary, consideration of a three-phase cable-to-cable hot short is not required.

Damage to cable 11EJG04AB will not cause the valve to spuriously open. Based on a review of the circuits associated with this valve, there are no failures or combinations of failures that could cause the valve to spuriously open.

Based on the above discussion, Train A RHR may be affected but Train B RHR is available.

References: E-15000, XX-E-013, E-13EG07, E-13EJ04A, E-13EJ04B, E-13EJ05A, E-13EJ05B, E-1F9205, M-12BB01, M-12BG03, M-12EJ01

5.2.21 Letdown Isolation Valves and Letdown Orifice Isolation Valves

Valves BGLCV0459 and BGLCV0460 are isolation valves installed in series on the inlet side of the regenerative heat exchanger. PFSSD requires that one of these valves be closed.

Cable 15BGK10AD is a control cable for the BGLCV0459 solenoid valve (BGHY0459). Cable 15BGK10BD is a control cable for the BGLCV0460 solenoid valve (BGHY0460). Air supplied by an open (energized) solenoid valve will open valve BGLCV0459 or BGLCV0460. A closed (de-energized) solenoid valve will cause loss of air pressure and close valves BGLCV0459 or BGLCV0460.

Either BGLCV0459 or BGLCV0460 must be closed or letdown orifice isolation valves BGHV8149A, BGHV8149B, and BGHV8149C must be closed. Cables for BGLCV0459 and BGLCV0460 are routed in a common enclosure in cable trays and conduit. An intra-cable hot short between conductors P1 and 1 on the cables could bypass the hand switches on RL001 and RP118A and cause the valves to remain open. Other cables routed in common cable trays have the proper voltage for hot shorts. The hot shorts bypass RL001 and RP118A hand switches for BGLCV0459 and BGLCV0460. BGLCV0459 and BGLCV0460 constitute a high/low pressure interface so multiple simultaneous hot shorts were considered.

Relays BGLCV0459X and BGLCV0460X will block power to the solenoid valve on BGLCV0459 and BGLCV0460, respectively, upon low level in the pressurizer. Cables associated with these relays do not run in area A-8. Also, as discussed in Section 5.2.9, pressurizer level transmitter BBLT0460 is unaffected by a fire in area A-8. Therefore, low level (17%) in the pressurizer will cause automatic closure of BGLCV0460, but the valve may re-open when level is established.

Letdown orifice isolation valves BGHV8149A, BGHV8149B, and BGHV8149C are listed as PFSSD components because of the interlock between these valves and BGLCV0459 and BGLCV0460. The interlock prevents closure of the letdown valves when any one or more orifice isolation valves are open. A cable associated with all three letdown orifice isolation valves is located in this fire area. Damage to these cables could prevent closure of the orifice

valves from the control room. As stated above, valve BGLCV0460 will automatically close upon low level in the pressurizer. Therefore, there is reasonable assurance that the letdown flow path will be isolated if a fire occurs in this area.

References: E-15000, XX-E-013, E-13BG10, E-13BG35, E-1R1343B, E-1R1343C, M-12BB02, M-12BG01

5.2.22 Boron Injection Tank Flowpath

The Boron Injection Tank (BIT) flowpath is credited for reactivity control and reactor coolant makeup. For reactivity control, the BIT flowpath is credited as an alternate source of boration in the event RCP seal injection is unavailable. Based on Calculation XX-E-013, RCP seal injection will provide sufficient boration to achieve and maintain cold shutdown reactivity conditions. Therefore, the BIT flowpath is not required for reactivity control if RCP seal injection is available. Since RCP seal injection is limited to 5 gpm per seal or 20 gpm total injection to the RCS, an additional RCS charging flowpath is required for adequate RCS makeup during plant transition from hot standby to cold shutdown. The BIT injection path was selected as the additional RCS charging flowpath.

Cables associated with all four BIT inlet and outlet valves (EMHV8803A, EMHV8803B, EMHV8801A and EMHV8801B) are run in this area. Terminal box TB13209 contains cables associated with BIT outlet valve EMHV8801A. Damage to these cables could prevent the valves from being opened from the control room if the BIT flowpath is needed. Cables associated with EMHV8801B are run in conduit 114U3D5R which has been protected by a qualified 1-hour fire wrap. However, cables for the remaining valves are not protected. Therefore, the BIT flowpath may not be available if a fire occurs in area A-8.

Train B CCP is credited for a fire in area A-8 since circuits and support systems for Train A CCP may be affected by the fire. Also, based on the discussion in 5.2.21, a fire in area A-8 has the possibility to cause a momentary loss of inventory through the letdown flow path until the letdown isolation valves close automatically or are failed closed. As discussed in Section 5.2.21, automatic closure of BGLCV0460 is assured upon low level in the pressurizer. Reactor coolant pump seal injection remains available.

If the BIT flowpath is used, then the SIS test line is required to be isolated to prevent inventory loss. Valve EMHV8964 is an isolation valve that can be used to isolate the SIS test line. The PFSSD position of this valve is closed to prevent flow diversion through this flow path. Cable 11EMK12BA is a control cable for EMHV8964. A +125 VDC external (inter-cable) hot short in cable 11EMK12BA will energize the solenoid and open valve EMHV8964. The cable is routed in raceways with cables carrying the proper voltage and polarity. The hot short would bypass the control room hand switch (EMHIS8964) on RL017 and control of this valve from the control room would be lost. Redundant valves EMHV8871, EMHV8843 and EMHV8882 are unaffected by the fire and are available to ensure the SIS test line remains isolated.

Based on the above discussion, a fire in area A-8 will not adversely impact the ability to isolate the SIS test line flow path. Charging through the BIT is not required to achieve and maintain hot standby due to the availability of seal injection to maintain inventory and the automatic closure of BGLCV0460 upon low level in the pressurizer. However, the BIT flowpath may need to be aligned locally when transitioning to cold shutdown.

References: E-15000, XX-E-013, E-13EM02, E-13EM02A, E-13EM02B, E-13EM02C, E-13EM12, E-1F9302, E-1R1343B

5.2.23 Safety Injection Accumulator Isolation Valves

PFSSD requires isolation of the SI accumulators prior to reducing RCS pressure below the injection pressure to avoid unnecessary accumulator discharge. This is accomplished by closing valves EPHV8808A, EPHV8808B, EPHV8808C and EPHV8808D. These valves are normally open with the MCC breaker locked in the open position. Cables for valves EPHV8808A and EPHV8808C are run in area A-8 and are listed in Table A-8-4.

Since the breakers for these valves are normally open, damage to these cables will not cause the valve to spuriously change position. However, damage to the cables will prevent closing the associated valve from the control room after power is restored.

The SI accumulators need to be isolated during cold shutdown, prior to the RCS reaching 1000 psig. If necessary, a containment entry can be made to manually close the valves.

A fire in area A-8 may require a containment entry to close valves EPHV8808A and EPHV8808C if these valves are unresponsive from the control room.

References: E-15000, XX-E-013, M-12EP01, E-13EP02A, E-1F9201

5.2.24 Containment Coolers

PFSSD requires containment cooling to maintain the containment environment within EQ limits. Cables associated with Train A containment coolers are run in area A-8. These cables are listed in Table A-8-4.

Damage to these cables could prevent operation of the Train A containment coolers if a fire occurs in area A-8. However, circuits for the Train B containment coolers are run in a separate fire area and are unaffected by a fire in area A-8.

As discussed earlier, Train B ESW is available if a fire occurs in area A-8. Therefore, the Train B containment coolers will have the necessary service water flow to ensure proper operation.

Therefore, the Train B containment coolers will be used to provide containment cooling in the event of a fire in area A-8.

References: E-15000, XX-E-013, E-13GN02, E-13GN02A, M-12GN01, E-1F9441

5.2.25 Emergency Diesel Generators

A fire-induced loss of off-site power requires operation of a single emergency generator to supply power to essential loads. Calculation XX-E-013, Appendix 2 evaluates the probability of a loss of off-site power in each fire area in the plant.

Based on Calculation XX-E-013, a loss of off-site power could occur on the NB01 bus if a fire occurs in area A-8. Therefore, to ensure power to essential Train A components, the Train A emergency diesel generator would need to supply power to the NB01 bus.

Cables 11NEB01AA, 11NE01AC and 11NEB01AE are the phase A, B and C power cables from the Train A EDG to NB01. Damage to these cables will prevent the EDG from supplying NB01.

Cable 11JEG01AD is a control cable for Train A EDG fuel oil transfer pump PJE01A. Damage to the cable could prevent operation of the pump, which will prevent fuel transfer from the main storage tank to the day tank.

Based on the above discussion, power to NB01 could be lost. However, bus NB02 off-site and on-site power is available to supply PFSSD loads on Train B. A fire in area A-8 uses primarily Train B equipment, so PFSSD is not affected by the loss of NB01.

References: E-15000, XX-E-013, E-13JE01, E-13NE01, E-13NB01, E-13NB02, E-1F9425

5.2.26 480 VAC Power Distribution

A fire in area A-8 could damage cables associated with the Train A 480 VAC power distribution system. Cables 11NGG01AD and 11NGG01AE supply power from NG0107 to NG01BAF1. Damage to these cables could result in loss of power to Train A PFSSD components fed from NG01B. Drawing E-1F9424A identifies the Train A PFSSD loads associated with NG01B.

Cable 11NGG01AJ is the power cable for containment cooler SGN01A. Cable 11NGG01BF is the power cable for containment cooler SGN01C. As stated earlier, loss of containment coolers SGN01A and SGN01C will not prevent PFSSD due to the availability of the Train B containment coolers.

The loss of NG01B will not prevent PFSSD. Loss of power to the associated loads is acceptable due to the availability of Train B 480 VAC power from NG02 and NG04. None of the PFSSD equipment associated with NG01B is required if a fire occurs in area A-8.

References: E-15000, XX-E-013, E-03NG01A, E-1F9424B

5.2.27 Control Room Emergency Lights

Emergency lighting is provided in the control room to ensure adequate lighting during a station blackout and in the event a fire damages cables associated with the normal and standby lighting system. Emergency lights are supplied power from Class 1E 125 VDC breaker NK5120.

The control room has four sources of lighting; 1) Normal; 2) Standby; 3) Emergency; and Self-contained battery units. The normal lighting system is not evaluated in the PFSSD analysis and is assumed lost.

The standby lighting system is supplied by the 480 VAC Class 1E electrical system through breakers NG01AHF1 and NG01AHF2. Power availability on NG01AHF1 and NG01AHF2 is monitored by auxiliary relays 27XQB1 and 27XQB2 in panel RP330. Upon loss of power to

both NG01AHF1 and NG01AHF2, the relay coils are de-energized and the normally open contacts close. This energizes the contactor control relay which closes a contact and energizes the control room emergency lighting panel NK051A, which automatically illuminates the 125 VDC (QD System) emergency lights in the control room.

Cable 11QBY03CA is a control cable that runs from NK051 to RP330 and provides control power to energize the contactor control relay to illuminate control room emergency lights upon loss of Class 1E power. A short in this cable due to a fire will illuminate emergency lights in the control room even though Class 1E power is available. This will have no impact on PFSSD.

An open in cable 11QBY03CA will prevent the control room emergency lights from illuminating upon loss of Class 1E power. Based on Calculation XX-E-013, Appendix 2, A fire in area A-8 could result in the loss of Train A off-site power and Train A emergency diesel generator. Therefore, the possibility exists for a fire in area A-8 to result in a loss of normal, standby and emergency lighting in the control room.

Self-contained Appendix R battery units are provided in the control room to provide minimum lighting for post-fire safe shutdown. Three units are provided in the front panel area, each with two light heads, to provide illumination on the main control boards. Two additional units are provided in the corridor area and two units are provided in the back panel area, each with two light heads. The Appendix R battery units are capable of providing minimum illumination for 8 hours, during which time action can be taken by maintenance to restore the normal or standby lighting system. Operations has indicated that installed Appendix R lights are sufficient to perform control room actions to achieve hot standby.

Based on the above discussion, the control room will have sufficient lighting to achieve and maintain PFSSD.

5.2.28 Reactor Trip Switchgear Cabinet SB102A

Cables associated with Train A reactor trip switchgear are located in fire area A-8. Cable 11SBS10AB is a power cable for SB102A from NK04116. Cable 11SBS12AC is a control cable from SB102A to RL003.

A fire in this area could damage these cables and affect the capability to trip the reactor using SB102A. However, redundant reactor trip switchgear cabinet SB102B is available and is unaffected by a fire in area A-8.

References: E-15000, XX-E-013, E-11NK01, E-13SB10, E-13SB12A, E-13SB12B

5.2.29 Source Range Monitoring

PFSSD requires source range (SR) flux monitoring to be available. Source range monitoring is provided by source range monitors SENE0031, SENE0032, SENY0060A & B, and SENY0061A & B. Cables run in fire area A-8 associated with these monitors are listed in Table A-8-4. Cables for SENY0060A/B run in area A-8. Cables for SENE0031, SENE0032 and do not run in area A-8 and are unaffected by a fire in area A-8.

Cable 14SES07BB is an indication circuit associated with SR monitor SENY0061A/B used for alternate PFSSD at remote shutdown panel RP118B. This cable is run in area A-8. A fire in this area does not use remote shutdown panel RP118B. Damage to this cable will not impact SR indication in the control room at panel RL020. Therefore, SR monitoring is available for a fire in area A-8 using SENY0061A/B.

Source range monitoring is available for a fire in area A-8 using SR monitors SENE0031, SENE0032, and SENY0061A/B. For a more detailed evaluation on Source Range monitoring, see Calculation XX-E-013, Attachment 3.

References: E-15000, XX-E-013, E-13SE01, E-13SE02, E-13SE07, E-13SR14, E-1F9101

5.2.30 Non-Class 1E 125 VDC Battery Charger PK22

Cable 16PKG11BA is the 480 VAC power cable from NG0409 to 125 VDC battery charger PK22. Damage to this cable could result in a loss of the PK22 power feed to 125 VDC bus PK02. PK02 supplies 125 VDC power to essential PFSSD loads on the Train B system.

Redundant power feed to the PK02 bus is unaffected by a fire in area A-8. This power feed originates from 125 VDC battery group PK12, and is normally aligned to feed power to PK02 in the event PK22 is lost.

Based on the above discussion, a fire in area A-8 could result in a loss of power to PK22 but redundant power source PK02 is available and is unaffected by the fire.

References: E-15000, XX-E-013, E-11PK02, E-13PK11, E-1F9422C

5.2.31 Normal Pressurizer Spray

The normal pressurizer spray valves are included in the PFSSD design because spurious operation of pressurizer sprays can cause a decrease in pressure which can lead to boiling in the core. The pressurizer spray valves are part of the pressurizer pressure control system.

The pressurizer normal spray valves (BBPCV0455B and BBPCV0455C) operate off a signal from the Ovation pressurizer pressure control system. The operation of the pressure control system is discussed in Calculation XX-E-013.

Cable 11BBI16KB associated with BBPT0455 is run in this area. Damage to this cable could cause a spurious high-pressure signal. As discussed in Calculation XX-E-013, Appendix 1, damage to a single pressure input channel will not cause the spurious operation of the pressurizer spray valves due to the Ovation 4-channel validation logic, which uses the 2nd highest signal as the validated signal and has built-in logic to detect and ignore a failed input.

Based on the above discussion, pressurizer spray valves will not spuriously open if a fire occurs in this area.

References: E-15000, XX-E-013, E-13BB16, E-13BB19, M-744-00028, M-761A-00063, DCP 13324

5.2.32 Containment Air Supply

Valve KAFV0029 is an isolation valve on the containment compressed air supply line. This valve is credited for PFSSD in the event of a fire in certain areas to isolate air to letdown isolation valves BGLCV0459 and BGLCV0460 and pressurizer spray valves BBPCV0455B and BBPCV0455C to fail the valves closed. Valve KAFV0029 is a diverse means of closing these valves if the fire prevents closing the valves using their respective control room hand switches.

Cable 11KAK02AA is a control cable associated with valve KAFV0029. Damage to this cable could prevent closure of the valve from the control room or could cause the valve to spuriously close. If the valve spuriously closes, PFSSD will not be affected as documented in WIP-E-1F9900-004-A-1.

A fire in area A-8 does not require closure of the air supply to containment to achieve PFSSD. Letdown isolation valves BGLCV0459 and BGLCV0460 are unaffected by a fire in this area and can be closed from the control room to isolate letdown. As stated in Section 5.2.31, pressurizer spray valves BBPCV0455B and BBPCV0455C could spuriously open in the event of a fire in this area but actions are available from the control room to close the valves.

Based on the above discussion, damage to cable 11KAK02AA will have no adverse impact on the ability to achieve and maintain safe shutdown following a fire in this area.

References: E-15000, XX-E-013, E-13KA02, WIP-E-1F9900-004-A-1

5.2.33 Control Room A/C Units

A control cable associated with Train A control room A/C unit SGK04A is run in area A-8. Damage to this cable could prevent operation of SGK04A.

Cables associated with Train B control room A/C unit SGK04B and associated dampers are run in a different fire area and are unaffected by a fire in area A-8. Therefore, control room A/C is available if a fire occurs in area A-8.

References: E-15000, XX-E-013, E-13GK02B, M-12GK01

5.2.34 Load Center Feeder Breakers PA0105, PA0106 and PA0206

Load center feeder breakers PA0105, PA0106 and PA0206 are credited for PFSSD because they supply power to credited non-safety related loads. Cables associated with these breakers run in this area. PFSSD impact due to damage to these cables is discussed below.

Cable 15PGA10AA is a control cable associated with breaker PA0105. An intra-cable hot short in this cable will trip PA0105. Breaker PA0105 supplies power to the following PFSSD components:

- PG11JFR2 – Main Steam Supply to 2nd Stage Reheat Valve ABHV0031
- PG11KBR3 – Auxiliary Steam System Control Valve FBHV0081

PG11JFR2 and PG11KBR3 supply power to components downstream of the MSIVs. The MSIVs are unaffected by a fire in this area and can be closed from the control room using hand switch ABHS0079. Therefore, the MSIV downstream components are not required if a fire occurs in this area.

Cables 15PGA10BA and 15PGA10BB are control cables associated with breaker PA0106. An intra-cable hot short in these cables will trip PA0106. Cable 15PGG02AC supplies power from PG1900 to PG1700. PG1700 is not credited for PFSSD but a fault on this cable could open breaker PA0106. Breaker PA0106 supplies power to the following PFSSD components:

- PG19GCR217 – MCB Misc. Power Circuits RL023
- PG19GFR3 – Instr. Bus Transformer Alt. Feed XPN07D

See Section 5.1.2 for discussion on loss of these components.

Cable 16PGA10CA is a control cable associated with breaker PA0206. An intra-cable hot short in this cable will trip PA0206. Breaker PA0206 supplies power to the following PFSSD components:

- PG12KAF4 – Main Steam Supply to 2nd Stage Reheat Valve ABHV0032

- PG12KAF5 – Main Steam Supply to Steam Seals Valve ABHV0046
- PG12KEF3 – Auxiliary Steam System Control Valve FBHV0080

PG12KAF4, PG12KAF5 and PG12KEF3 supply power to components downstream of the MSIVs. The MSIVs are unaffected by a fire in this area and can be closed from the control room using hand switch ABHS0079. Therefore, the MSIV downstream components are not required if a fire occurs in this area.

Based on the above discussion and the discussion in Section 5.1.2, loss of breakers PA0105, PA0106 and PA0206 will not adversely affect PFSSD.

References: XX-E-013, E-15000, E-11PG20, E-11PG21, E-13PG02, E-13PG10, E-1F9424E, E-1F9425, KD-7496

5.2.35 Non-Class 1E 125 VDC Battery Charger PK24

Cable 16PKG13AA is the 480 VAC power cable from NG0410 to 125 VDC battery charger PK24. Damage to this cable could result in a loss of the PK24 power feed to 125 VDC bus PK04. PK04 supplies 125 VDC power to 10 kVA inverter PN04, which supplies backup 120 VAC power to RP043 and primary 120 VAC power to RP047.

Redundant power feed to the PK04 bus is unaffected by a fire in area A-8. This power feed originates from 125 VDC battery group PK14 and is normally aligned to feed power to PK04 in the event PK24 is lost.

Based on the above discussion, a fire in area A-8 could result in a loss of power to PK24 but redundant power source PK14 is available and is unaffected by the fire. In addition, redundant power to panels RP043 and RP047 is available from PN310. Therefore, 120 VAC power to panels RP043 and RP047 is available if a fire occurs in fire area A-8.

1.0 GENERAL AREA DESCRIPTION

Fire area A-9 is located on the 2000 elevation of the Auxiliary Building and includes the rooms listed in Table A-9-1.

Table A-9-1
Rooms Located in Fire Area A-9

ROOM #	DESCRIPTION
1309	Train B RHR Heat Exchanger Room

Fire area A-9 has no automatic suppression or detection installed. The area is separated from adjacent areas by minimum 3-hour fire rated construction.

2.0 PRIMARY EQUIPMENT USED FOR PFSSD

Table A-9-2 lists each system credited for post-fire safe shutdown and provides a discussion regarding the availability of the system to perform its Post Fire Safe Shutdown (PFSSD) function if a severe fire occurs in this area. For a summary of the area analysis results, see Section 8.0 of the Fire Area Analysis Narrative section.

Table A-9-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-9

System	System Name	PFSSD Function*	Comments
AB	Main Steam	R, M, H, P, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-9.
AC	Main Turbine	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-9.
AE	Main Feedwater	H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-9.
AL	Aux. Feedwater System	H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-9.
AP	Condensate Storage System	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-9.
BB	Reactor Coolant System	R, M, H, P, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-9.
BG	Chemical and Volume Control System	R, M, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-9.
BM	Steam Generator Blowdown System	R, M, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-9.

3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD

This section describes operator actions that may need to be performed inside or outside the control room to achieve and maintain hot standby if a fire occurs in area A-9. This section also describes cold shutdown repairs that may need to be made to achieve and maintain cold shutdown conditions. Operator actions are proceduralized in OFN KC-016.

3.1 ACTIONS OUTSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

None

3.2 ACTIONS INSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

None

3.3 ACTIONS TO ACHIEVE AND MAINTAIN COLD SHUTDOWN

None

4.0 CONCLUSION

Post-fire safe shutdown is assured if a fire occurs in this area.

5.0 DETAILED ANALYSIS

This section describes the detailed component-by-component and cable-by-cable analysis for a fire in area A-9.

5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA A-9

PFSSD components (S. in E-15000) located in fire area A-9 are shown in Table A-9-3. An evaluation of each component and associated cables is provided in the sections that follow. The applicable evaluation section is listed in Table A-9-3.

Table A-9-3
PFSSD Equipment Located in Fire Area A-9

Room #	PFSSD Equipment	Description	Evaluation Section	Comments
1309	EJHCV0607	Train B RHR Heat Exchanger Discharge Control Valve	5.1.1	
1309	EJHY0607	EJHCV0607 Valve Positioner	5.1.1	

5.1.1 Residual Heat Removal

The decay heat removal function requires an available RHR flowpath taking suction from the RCS and discharging cooled water back to the RCS. RHR Train B discharge control valve EJHCV0607 and associated valve positioner and cable are located in this fire area. Damage to this cable and/or associated components due to a fire could cause spurious operation of EJHCV0607 and could prevent operation of the Train B RHR system.

The Train A RHR system is unaffected by a fire in fire area A-9. Therefore, the decay heat removal function is satisfied if a fire occurs in area A-9.

3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD

This section describes operator actions that may need to be performed inside or outside the control room to achieve and maintain hot standby if a fire occurs in area A-10. This section also describes cold shutdown repairs that may need to be made to achieve and maintain cold shutdown conditions. Operator actions are proceduralized in OFN KC-016.

3.1 ACTIONS OUTSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

None

3.2 ACTIONS INSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

None

3.3 ACTIONS TO ACHIEVE AND MAINTAIN COLD SHUTDOWN

None

4.0 CONCLUSION

Post-fire safe shutdown is assured if a fire occurs in this area.

5.0 DETAILED ANALYSIS

This section describes the detailed component-by-component and cable-by-cable analysis for a fire in area A-10.

5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA A-10

PFSSD components (S. in E-15000) located in fire area A-10 are shown in Table A-10-3. An evaluation of each component and associated cables is provided in the sections that follow. The applicable evaluation section is listed in Table A-10-3.

Table A-10-3
PFSSD Equipment Located in Fire Area A-10

Room #	PFSSD Equipment	Description	Evaluation Section	Comments
1310	EJHCV0606	Train A RHR Heat Exchanger Discharge Control Valve	5.1.1	
1310	EJHV8804A	RHR A to CVCS CCP Isolation Valve	5.1.1	
1310	EJHY0606	EJHCV0606 Valve Positioner	5.1.1	
1310	EJZS8804A	RHR A to CVCS CCP Isolation Valve Position Switch	5.1.1	

5.1.1 Residual Heat Removal

The decay heat removal function requires an available RHR flowpath taking suction from the RCS and discharging cooled water back to the RCS. During normal operation and hot standby, the RHR system is not required and the RCS to RHR suction isolation valves must remain closed.

Train A RHR discharge control valve EJHCV0606 and associated valve positioner (EJHY0606) and cable (15EJI12AA) are located in this fire area. Damage to this cable and/or associated components due to a fire could cause spurious operation of EJHCV0606 and could prevent operation of the Train A RHR system.

Valve EJHV8804A and associated power and control cables are run in fire area A-10. Valve EJHV8804A is required to remain closed for PFSSD when operating the Train A RHR system to prevent flow diversion from the RCS to the CVCS. Damage to cables 11EJG04AA and 11EJG04AB will not cause the valve to spuriously open but could prevent operation of this valve from the control room. Therefore, valve EJHV8804A will remain closed during the fire.

Position switch EJZS8804A is part of the open circuit on Train A RCS to RHR suction valve BBPV8702A. During normal operation valve BBPV8702A is closed with the breaker padlocked in the off position per CKL BB-110. Damage to cable 14BBG12AC could provide a false open permissive but valve BBPV8702A will not open because other contacts in the circuit will remain open and the valve breaker is normally in the off position. The valve is a high-low pressure interface valve so consideration of proper polarity three-phase hot shorts is required. The power cables for this valve are not run in this area. Therefore, a fire in this area will not cause the spurious opening of BBPV8702A.

Cable 11EJG05AF is part of the open circuit on Train A RCS to RHR suction valve EJHV8701A. During normal operation valve EJHV8701A is closed with the breaker padlocked in the off position per CKL EJ-120. A hot short in this cable will provide a false open permissive but valve EJHV8701A will not open because other contacts in the circuit will remain open and the valve breaker is normally in the off position. The valve is a high-low pressure interface valve so consideration of proper polarity three-phase hot shorts is required. The power cables for this valve are not run in this area. Therefore, a fire in this area will not cause the spurious opening of EJHV8701A.

The Train B RHR system is unaffected by a fire in fire area A-10. Therefore, the decay heat removal function is satisfied using Train B RHR if a fire occurs in area A-10.

1.0 GENERAL AREA DESCRIPTION

Fire area A-11 is located on the 2000 elevation of the Auxiliary Building and includes the rooms listed in Table A-11-1.

Table A-11-1
Rooms Located in Fire Area A-11

ROOM #	DESCRIPTION
1335	North Electrical Chase - 2000 Elevation

Fire area A-11 is protected with an automatic wet-pipe sprinkler system. In addition, automatic fire detection is installed throughout. The automatic suppression and detection system meets the requirements of 10CFR50, Appendix R, Section III.G.2.c.

2.0 PRIMARY EQUIPMENT USED FOR PFSSD

Table A-11-2 lists each system credited for post-fire safe shutdown and provides a discussion regarding the availability of the system to perform its Post Fire Safe Shutdown (PFSSD) function if a severe fire occurs in this area. For a summary of the area analysis results, see Section 8.0 of the Fire Area Analysis Narrative section.

Table A-11-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-11

System	System Name	PFSSD Function*	Comments
AB	Main Steam	R, M, H, P, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-11. ABPT0516 and ABPT0546 are available to provide indication of cooldown on RCS loops 1 and 4.
AC	Main Turbine	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-11.
AE	Main Feedwater	H, P	Steam Generator A wide range level on AELI0501 may be affected. The separation group 1 (Train A) narrow range level transmitter on each steam generator could be affected. The remaining wide range and narrow range level transmitters are unaffected.
AL	Aux. Feedwater System	H, P	Train A motor driven auxiliary feedwater pump (MDAFP) may not be available. Train B motor driven auxiliary feedwater pump and the turbine driven auxiliary feedwater pump (TDAFP) are available. Cables associated with Train A MDAFP to Steam Generators (SGs) B and C control valves ALHV0009 and ALHV0011 may be affected. All remaining auxiliary feedwater pump supply and discharge valves are unaffected.
AP	Condensate Storage System	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-11.
BB	Reactor Coolant System	R, M, H, P, S	RCS wide range hot and cold leg temperature elements BBTE0413B (WR HL Loop 1) and BBTE0443A (WR CL Loop 4), as well as ABPT0516 and ABPT0546, will provide indication of cooldown on RCS loops 1 and 4. Pressurizer pressure indication is available using BBPI0456, BBPI0457 and BBPI0458. Pressurizer level indication is available using BBLI0460A. Reactor head vent flowpath is isolated by maintaining valve BBHV8002A and either head vent valve BBHV8001B or BBHV8002B closed. RCP thermal barrier cooling could be affected due to spurious closure of BBHV0013, BBHV0014, BBHV0015 and BBHV0016. Reactor coolant pumps A and B may not stop using the control room hand switch. RCP seal injection remains available. Therefore, the inability to stop the RCPs will have no adverse impact on PFSSD. Pressurizer spray valves BBPCV0455B and BBPCV0455C could spuriously open. If this occurs, pressurizer spray can be stopped by closing KAFV0029 using KAHIS0029 in the main control room.
BG	Chemical and Volume Control System	R, M, S	Valve BGHV8106 may fail to close from the control room. Valve BGHV8105 is unaffected by the fire and can be closed from the control room using BGHIS8105. Valves BGHV8153A and either BGHV8153B or BGHV8154B are maintained closed to isolate excess letdown. Letdown isolation valves BGLCV0459 and BGLCV0460 and letdown orifice isolation valves BGHV8149A, BGHV8149B, and BGHV8149C may need to be failed closed by closing valve KAFV0029 using KAHIS0029 in the main control room.

Table A-11-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-11

System	System Name	PFSSD Function*	Comments
BM	Steam Generator Blowdown System	R, M, H	All PFSSD functions associated with the steam generator blowdown system are satisfied. Steam generator blowdown is isolated by closing valves BMHV0001, BMHV0002, BMHV0003 and BMHV0004 using BMHIS0001A, BMHIS0002A, BMHIS0003A and BMHIS0004A, located on the RL024 panel in the main control room.
BN	Borated Refueling Water Storage System	R, M, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-11.
EF	Essential Service Water System	H, S	The ESW supply to the Train A containment coolers may be affected. ESW supply to Train B containment coolers is unaffected.
EG	Component Cooling Water System	S	CCW flow to the RCP thermal barriers could be affected. Seal injection remains available to ensure RCP seal cooling. CCW flow indicators EGFI0128 and EGFI0129 are unaffected.
EJ	Residual Heat Removal System	M, H, P	Valve EJHV8811A could spuriously open but valve BNHV8812A will automatically close when EJHV8811A is fully open. If EJHV8811A does not fully open, then BNHV8812A can be closed using BNHIS8812A in the control room. Train A RHR components are affected by the fire. Train B RHR is unaffected and remains available for shutdown cooling. However, it may be necessary to manually open EJHV8701B to provide a suction source to the Train B RHR pump.
EM	High Pressure Coolant Injection	R, M	The Train A BIT flowpath may not be available. Charging through the BIT is available using the B CCP flowing through valves EMHV8803B and EMHV8801B. Valves EMHV8882 and EMHV8964 may spuriously open. Redundant valve EMHV8871 will remain closed to isolate the SI Test line.
EN	Containment Spray	R, M	Train A containment spray isolation valve ENHV0006 could spuriously open. A spurious CSAS is not credible for a fire in this area and the Train A containment spray pump will not spuriously start. Therefore, spurious opening of ENHV0006 will not result in an actual containment spray.
EP	Safety Injection Accumulators	H	A containment entry may be required to close valves EPHV8808A and EPHV8808C.
FB	Auxiliary Steam	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-11.
FC	Auxiliary Turbines	R, H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-11.
GD	ESW Pump House HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-11.

Table A-11-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-11

System	System Name	PFSSD Function*	Comments
GF	AFW Pump Room Coolers	S	Train A AFW pump room cooler SGF02A may be affected. Train B AFW pump room cooler SGF02B is unaffected.
GK	Control Room and Class 1E Switchgear Room Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-11.
GL	Auxiliary Building HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-11.
GM	Emergency Diesel Generator Room HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-11.
GN	Containment Coolers	S	Train A containment coolers may be affected. Train B containment coolers are unaffected.
JE	Diesel Fuel Oil	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-11.
KA	Instrument Air	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-11.

3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD

This section describes operator actions that may need to be performed inside or outside the control room to achieve and maintain hot standby if a fire occurs in area A-11. This section also describes cold shutdown repairs that may need to be made to achieve and maintain cold shutdown conditions. Operator actions are proceduralized in OFN KC-016.

3.1 ACTIONS OUTSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

None

3.2 ACTIONS INSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

3.2.1 RWST Draindown to Containment Sump

Valve EJHV8811A may spuriously open, allowing water from the RWST to drain to the sump. If the valve opens fully, valve BNHV8812A will automatically close, as designed. However, if EJHV8811A partially opens, then BNHV8812A will not automatically close. In this case, if a decreasing RWST inventory is observed, close BNHV8812A using BNHIS8812A on RL017.

3.2.2 Normal Pressurizer Spray

Pressurizer spray valves BBPCV0455B and BBPCV0455C could spuriously open. If this occurs, the spray can be stopped by isolating air to the valves. This can be accomplished by depressing the CLOSE push button on KAHIS0029 to close KAFV0029. KAHIS0029 is located on RL024. Pressurizer pressure indication is available using BBPI0456, BBPI0457 and BBPI0458.

3.2.3 Isolation of Letdown

A fire in area A-11 could prevent valves BGLCV0459, BGLCV0460, BGHV8149A, BGHV8149B, and BGHV8149C from being closed using their associated control room hand switches. If this occurs, the valves can be closed by isolating air to the valves. This can be accomplished by depressing the CLOSE push button on KAHIS0029 to close KAFV0029. KAHIS0029 is located on RL024. Pressurizer level indication is available using BBLI0460A.

3.3 ACTIONS TO ACHIEVE AND MAINTAIN COLD SHUTDOWN

3.3.1 RHR

Valve EJHV8701B may need to be manually opened when initiating Train B RHR for cold shutdown.

3.3.2 SI Accumulators

A fire in area A-11 may require a containment entry to close SI Accumulator injection valves EPHV8808A and EPHV8808C if these valves are unresponsive from the control room. The SI accumulators need to be isolated for cold shutdown, prior to the RCS reaching 1000 psig.

4.0 CONCLUSION

Redundant post fire safe shutdown capability, unaffected by a severe design basis fire, does not exist in area A-11. However, feasible manual actions are available and are unaffected by the fire. Manual actions are documented in Section 3.0.

5.0 DETAILED ANALYSIS

This section describes the detailed component-by-component and cable-by-cable analysis for a fire in area A-11.

5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA A-11

There are no PFSSD components (S. in E-15000) located in fire area A-11. Fire area A-11 is an electrical chase containing only cables.

5.2 PFSSD CABLE EVALUATION

Table A-11-3 lists all the PFSSD cables (S. in E-15000) located in fire area A-11. The applicable evaluation section is also listed in Table A-11-3.

Table A-11-3

5.2.1 Steam Generator Level Indication

The decay heat removal function for PFSSD requires the use of two RCS loops and two Steam Generators. Steam generator (SG) level indication is required to support this function. Therefore, level transmitters/indicators associated with the operable steam generators are required to be available and unaffected by the fire.

A fire in area A-11 could affect the Train A MDAFP, which is aligned to supply steam generators B and C. The TDAFP is available to supply auxiliary feedwater to all four Steam Generators and the Train B MDAFP is available to supply auxiliary feedwater to Steam Generators A and D.

Each steam generator is provided with five (5) level transmitters; one (1) wide range and four (4) narrow range. As long as one of the five level transmitters is available, steam generator level indication is satisfied for the associated steam generator. Table A-11-3 identifies the level transmitters that could be affected by a fire in area A-11. Based on Table A-11-3, only one narrow range level transmitter on each steam generator and the wide range transmitter on steam generator A is potentially affected by a fire in area A-11. Therefore, at least one level transmitter on each steam generator is available if a fire occurs in area A-11.

Based on the above discussion, steam generator A, B, C and D level indication is assured if a fire occurs in area A-11.

References: E-15000, XX-E-013, E-1F9203, E-13AE08, E-13AE12, M-12AE02

5.2.2 Auxiliary Feedwater

The PFSSD design requires auxiliary feedwater (AFW) flow to at least two steam generators. Cables associated with Train A MDAFP to Steam Generators (SGs) B and C control valves ALHV0009 and ALHV0011 are run in area A-11. Damage to these cables due to a fire could cause the valves to close, thereby preventing auxiliary feedwater flow from the Train A MDAFP to SGs B and C.

Power and control cables associated with Train A AFW pump room cooler DSGF02A are run in area A-11. Damage to these cables could prevent operation of the room cooler. Cables associated with redundant Train B AFW pump room cooler DSGF02B are unaffected by the fire.

Redundant capability exists and is unaffected by a fire in area A-11. The TDAFP is available to supply auxiliary feedwater to SGs A, B, C and D via valves ALHV0008, ALHV0010, ALHV0012 and ALHV0006, respectively. In addition, the Train B MDAFP is available to supply auxiliary feedwater to SGs A and D via valves ALHV0007 and ALHV0005, respectively. The Train B AFW pump room cooler is available to ensure a proper room environment during operation of the pump.

Based on the above discussion, auxiliary feedwater flow to at least two steam generators is available if a fire occurs in area A-11. Therefore, the auxiliary feedwater function is satisfied.

References: E-15000, XX-E-013, E-13AL09, E-13GF01, E-1F9201, E-1F9202, E-1F9203, E-1F9204, E-1F9444, M-12AL01

5.2.3 Pressurizer Power Operated Relief Valves and Associated Block Valves

PFSSD requires that either the pressurizer power operated relief valve (PORV) or its associated block valve be closed. Cables and components associated with PORV BBPCV0455A and associated block valve BBHV8000A are run through area A-11. Cables and components associated with PORV BBPCV0456A and associated block valve BBHV8000B are not located in area A-11.

The pressurizer PORVs are not considered high/low pressure interfaces. The valves are supplied power by an ungrounded 125 VDC system. Therefore, based on GL 86-10, consideration of multiple proper polarity hot shorts is not required. A single proper polarity hot short still needs to be considered.

Cables 11BBK40AG and 11BBK40AJ associated with PORV BBPCV0455A are run in this area. Based on a review of drawing E-13BB40, it would take two concurrent proper polarity hot shorts to cause the PORV to spuriously open. Therefore, a fire in area A-11 is not postulated to open PORV BBPCV0455A due to damage to the control cables associated with the PORV.

An instrument cable (11BBI16KB) associated with pressurizer pressure transmitter BBPT0455 is run in fire area A-11. Damage to this cable could send a spurious high-pressure signal to the pressurizer master controller. However, as discussed in Calculation XX-E-013, Appendix 1, damage to a single pressure channel will not cause the spurious operation of the pressurizer PORVs. Pressurizer level and RCS pressure indication are available to diagnose a failed open PORV using BBLI0460A and BBPI0406, respectively. In addition, pressurizer pressure indication is available using BBPI0456, BBPI0457 and BBPI0458.

Based on the above discussion, pressurizer PORV BBPCV0455A will not spuriously open due to a spurious high pressurizer pressure signal or due to damage to control cables in the area.

References: E-15000, XX-E-013, E-13BB16, E-13BB39, E-13BB40, E-1F9301, M-12BB02, M-744-00028, OFN KC-016, CR 13079, DCP 12944, DCP 13324.

5.2.4 RCS Hot and Cold Leg Temperature Elements

PFSSD requires RCS hot and cold leg temperature indication on at least one loop to verify flow through the steam generators. The temperature elements used for this purpose are listed in Table A-11-4.

As identified in Table A-11-3, cables associated with RCS temperature elements BBTE0413A, BBTE0423A, BBTE0433B and BBTE0443B are run in area A-11. These cables are run in the same raceway through fire area A-11. A fire could damage these cables and cause temperature indication on these four temperature elements to be unavailable. Consequently, temperature indication on at least one leg on each loop could be lost, which is not in accordance with the PFSSD methodology at Wolf Creek.

Table A-11-4 RCS Hot and Cold Leg Temperature Elements Used for PFSSD	
COMPONENT	**FUNCTION**
BBTE0413A	RCS Hot Leg Temperature Element (WR) Loop 1
BBTE0413B	RCS Cold Leg Temperature Element (WR) Loop 1
BBTE0423A	RCS Hot Leg Temperature Element (WR) Loop 2
BBTE0423B	RCS Cold Leg Temperature Element (WR) Loop 2
BBTE0433A	RCS Hot Leg Temperature Element (WR) Loop 3
BBTE0433B	RCS Cold Leg Temperature Element (WR) Loop 3
BBTE0443A	RCS Hot Leg Temperature Element (WR) Loop 4
BBTE0443B	RCS Cold Leg Temperature Element (WR) Loop 4

Procedure EMG ES-04, Attachment B Section B1 provides alternate indication in the control room that may be used to verify natural circulation flow. One of these methods verifies that steam generator pressure is stable or decreasing. S/G “A” and S/G “D” pressure instruments ABPT0516 and ABPT0546 are unaffected by a fire in A-11 and can be used per EMG ES-04 to verify heat removal in loops 1 and 4.

The configuration is acceptable because, in the event of a fire in fire area A-11, cooldown can be performed using RCS loops 1 and 4. RCS wide range hot and cold leg temperature elements (BBTE0413B and BBTE0443A) as well as ABPT0516 and ABPT0546 will provide indication of flow through the steam generators.

References: E-15000, XX-E-013, E-13BB15, E-1F9201, M-12AB01, M-12BB01, EMG ES-04

5.2.5 Safety Injection and Containment Spray

A spurious safety injection signal (SIS) could cause the safety injection pumps to operate. A spurious containment spray actuation signal (CSAS) could cause the containment spray pumps to operate, depleting inventory in the RWST. These conditions are not desirable for PFSSD at Wolf Creek.

Safety injection (SI) is initiated automatically by any of the following conditions:

1. Two out of three high containment pressures monitored by pressure transmitters GNPT0934, GNPT0935 and GNPT0936.
2. Two out of four low pressurizer pressures monitored by pressure transmitters BBPT0455, BBPT0456, BBPT0457 and BBPT0458.
3. Two out of three low steam line pressures on any steam generator monitored by ABPT0514, ABPT0515 and ABPT0516 on SG A; ABPT0524, ABPT0525 and ABPT0526 on SG B; ABPT0534, ABPT0535 and ABPT0536 on SG C; and ABPT0544, ABPT0545 and ABPT0546 on SG D. Two out of three logic must be satisfied on a single steam generator line. Low pressure on a single pressure transmitter co-incident with low pressure on another pressure transmitter on a different steam generator line will not initiate SIS.

Containment spray (CS) is initiated automatically by two out of four high containment pressures monitored by pressure transmitters GNPT0934, GNPT0935, GNPT0936 and GNPT0937.

Only cables associated with BBPT0455 and GNPT0937 are run in area A-11. Cables associated with the remaining transmitters are unaffected by a fire in area A-11. Therefore,

none of the safety injection or containment spray actuation signal initiators can be satisfied by spurious signals and a spurious start of either the safety injection or containment spray pumps is not credible.

Power and control cables associated with Train A containment spray isolation valve ENHV0006 are run in fire area A-11. Damage to these cables could cause the valve to spuriously open. However, as stated in the previous paragraph, a spurious CSAS is not credible if a fire occurs in this area. In addition, control cables associated with the Train A containment spray pump are located outside fire area A-11. Therefore, the Train A containment spray pump will not spuriously start if a fire occurs in area A-11.

References: E-15000, XX-E-013, E-13BB16, E-13EN03, E-13GN05, E-1F9431, E-1F9432, E-1F9433, M-12BB02, M-12EN01, M-12GN01

5.2.6 Pressurizer Level Transmitters

PFSSD requires available pressurizer level indication. Pressurizer level indication is provided by level transmitters BBLT0459 and BBLT0460. One cable associated with BBLT0459 runs in area A-11. Consequently, BBLT0459 may not be available if a fire occurs in this area.

Cables associated with pressurizer level transmitter BBLT0460 do not run through fire area A-11. Therefore, pressurizer level indication is available if a fire occurs in area A-11 using BBLT0460/BBLI0460A.

References: E-15000, XX-E-013, E-1F9301, E-13BB16, M-12BB02

5.2.7 Reactor Head Vent Valves

PFSSD requires that one of the two reactor vessel head vent valves on each flow path (2 flow paths total) be closed to prevent uncontrolled depressurization of the RCS. Either BBHV8001A or BBHV8002A and either BBHV8001B or BBHV8002B needs to be closed.

Only one cable associated with head vent valve BBHV8001A is run through A-11. An external (+) 125VDC hot short across conductor 2 in this cable is the only failure that will spuriously open this valve. Since this cable is run in tray with other cables carrying the proper voltage and polarity, this failure is considered credible.

Cables for the remaining three head vent valves are not run through area A-11 and are unaffected by a fire. Therefore, the spurious opening of BBHV8001A is mitigated by maintaining valve BBHV8002A closed. The second flow path is isolated using either head vent valve BBHV8001B or BBHV8002B.

Based on this discussion, both head vent valve flow paths can be isolated if a fire occurs in area A-11.

References: E-15000, XX-E-013, E-1F9301, E-13BB30, M-12BB04

5.2.8 Charging Flow to Regenerative Heat Exchanger Isolation Valves

PFSSD requires charging flow be directed to the RCP seals. To ensure adequate flow to RCP seals, flow diversion to the regenerative heat exchanger needs to be prevented. Valves BGHV8105 and BGHV8106 are included in the PFSSD design to accomplish this task. Manual valve BG8402B is also included to provide an alternate means of closing this flow path if either BGHV8105 or BGHV8106 are unavailable and is also used during alternate safe shutdown per OFN RP-017.

Cables associated with BGHV8106 are run in area A-11 and could be damaged by a fire, preventing valve BGHV8106 from being closed from the control room. Cables associated with

BGHV8105 are not located in area A-11 and are unaffected by a fire in this area. Therefore, valve BGHV8105 can be closed from the control room using BGHIS8105.

References: E-15000, XX-E-013, E-1F9102, E-1F9302, E-13BG11A, M-12BG03

5.2.9 Excess Letdown

PFSSD requires the excess letdown path be isolated to prevent uncontrolled depressurization of the RCS. To accomplish this, either normally closed valve BGHV8153A or BGHV8154A must be maintained closed and either normally closed valve BGHV8153B or BGHV8154B must be maintained closed.

Only one cable associated with BGHV8154A runs through area A-11. Cables associated with the remaining valves are unaffected by a fire in area A-11. Therefore, at least one valve on each flowpath will remain closed or can be controlled from the control room.

References: E-15000, XX-E-013, E-1F9301, E-13BG48, M-12BG01

5.2.10 Containment Coolers

PFSSD requires containment cooling to maintain the containment environment within EQ limits. Cables associated with Train A containment coolers are run in area A-11. These cables are listed in Table A-11-3.

Damage to these cables could prevent operation of the Train A containment coolers if a fire occurs in area A-11. However, circuits for the Train B containment coolers are run in a separate fire area and are unaffected by a fire in area A-11.

Train B ESW is available if a fire occurs in area A-11. Therefore, the Train B containment coolers will have the necessary service water flow to ensure proper operation.

Based on the above discussion, the Train B containment coolers will be used to provide containment cooling in the event of a fire in area A-11.

References: E-15000, XX-E-013, E-13EF07, E-13EF08, E-13EF09, E-13GN02, E-13GN02A, E-1F9403, E-1F9441, M-12EF02, M-12GN01

5.2.11 CCW to/from RCP Thermal Barriers

The Wolf Creek plant design provides two redundant methods of cooling the RCP seals, thermal barrier cooling using CCW and seal injection using the CCP. The PFSSD methodology at Wolf Creek requires tripping the RCPs and performing a natural circulation cooldown upon loss of both thermal barrier cooling (TBC) and seal injection. If only one method is lost, continued operation of the RCP is allowed by present established procedures until the other method is re-established.

Valves BBHV0013, BBHV0014, BBHV0015, BBHV0016, EGHV0058, EGHV0061, EGHV0126 and EGHV0132 provide isolation capability for CCW flow to/from the RCP thermal barriers. Cables associated with these components are located in area A-11. If the valves fail to the open position, CCW would continue to flow to the RCP components, including the thermal barrier. This continued flow of water will not adversely impact PFSSD. If the valves fail to the closed position, CCW flow to the thermal barrier could be lost. This is acceptable since RCP seal injection is available.

Flow transmitters BBFT0017, BBFT0018, BBFT0019 and BBFT0020 are associated with valves BBHV0013, BBHV0014, BBHV0015 and BBHV0016, respectively. The flow transmitters monitor flow in the CCW piping and shut the valves on high CCW flow. Cables associated with these flow transmitters are run in this area. Damage to these cables could

cause a spurious high CCW flow signal and close the valves. Damage to the valve cables could prevent re-opening the valves.

Loss of thermal barrier cooling would be indicated in the control room as a reduction in flow on flow indicators EGFI0128 and EGFI0129. Therefore, operators can diagnose a loss of thermal barrier cooling.

Based on the above discussion, a fire in area A-11 could affect CCW flow to/from the RCP thermal barriers. However, RCP seal injection is unaffected.

References: E-15000, XX-E-013, E-13BB03, E-13BB28, E-13EG09, E-13EG09A, E-13EG10, E-13EG17A, E-13EG18, E-1F9303, M-12BB03, M-12EG03

5.2.12 Reactor Coolant System (RCS) to Residual Heat Removal (RHR) Isolation Valves

Loss of inventory from the RCS to the RHR system is prevented by maintaining either valves BBPV8702A or EJHV8701A and either valves BBPV8702B or EJHV8701B closed. All four valves are normally closed with their breakers administratively locked in the off position.

Control cables associated with valves EJHV8701A and EJHV8701B are run in area A-11. Cables associated with BBPV8702A and BBPV8702B are not run in area A-11. Consequently, the RCS to RHR flowpath on both trains will remain isolated if a fire occurs in area A-11.

When aligning RHR for cold shutdown, at least one flowpath to one RHR pump is required. Valves BBPV8702A and BBPV8702B can be opened from the control room when power is restored at the MCC. As discussed in Section 5.2.13, valve EJHV8811A could spuriously open. Therefore, Train B RHR should be used for decay heat removal to ensure the RCS does not drain to the containment sump. It may be necessary to manually open EJHV8701B to provide a suction source to the Train B RHR pump.

References: E-15000, XX-E-013, CKL BB-110, CKL EJ-120, E-13EJ05A, E-13EJ05B, E-1F9205, E-1F9301, M-12BB01, M-12EJ01

5.2.13 Containment Sump Isolation Valves

To prevent draindown of the RWST into the containment sump, PFSSD requires that either valves BNHV8812A or EJHV8811A and either valves BNHV8812B or EJHV8811B be closed during hot standby. For cold shutdown, the operating train containment sump valve (EJHV8811A or EJHV8811B) must be maintained closed to prevent flow diversion from the RCS to the containment sump. Valves BNHV8812A and BNHV8812B are normally open and valves EJHV8811A and EJHV8811B are normally closed.

Cables associated with valve EJHV8811A run through fire area A-11. In order for valve EJHV8811A to spuriously open, it will take two simultaneous intra-cable hot shorts to occur. The hot shorts need to involve conductors 62 and 52 in 2-conductor cable 11EJG06AU and conductors 2 and 42 in 7-conductor cable 11EJG06AC. Although extremely unlikely, if this occurs, valve BNHV8812A will automatically close, as designed, to prevent draindown of the RWST into the containment sump. However, if EJHV8811A partially opens, then BNHV8812A will not automatically close. In this case, operators will recognize a decreasing RWST inventory and can close BNHV8812A from the control room using BNHIS8812A. Cables associated with valve BNHV8812A do not run in area A-11.

During cold shutdown, Train B RHR is available since EJHV8811B will remain closed and the RCS will not drain to the sump.

Based on the above discussion, redundant capability exists to ensure the RWST and RCS do not drain to the containment sump.

References: E-15000, XX-E-013, E-13BN03, E-13BN03A, E-13EJ06A, E-13EJ06B, E-1F9102, E-1F9205, M-12BN01, M-12EJ01, M-10BN

5.2.14 RHR to Accumulator Injection Loop Isolation Valves

The RHR pump discharge to RCS cold leg isolation valve (EJHV8809A or EJHV8809B) needs to be open on the operating train. Damage to cables 11EJG09CA, 11EJG09CB, 11EJG09CC and 11EJG09CD would likely result in valve EJHV8809A remaining in its as-is normally open position, which is the preferred PFSSD position. However, two proper intra-cable hot shorts in cable 11EJG09CD or one intra-cable hot short in cable 11EJG09CD combined with a short to ground on conductor 31 would spuriously close valve EJHV8809A.

Cables for valve EJHV8809B are run in a separate fire area and are unaffected by a fire in area A-11. Therefore, the Train B RHR pump discharge to RCS cold leg flow path is available for a fire in area A-11.

Based on the above discussion, the Train A RHR system could be affected but the Train B RHR system is available in the event of a fire in area A-8.

References: E-15000, XX-E-013, E-13EJ09A, E-1F9205, M-12EJ01

5.2.15 Boron Injection Tank Flowpath

The Boron Injection Tank (BIT) flowpath is credited for reactivity control and reactor coolant makeup. For reactivity control, the BIT flowpath is credited as an alternate source of boration in the event RCP seal injection is unavailable. Based on Calculation XX-E-013, RCP seal injection will provide sufficient boration to achieve and maintain cold shutdown reactivity conditions. Therefore, the BIT flowpath is not required for reactivity control if RCP seal injection is available. Since RCP seal injection is limited to 5 gpm per seal or 20 gpm total injection to the RCS, an additional RCS charging flowpath is required for adequate RCS makeup during plant transition from hot standby to cold shutdown. The BIT injection path was selected as the additional RCS charging flowpath.

A fire in area A-11 will not result in a loss of seal injection. However, based on the discussion in 5.2.19, a fire in area A-11 has the possibility to cause a momentary loss of inventory through the letdown flow path until the letdown isolation valves are failed closed. Therefore, charging through the BIT flow path may be required for hot standby. In addition, as discussed above, the BIT flowpath is required for transition to cold shutdown.

Power and control cables associated with BIT outlet valve EMHV8801A and BIT inlet valve EMHV8803A run through area A-11. Damage to these cables could prevent operation of the valves from the control room. Cables associated with redundant valves EMHV8801B and EMHV8803B do not run in area A-11 and would be available to provide a flowpath from Train B charging pump to the RCS.

When charging through the BIT, the SIS test line is required to be isolated to prevent inventory loss. Valves EMHV8843, EMHV8882, EMHV8964 and EMHV8871 are used to isolate this flowpath. Either valves EMHV8964 or EMHV8871 are required to be closed or both valves EMHV8843 and EMHV8882 are required to be closed to isolate the SI test line.

Control cables associated with valves EMHV8882 and EMHV8964 are run in area A-11. Damage to these cables could cause the valves to spuriously open. Cables associated with redundant valve EMHV8871 are run in a different fire area and are unaffected by a fire in area A-11. Therefore, the SI test line can be isolated if a fire occurs in area A-11.

Based on the above discussion, a fire in area A-11 will not adversely impact the ability to isolate the SIS test line and charge through the BIT.

References: E-15000, XX-E-013, E-13EM02, E-13EM02C, E-13EM05A, E-13EM12, E-1F9302, M-12EM01, M-12EM02

5.2.16 Safety Injection Accumulator Isolation Valves

PFSSD requires isolation of the SI accumulators prior to reducing RCS pressure below the injection pressure to avoid unnecessary accumulator discharge. This is accomplished by closing valves EPHV8808A, EPHV8808B, EPHV8808C and EPHV8808D. These valves are normally open with the MCC breaker administratively locked in the open position. Cables for valves EPHV8808A and EPHV8808C are run in area A-11.

Since the breakers for these valves are normally open, damage to these cables will not cause the valves to spuriously change position. However, damage to the cables will prevent closing the associated valve from the control room after power is restored.

The SI accumulators need to be isolated during cold shutdown, prior to the RCS reaching 1000 psig. If necessary, a containment entry can be made to manually close the valves.

References: E-15000, XX-E-013, M-12EP01, E-13EP02A, E-1F9201, CKL EP-120

5.2.17 480 VAC Power Distribution

A fire in area A-11 could damage cables associated with the Train A 480 VAC power distribution system. Cables 11NGG01AD and 11NGG01AE supply power from NG0107 to NG01BAF1. Damage to these cables could result in loss of power to Train A PFSSD components fed from NG01B. Drawing E-1F9424A identifies the Train A PFSSD loads associated with NG01B.

Cable 11NGG01AJ is the power cable for containment cooler SGN01A. Cable 11NGG01BF is the power cable for containment cooler SGN01C. As stated in Section 5.2.10, loss of containment coolers SGN01A and SGN01C will not prevent PFSSD due to the availability of the Train B containment coolers.

The loss of NG01B will not prevent PFSSD. Loss of power to the associated loads is acceptable due to the availability of Train B 480 VAC power from NG02 and NG04. None of the PFSSD equipment associated with NG01B is required if a fire occurs in area A-11.

References: E-15000, XX-E-013, E-13NG01A, E-1F9424A, E-1F9441

5.2.18 Main Control Board RL017/RL018 120 VAC Non Class 1E Power

120 VAC non-class 1E distribution switchboards PN07 and PN08 supply power to separation groups 5 and 6, 120 VAC loads on RL017/RL018. Each distribution switchboard relies on two redundant sources of power. PN07 is powered from either transformer XPN07A or XPN07D. PN08 is powered from either transformer XPN08A or XPN08D.

Cable 11PNG01AE is a power cable that runs from NG001BEF4 to NG001ABF1, through area A-11, and feeds transformer XPN07A. Damage to this cable could cause a loss of power to XPN07A, which will result in a loss of power to one of the two redundant feeds to PN07. Transformer XPN07D is unaffected by the fire and will remain available to supply power to PN07.

References: E-15000, XX-E-013, E-13PN01, E-13PN01A, E-13RL01, E-13RL04, E-1F9421

5.2.19 Letdown Isolation Valves

Valves BGLCV0459 and BGLCV0460 are isolation valves installed in series on the inlet side of the regenerative heat exchanger. PFSSD requires that either of these valves be closed.

Cables 15BGK10AA and 15BGK10AD are power/control cables for the BGLCV0459 solenoid valve (BGHY0459). Air supplied by an open (energized) solenoid valve will open valve BGLCV0459. A closed (de-energized) solenoid valve will cause loss of air pressure and closure of valve BGLCV0459.

Cables 15BGK10BA and 15BGK10BD are power/control cables for the BGLCV0460 solenoid valve (BGHY0460). Air supplied by an open (energized) solenoid valve will open valve BGLCV0460. A closed (de-energized) solenoid valve will cause loss of air pressure and closure of valve BGLCV0460.

Either BGLCV0459 or BGLCV0460 must be closed or letdown orifice isolation valves BGHV8149A, BGHV8149B, and BGHV8149C must be closed. The cables for BGLCV0459 or BGLCV0460 are routed in a common enclosure in cable trays. A hot short on the cables could cause the valves to open. An intra-cable hot short in cables 15BGK10AA and 15BGK10BA prevents closing BGLCV0459 and BGLCV0460 from the control room. Other cables routed in the cable trays have the proper voltage for inter-cable hot shorts which can bypass MCB hand switches for BGLCV0459 and BGLCV0460. BGLCV0459 and BGLCV0460 constitute a high/low pressure interface. Therefore, multiple simultaneous hot shorts must be considered.

Letdown orifice isolation valves BGHV8149A, BGHV8149B, and BGHV8149C are listed as PFSSD components because of the interlock between these valves and BGLCV0459 and BGLCV0460. The interlock prevents closure of the letdown valves when any one or more orifice isolation valves are open. Cables associated with all three letdown orifice isolation valves are located in this fire area. Damage to these cables could prevent closure of the valves from the control room. Therefore, a fire in area A-11 will prevent closure of all three letdown orifice isolation valves (BGHV8149A, BGHV8149B, and BGHV8149C) as well as the two letdown isolation valves (BGLCV0459 and BGLCV0460).

BGHV8152 is located in the low-pressure piping rated for only 600 psi pressure down stream of BGLCV0459 and BGLCV0460. Isolating BGHV8152 with the reactor pressure above 600 psi will cause relief valve BGV8117 to open to protect the pipe and discharge the water to the PRT. A maximum of 195 gpm can be passed through the three orifice isolation valves if they are all open. The centrifugal charging pump capacity is 150-gpm. Therefore approximately 45-gpm could be lost while BGLCV0459 and BGLCV0460 remain open.

Valves BGLCV0459, BGLCV0460, BGHV8149A, BGHV8149B, and BGHV8149C are air operated and fail in the closed position. The valves are located in containment. Instrument air to containment is controlled by valve KAFV0029, which is unaffected by a fire in area A-11. Hand switch KAHIS0029 can be used to close the valve from the control room and isolate instrument air to containment. Pressurizer level indication is available using BBLI0460A.

Based on the above discussion, letdown valves BGLCV0459 and BGLCV0460 and letdown orifice valves BGHV8149A, BGHV8149B, and BGHV8149C can be closed from the control room if a fire occurs in area A-11.

References: E-15000, XX-E-013, E-13BG10, E-13BG35, E-13KA02, E-1F9301, M-12BG01, M-12KA01

5.2.20 Steam Generator Blowdown to Blowdown Flash Tank Valves

Blowdown valves BMHV0001, BMHV0002, BMHV0003 and BMHV0004 are required to be closed to prevent reactivity addition due to uncontrolled cooldown. The valves are air operated, and each valve is controlled by three solenoid valves. All three solenoid valves are required to be energized to open the valve. If any one solenoid is de-energized, the associated valve will close or remain closed. Only two of the three solenoids for each valve are considered in the PFSSD analysis, so the third solenoid is assumed energized throughout the event.

Cables associated with one of the three solenoid valves for each main valve are run in area A-11. These cables are associated with the BM157 panel hand switches located in the Radwaste Building control room. Damage to these cables could result in the associated solenoid valves becoming energized.

Cables associated with the main control room hand switches for each main valve are not located in area A-11. Therefore, the solenoid valve associated with the main control room hand switches remains available to ensure the main valves are closed.

Based on the above discussion, isolation of the Steam Generator Blowdown valves is achievable if a fire occurs in area A-11.

References: E-15000, XX-E-013, E-13BM06A, E-13BM06D, E-1F9101, M-12BM01

5.2.21 Reactor Coolant Pumps

The reactor coolant pumps are not credited in the PFSSD analysis. However, the capability to stop the pumps from the control room in the event of a loss of all seal cooling or spuriously open pressurizer spray is credited. Westinghouse Technical Bulletin TB-04-22, Rev. 1 recommends that if all seal cooling is lost (RCP seal injection and thermal barrier heat exchanger flow), operators need to stop the pumps before a seal LOCA occurs. Calculation WCNOC-CP-002 shows that if pressurizer spray spuriously actuates, the spray flow needs to be stopped within 50 minutes.

Control cables associated with reactor coolant pumps A and B are run in fire area A-11. Damage to these cables in the event of a fire could prevent operators from stopping the A and B RCPs from the control room. However, a fire in A-11 will not cause a loss of all seal cooling since RCP seal injection remains available. As discussed in Section 5.2.22, if pressurizer spray spuriously operates, operators can stop the spray by isolating air to the valve from the control room. Therefore, tripping the RCPs is not required to mitigate spurious pressurizer spray.

Based on the above discussion, the inability to trip RCPs A and B from the control room will have no adverse impact on PFSSD. If pressurizer spray spuriously actuates, the valves can be closed by isolating air to the valves from the control room. In addition, seal injection is unaffected by a fire in area A-11. Therefore, the RCPs do not have to be tripped in the event of a fire in area A-11.

References: E-15000, XX-E-013, E-13BB01, Westinghouse TB-04-22 Rev. 1, WCNOC-CP-002, CR 25002

5.2.22 Normal Pressurizer Spray

The normal pressurizer spray valves are included in the PFSSD design because spurious operation of pressurizer sprays can cause a decrease in pressure which can lead to boiling in the core. The pressurizer spray valves are part of the pressurizer pressure control system.

The pressurizer normal spray valves (BBPCV0455B and BBPCV0455C) operate off a signal from the Ovation pressurizer pressure control system. The operation of the pressure control system is discussed in Calculation XX-E-013.

Cable 11BBI16KB associated with BBPT0455 is run in this area. Damage to this cable could cause a spurious high-pressure signal. As discussed in Calculation XX-E-013, Appendix 1, damage to a single pressure input channel will not cause the spurious operation of the pressurizer spray valves due to the Ovation 4-channel validation logic, which uses the 2nd highest signal as the validated signal and has built-in logic to detect and ignore a failed input.

Cable 15BBI19AA associated with pressurizer spray valve BBPCV0455B, and cable 15BBI19BA associated with pressurizer spray valve BBPCV0455C are run in this area. Damage to these cables could cause the spurious opening of the spray valves.

The pressurizer spray valves are electro/pneumatic operated, and loss of air pressure will close the valves. The air supply comes from the compressed air system. Closing valve KAFV0029 using KAHIS0029 on RL024 will isolate compressed air to containment which will cause the pressurizer spray valves to close or prevent them from opening. Based on WCNOC-CP-002, spray flow needs to be stopped within 50 minutes. Since this is a control room action, this can be completed well within 50 minutes.

Based on the above discussion, the pressurizer spray valves could spuriously open if a fire occurs in this area. Pressurizer spray can be stopped by closing valve KAFV0029 from the main control room. Pressurizer pressure indication is available using BBPI0456, BBPI0457 and BBPI0458.

1.0 GENERAL AREA DESCRIPTION

Fire area A-12 is located on the 2000 elevation of the Auxiliary Building and includes the room listed in Table A-12-1.

Table A-12-1
Rooms Located in Fire Area A-12

ROOM #	DESCRIPTION
1336	South Electrical Chase

Fire area A-12 is protected with an automatic fire suppression system. In addition, automatic fire detection is installed throughout. The area is bounded on all sides by minimum 3-hour fire rated construction.

2.0 PRIMARY EQUIPMENT USED FOR PFSSD

Table A-12-2 lists each system credited for post-fire safe shutdown and provides a discussion regarding the availability of the system to perform its Post Fire Safe Shutdown (PFSSD) function if a severe fire occurs in this area. For a summary of the area analysis results, see Section 8.0 of the Fire Area Analysis Narrative section.

Table A-12-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-12

System	System Name	PFSSD Function*	Comments
AB	Main Steam	R, M, H, P, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-12.
AC	Main Turbine	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-12.
AE	Main Feedwater	H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-12.
AL	Aux. Feedwater System	H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-12.
AP	Condensate Storage System	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-12.
BB	Reactor Coolant System	R, M, H, P, S	All PFSSD functions associated with the reactor coolant system are satisfied. Cables associated with all four RCP seal injection valves could be affected, however seal injection is unaffected because the cable damage will not cause the valves to close. RCS pressure indication is available using BBPI0405. Reactor coolant pumps C and D may not stop using the control room hand switch. RCP seal injection and thermal barrier cooling remain available. Therefore, the inability to stop the RCPs will have no adverse impact on PFSSD.
BG	Chemical and Volume Control System	R, M, S	All PFSSD functions associated with the chemical and volume control system are satisfied. RCP seal flow indication is available using BGFI0215A. RCP seal flow indicator BGFI0215B may be affected.
BM	Steam Generator Blowdown System	R, M, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-12.
BN	Borated Refueling Water Storage System	R, M, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-12.
EF	Essential Service Water System	H, S	All PFSSD functions associated with the Essential Service Water (ESW) system are satisfied. Train B ESW to containment cooler valves EFHV0032 and EFHV0050 may not be operable from the control room. If the valves are open at the time of the fire, they will not spuriously close. Train A ESW is available to supply cooling water to Containment Air Coolers SGN01A and SGN01C, as well as all other required PFSSD loads.

Table A-12-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-12

System	System Name	PFSSD Function*	Comments
EG	Component Cooling Water System	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-12.
EJ	Residual Heat Removal System	M, H, P	All PFSSD functions associated with the Residual Heat Removal (RHR) system are satisfied. Train B RHR may not be available due to the spurious closure of EJHV8809B. Train A RHR is unaffected. In the unlikely event valve EJHV8840 spuriously opens and does not respond to a close signal, perform a cold shutdown repair to close the valve or isolate valve EJHV8716A to prevent flow from Train A RHR through this flow path.
EM	High Pressure Coolant Injection	R, M	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-12.
EN	Containment Spray	R, M	All PFSSD functions associated with the Containmant Spray system are satisfied. Cables for valve ENHV0012 could be damaged but will not cause the valve to open.
EP	Safety Injection Accumulators	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-12.
FB	Auxiliary Steam	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-12.
FC	Auxiliary Turbines	R, H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-12.
GD	ESW Pump House HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-12.

3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD

This section describes operator actions that may need to be performed inside or outside the control room to achieve and maintain hot standby if a fire occurs in area A-12. This section also describes cold shutdown repairs that may need to be made to achieve and maintain cold shutdown conditions. Operator actions are proceduralized in OFN KC-016.

3.1 ACTIONS OUTSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

None

3.2 ACTIONS INSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

None

3.3 ACTIONS TO ACHIEVE AND MAINTAIN COLD SHUTDOWN

3.3.1 RHR

If valve EJHV8840 spuriously opens, perform a cold shutdown repair or manually close valve EJHV8716A to isolate RHR Train A flow to the hot leg.

4.0 CONCLUSION

Post-Fire Safe Shutdown capability is assured if a severe fire occurs in this area.

5.0 DETAILED ANALYSIS

This section describes the detailed component-by-component and cable-by-cable analysis for a fire in area A-12.

5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA A-12

There are no PFSSD components located in area A-12. This fire area only contains cables associated with PFSSD equipment located in other areas.

5.2 PFSSD CABLE EVALUATION

Table A-12-3 lists all the PFSSD cables (S. in E-15000) located in fire area A-12. The applicable evaluation section is also listed in Table A-12-3.

Table A-12-3
PFSSD Cables Located in Fire Area A-12

Cable #	Location	Primary PFSSD Equipment	Cable Function (P) Power (C) Control (I) Instrumentation	Evaluation Section	Comments
14BBG04AA	1336	BBHV8351A	P	5.2.1	RCP A Seal Water Injection Valve

5.2.1 Reactor Coolant Pump (RCP) Seal Injection

PFSSD requires RCP seal injection to provide a boron injection path, provide makeup to the RCS to maintain hot standby inventory and prevent damage to the RCP seals. The Component Cooling Water (CCW) system is an alternative means of cooling the RCP seals.

Cables associated with all four seal injection valves (BBHV8351A, BBHV8351B, BBHV8351C and BBHV8351D) are run in area A-12, and are listed in Table A-12-3. The valves are normally open and de-energized and are required to remain open during a fire. The valves are not high/low pressure interface valves so three-phase hot shorts do not have to be considered and, consequently, damage to the power cables will not cause the valves to close. Damage to the control cable for each valve located in this area will not cause the valves to spuriously close since a hot short or open circuit in these cables will not bypass the control room hand switch. Furthermore, the valves are de-energized so cable damage could not cause the valves to close.

Cable 14BGI51BA is associated with RCP seal total flow indicator BGFT0215B. Damage to this cable could prevent operation of the flow transmitter and could prevent operators from determining total RCP seal injection flow using flow indicator BGFI0215B. Flow indicator BGFI0215A is unaffected by a fire in area A-12 and can be used by operators to determine if seal injection flow is functioning.

Based on the above discussion, there is reasonable assurance that the seal injection valves will remain open in the event of a fire in area A-12. Therefore, RCP seal injection is available to provide hot standby inventory control and seal cooling. Loss of the operating charging pump would be indicated by loss of flow to the RCP seals using flow indicator BGFI0215A.

References: E-15000, XX-E-013, E-13BB04, E-13BG51, E-1F9303

5.2.2 Reactor Coolant System (RCS) Pressure Indication

PFSSD requires RCS pressure indication to be available. RCS pressure indication is provided in the control room using BBPI0405 or BBPI0406.

Cable 14BBI16BA, associated with BBPT0406 runs through fire area A-12. Damage to this cable could prevent operation of pressure indicator BBPI0406.

Cables for BBPT0405 are run in a separate fire area and are unaffected by a fire in area A-12. Therefore, RCS pressure indication will be available using BBPI0405 if a fire occurs in area A-12.

References: E-15000, XX-E-013, E-13BB15, E-13BB16, E-1F9201, M-12BB04

5.2.3 Containment Coolers

PFSSD requires containment cooling to maintain credited equipment within operational limits. Power and control cables associated with normally open valves EFHV0032 and EFHV0050 (ESW supply to the Train B containment coolers) are run in area A-12. Damage to these cables could prevent operation of the valves from the control room but will not cause the valves to spuriously close. If the valves are closed at the time of the fire, then Train B containment cooling may not be available.

Cables associated with the ESW supply to the Train A containment coolers are run in a separate fire area and are unaffected by a fire in area A-12. Therefore, the Train A containment coolers are available to provide containment cooling in the event of a fire in area A-12.

References: E-15000, XX-E-013, E-13EF07, E-13EF08, M-12EF02, E-1F9403, E-1F9441

5.2.4 RHR To RCS Hot and Cold Legs

During cold shutdown mode, PFSSD requires one RHR pump operating and discharging into the cold legs of either Loops 1 and 2 (Train A RHR) or 3 and 4 (Train B RHR). In addition, hot leg injection needs to be isolated.

Valve EJHV8840 is required to be closed to prevent injection through the hot leg of loops 2 and 3. Cables associated with this valve run through area A-12. In order for the valve to spuriously open, it would take two simultaneous hot shorts within the same multi-conductor cable. This is unlikely to occur since it would take the proper source conductor shorting to a specific target conductor without shorting to a different conductor or shorting to ground to cause the valve to open. In the unlikely event the valve spuriously opens, a cold shutdown repair can be performed, or valve EJHV8716A can be locally manually closed, to prevent flow from Train A RHR through this flow path. If Train B RHR is being used, then valve EJHV8716B can be closed to isolate this flow path.

Either EJHV8809A or EJHV8809B needs to be open when operating RHR pumps A or B, respectively. Cables associated with EJHV8809B run through area A-12 and could be damaged such that the valve spuriously closes. Cables associated with valve EJHV8809A are not run in area A-12. Consequently, valve EJHV8809A is unaffected if a fire occurs in area A-12.

Based on the above discussion, a flow path is available to ensure RHR flow to the RCS.

References: E-15000, XX-E-013, E-13EJ09A, E-1F9205, M-12EJ01

5.2.5 Containment Spray Isolation Valve

Power and control cables associated with containment spray isolation valve ENHV0012 are located in this area. Damage to these cables will not cause the valve to spuriously open. Therefore, RWST inventory reduction due to containment spray actuation will not occur.

References: E-15000, XX-E-013, E-13EN03, E-1F9424B, E-1F9433, M-12EN01

5.2.6 Reactor Coolant Pumps

The reactor coolant pumps are not credited in the PFSSD analysis. However, the capability to stop the pumps from the control room in the event of a loss of all seal cooling is credited. Westinghouse Technical Bulletin TB-04-22, Rev. 1 recommends that if all seal cooling is lost (RCP seal injection and thermal barrier heat exchanger flow), operators need to stop the pumps before a seal LOCA occurs.

Control cables associated with reactor coolant pumps C and D are run in fire area A-12. Damage to these cables in the event of a fire could prevent operators from stopping the C and D RCPs from the control room. However, a fire in A-12 will not cause a loss of all seal cooling since RCP seal injection and thermal barrier cooling remain available.

Based on the above discussion, the inability to trip the C and D RCPs from the control room will have no adverse impact on PFSSD. The pumps can continue to operate, providing forced flow circulation. If the pumps spuriously stop, natural circulation cooldown can be used.

References: E-15000, XX-E-013, E-13BB01, Westinghouse TB-04-22 Rev. 1

5.2.7 Load Center Feeder Breaker PA0206

Load center feeder breaker PA0206 is credited for PFSSD because it supplies power to credited non-safety related loads. Cable 16PGA10CA is a control cable associated with breaker PA0206. An intra-cable hot short in this cable will trip PA0206. Breaker PA0206 supplies power to the following PFSSD components:

- PG12KAF4 – Main Steam Supply to 2nd Stage Reheat Valve ABHV0032
- PG12KAF5 – Main Steam Supply to Steam Seals Valve ABHV0046
- PG12KEF3 – Auxiliary Steam System Control Valve FBHV0080

PG12KAF4, PG12KAF5 and PG12KEF3 supply power to components downstream of the MSIVs. The MSIVs are unaffected by a fire in this area and can be closed from the control room using either hand switch ABHS0079 or ABHS0080. Therefore, the MSIV downstream components are not required if a fire occurs in this area.

Based on the above discussion, loss of breaker PA0206 due to a fire in area A-12 will not adversely impact PFSSD.

1.0 GENERAL AREA DESCRIPTION

Fire area A-13 is located on the 2000 elevation of the Auxiliary Building and includes the room listed in Table A-13-1.

Table A-13-1
Rooms Located in Fire Area A-13

ROOM #	DESCRIPTION
1325	Aux Feed Water Pump Room B

Fire area A-13 is protected with automatic smoke detection. There is no automatic fire suppression installed. The room is separated from adjacent areas by minimum 3-hour fire rated barriers.

2.0 PRIMARY EQUIPMENT USED FOR PFSSD

Table A-13-2 lists each system credited for post-fire safe shutdown and provides a discussion regarding the availability of the system to perform its Post Fire Safe Shutdown (PFSSD) function if a severe fire occurs in this area. For a summary of the area analysis results, see Section 8.0 of the Fire Area Analysis Narrative section.

Table A-13-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-13

System	System Name	PFSSD Function*	Comments
AB	Main Steam	R, M, H, P, S	Steam Generator B ARV ABPV0002 may need to be controlled using local controller ABFHC0002. The controller for Steam Generators A and D ARVs may need to placed in manual and closed from the main control room. Steam generator C ARV is unaffected by a fire in this area. Cables for hand switch ABHS0079 may be damaged by the fire. Cables for redundant hand switch ABHS0080 are unaffected. Use ABHS0080 to close the MSIVs and MSIV bypass valves. Both steam supply valves (ABHV0005 and ABHV0006) to the TDAFP may be affected. Steam generators B and C pressure indication is available using ABPI0524A, ABPI0526A, ABPI0534A and ABPI0536A. Pressure indication on steam generators A and D may be lost.
AC	Main Turbine	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-13.
AE	Main Feedwater	H, P	Cables for hand switch AEHS0081 may be damaged. Cables for redundant hand switch AEHS0080 are unaffected. Use AEHS0080 to close the MFIVs.
AL	Aux. Feedwater System	H, P	The Train B MDAFP and the TDAFP are unavailable. The Train A MDAFP is unaffected. Spurious ESFAS swap over to the ESW system could occur due to damage to circuits for two of the three pressure transmitters. This is acceptable since the ESW system is the safety related source for auxiliary feedwater.
AP	Condensate Storage System	H	The CST is available, however as stated in AL system, a spurious swap over to ESW could occur.
BB	Reactor Coolant System	R, M, H, P, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-13. RCS pressure indication is available using BBPI0405 and BBPI0406. Pressurizer level indication is available using BBLI0459A and BBLI0460A.
BG	Chemical and Volume Control System	R, M, S	A spurious SI signal will cause CCPs PBG05A and PBG05B to start. PBG05A is credited for PFSSD if a fire occurs in this area. PBG05B can be stopped, if necessary, by placing hand switch BGHIS0002A in pull-to-lock.
BM	Steam Generator Blowdown System	R, M, H	Blowdown through BMHV0002 and BMHV0003 may need to be isolated using BMHIS0002C and BMHIS0003C located on the BM157 panel in the Radwaste Control room. The remaining blowdown valves can be closed from the main control room.
BN	Borated Refueling Water Storage System	R, M, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-13.

Table A-13-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-13

System	System Name	PFSSD Function*	Comments
EF	Essential Service Water System	H, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-13.
EG	Component Cooling Water System	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-13.
EJ	Residual Heat Removal System	M, H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-13.
EM	High Pressure Coolant Injection	R, M	A spurious start of the SI pumps due to two out of three low steam line pressures can be terminated by placing the pump control hand switches EMHIS0004 and EMHIS0005 on panel RL017 in pull-to-lock.
EN	Containment Spray	R, M	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-13.
EP	Safety Injection Accumulators	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-13.
FB	Auxiliary Steam	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-13.
FC	Auxiliary Turbines	R, H, P	The Turbine Driven Auxiliary Feedwater Pump may not be available if a fire occurs in this area. Cables associated with FCHV0312 and FCFV0313 run in this area and could cause the valves to close, isolating steam supply to the TDAFP. A cable associated with steam trap valve FCFV0310 runs in this area and could cause the valve to remain open. This is acceptable since steam flow through a 1-inch line is bounded by the main steam line break analysis.
GD	ESW Pump House HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-13.
GF	AFW Pump Room Coolers	S	The Train B AFW pump room cooler and associated cables are located in this area. The Train A AFW pump room cooler and cables are unaffected.
GK	Control Room and Class 1E Switchgear Room Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-13.
GL	Auxiliary Building HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-13.

3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD

This section describes operator actions that may need to be performed inside or outside the main control room to achieve and maintain hot standby if a fire occurs in area A-13. This section also describes cold shutdown repairs that may need to be made to achieve and maintain cold shutdown conditions. Operator actions are proceduralized in OFN KC-016.

3.1 ACTIONS OUTSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

Operator Manual Actions (OMAs) are those actions outside the main control room required to achieve and maintain hot standby. OMAs are identified in E-1F9900 and were determined from thermal hydraulic analysis WCNOC-CP-002. Applicable E-1F9900 OMAs are annotated herein. All other actions outside the control room are desirable for plant control in support of hot standby but not required to achieve and maintain hot standby.

3.1.1 Steam Generator ARVs

It may be necessary to control ABPV0002 using local control station ABFHC0002. This action can be performed by an operator in fire area A-23. Emergency lighting and communication are available.

3.1.2 Steam Generator Blowdown to Blowdown Flash Tank Isolation

If a fire occurs in area A-13, BMHV0002 and BMHV0003 may not close using their associated hand switch in the main control room. Therefore, use BMHIS0002C and BMHIS0003C located on the BM157 panel in the Radwaste Control room to close valves BMHV0002 and BMHV0003.

3.2 ACTIONS INSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

3.2.1 Steam Generator ARVs

ARVs ABPV0001 and ABPV0004 may spuriously open. If this occurs, place ABPIC0001A and ABPIC0004A in manual and control the ARVs from the main control room.

3.2.7 Spurious SI

If a fire-induced spurious SI signal is received, enter EMG E-0 and terminate the spurious SI.

3.2.8 Main Steam Isolation Valves (MSIVs) and MSIV Bypass Valves

Cables for hand switch ABHS0079 may be damaged by the fire. Cables for redundant hand switch ABHS0080 are unaffected. Use ABHS0080 to close the MSIVs and MSIV bypass valves.

3.2.9 Main Feedwater Isolation Valves (MFIVs)

Cables for hand switch AEHS0081 may be damaged. Cables for redundant hand switch AEHS0080 are unaffected. Use AEHS0080 to close the MFIVs.

3.3 ACTIONS TO ACHIEVE AND MAINTAIN COLD SHUTDOWN

None specific to PFSSD for a fire in this area.

4.0 CONCLUSION

Redundant post fire safe shutdown capability, unaffected by a severe design basis fire, does not exist in area A-13. However, feasible manual actions are available and are unaffected by the fire. Manual actions are documented in Section 3.0.

5.0 DETAILED ANALYSIS

This section describes the detailed component-by-component and cable-by-cable analysis for a fire in area A-13.

5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA A-13

PFSSD components (S. in E-15000) located in fire area A-13 are shown in Table A-13-3. An evaluation of each component and associated cables is provided in the sections that follow. The applicable evaluation section is listed in Table A-13-3.

Table A-13-3 PFSSD Equipment Located in Fire Area A-13				
Room #	**PFSSD Equipment**	**Description**	**Evaluation Section**	**Comments**
1325	ALPT0024	Motor Driven Aux Feedwater Pump PAL01B Suction Pressure	5.1.1	
1325	DPAL01B	Auxiliary Feedwater Pump B Motor	5.1.1	
1325	DSGF02B	Auxiliary Feedwater Pump Room B Cooler Motor	5.1.2	
1325	GFHIS0016	Aux Feedwater Pump Room B Cooler Local Hand Switch	5.1.2	

5.1.1 Auxiliary Feedwater

The PFSSD design requires the use of one auxiliary feedwater pump (AFP) supplying water to at least two steam generators. The turbine driven auxiliary feedwater pump (TDAFP) is normally aligned to supply all four steam generators. The Train A motor driven auxiliary feedwater pump (MDAFP) is aligned to supply steam generators B and C. The Train B MDAFP is aligned to supply steam generators A and D.

The normal source of water to the AFPs is the condensate storage tank (CST). The emergency supply is from the essential service water (ESW) system. For commercial concerns, the CST is the preferred source and contains sufficient volume to supply the entire AFW demand to achieve cold shutdown.

Fire Area A-13 contains the Train B motor driven auxiliary feedwater pump PAL01B and associated cables and components. Therefore, if a fire occurs in this area, operators cannot rely on Train B auxiliary feedwater.

Cable 14ALI09AA, associated with flow transmitter ALFT0007, is run in this area. This flow transmitter provides a signal to throttle valve ALHV0007 to prevent overflowing into steam generator A. Damage to this cable could prevent proper operation of the valve. This is acceptable for PFSSD since steam generator A is not credited in the event of a fire in this area.

Cable 12ABK01AF is a control cable for valve ABHV0005. Cable 12SAZ23AA is a status panel input for valve ABHV0005. Cable 12ABK01BF is a control cable for valve ABHV0006. Cable 12SAZ23BA is a status panel input for valve ABHV0006. Valves ABHV0005 and ABHV0006 are the only two steam supply valves to the TDAFP. Damage to these cables could prevent the valves from opening, which would prevent operation of the TDAFP. The Train A MDAFP remains available if a fire occurs in this area.

Cable 12ALI07KD is associated with TDAFP suction pressure transmitter ALPT0026. Damage to this cable will cause a loss of pressure indication in the main control room. As stated previously, the Train A MDAFP is credited for a fire in this area so damage to this cable will have no adverse impact on PFSSD.

Cable 12ALI08BA is associated with pressure transmitter ALPT0038. Cable 14ALI08CA is associated with pressure transmitter ALPT0039. Damage to these cables could cause a spurious low suction pressure signal (2/3 logic) and initiate auxiliary feedwater suction swap over to the ESW system. This is acceptable for PFSSD since the ESW system is the safety related water source for AFW.

Cable 14ALI07AD is associated with Steam Generator D flow transmitter ALFT0001. Steam generator D is not credited for a fire in area A-13 so damage to this cable will not affect PFSSD.

Several cables associated with TDAFP trip and throttle valve FCHV0312 and speed governing valve FCFV0313 are run in area A-13. Damage to these cables could prevent operation of the TDAFP. The Train A MDAFP is available if a fire occurs in area A-13.

Cable 14FCK21AA, associated with TDAFP steam trap isolation valve FCFV0310, is run in this area. This 1-inch valve is required to be closed to prevent steam flow through the trap. An intra-cable hot short will not prevent closing the valve from the main control room. An inter-cable hot short could prevent closing the valve from the main control room. Loss of steam through a 1-inch line is bounded by the main steam line break analysis and loss of steam through this line will not result in uncontrolled cooldown. Therefore, if the valve remains open, PFSSD is still assured.

In addition to the valves described above, several additional valves in the AFW system could be affected by a fire in this area. These valves are located in the Train B MDAFP and TDAFP flowpath and are listed in Table A-13-4. Spurious operation of these valves will not affect PFSSD since Train A MDAFP is available.

Based on the above discussion, the Train A MDAFP is available to supply auxiliary feedwater to steam generators B and C. The Train B MDAFP and the TDAFP are not available.

5.1.2 Auxiliary Feedwater Pump Room Cooler

The Train B auxiliary feedwater pump room cooler SGF02B and associated cables are located in area A-13. Therefore, if a fire occurs in this area, operators cannot rely on Train B auxiliary feedwater.

Cables and components associated with Train A auxiliary feedwater pump room cooler SGF02A are run in a separate fire area and are unaffected by a fire in area A-13. Therefore, Train A AFW pump room cooling is available if a fire occurs in area A-13.

5.2.1 Steam Generator Atmospheric Relief Valves

Cables associated with steam generator atmospheric relief valves (ARVs) ABPV0001, ABPV0002 and ABPV0004 are run in area A-13. The effects of fire damage to these cables are discussed in the following paragraphs.

Cable 11ABI20EA provides a signal from pressure transmitter ABPT0001 to ARV ABPV0001 controller and opens the valve when steam line pressure reaches a designated set point. Damage to this cable due to a fire could cause a spurious high pressure signal which would open the ARV. If this occurs, operators can place ABPIC0001A in manual and control the ARV from the main control room. Cables associated with the ARV controller I/P device (ABPY0001) do not run in area A-13.

Cable 12ABI20FE provides a signal from ARV ABPV0002 controller to pressure transducer ABPY0002. Cable 12ABI20FH provides a signal from ABPT0002 to ARV ABPV0002 controller. The transducer signals the position controller (ABZC0002) on ABPV0002 to open whenever steam line pressure reaches a designated set point. Damage to the cables due to a fire could cause a spurious signal which could open the ARV. Damage to cable 12ABI20FE could prevent manual operation of the valve from the main control room. Therefore, it may be necessary to control ABPV0002 using local controller ABFHC0002 in area A-23.

Cable 14ABI20HH provides a signal from ABPT0004 to ARV ABPV0004 controller and opens the valve when steam line pressure reaches a designated set point. Damage to this cable due to a fire could cause a spurious high pressure signal which would open the ARV. If this occurs, operators can place ABPIC0004A in manual and control the ARV from the main control room. Cables associated with the ARV controller I/P device (ABPY0004) do not run in area A-13.

Based on the above discussion, ARVs ABPV0001 and ABPV0004 can be controlled manually from the main control room using ABPIC0001A and ABPIC0004A, respectively. ARV ABPV0002 may need to be controlled using local controller ABFHC0002.

Up to three ARVs can fail closed or open without impacting ability to achieve and maintain hot standby according to thermal hydraulic analysis WCNOC-CP-002. With at least one ARV unaffected, no E-1F9900 OMA is required to address ARV closure or control. Reference Attachment 4, MSO Evaluation Scenario ID PWROG 23.

5.2.2 Safety Injection and Containment Spray

Calculation XX-E-013, Appendix 1 (PFSSD Support Section) provides a detailed discussion about the potential PFSSD impact of a spurious safety injection signal (SIS) and spurious containment spray actuation signal (CSAS). This section discusses the specific PFSSD impact if a fire occurs in this area.

A spurious CSAS cannot occur if a fire occurs in area A-13.

Cables associated with steam line pressure transmitters ABPT0514, ABPT0515, ABPT0516, ABPT0525, ABPT0535, ABPT0544, ABPT0545, and ABPT0546 are run in area A-13. Consequently, the two out of three logic for low steam line pressure initiation of SIS can be satisfied on steam generators A and D if a fire occurs in area A-13.

A spurious SIS starts the charging sequence which starts the CCPs and opens the BIT flowpath valves. For a fire in this area, the BIT flowpath valves are unaffected and would open on a SIS. The RWST valves are unaffected and would open on a SIS. Also, the CCP mini flow valves are unaffected and CCW flow to the seal water heat exchanger is unaffected to ensure cooling of the recirc flow and RCP seal return. CCW flow is available for the CCP oil

coolers. Therefore, the charging pumps will not be affected by a spurious SIS caused by a fire in this area.

A start of the credited CCW system (Train A) will not adversely impact the system. The Train A ESW system is unaffected and will start on a spurious SIS, providing necessary cooling water to the CCW heat exchanger.

A start of the AFW pumps will not adversely impact PFSSD. The Train A AFW pump is credited for a fire in this area. Suction from the CST to the Train A AFW pump is unaffected. Discharge flow will either return to the CST or flow to the steam generators through the discharge control valves. Therefore, the Train A AFW pump is unaffected by a spurious SIS caused by a fire in this area.

A start of the RHR pumps due to a spurious SIS will not adversely impact either pump. The RWST supply to the pumps is not affected and the recirculation valves will remain in the open position. Component cooling water is available to both RHR heat exchangers. Operators will have time to terminate the spurious SIS and stop the pumps.

Based on the above discussion, a SIS due to spurious low steam line pressure can occur if a fire occurs in this area. Credited PFSSD equipment will not be damaged by the spurious SIS. Therefore, the spurious SIS will not adversely impact PFSSD.

References: E-15000, XX-E-013, E-13AB21, E-13BG01A, E-13EM01, E-1F9431, E-1F9432, M-12AB01, M-12BG03, M-12EM01

5.2.3 Steam Generator Main Steam Isolation Valves (MSIVs) and Bypass Valves

PFSSD requires the MSIVs be closed to prevent reactivity addition due to uncontrolled cooldown. The MSIVs are closed from the control room using all close hand switches ABHS0079 or ABHS0080.

Each MSIV is designed to utilize system fluid (main steam) as the motive force to open and close. The valve actuation (open or close) is accomplished through positioning a series of six electric solenoid pilot valves to either direct the system fluid to the Upper Piston Chamber (UPC) and/or the Lower Piston Chamber (LPC), or vent either or both piston chambers. The six solenoid pilot valves are divided into two trains (3 per train) that are independently powered and controlled. Either train can independently perform the PFSSD function to close the valve and isolate main steam. This is done by actuating either all close hand switch ABHS0079 (separation group 4) or ABHS0080 (separation group 1) to de-energize the associated solenoid valves.

The following table identifies the solenoids and associated control cables for each hand switch.

MSIV	ABHS0079 (Sep Group 4)		ABHS0080 (Sep Group 1)	
	Solenoids	Cable	Solenoids	Cable
ABHV0011	MV2, MV4, MV6	14ABK28BH	MV1, MV3, MV5	11ABK29BH
ABHV0014	MV2, MV4, MV6	14ABK29AH	MV1, MV3, MV5	11ABK28AH
ABHV0017	MV2, MV4, MV6	14ABK28AH	MV1, MV3, MV5	11ABK29AH
ABHV0020	MV2, MV4, MV6	14ABK29BH	MV1, MV3, MV5	11ABK28BH

Cables 14ABK28AH and 14ABK29BH associated with ABHV0017 and ABHV0020 are run in fire area A-13. Cable damage due to a fire will likely result in disruption of power to the solenoids, which will close the valves. The four separation group 1 cables associated with hand switch ABHS0080 are unaffected by a fire in area A-13. Therefore, hand switch ABHS0080 is available to close the four MSIVs.

Based on the above discussion, hand switch ABHS0080 is available to close the MSIVs in the event of a fire in area A-13.

References: E-15000, XX-E-013, E-13AB23A, E-13AB23B, E-13AB26, E-13AB27, E-13AB28, E-13AB29, E-1F9101, M-12AB02

5.2.4 Steam Generator Main Feedwater Isolation Valves

PFSSD requires that either the main feedwater isolation valves (MFIVs) be closed or the main feedwater pumps be stopped to prevent overfilling the steam generators. Flow diversion from auxiliary feedwater (AFW) to the main feedwater system piping is prevented by check valves AEV0420, AEV0421, AEV0422 and AEV0423. Closure of the main feedwater isolation valves is not required to prevent AFW flow diversion.

Each MFIV is designed to utilize system fluid (feedwater) as the motive force to open and close. The valve actuation (open or close) is accomplished through positioning a series of six electric solenoid pilot valves to either direct the system fluid to the Upper Piston Chamber (UPC) and/or the Lower Piston Chamber (LPC), or vent either or both piston chambers. The six solenoid pilot valves are divided into two trains (3 per train) that are independently powered and controlled. Either train can independently perform the PFSSD function to close the valve and isolate main feedwater. This is done by actuating either all close hand switch AEHS0080 (separation group 1) or AEHS0081 (separation group 4) to de-energize the associated solenoid valves.

The following table identifies the solenoids and associated control cables for each hand switch.

MFIV	AEHS0080 (Sep Group 1)		AEHS0081 (Sep Group 4)	
	Solenoids	Cable	Solenoids	Cable
AEFV0039	MV1, MV3, MV5	11AEK16AH	MV2, MV4, MV6	14AEK17AH
AEFV0040	MV1, MV3, MV5	11AEK17AH	MV2, MV4, MV6	14AEK16AH
AEFV0041	MV1, MV3, MV5	11AEK16BH	MV2, MV4, MV6	14AEK17BH
AEFV0042	MV1, MV3, MV5	11AEK17BH	MV2, MV4, MV6	14AEK16BH

Cables 14AEK16AH and 14AEK17BH associated with AEFV0040 and AEFV0041 are run in fire area A-13. Cable damage due to a fire will likely result in disruption of power to the solenoids, which will close the valves. The four separation group 1 cables associated with hand switch AEHS0080 are unaffected by a fire in area A-13. Therefore, hand switch AEHS0080 is available to close the four MFIVs.

Based on the above discussion, MFIV isolation is assured using hand switch AEHS0080.

References: E-15000, XX-E-013, E-13AE14, E-13AE15, E-13AE16, E-13AE17, E-1F9201, M-12AE02

5.2.5 Steam Generator Blowdown to Blowdown Flash Tank Valves

The reactivity control function requires the steam generator blowdown to blowdown flash tank valves (BMHV0001, BMHV0002, BMHV0003, and BMHV0004) be closed to prevent reactivity addition from uncontrolled cooldown. The air operated valves are normally open and each valve is controlled by three solenoid valves. All three solenoid valves are required to be energized to open the valve. If any one solenoid is de-energized, the associated valve will close or remain closed. Only two of the three solenoids for each valve are considered in the PFSSD analysis, so the third solenoid is assumed energized throughout the event.

Cables 14BMK06BA and 14BMK06CA associated with one of the three solenoid valves on BMHV0002 and BMHV0003, respectively, are run in area A-13. A hot short within cables 14BMK06BA and 14BMK06CA will not cause the valves to spuriously open due to the absence of a +125 VDC source conductor. However, the cables are run in raceway that could contain other cables carrying 125 VDC that, if an inter-cable hot short occurs, could spuriously open

the valves and prevent them from being closed using hand switches BMHIS0002A and BMHIS0003A. Although this is unlikely due to the use of thermoset cables, it is postulated to occur for the purpose of this analysis.

Cables associated with the other credited solenoid valve for BMHV0002 and BMHV0003 are not run in area A-13. To de-energize this solenoid, an operator will have to use the respective hand switch (BMHIS0002C and BMHIS0003C) at the BM157 panel in the Radwaste Control Room.

Based on the above discussion, a fire in area A-13 will not prevent closing steam generator blowdown valves BMHV0001, BMHV0002, BMHV0003 and BMHV0004.

Thermal hydraulic analysis WCNOC-CP-002 shows insignificant impact on SG inventory even with all four blowdown valves open. Therefore, no E-1F9900 OMA is required to close blowdown valves to achieve and maintain hot standby. Reference Attachment 4, MSO Evaluation Scenario ID PWROG 34.

1.0 GENERAL AREA DESCRIPTION

Fire area A-14 is located on the 2000 elevation of the Auxiliary Building and includes the room listed in Table A-14-1.

Table A-14-1
Rooms Located in Fire Area A-14

ROOM #	DESCRIPTION
1326	Aux Feedwater Pump Room A

Fire area A-14 is protected with automatic smoke detection. There is no automatic fire suppression installed. The room is separated from adjacent areas by minimum 3-hour fire rated barriers.

2.0 PRIMARY EQUIPMENT USED FOR PFSSD

Table A-14-2 lists each system credited for post-fire safe shutdown and provides a discussion regarding the availability of the system to perform its Post Fire Safe Shutdown (PFSSD) function if a severe fire occurs in this area. For a summary of the area analysis results, see Section 8.0 of the Fire Area Analysis Narrative section.

Table A-14-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-14

System	System Name	PFSSD Function*	Comments
AB	Main Steam	R, M, H, P, S	The controller for Steam Generator A ARV (ABPV0001) may need to placed in manual so the ARV can be controlled from the control room. Cables for hand switch ABHS0080 may be damaged by the fire. Cables for redundant hand switch ABHS0079 are unaffected. Use ABHS0079 to close the MSIVs and MSIV bypass valves.
AC	Main Turbine	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-14.
AE	Main Feedwater	H, P	Cables for hand switch AEHS0080 may be damaged. Cables for redundant hand switch AEHS0081 are unaffected. Use AEHS0081 to close the MFIVs.
AL	Aux. Feedwater System	H, P	The Train A MDAFP may be unavailable. The Train B MDAFP is unaffected.
AP	Condensate Storage System	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-14.
BB	Reactor Coolant System	R, M, H, P, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-14.
BG	Chemical and Volume Control System	R, M, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-14.
BM	Steam Generator Blowdown System	R, M, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-14.
BN	Borated Refueling Water Storage System	R, M, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-14.
EF	Essential Service Water System	H, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-14.
EG	Component Cooling Water System	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-14.
EJ	Residual Heat Removal System	M, H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-14.

Table A-14-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-14

System	System Name	PFSSD Function*	Comments
EM	High Pressure Coolant Injection	R, M	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-14.
EN	Containment Spray	R, M	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-14.
EP	Safety Injection Accumulators	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-14.
FB	Auxiliary Steam	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-14.
FC	Auxiliary Turbines	R, H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-14.
GD	ESW Pump House HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-14.
GF	AFW Pump Room Coolers	S	The Train A AFW pump room cooler and associated cables are located in this area. The Train B AFW pump room cooler and cables are unaffected.
GK	Control Room and Class 1E Switchgear Room Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-14.
GL	Auxiliary Building HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-14.
GM	Emergency Diesel Generator Room HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-14.
GN	Containment Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-14.
JE	Diesel Fuel Oil	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-14.
KA	Instrument Air	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-14.
KC	Fire Protection	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-14.
KH	Service Gas	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-14.
KJ	Standby Diesel Engine	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-14.

3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD

This section describes operator actions that may need to be performed inside or outside the control room to achieve and maintain hot standby if a fire occurs in area A-14. This section also describes cold shutdown repairs that may need to be made to achieve and maintain cold shutdown conditions. Operator actions are proceduralized in OFN KC-016.

3.1 ACTIONS OUTSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

None

3.2 ACTIONS INSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

3.2.1 Steam Generator ARVs

ARV ABPV0001 may spuriously open. If this occurs, place ABPIC0001A in manual and control the ARV from the control room.

3.2.2 Main Steam Isolation Valves (MSIVs) and MSIV Bypass Valves

Cables for hand switch ABHS0080 may be damaged by the fire. Cables for redundant hand switch ABHS0079 are unaffected. Use ABHS0079 to close the MSIVs and MSIV bypass valves.

3.2.3 Main Feedwater Isolation Valves (MFIVs)

Cables for hand switch AEHS0080 may be damaged. Cables for redundant hand switch AEHS0081 are unaffected. Use AEHS0081 to close the MFIVs.

3.3 ACTIONS TO ACHIEVE AND MAINTAIN COLD SHUTDOWN

None specific to PFSSD for a fire in this area.

4.0 CONCLUSION

Post Fire Safe Shutdown is assured for a fire in area A-14. Redundant capability exists and is unaffected by a fire.

5.0 DETAILED ANALYSIS

This section describes the detailed component-by-component and cable-by-cable analysis for a fire in area A-14.

5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA A-14

PFSSD components (S. in E-15000) located in fire area A-14 are shown in Table A-14-3. An evaluation of each component and associated cables is provided in the sections that follow. The applicable evaluation section is listed in Table A-14-3.

Table A-14-3
PFSSD Equipment Located in Fire Area A-14

Room #	PFSSD Equipment	Description	Evaluation Section	Comments
1326	ALPT0025	Motor Driven Aux Feedwater Pump PAL01A Suction Pressure	5.1.1	
1326	DPAL01A	Auxiliary Feedwater Pump Motor	5.1.1	
1326	DSGF02A	Auxiliary Feedwater Pump Room A Cooler Motor	5.1.2	
1326	GFHIS0015	Aux Feedwater Pump Room A Cooler Local Hand Switch	5.1.2	

5.1.1 Auxiliary Feedwater

The PFSSD design requires the use of one auxiliary feedwater pump (AFP) supplying water to at least two steam generators. The turbine driven auxiliary feedwater pump (TDAFP) is normally aligned to supply all four steam generators. The Train A motor driven auxiliary feedwater pump (MDAFP) is aligned to supply steam generators B and C. The Train B MDAFP is aligned to supply steam generators A and D.

The normal source of water to the AFPs is the condensate storage tank (CST). The emergency supply is from the essential service water (ESW) system. For commercial concerns, the CST is the preferred source and contains sufficient volume to supply the entire AFW demand to achieve cold shutdown.

Fire Area A-14 contains the Train A MDAFP PAL01A and associated cables and components. Therefore, if a fire occurs in this area, operators cannot rely on Train A auxiliary feedwater.

Cables associated with Train A auxiliary feedwater flowpath valves are run in area A-14. These cables are listed in Table A-14-4. Damage to these cables could impact the ability to supply auxiliary feedwater to steam generators B and C using Train A MDAFP. The CST supply to the TDAFP could be affected. The TDAFP to steam generators A and D flowpath could be affected. The TDAFP remains available to supply steam generators B and C using Train B ESW.

Pressure transmitters ALPT0037, ALPT0038 and ALPT0039 monitor CST pressure and initiate swap over to ESW on 2/3 low suction pressures (LSP). A cable associated with pressure transmitter ALPT0037 runs in this area. Cables associated with the other two pressure transmitters are unaffected. Therefore, spurious LSP swap over will not occur in the event of a fire in this area.

Cables associated with flow transmitters ALFT0009 and ALFT0011 run in this area. These flow transmitters provide a signal to throttle valves ALHV0009 and ALHV0011, respectively, to prevent overflowing into steam generators B and C. Damage to these cables could prevent proper operation of the valves. This is acceptable for PFSSD since steam generators B and C are not credited in the event of a fire in this area.

The assured auxiliary feedwater flowpath in the event of a fire in area A-14 is the Train B MDAFP taking suction from the CST and supplying steam generators A and D via valves ALHV0005 and ALHV0007. The TDAFP is also available to supply steam generators B and C, but the only assured suction source is the ESW system which meets PFSSD requirements but introduces commercial concerns.

5.1.2 Auxiliary Feedwater Pump Room Cooler

The Train A auxiliary feedwater pump room cooler SGF02A and associated cables are located in area A-14. Therefore, if a fire occurs in this area, operators cannot rely on Train A auxiliary feedwater.

Cables and components associated with Train B auxiliary feedwater pump room cooler SGF02B are run in a separate fire area and are unaffected by a fire in area A-14. Therefore, Train B AFW pump room cooling is available if a fire occurs in area A-14.

5.2.1 Steam Generator Atmospheric Relief Valves

One cable associated with steam generator atmospheric relief valve (ARV) ABPV0001 runs in area A-14. Cable 11ABI20EA provides a signal from pressure transmitter ABPT0001 to ARV ABPV0001 controller and opens the valve when steamline pressure reaches a designated setpoint. Damage to this cable due to a fire could cause a spurious high pressure signal which would open the ARV. If this occurs, operators can place ABPIC0001A in manual and control the ARV from the control room. Position indication for ABPV0001 on RL006 remains available, so operators would quickly recognize if the ARV is open. Cables associated with the ARV controller I/P device (ABPY0001) do not run in area A-14.

Based on the above discussion, damage to cable 11ABI20EA will not impact the ability to control ARV ABPV0001 from the control room.

References: E-15000, XX-E-013, E-13AB20A, E-1F9101, M-12AB01

5.2.2 Safety Injection and Containment Spray

A spurious safety injection signal (SIS) could cause the safety injection pumps to operate. A spurious containment spray actuation signal (CSAS) could cause the containment spray pumps to operate, depleting inventory in the RWST. These conditions are not desirable for PFSSD at Wolf Creek.

Safety injection (SI) is initiated automatically by any of the following conditions:

1. Two out of three high containment pressures monitored by pressure transmitters GNPT0934, GNPT0935 and GNPT0936.
2. Two out of four low pressurizer pressures monitored by pressure transmitters BBPT0455, BBPT0456, BBPT0457 and BBPT0458.
3. Two out of three low steam line pressures on any steam generator monitored by ABPT0514, ABPT0515 and ABPT0516 on SG A; ABPT0524, ABPT0525 and ABPT0526 on SG B; ABPT0534, ABPT0535 and ABPT0536 on SG C; and, ABPT0544, ABPT0545 and ABPT0546 on SG D. Two out of three logic must be satisfied on a single steam generator line. Low pressure on a single pressure transmitter co-incident with low pressure on another pressure transmitter on a different steam generator line will not initiate SIS.

Containment spray (CS) is initiated automatically by two out of four high containment pressures monitored by pressure transmitters GNPT0934, GNPT0935, GNPT0936 and GNPT0937. There are no containment pressure transmitter cables in area A-14. Consequently, a spurious CSAS due to high containment pressure cannot occur if a fire occurs in area A-14. Also, a spurious SIS due to high containment pressure cannot occur since none of the three containment pressure SIS initiators have cables located in area A-14.

Cables associated with steam line pressure transmitters ABPT0514, ABPT0524, ABPT0534 and ABPT0544 are run in area A-14. Consequently, the two out of three logic for low steam line pressure initiation of SIS cannot be satisfied if a fire occurs in area A-14.

Based on the above discussion, a spurious SIS and CSAS cannot occur if a fire occurs in area A-14.

References: E-15000, XX-E-013, E-13AB21, E-1F9431, E-1F9432, E-1F9433, M-12AB01

5.2.3 Steam Generator Main Steam Isolation Valves (MSIVs) and Bypass Valves

PFSSD requires the MSIVs be closed to prevent reactivity addition due to uncontrolled cooldown. The MSIVs are closed from the control room using all close hand switches ABHS0079 or ABHS0080.

Each MSIV is designed to utilize system fluid (main steam) as the motive force to open and close. The valve actuation (open or close) is accomplished through positioning a series of six electric solenoid pilot valves to either direct the system fluid to the Upper Piston Chamber (UPC) and/or the Lower Piston Chamber (LPC), or vent either or both piston chambers. The six solenoid pilot valves are divided into two trains (3 per train) that are independently powered and controlled. Either train can independently perform the PFSSD function to close the valve and isolate main steam. This is done by actuating either all close hand switch ABHS0079 (separation group 4) or ABHS0080 (separation group 1) to de-energize the associated solenoid valves.

The following table identifies the solenoids and associated control cables for each hand switch.

MSIV	ABHS0079 (Sep Group 4)		ABHS0080 (Sep Group 1)	
	Solenoids	Cable	Solenoids	Cable
ABHV0011	MV2, MV4, MV6	14ABK28BH	MV1, MV3, MV5	11ABK29BH
ABHV0014	MV2, MV4, MV6	14ABK29AH	MV1, MV3, MV5	11ABK28AH
ABHV0017	MV2, MV4, MV6	14ABK28AH	MV1, MV3, MV5	11ABK29AH
ABHV0020	MV2, MV4, MV6	14ABK29BH	MV1, MV3, MV5	11ABK28BH

All 4 cables associated with the 12 separation group 1 solenoid valves are run in area A-14. Cable damage due to a fire will likely result in disruption of power to the solenoids, which will close the valves. The four separation group 4 cables associated with hand switch ABHS0079 are unaffected by a fire in area A-14. Therefore, hand switch ABHS0079 is available to close the four MSIVs.

Based on the above discussion, hand switch ABHS0079 is available to close the MSIVs in the event of a fire in area A-14.

References: E-15000, XX-E-013, E-13AB23A, E-13AB23B, E-13AB26, E-13AB27, E-13AB28, E-13AB29, E-1F9101, M-12AB02

5.2.4 Steam Generator Main Feedwater Isolation Valves

PFSSD requires that either the main feedwater isolation valves (MFIVs) be closed or the main feedwater pumps be stopped to prevent overfilling the steam generators. Flow diversion from auxiliary feedwater (AFW) to the main feedwater system piping is prevented by check valves AEV0420, AEV0421, AEV0422 and AEV0423. Closure of the main feedwater isolation valves is not required to prevent AFW flow diversion.

Each MFIV is designed to utilize system fluid (feedwater) as the motive force to open and close. The valve actuation (open or close) is accomplished through positioning a series of six electric solenoid pilot valves to either direct the system fluid to the Upper Piston Chamber (UPC) and/or the Lower Piston Chamber (LPC), or vent either or both piston chambers. The six solenoid pilot valves are divided into two trains (3 per train) that are independently powered and controlled. Either train can independently perform the PFSSD function to close the valve and isolate main feedwater. This is done by actuating either all close hand switch AEHS0080 (separation group 1) or AEHS0081 (separation group 4) to de-energize the associated solenoid valves.

The following table identifies the solenoids and associated control cables for each hand switch.

MFIV	AEHS0080 (Sep Group 1)		AEHS0081 (Sep Group 4)	
	Solenoids	Cable	Solenoids	Cable
AEFV0039	MV1, MV3, MV5	11AEK16AH	MV2, MV4, MV6	14AEK17AH
AEFV0040	MV1, MV3, MV5	11AEK17AH	MV2, MV4, MV6	14AEK16AH
AEFV0041	MV1, MV3, MV5	11AEK16BH	MV2, MV4, MV6	14AEK17BH
AEFV0042	MV1, MV3, MV5	11AEK17BH	MV2, MV4, MV6	14AEK16BH

Cables 11AEK17AH and 11AEK16BH associated with valves AEFV0040 and AEFV0041 are run in area A-14. Cable damage due to a fire will likely result in disruption of power to the solenoids, which will close the valves. The four separation group 4 cables associated with hand switch AEHS0081 are unaffected by a fire in area A-8. Therefore, hand switch AEHS0081 is available to close the four MFIVs.

Based on the above discussion, MFIV isolation is assured using hand switch AEHS0081.

5.2.5 Steam Generator Blowdown to Blowdown Flash Tank Valves

The reactivity control function requires the steam generator blowdown to blowdown flash tank valves (BMHV0001, BMHV0002, BMHV0003, and BMHV0004) be closed to prevent reactivity addition from uncontrolled cooldown. The air operated valves are normally open and each valve is controlled by three solenoid valves. All three solenoid valves are required to be energized to open the valve. If any one solenoid is de-energized, the associated valve will close or remain closed. Only two of the three solenoids for each valve are considered in the PFSSD analysis, so the third solenoid is assumed energized throughout the event.

Cables 11BMK06FA and 11BMK06GA, associated with BMHV0002 and BMHV0003, respectively, are run in area A-14. These cables are associated with the hand switch at the BM157 panel. An intra-cable short within these cables will have the same effect as if the valve is closed, which is the desired position. An open circuit will de-energize the AR, close the seal-in contact on schemes 5BMK06B and 5BMK06C, and energize solenoid valves BMHY0002C and BMHY0003C. A short to ground would not affect the circuit because the AR is energized by a floating 125 VDC system.

As stated above, an open circuit in cables 11BMK06FA and 11BMK06GA will prevent closing BMHV0002 and BMHV0003 from the Radwaste Control Room panel BM157. Damage to these cables will not prevent closing the blowdown valves from the Main Control Room.

Based on the above discussion, a fire in area A-14 will not prevent closing steam generator blowdown valves BMHV0001, BMHV0002, BMHV0003 and BMHV0004.

1.0 GENERAL AREA DESCRIPTION

Fire area A-15 is located on the 2000 elevation of the Auxiliary Building and includes the room listed in Table A-15-1.

Table A-15-1
Room Located in Fire Area A-15

ROOM #	DESCRIPTION
1331	Turbine Driven Aux Feedwater Pump Room

The turbine driven auxiliary feedwater pump is protected with a manually actuated water spray system. Rate compensated heat detectors are installed around the pump. The room is also provided with automatic smoke detection at the ceiling.

2.0 PRIMARY EQUIPMENT USED FOR PFSSD

Table A-15-2 lists each system credited for post-fire safe shutdown and provides a discussion regarding the availability of the system to perform its Post Fire Safe Shutdown (PFSSD) function if a severe fire occurs in this area. For a summary of the area analysis results, see Section 8.0 of the Fire Area Analysis Narrative section.

Table A-15-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-15

System	System Name	PFSSD Function*	Comments
AB	Main Steam	R, M, H, P, S	Steam Generator B ARV ABPV0002 may need to be isolated using local controller ABFHC0002. Both steam supply valves (ABHV0005 and ABHV0006) to the TDAFP may be affected. MSIVs ABHV0017 and ABHV0020 may not close and MSIV bypass valves ABHV0018 and ABHV0021 could spuriously open. Operators may need to isolate redundant components located downstream of the MSIVs using hand switches in the main control room. Steam generator pressure indication is available using ABPI0514A, ABPI0515A, ABPI0516A, ABPI0526A, ABPI0536A, ABPI0544A, ABPI0545A and ABPI0546A.
AC	Main Turbine	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-15.
AE	Main Feedwater	H, P	AEFV0040 and AEFV0041 may not close using either hand switch AEHS0080 or AEHS0081. Main feedwater flow can be stopped from the control room using FCHS0018A, FCHS0018B, FCHS0118A, FCHS0118B and AEHIS0104.
AL	Aux. Feedwater System	H, P	The TDAFP (PAL02) and all four discharge valves are affected by a fire in this area. The Train A MDAFP (PAL01A) is unaffected but the discharge valves to steam generators B and C are affected. The Train B MDAFP (PAL01B) and associated discharge valves are unaffected and are available to provide auxiliary feedwater to steam generators A and D.
AP	Condensate Storage System	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-15.
BB	Reactor Coolant System	R, M, H, P, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-15. RCS pressure indication is available using BBPI0405 and BBPI0406. Pressurizer level indication is available using BBLI0459A and BBLI0460A.
BG	Chemical and Volume Control System	R, M, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-15.
BM	Steam Generator Blowdown System	R, M, H	Blowdown valves BMHV0002 and BMHV0003 may have to be failed closed by opening breaker NK4411 in room 3404 (fire area C-15). This will also fail close BMHV0001 and BMHV0004, which is acceptable for PFSSD.
BN	Borated Refueling Water Storage System	R, M, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-15.
EF	Essential Service Water System	H, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-15.

Table A-15-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-15

System	System Name	PFSSD Function*	Comments
EG	Component Cooling Water System	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-15.
EJ	Residual Heat Removal System	M, H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-15.
EM	High Pressure Coolant Injection	R, M	A spurious start of the SI pumps due to two out of three low steam line pressures can be terminated by placing the pump control hand switches EMHIS0004 and EMHIS0005 on panel RL017 in pull-to-lock.
EN	Containment Spray	R, M	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-15.
EP	Safety Injection Accumulators	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-15.
FB	Auxiliary Steam	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-15.
FC	Auxiliary Turbines	R, H, P	The Turbine Driven Auxiliary Feedwater Pump may not be available if a fire occurs in this area. The pump and a number of associated components and cables are located in this area.
GD	ESW Pump House HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-15.
GF	AFW Pump Room Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-15.
GK	Control Room and Class 1E Switchgear Room Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-15.
GL	Auxiliary Building HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-15.
GM	Emergency Diesel Generator Room HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-15.
GN	Containment Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-15. Containment pressure indicators GNPI0934, GNPI0935, GNPI0936 and GNPI0937 are available.
JE	Diesel Fuel Oil	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-15.

3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD

This section describes operator actions that may need to be performed inside or outside the control room to achieve and maintain hot standby if a fire occurs in area A-15. This section also describes cold shutdown repairs that may need to be made to achieve and maintain cold shutdown conditions. Operator actions are proceduralized in OFN KC-016.

3.1 ACTIONS OUTSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

Operator Manual Actions (OMAs) are those actions outside the main control room required to achieve and maintain hot standby. OMAs are identified in E-1F9900 and were determined from thermal hydraulic analysis WCNOC-CP-002. Applicable E-1F9900 OMAs are annotated herein. All other actions outside the control room are desirable for plant control in support of hot standby but not required to achieve and maintain hot standby.

3.1.1 Steam Generator Blowdown

Blowdown valves BMHV0002 and BMHV0003 may have to be failed closed by opening breaker NK4411 in room 3404 (fire area C-15). This will also fail close BMHV0001 and BMHV0004.

3.1.2 Steam Generator ARVs

It may be necessary to isolate ABPV0002 using local control station ABFHC0002. This action can be performed by an operator in fire area A-23. Emergency lighting and communication are available.

3.2 ACTIONS INSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

3.2.7 Spurious SI

If a fire-induced spurious SI signal is received, enter EMG E-0 and terminate the spurious SI.

3.2.8 Main Steam Isolation

MSIVs ABHV0017 and ABHV0020 may not close and MSIV bypass valves ABHV0018 and ABHV0021 could spuriously open. Operators may need to isolate redundant components located downstream of the MSIVs using applicable hand switches in the main control room.

3.2.9 Main Feedwater Isolation

Main feedwater isolation valves AEFV0040 and AEFV0041 may not close using either hand switch AEHS0080 or AEHS0081. Main feedwater flow can be stopped from the control room using FCHS0018A, FCHS0018B, FCHS0118A, FCHS0118B and AEHIS0104.

3.3 ACTIONS TO ACHIEVE AND MAINTAIN COLD SHUTDOWN

None

4.0 CONCLUSION

With some exceptions, redundant Post Fire Safe Shutdown capability exists if a severe fire occurs in area A-15. For those exceptions, feasible manual actions are available and are unaffected by the fire. Manual actions are documented in Section 3.0.

5.0 DETAILED ANALYSIS

This section describes the detailed component-by-component and cable-by-cable analysis for a fire in area A-15.

5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA A-15

PFSSD components (S. in E-15000) located in fire area A-15 are shown in Table A-15-3. An evaluation of each component and associated cables is provided in the sections that follow. The applicable evaluation section is listed in Table A-15-3.

Table A-15-3
PFSSD Equipment Located in Fire Area A-15

Room #	PFSSD Equipment	Description	Evaluation Section	Comments
1331	ALPT0026	TDAFP Suction Pressure	5.1.1	
1331	FC219	TDAFP Electrical Control Panel	5.1.1

1331	FCSI0313A	TDAFP Turbine Speed and Setpoint Indicator	5.1.1	
1331	FCSI0313B	TDAFP Turbine Speed and Setpoint Indicator	5.1.1	
1331	FCZC0313	TDAFP Turbine Speed Governing Valve Positioner	5.1.1	
1331	FCZS0312D	TDAFP Overspeed Trip Limit Switch	5.1.1	
1331	KFC02	Auxiliary Feedwater Pump PAL02 Turbine	5.1.1	
1331	PAL02	Turbine Driven Auxiliary Feedwater Pump	5.1.1	
1331	TVFC04	KFC02 Terminal Box	5.1.1	

5.1.1 Auxiliary Feedwater

The PFSSD design requires the use of one auxiliary feedwater pump supplying water to at least two steam generators. The turbine driven auxiliary feedwater pump (TDAFP) is normally aligned to supply all four steam generators. The Train A motor driven auxiliary feedwater pump (MDAFP) is aligned to supply steam generators B and C. The Train B MDAFP is aligned to supply steam generators A and D.

Fire area A-15 contains the TDAFP PAL02 and associated cables and components as shown in Table A-15-3 and A-15-4. A fire in this area could prevent operation of the TDAFP. Therefore, one of the motor driven auxiliary feedwater pumps will need to be used if a fire occurs in this area. The following paragraphs discuss availability of the motor driven auxiliary feedwater pumps.

Cables associated with a number of valves in the auxiliary feedwater system are run in area A-15. These valves are in the discharge piping from the auxiliary feedwater pumps to the steam generators. The cables and associated valves are shown in Table A-15-4. Only valves ALHV0005 and ALHV0007 are unaffected by a fire in this area. These valves are in the piping from the Train B MDAFP to steam generators A and D. The Train B MDAFP is unaffected by a fire in this area. Therefore, auxiliary feedwater flow to at least 2 steam generators can be achieved if a fire occurs in area A-15.

Cables associated with pressure transmitters ALPT0037, ALPT0038 and ALPT0039 are run in area A-15. Damage to these cables could cause a spurious low suction pressure signal (2/3 logic) and initiate auxiliary feedwater suction swapover to the ESW system. This is acceptable for PFSSD since the ESW system is the safety related water source for AFW.

5.2.1 Safety Injection and Containment Spray

Calculation XX-E-013, Appendix 1 (PFSSD Support Section) provides a detailed discussion about the potential PFSSD impact of a spurious safety injection signal (SIS) and spurious containment spray actuation signal (CSAS). This section discusses the specific PFSSD impact if a fire occurs in this area.

A spurious CSAS cannot occur if a fire occurs in area A-15.

Cables associated with steam line pressure transmitters ABPT0524, ABPT0525, ABPT0534 and ABPT0535 are run in area A-15. Consequently, the two out of three logic for low steam line pressure initiation of SIS can be satisfied on steam generators B and C if a fire occurs in area A-15.

A spurious SIS starts the charging sequence which starts the CCPs and opens the BIT flowpath valves. For a fire in this area, the BIT flowpath valves are unaffected and would open on a SIS. The RWST valves are unaffected and would open on a SIS. Also, the CCP mini flow valves are unaffected and CCW flow to the seal water heat exchanger is unaffected to ensure cooling of the recirc flow and RCP seal return. CCW flow is available for the CCP oil coolers. Therefore, the charging pumps will not be affected by a spurious SIS caused by a fire in this area.

A start of the credited CCW system (Train B) will not adversely impact the system. The Train B ESW system is unaffected and will start on a spurious SIS, providing necessary cooling water to the CCW heat exchanger.

A start of the AFW pumps will not adversely impact PFSSD. The Train B AFW pump is credited for a fire in this area. Suction from the CST to the Train B AFW pump is unaffected. Discharge flow will either return to the CST or flow to the steam generators through the discharge control valves. Therefore, the Train B AFW pump is unaffected by a spurious SIS caused by a fire in this area.

A start of the RHR pumps due to a spurious SIS will not adversely impact either pump. The RWST supply to the pumps is not affected and the recirculation valves will remain in the open position. Component cooling water is available to both RHR heat exchangers. Operators will have time to terminate the spurious SIS and stop the pumps.

Based on the above discussion, a SIS due to spurious low steam line pressure can occur if a fire occurs in this area. Credited PFSSD equipment will not be damaged by the spurious SIS. Therefore, the spurious SIS will not adversely impact PFSSD.

5.2.2 Steam Generator Main Steam Isolation Valves (MSIVs) and Bypass Valves

PFSSD requires the MSIVs and bypass valves be closed to prevent reactivity addition due to uncontrolled cooldown. The MSIVs and bypass valves are closed from the control room using hand switches ABHS0079 or ABHS0080. The bypass valves are normally closed.

Each MSIV is designed to utilize system fluid (main steam) as the motive force to open and close. The valve actuation (open or close) is accomplished through positioning a series of six electric solenoid pilot valves to either direct the system fluid to the Upper Piston Chamber (UPC) and/or the Lower Piston Chamber (LPC), or vent either or both piston chambers. The six solenoid pilot valves are divided into two trains (3 per train) that are independently powered and controlled. Either train can independently perform the PFSSD function to close the valve and isolate main steam. This is done by actuating either all close hand switch ABHS0079 (separation group 4) or ABHS0080 (separation group 1) to de-energize the associated solenoid valves.

The following table identifies the solenoids and associated control cables for each hand switch.

MSIV	ABHS0079 (Sep Group 4)		ABHS0080 (Sep Group 1)	
	Solenoids	Cable	Solenoids	Cable
ABHV0011	MV2, MV4, MV6	14ABK28BH	MV1, MV3, MV5	11ABK29BH
ABHV0014	MV2, MV4, MV6	14ABK29AH	MV1, MV3, MV5	11ABK28AH
ABHV0017	MV2, MV4, MV6	14ABK28AH	MV1, MV3, MV5	11ABK29AH
ABHV0020	MV2, MV4, MV6	14ABK29BH	MV1, MV3, MV5	11ABK28BH

Cables 11ABK28BH, 11ABK29AH, 14ABK28AH and 14ABK29BH are run in area A-15. Damage to these cables could prevent closing ABHV0017 and ABHV0020 using either hand switch ABHS0079 or ABHS0080.

Each MSIV bypass valve is normally closed and is required to remain closed for PFSSD. Two (2) redundant solenoid valves (one on each train) are installed on the air supply line and control air to the pneumatic actuator. The valves are normally closed with the solenoid valves de-energized. Actuation of either hand switch will de-energize power to the solenoids to ensure they remain closed.

Cables 11ABK23AC and 11ABK23AD associated with separation group 1 (Train A) solenoids for bypass valves ABHV0018 and ABHV0021 are run in this area. Cables 14ABK23FC and 14ABK23FD associated with separation group 4 (Train B) solenoids for bypass valves ABHV0018 and ABHV0021 are run in this area. An intra-cable hot short, open circuit or short to ground will not energize the solenoids and will maintain the valves in their normally closed position. However, a +125 vdc single conductor inter-cable hot short will cause the solenoid valves to energize and open the bypass valves. Although the NRC has indicated in RIS 2004-03, Rev. 1 that this is a very unlikely scenario due to the use of thermoset cables, it is postulated to occur based on Wolf Creek's licensing requirements. Therefore, the possibility exists for MSIV bypass valves ABHV0018 and ABHV0021 to open.

Based on the above discussion, a fire in area A-15 could prevent operators from closing MSIVs ABHV0017 and ABHV0020 and could cause the spurious opening of MSIV bypass valves ABHV0018 and ABHV0021. If this occurs, operators can isolate redundant components located downstream of the MSIVs using hand switches in the main control room. These include the steam dumps, the main steam drain valves, main feed pump turbine valves and others as indicated on E-1F9103. Cables associated with these components are not located in area A-15.

References: E-15000, XX-E-013, E-13AB23A, E-13AB23B, E-13AB26, E-13AB27, E-13AB28, E-13AB29, E-1F9101, E-1F9103, M-12AB02, M-628-00049

5.2.3 Steam Generator Main Feedwater Isolation Valves

PFSSD requires that either the main feedwater isolation valves (MFIVs) be closed or the main feedwater pumps be stopped to prevent overfilling the steam generators. Flow diversion from auxiliary feedwater (AFW) to the main feedwater system piping is prevented by check valves AEV0420, AEV0421, AEV0422 and AEV0423. Closure of the main feedwater isolation valves is not required to prevent AFW flow diversion.

Each MFIV is designed to utilize system fluid (feedwater) as the motive force to open and close. The valve actuation (open or close) is accomplished through positioning a series of six electric solenoid pilot valves to either direct the system fluid to the Upper Piston Chamber (UPC) and/or the Lower Piston Chamber (LPC), or vent either or both piston chambers. The six solenoid pilot valves are divided into two trains (3 per train) that are independently powered and controlled. Either train can independently perform the PFSSD function to close the valve and isolate main feedwater. This is done by actuating either all close hand switch AEHS0080

(separation group 1) or AEHS0081 (separation group 4) to de-energize the associated solenoid valves.

The following table identifies the solenoids and associated control cables for each hand switch.

MFIV	AEHS0080 (Sep Group 1)		AEHS0081 (Sep Group 4)	
	Solenoids	Cable	Solenoids	Cable
AEFV0039	MV1, MV3, MV5	11AEK16AH	MV2, MV4, MV6	14AEK17AH
AEFV0040	MV1, MV3, MV5	11AEK17AH	MV2, MV4, MV6	14AEK16AH
AEFV0041	MV1, MV3, MV5	11AEK16BH	MV2, MV4, MV6	14AEK17BH
AEFV0042	MV1, MV3, MV5	11AEK17BH	MV2, MV4, MV6	14AEK16BH

Cables 11AEK16BH, 11AEK17AH, 14AEK16AH and 14AEK17BH are run in area A-15. Cable damage due to a fire could prevent closing AEFV0040 and AEFV0041 using either hand switch AEHS0080 or AEHS0081.

As discussed in Section 5.2.2, the MSIVs may not close due to a fire in this area but the downstream MSIV components are unaffected. The steam driven main feedwater pumps and the motor driven feedwater pump can be stopped from the control room.

Based on the above discussion, steam generator overfilling can be prevented by stopping all three main feedwater pumps from the control room.

References: E-15000, XX-E-013, E-13AE14, E-13AE15, E-13AE16, E-13AE17, E-1F9201, M-12AE02

5.2.4 Steam Generator Blowdown to Blowdown Flash Tank Valves

The reactivity control function requires the steam generator blowdown to blowdown flash tank valves (BMHV0001, BMHV0002, BMHV0003, and BMHV0004) be closed to prevent reactivity addition from uncontrolled cooldown. The air operated valves are normally open and each valve is controlled by three solenoid valves. All three solenoid valves are required to be energized to open the valve. If any one solenoid is de-energized, the associated valve will close or remain closed. Only two of the three solenoids for each valve are considered in the PFSSD analysis, so the third solenoid is assumed energized throughout the event.

Cables 11BMK06FA, 11BMK06GA, 14BMK06BA and 14BMK06CA are run in area A-15. An open circuit within cables 11BMK06FA and 11BMK06GA will prevent closing BMHV0002 and BMHV0003 from the Radwaste Control Room panel BM157. A hot short within cables 14BMK06BA and 14BMK06CA will not cause valves BMHV0002 and BMHV0003 to spuriously open due to the absence of a +125 VDC source conductor. However, the cables are run in raceway that could contain other cables carrying 125 VDC that, if an inter-cable hot short occurs, could spuriously open the valves and prevent them from being closed using hand switches BMHIS0002A and BMHIS0003A in the main control room. Although this is unlikely due to the use of thermoset cables, it is postulated to occur due to Wolf Creeks licensing basis.

Based on the above discussion, it may not be possible to close BMHV0002 and BMHV0003 using hand switches in the main control room and the radwaste control room. In the unlikely event that cable damage described above occurs, all four blowdown valves can be failed closed by opening breaker NK4411 in room 3404 (fire area C-15). Access to this room is available without having to pass through area A-15 and emergency lighting is available.

Thermal hydraulic analysis WCNOC-CP-002 shows insignificant impact on SG inventory even with all four blowdown valves open. Therefore, no E-1F9900 OMA is required to close blowdown valves to achieve and maintain hot standby. Reference Attachment 4, MSO Evaluation Scenario ID PWROG 34.

References: E-15000, XX-E-013, E-13BM06A, E-13BM06C, E-13BM06D, E-1F9101, M-12BM01

5.2.5 Steam Generator Atmospheric Relief Valves

Cables associated with steam generator atmospheric relief valve (ARV) ABPV0002 are run in area A-15. The effects of damage to these cables is discussed in the following paragraphs.

Cable 12ABI20FE provides a signal from ARV ABPV0002 controller to pressure transducer ABPY0002. The transducer signals the position controller (ABZC0002) on ABPV0002 to open whenever steamline pressure reaches a designated setpoint. Damage to the cable due to a fire could cause a spurious signal which could open the ARV and could prevent manual operation of the valve from the control room.

If ARV ABPV0002 cannot be isolated from the main control room, operators can isolate it using local controller ABFHC0002 in area A-23. Area A-23 is accessible and emergency lighting is provided.

Up to three ARVs can fail closed or open without impacting ability to achieve and maintain hot standby according to thermal hydraulic analysis WCNOC-CP-002. With at least one ARV unaffected, no E-1F9900 OMA is required to address ARV closure or control. Reference Attachment 4, MSO Evaluation Scenario ID PWROG 23.

5.2 PFSSD CABLE EVALUATION 29

1.0 GENERAL AREA DESCRIPTION

Fire area A-16 is located on the 2026 elevation of the Auxiliary Building and includes the rooms listed in Table A-16-1.

Table A-16-1
Rooms Located in Fire Area A-16

ROOM #	DESCRIPTION
1401	CCW pump and heat exchanger area (B)
1402	Corridor (No.1)
1406	CCW pump and heat exchanger area (A)
1408	Corridor (No. 2)

Fire area A-16 is divided into two sections. The North section (A-16 North) starts from approximately 2'-0" South of column line A7 and ends at the North wall at column line A1. The South section (A-16 South) starts at column line A14 and runs North to approximately 2'-0" South of column line A8. Area A-16 South also includes room 1402.

The area between A-16 North and A-16 South is a minimum of 20'-0" in width and is considered an area free of combustibles and fire hazards in accordance with 10CFR50, Appendix R Section III.G.2.b, which states:

> *b. Separation of cables and equipment and associated non-safety circuits of redundant trains by a horizontal distance of more than 20 feet with no intervening combustible or fire hazards. In addition, fire detectors and an automatic fire suppression system shall be installed in the area.*

The 20'-0" wide combustible/fire hazard free zone extends from the East wall of fire area A-9 to the West containment wall. This area shall be maintained free of combustibles and fire hazards at all times, except as approved in the fire hazard analysis.

The separation criteria of 10CFR50, Appendix R Section III.G.2.b, as stated above, is utilized for a number of redundant PFSSD components and cables located in fire area A-16. Intervening combustibles between redundant PFSSD components and cables are limited to cables in sheet metal enclosed cable trays. Fire stops are installed within the cable trays to prevent the spread of fire between redundant PFSSD components and cables. Sheet metal covers will prevent direct flame impingement onto the cables to reduce the likelihood that these cables will become involved in an exposure fire.

The automatic pre-action sprinkler system installed in the area meets the intent of 10CFR50, Appendix R Section III.G.2.b. This system is installed over cable concentrations as described in the Wolf Creek Fire Hazards Analysis. In some areas, sprinklers are installed under the cable trays to protect against exposure fires originating at the floor. Automatic detection is installed throughout the area.

The fire protection features provided in fire area A-16 along with the 20-foot combustible and fire hazard free zone provides reasonable assurance that a fire originating in one section will not affect PFSSD cables and components in the other section.

2.0 PRIMARY EQUIPMENT USED FOR PFSSD

Table A-16-2 lists each system credited for post-fire safe shutdown in fire area A-16 North and provides a discussion regarding the availability of the system to perform its Post Fire Safe Shutdown (PFSSD) function if a severe fire occurs in this area. Table A-16-3 lists each system credited for post-fire safe shutdown in fire area A-16 South and provides a discussion regarding the availability of the system to perform its Post Fire Safe Shutdown (PFSSD) function if a severe fire occurs in this area. For a summary of the area analysis results, see Section 8.0 of the Fire Area Analysis Narrative section.

Table A-16-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-16 North

System	System Name	PFSSD Function*	Comments
AB	Main Steam	R, M, H, P, S	Steam generators B and C ARVs may need to be controlled using the local controllers. Steam generator D ARV may need to be closed by isolating the air and nitrogen supplies. Steam generator A ARV is unaffected. Hand switch ABHS0080 is available to close the MSIVs and MSIV bypass valves. Main steam to TDAFP valves ABHV0005 and ABHV0006 could be affected. PFSSD is assured using Train A MDAFP as discussed in AL system comments below. Steam generator pressure indication is available using ABPI0514A, ABPI0524A, ABPI0534A and ABPI0544A.
AC	Main Turbine	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-16 North.
AE	Main Feedwater	H, P	All PFSSD functions associated with the main feedwater system are satisfied. A number of level indicators on all four steam generators could be affected. Level indication is available using the folowing indicators: SG A: AELI0501, AELI0517, AELI0551; SG B: AELI0527, AELI0529; SG C: AELI0537, AELI0539; SG D: AELI0504, AELI0547, AELI0554. All four main feedwater isolation valves can be isolated using hand switch AEHS0080.
AL	Aux. Feedwater System	H, P	All PFSSD functions associated with the auxiliary feedwater system are satisfied. Train A MDAFP is available to supply S/Gs B and C. The Train B MDAFP and the TDAFP could be affected. ALFT0009 and ALFT0011 are available to provide auxiliary feedwater flow indication from MDAFP A to SGs B and C, respectively. Circuits for two of three transmitters that monitor auxiliary feedwater suction pressure run in area A-16 North. Damage to these circuits could send a spurious low suction pressure (LSP) signal to the ESFAS and cause a spurious swapover to ESW. This is acceptable for PFSSD since the Train A ESW system is available.
AP	Condensate Storage System	H	The condensate storage tank is available to supply water to Train A MDAFP.

Table A-16-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-16 North

System	System Name	PFSSD Function*	Comments
BB	Reactor Coolant System	R, M, H, P, S	All PFSSD functions associated with the reactor coolant system are satisfied. Boration through all four RCP seals is unaffected. Loss of inventory through the head vent valves is prevented by maintaining valves BBHV8001A and BBHV8001B closed. Pressurizer level indication is available using BBLI0459A. RCS wide range hot leg temperature element BBTE0423A (Steam Generator B) and wide range cold leg temperature element BBTE0433B (Steam Generator C) are available. RCS pressure indication is available using BBPI0405 or BBPI0406. When transferring to RHR, valve BBPV8702B may need to be manually opened to provide a suction source from the RCS to RHR pump B. A spurious SIS due to low pressurizer pressure on two out of four pressurizer pressure transmitters is mitigated by entering EMG E-0 and terminating the spurious SIS. Pressurizer pressure indication is available using BBPI0455A and BBPI0458.
BG	Chemical and Volume Control System	R, M, S	All PFSSD functions associated with the chemical and volume control system are satisfied. Train A CCP may be affected. Train B Centrifugal Charging Pump (CCP) is available to provide charging flow from the RWST to the RCP seals. Flow from the VCT can be isolated by closing BGLCV0112B. Valves BGHV8154A and BGHV8153B are maintained closed to isolate excess letdown. BGHV8105 may not respond to a close signal from the control room. Valve BGHV8106, and its hand switch (BGHIS8106), are unaffected by a fire in area A-16.
BM	Steam Generator Blowdown System	R, M, H	All PFSSD functions associated with the steam generator blowdown system are satisfied. Steam generator blowdown is isolated by closing valves BMHV0001, BMHV0002, BMHV0003 and BMHV0004 using BMHIS0001C, BMHIS0002C, BMHIS0003C and BMHIS0004C, located on the BM157 panel in the radwaste control room.
BN	Borated Refueling Water Storage System	R, M, H	The RWST is available to provide a suction source to Centrifugal Charging Pump B via valve BNLCV0112E. RWST level indicators BNLI0930, BNLI0931, BNLI0932 and BNLI0933 are available. When initiating RHR, flow from the RWST to RHR pump B can be isolated using BNHV8812B.

Table A-16-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-16 North

System	System Name	PFSSD Function*	Comments
EF	Essential Service Water System	H, S	All PFSSD functions associated with the Essential Service Water (ESW) system are satisfied. Train A ESW is available to supply cooling water to Auxiliary Feedwater Pump room cooler SGF02A and Containment Air Coolers SGN01A and SGN01C. In addition, the Train A ESW system is available to provide a source of auxiliary feedwater to the Train A MDAFP. Train B ESW is available to supply cooling to the Train B Component Cooling Water (CCW) Heat Exchanger, CCW B pump room cooler SGL11B, CCP B room cooler SGL12B, RHR B room cooler SGL10B, and Containment Air Coolers SGN01B and SGN01D.
EG	Component Cooling Water System	S	All PFSSD functions associated with the Component Cooling Water (CCW) system are satisfied. A number of Train A CCW components could be affected. If Train A CCW is operating, it may be necessary to swap to Train B. Train B CCW is unaffected. Temperature control valve EGTV0030 may not close as desired for PFSSD. However, this valve is designed to modulate based on CCW outlet temperature, which is acceptable for PFSSD. Valve EGHV0062 could spuriously close due to a spurious high CCW flow condition caused by damage to EGFT0062. Bypass valve EGHV0132 is unaffected and can be opened using EGHIS0132 to restore thermal barrier cooling. CCW to RCP flow indicator EGFI0129 could be affected. CCW to RCP flow indicator EGFI0128 is unaffected. Valve EGHV0101 could be affected. Valve EGHV0102 is unaffected.
EJ	Residual Heat Removal System	M, H, P	All PFSSD functions associated with the Residual Heat Removal (RHR) system are satisfied. Loss of RCS inventory through the RHR flow path is prevented by maintaining valves EJHV8701A and EJHV8701B closed. RHR Train B is available via RCS suction valve EJHV8701B and discharge valves EJHCV0607 and EJHV8809B. RHR system flow diagnostic instrumentation is available using various available temperature indicators.
EM	High Pressure Coolant Injection	R, M	All PFSSD functions associated with the High Pressure Coolant Injection system are satisfied. A spurious SIS can be mitigated by entering EMG E-0 and terminating the spurious SIS.
EN	Containment Spray	R, M	All PFSSD functions associated with the Containment Spray system are satisfied. A spurious containment spray actuation signal (CSAS) due to spurious signals on two out of four containment pressure transmitters can be terminated by placing pump control hand switches ENHIS0003 and ENHIS0009 on control room panel RL017 in pull-to-lock.
EP	Safety Injection Accumulators	H	The PFSSD Decay Heat Removal function associated with the Safety Injection Accumulators is satisfied. Accumulator injection lines can be isolated by closing valves EPHV8808A, EPHV8808B, EPHV8808C and EPHV8808D.

Table A-16-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-16 North

System	System Name	PFSSD Function*	Comments
FB	Auxiliary Steam	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-16 North.
FC	Auxiliary Turbines	R, H, P	All PFSSD functions associated with the Auxiliary Turbines are satisfied. The Turbine Driven Auxiliary Feedwater Pump is not used for a fire in area A-16 North
GD	ESW Pump House HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-16 North.
GF	AFW Pump Room Coolers	S	The PFSSD Support function associated with the AFW Pump Room Coolers is satisfied. The Train A Motor Driven AFW Pump is used for a fire in area A-16 North. Auxiliary Feedwater Pump A room cooler SGF02A is available. ESW Train A is available to supply the room cooler.
GK	Control Room and Class 1E Switchgear Room Coolers	S	The PFSSD Support function associated with the Control Room and Class 1E Switchgear Room Coolers is satisfied. The control room A/C units SGK04A and SGK04B are not affected by a fire in area A-16. Both trains of Class 1E Switchgear Room Coolers are required for PFSSD. SGK05A is unaffected by a fire in area A-16 North. SGK05B could be affected due to a spurious fire protection system isolation signal. A spurious fire isolation signal can be bypassed by placing GKHS0104 on panel RP068 in BYPASS then rotate switch GKHIS0103 to the RUN position.
GL	Auxiliary Building HVAC	S	The PFSSD Support function associated with the Auxiliary Building HVAC system is satisfied. Train B CCW pump room cooler SGL11B is available.
GM	Emergency Diesel Generator Room HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-16 North.
GN	Containment Coolers	S	The PFSSD Support function associated with the Containment Coolers is satisfied. Train A (SGN01A and SGN01C) Containment Coolers are available. ESW Train A is available to supply cooling water to the Train A containment coolers. A spurious containment spray actuation signal (CSAS) due to spurious signals on two out of four containment pressure transmitters can be avoided by entering the EMG procedure network and, if necessary, placing the pump control hand switches ENHIS0003 and ENHIS0009 on control room panel RL017 in pull-to-lock. A spurious SIS due to low containment pressure on two out of three containment pressure transmitters is averted by entering the EMG procedure network and, if necessary, placing EMHIS0004 and EMHIS0005 in pull-to-lock. Containment pressure indicators GNPI0934 and GNPI0937 are available.
JE	Diesel Fuel Oil	S	Diesel fuel oil transfer pump PJE01B could be affected.

Table A-16-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-16 North

System	System Name	PFSSD Function*	Comments
KA	Instrument Air	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-16 North.
KC	Fire Protection	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-16 North.
KH	Service Gas	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-16 North.
KJ	Standby Diesel Engine	S	Diesel fuel oil transfer pump PJE01B could be affected, preventing operation of the Train B EDG.
MA	Main Generation	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-16 North.
MR	Startup Transformer	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-16 North.
NB	4.16 kV System	S	The PFSSD Support function associated with the 4.16 kV system is satisfied. Offsite power is unaffected to NB01 and NB02.
NE	Standby Diesel Generator	S	Diesel fuel oil transfer pump PJE01B could be affected, preventing operation of the Train B EDG.
NF	Load Shed and Emergency Load Sequencing	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-16 North.
NG	480V Load Centers and MCCs	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-16 North.

Table A-16-3
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-16 South

System	System Name	PFSSD Function*	Comments
AB	Main Steam	R, M, H, P, S	All PFSSD functions associated with the main steam system are satisfied. Hand switch ABHS0080 is available to close the MSIVs and MSIV bypass valves. All three steam generator pressure indicators on all four steam generators are available.
AC	Main Turbine	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-16 South.
AE	Main Feedwater	H, P	All PFSSD functions associated with the main feedwater system are satisfied. A number of level indicators on all four steam generators could be affected. Level indication is available using the following indicators: SG A: AELI0501, AELI0518, AELI0551; SG B: AELI0502, AELI0528, AELI0529, AELI0552; SG C: AELI0503, AELI0538, AELI0539, AELI0553; SG D: AELI0548, AELI0554.
AL	Aux. Feedwater System	H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-16 South.
AP	Condensate Storage System	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-16 South.
BB	Reactor Coolant System	R, M, H, P, S	All PFSSD functions associated with the reactor coolant system are satisfied. Boration through all four RCP seals is unaffected. Loss of inventory through the head vent valves is prevented by maintaining valves BBHV8001A and BBHV8001B closed. Pressurizer level indication is available using BBLI0459A. RCS wide range hot leg temperature element BBTE0423A (Steam Generator B) and wide range cold leg temperature element BBTE0433B (Steam Generator C) are available. RCS pressure indication is available using BBPI0405. Pressurizer pressure indication is available using BBPI0455A and BBPI0457. When transferring to RHR, valve BBPV8702A may need to be manually opened to provide a suction source from the RCS to RHR pump A. A spurious SIS due to low pressurizer pressure on two out of four pressurizer pressure transmitters is mitigated by entering EMG E-0 and terminating the spurious SIS. Pressurizer PORV BBPCV0456A may open and block valve BBHV8000B may not close. The PORV can be closed using BBHIS0456A in the control room.

Table A-16-3
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-16 South

System	System Name	PFSSD Function*	Comments
BG	Chemical and Volume Control System	R, M, S	All PFSSD functions associated with the chemical and volume control system are satisfied. Train A Centrifugal Charging Pump (CCP) is available to provide charging flow from the RWST to the RCP seals. Flow from the VCT can be isolated by closing either BGLCV0112B or BGLCV0112C. Valves BGHV8154A and BGHV8153B are maintained closed to isolate excess letdown. Valve BGHV8112 may need to be isolated to prevent overheating the CCP. This may be necessary due to the potential for EGHV0053 to remain closed if swapping from Train B CCW to Train A CCW. RCP seal flow indication is available using BGFI0215A. RCP seal flow indicator BGFI0215B may be affected.
BM	Steam Generator Blowdown System	R, M, H	All PFSSD functions associated with the steam generator blowdown system are satisfied. Steam generator blowdown is isolated by closing valves BMHV0001, BMHV0002, BMHV0003 and BMHV0004 using BMHIS0001C, BMHIS0002C, BMHIS0003C and BMHIS0004C, located on the BM157 panel in the radwaste control room.
BN	Borated Refueling Water Storage System	R, M, H	The RWST is available to provide a suction source to Centrifugal Charging Pump A via valve BNLCV0112D. RWST level indicators BNLI0930, BNLI0931 and BNLI0932 are available. When initiating RHR, flow from the RWST to the RHR pumps can be isolated by closing BNHV8812A and BNHV8812B from the control room.
EF	Essential Service Water System	H, S	All PFSSD functions associated with the Essential Service Water (ESW) system are satisfied. Train A ESW is available to supply cooling water to Auxiliary Feedwater Pump room cooler SGF02A, Containment Air Coolers SGN01A and SGN01C, Train A Component Cooling Water (CCW) Heat Exchanger, CCW A pump room cooler SGL11A, CCP A room cooler SGL12A and RHR A room cooler SGL10A.
EG	Component Cooling Water System	S	All PFSSD functions associated with the Component Cooling Water (CCW) system are satisfied. A number of Train B CCW components could be affected. If Train B CCW is operating, it may be necessary to swap to Train A. Train A CCW flow to service loop valve EGHV0053 may be affected. If the valve was closed at the time of the fire, it may not open using the control room hand switch. If this occurs operators should follow OFN EG-004 and maintain minimum flow through the RCP seals. In addition, operators should close seal return containment isolation valve BGHV8112 to prevent overheating the Train A CCP. Thermal barrier cooling could be lost due to the potential failure of EGHV0053 to open and the potential loss of Train B CCW. Also, valve EGHV0062 could spuriously close. No actions are necessary as long as RCP seal injection is available. CCW to RCP flow indicators EGFI0128 and EGFI0129 are available to diagnose a loss of CCW flow to the RCP thermal barriers. Valve EGHV0102 could be affected. Valve EGHV0101 is unaffected.

Table A-16-3
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-16 South

System	System Name	PFSSD Function*	Comments
EJ	Residual Heat Removal System	M, H, P	All PFSSD functions associated with the Residual Heat Removal (RHR) system are satisfied. Valve EJHV8811B could spuriously open. Valve BNHV8812B can be closed from the control room using BNHIS8812B. Loss of RCS inventory through the RHR flow path is prevented by maintaining valves EJHV8701A and EJHV8701B closed. RHR Train A is available via RCS suction valve EJHV8701A and discharge valves EJHCV0606 and EJHV8809A. Valve EJHV8840 could spuriously open. This will not affect hot standby but the valve will need to be closed prior to shutdown cooling. Both RHR pump mini-flow valves EJFCV0610 and EJFCV0611 are available. RHR system flow diagnostic instrumentation is available using various available temperature indicators.
EM	High Pressure Coolant Injection	R, M	All PFSSD functions associated with the High Pressure Coolant Injection system are satisfied. A spurious SIS is mitigated by entering EMG E-0 and terminating the spurious SIS.
EN	Containment Spray	R, M	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-16 South.
EP	Safety Injection Accumulators	H	The PFSSD Decay Heat Removal function associated with the Safety Injection Accumulators is satisfied. Accumulator injection lines can be isolated by closing valves EPHV8808A, EPHV8808B, EPHV8808C and EPHV8808D. It may be necessary to make a containment entry to manually close EPHV8808B and EPHV8808D.
FB	Auxiliary Steam	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-16 South.
FC	Auxiliary Turbines	R, H, P	All PFSSD functions associated with the Auxiliary Turbines are satisfied. The Turbine Driven Auxiliary Feedwater Pump (TDAFP) is not used for a fire in area A-16 South. Valve FCHV0312 will remain closed to prevent uncontrolled steam release through the TDAFP.
GD	ESW Pump House HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-16 South.
GF	AFW Pump Room Coolers	S	The PFSSD Support function associated with the AFW Pump Room Coolers is satisfied. The Train A Motor Driven AFW Pump is used for a fire in area A-16 South. Auxiliary Feedwater Pump A room cooler SGF02A is available. ESW Train A is available to supply the room cooler.

Table A-16-3
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-16 South

System	System Name	PFSSD Function*	Comments
GK	Control Room and Class 1E Switchgear Room Coolers	S	The PFSSD Support function associated with the Control Room and Class 1E Switchgear Room Coolers is satisfied. The control room A/C units SGK04A and SGK04B are not affected by a fire in area A-16. Train A Class 1E Switchgear Room Cooler SGK05A is unaffected by a fire in area A-16 South. Train B Class 1E equipment is not used for a fire in area A-16 South.
GL	Auxiliary Building HVAC	S	The PFSSD Support function associated with the Auxiliary Building HVAC system is satisfied. Train A CCW pump room cooler SGL11A is available.
GM	Emergency Diesel Generator Room HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-16 South.
GN	Containment Coolers	S	The PFSSD Support function associated with the Containment Coolers is satisfied. Train A (SGN01A and SGN01C) Containment Coolers are available. ESW Train A is available to supply cooling water to the containment coolers. Containment pressure indicators GNPI0934, GNPI0935 and GNPI0937 are available.
JE	Diesel Fuel Oil	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-16 South.
KA	Instrument Air	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-16 South.
KC	Fire Protection	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-16 South.
KH	Service Gas	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-16 South.
KJ	Standby Diesel Engine	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-16 South.
MA	Main Generation	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-16 South.
MR	Startup Transformer	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-16 South.
NB	4.16 kV System	S	The PFSSD Support function associated with the 4.16 kV system is satisfied. Offsite and onsite power is available to NB01. Offsite power to bus NB02 could be lost. A fire in A-16 South uses Train A equipment which is fed from NB01. Therefore, loss of NB02 will not affect PFSSD. If necessary, the Train B Emergency Diesel Generator can supply power to NB02.
NE	Standby Diesel Generator	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-16 South.

Table A-16-3
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-16 South

System	System Name	PFSSD Function*	Comments
NF	Load Shed and Emergency Load Sequencing	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-16 South.
NG	480V Load Centers and MCCs	S	Train A 480 VAC MCC NG01B is unaffected by a fire in area A-16 South.
NK	125VDC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-16 South.
NN	120VAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-16 South.
PA	13.8kV	S	Breakers PA0105 and PA0206 could be affected.
PB	4.16kV	H, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-16 South.
PG	480V Load Centers and MCCs	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-16 South.
PK	125VDC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-16 South.
PL	Local Instrument Panels	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-16 South.
PN	120VAC	S	One of the two redundant power feeds to PN08 could be affected. The remaining power feed is unaffected. Therefore, PN08 is available to perform its intended function.
QB	Standby AC Lighting	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-16 South.
QD	Emergency Lighting	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-16 South.
RL	Control Room MCB	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-16 South.
RP	Miscellaneous Control Panels	R, M, H, P, S	The PFSSD functions associated with panel RP210 is affected by a fire in area A-16 South. Redundant capability exists in a separate area and is unaffected by the fire.
SA	ESFAS	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-16 South.

Table A-16-3 Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-16 South			
System	**System Name**	**PFSSD Function***	**Comments**
SB	Reactor Protection System	R, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-16 South.
SC	Reactor Instrumentation	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-16 South.
SE	Ex-Core Neutron Monitoring	R, P	Source Range monitors SENE0031, SENY0060A/B, or SENY0061A/B are available.
SY	Switchyard	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-16 South.

* R - Reactivity Control; M - Reactor Coolant Makeup; H - Decay Heat Removal; P - Process Monitoring; S - Support Function

3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD

This section describes operator actions that may need to be performed inside or outside the control room to achieve and maintain hot standby if a fire occurs in area A-16. This section also describes cold shutdown repairs that may need to be made to achieve and maintain cold shutdown conditions. Operator actions are generally described in OFN KC-016.

3.1 ACTIONS OUTSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

Operator Manual Actions (OMAs) are those actions outside the main control room required to achieve and maintain hot standby. OMAs are identified in E-1F9900 and were determined from thermal hydraulic analysis WCNOC-CP-002. Applicable E-1F9900 OMAs are annotated herein. All other actions outside the control room are desirable for plant control in support of hot standby but not required to achieve and maintain hot standby.

3.1.1 Steam Generator ARVs (OMA, refer to E-1F9900)

If a fire occurs in area A-16 North, it may be necessary to fail close ABPV0004 by isolating the air and nitrogen supply, then venting air from the regulators. Local control stations ABFHC0002 and ABFHC0003, located in fire area A-23, can be used to control ARVs ABPV0002 and ABPV0003, respectively. These actions can be performed by a single operator in fire area A-23, which is accessible without having to traverse area A-16.

3.1.2 Steam Generator to SG Blowdown Flash Tank Isolation

If a fire occurs in area A-16 North or South, cables for BMHIS0001A, BMHIS0002A, BMHIS0003A and BMHIS0004A may be damaged by the fire. Therefore, use BMHIS0001C, BMHIS0002C, BMHIS0003C and BMHIS0004C located on the BM157 panel in the Radwaste Control room to close valves BMHV0001, BMHV0002, BMHV0003, and BMHV0004.

3.2 ACTIONS INSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

3.2.1 Component Cooling Water

A fire in area A-16 North will damage cables and components associated with Train A CCW. If Train A CCW is operating at the time of the fire, it may be necessary to swap to Train B CCW using normal operating procedures.

A fire in area A-16 South will damage cables and components associated with Train B CCW. If Train B CCW is operating at the time of the fire, it may be necessary to swap to Train A CCW using normal operating procedures. However, valve EGHV0053 may not open, preventing CCW flow to the RCP thermal barriers and the seal water heat exchanger. See 3.2.8 and 3.2.9 for actions in the event EGHV0053 cannot be opened.

3.2.2 Containment Spray and Safety Injection

If a fire occurs in area A-16 North or South, a spurious Safety Injection Signal (SIS) could occur. This can be mitigated by consulting EMG E-0 and terminating the spurious SIS.

If a fire occurs in area A-16 North, a spurious Containment Spray Actuation Signal (CSAS) could occur. This can be mitigated by placing CS pump control hand switches ENHIS0003 and ENHIS0009 in pull-to-lock. These switches are located on control room panel RL017.

3.2.3 Mitigation of RWST Draindown to Containment Sump

If a fire occurs in area A-16 South it may be necessary to close valve BNHV8812B from the control room using BNHIS8812B to mitigate draindown of the RWST into the containment sump. This condition could occur due to cable damage to EJHV8811B that causes the valve to partially open and stall before reaching full open position, preventing valve BNHV8812B from automatically closing as designed. Level indicators BNLI0930, BNLI0931 and BNLI0932 are available to diagnose loss of inventory from the RWST.

3.2.4 Main Steam Isolation Valves (MSIVs) and MSIV Bypass Valves

If a fire occurs in area A-16 North or South, cables for hand switch ABHS0079 may be damaged by the fire. Cables for redundant hand switch ABHS0080 are unaffected. Use ABHS0080 to close the MSIVs and MSIV bypass valves.

3.2.5 Charging Pumps to Regenerative Heat Exchanger Isolation

Valve BGHV8105 may not function due to a fire in the North section. Valve BGHV8106, and its hand switch (BGHIS8106), are unaffected by a fire in area A-16 and can be used to isolate flow to the regenerative heat exchanger and therefore satisfy the PFSSD requirement.

3.2.6 Main Feedwater Isolation Valves (MFIVs)

If a fire occurs in area A-16 North, cables for hand switch AEHS0081 may be damaged. Cables for redundant hand switch AEHS0080 are unaffected. Use AEHS0080 to close the MFIVs.

3.2.7 Class 1E Switchgear Room Cooler SGK05B

If a fire occurs in area A-16 North, SGK05B may not respond to an automatic start signal or may shut down due to a fire isolation signal. If this occurs, the spurious fire isolation signal can be bypassed by placing GKHS0104 on panel RP068 in BYPASS and SGK05B can be started by rotating switch GKHIS0103 to the RUN position. Indication for SGK05B is available on the back panel in the CR.

3.2.8 Seal Water Return Flow

If the fire is in A-16 South and Train B CCW is operating at the time of the fire, it may be necessary to swap to Train A CCW. In this case, valve EGHV0053 may not open. Operators should maintain 32 gpm flow to the RCP seals and isolate seal return containment isolation valve BGHV8112 using BGHIS8112 per OFN EG-004. (See Section 5.1.14)

3.2.9 Thermal Barrier Cooling

If the fire is in A-16 North, valve EGHV0062 could spuriously close due to a spurious high CCW flow condition caused by damage to EGFT0062. Bypass valve EGHV0132 is unaffected and can be opened using EGHIS0132 to restore thermal barrier cooling. CCW to RCP flow indicator EGFI0128 is available to diagnose a loss of CCW flow to the RCP thermal barriers.

A fire in A-16 South could result in a loss of thermal barrier cooling due to the potential failure of EGHV0053 to open or spurious closure of EGHV0062. If this occurs, maintain RCP seal injection using Train A charging system. Valve EGHV0062 bypass valve EGHV0132 can be opened from the control room. CCW to RCP flow indicators EGFI0128 and EGFI0129 are available to diagnose a loss of CCW flow to the RCP thermal barriers.

3.2.10 Pressurizer PORV/Block Valve

If the fire is in A-16 South, pressurizer PORV BBPCV0456A could spuriously open due to control cable damage and block valve BBHV8000B may not close. If this occurs, Operators can close the PORV by placing BBHIS0456A in the CLOSE position. Pressurizer pressure indication is available using BBPI0455A and BBPI0457 located on RL002.

3.3 ACTIONS TO ACHIEVE AND MAINTAIN COLD SHUTDOWN

3.3.1 RHR

If either valve BBPV8702A (fire in A-16 South) or BBPV8702B (fire in A-16 North) fails to respond when initiating RHR for cold shutdown, make a containment entry to manually open the valve or perform a cold shutdown repair to fix the damaged circuit.

Valve EJHV8840 could spuriously open in the event of a fire in area A-16 South. This will not affect hot standby, however the valve will need to be locally closed prior to entering shutdown cooling mode.

3.3.2 SI Accumulators

A fire in area A-16 South may require a containment entry to close SI Accumulator injection valves EPHV8808B and EPHV8808D if these valves are unresponsive from the control room.

4.0 CONCLUSION

With some exceptions, redundant Post-Fire Safe Shutdown capability exists if a severe fire occurs in this area. For those exceptions, feasible manual actions are available and are unaffected by the fire. Manual actions are documented in Section 3.0.

5.0 DETAILED ANALYSIS

This section describes the detailed component-by-component and cable-by-cable analysis for a fire in area A-16.

5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA A-16

PFSSD components (S. in E-15000) located in fire area A-16 are shown in Table A-16-4. An evaluation of each component and associated cables is provided in the sections that follow. The applicable evaluation section is listed in Table A-16-4.

Table A-16-4
PFSSD Components Located in Fire Area A-16

Room #	PFSSD Component	Component Description	Evaluation Section	Comments
1401	DPEG01B	CCW Pump B (PEG01B) Motor	5.1.1

5.1.1 Component Cooling Water Pumps

For PFSSD, the component cooling water (CCW) system is used to provide cooling to the centrifugal charging pump (CCP) oil cooler, seal water heat exchanger, RHR heat exchangers and RHR pump seal coolers. In addition, the CCW system provides cooling to the RCP thermal barriers and is credited as a backup to RCP seal injection for maintaining seal cooling.

The component cooling water pumps support the above PFSSD function by providing the motive force necessary to circulate cooling water to these PFSSD credited components. All four component cooling water pumps are located in this fire area. Train A pumps PEG01A and PEG01C are located in area A-16 North and Train B pumps PEG01B and PEG01D are located in area A-16 South.

Cables 11EGB01AA and 11EGB01CA are power cables for Train A CCW pump motors DPEG01A and DPEG01C, respectively, and are run in fire area A-16 North. Damage to these cables will result in loss of power to the associated CCW pump.

Cables 14EGB01BA and 14EGB01DA are power cables for Train B CCW pump motors DPEG01B and DPEG01D, respectively, and are run in fire area A-16 South. Damage to these cables will result in loss of power to the associated CCW pump.

If the fire causes a loss of one CCW pump, Operators can use hand switches on RL019 to start another pump on the affected train or swap to the opposite CCW train. Cables associated with CCW pump hand switches do not run through area A-16.

Each CCW Pump can supply 100 percent of the required cooling water to selected Engineered Safety Features (ESF) components. If a fire occurs in area A-16 North, Train B CCW is available using either CCW pump PEG01B or PEG01D. If a fire occurs in area A-16 South, Train A CCW is available using either PEG01A or PEG01C.

Based on the above discussion, at least one train of CCW pumps will be available if a fire occurs in area A-16.

References: E-15000, XX-E-013, E-1F9401A, E-0R1412, E-0R1422, E-1R1411, E-1R1413A, E-1R1413C, E-1R1421, E-1R1423B, E-1R1423C, E-13EG01A, E-13EG01B, E-13EG01C, E-13EG01D, E-13EG13, E-13NB02, E-13NB05, M-12EG01, M-12EG02, M-12EG03

5.1.2 Component Cooling Water Pump Room Cooling

The CCW pump room coolers are required to ensure the CCW pump motors do not exceed temperature limits. DSGL11A is the room cooler motor for Train A CCW pumps PEG01A and PEG01C. GLHIS0002 is a local hand switch for DSGL11A. These components are located in area A-16 North.

DSGL11B is the room cooler motor for the PEG01B and PEG01D (Train B) CCW pumps. GLHIS0023 is a local hand switch for DSGL11B. These components are located in area A-16 South.

Cables 11GLG06AA and 11GLG06AC are run in area A-16 North and are associated with DSGL11A and GLHIS0002, respectively. Redundant cables 14GLG06BA and 14GLG06BC are run in area A-16 South and are associated with DSGL11B and GLHIS0023, respectively.

GLHZ0080 and GLHZ0081 are exhaust dampers on the Train A CCW pump room cooler (SGL11A). There are no exhaust dampers on the Train B CCW pump room cooler. Cables 11GLY27AB and 11GLY27AD are associated with GLHZ0080 and GLHZ0081, respectively and are run in area A-16 North.

There are no dampers installed on the Train B CCW pump room coolers so there are no cables to evaluate.

PFSSD requires that either train room cooler be operable for the associated train CCW pumps. A fire in area A-16 North will affect Train A room cooler SGL11A but Train B room cooler SGL11B will be available. A fire in area A-16 South will affect Train B room cooler SGL11B but Train A room cooler SGL11A will be available. Therefore, CCW pump room cooling is available to the credited train if a fire occurs in this area.

References: E-15000, XX-E-013, E-13GL06, E-13GL27, E-1F9444, E-1R1411, E-1R1413B, E-1R1413C, E-1R1413D, E-1R1421, E-1R1423A, E-1R1423B, E-1R1423C, E-1R1423D, E-1R1431, E-1R1433A, E-1R1433B, M-12GL01, M-12GL02

5.1.3 Component Cooling Water Heat Exchangers

The CCW heat exchangers ensure adequate transfer of heat from plant components to the ultimate heat sink. The heat exchanger on the credited train is required to be available to ensure this function. The heat exchangers themselves are mechanical components and do not rely on electrical input to operate.

Train A CCW heat exchanger EEG01A is located in area A-16 North and Train B CCW heat exchanger EEG01B is located in area A-16 South. A fire is unlikely to damage the heat exchanger but could affect associated train components as discussed throughout this evaluation.

Based on the above evaluation, the CCW heat exchanger on the credited train will be unaffected by a fire in area A-16 North or A-16 South.

References: E-15000, XX-E-013, E-1F9403, M-12EG02

5.1.4 Essential Service Water to Component Cooling Water Valves

EFHV0051 is the Essential Service Water (ESW) Train A to CCW Train A heat exchanger supply isolation valve and is required to be open when using Train A for PFSSD. EFHV0059 is the return isolation valve from CCW Train A heat exchanger to the Ultimate Heat Sink (UHS). PFSSD requires that EFHV0059 be closed when using Train A CCW for plant shutdown following a fire and that valve EFV0058 be maintained in a locked throttled position to provide the minimum required ESW water flow. If valve EFHV0059 were to spuriously open when operating Train A ESW, flow imbalance could occur, which will result in flow depletion and inoperability of essential PFSSD components.

EFHV0052 is the Essential Service Water (ESW) Train B to CCW Train B heat exchanger supply isolation valve and is required to be open when using Train B for PFSSD. EFHV0060 is the return isolation valve from CCW Train B heat exchanger to the Ultimate Heat Sink (UHS). PFSSD requires that EFHV0060 be closed when using Train B CCW for plant shutdown following a fire and that valve EFV0090 be maintained in a locked throttled position to provide the minimum required ESW water flow. If valve EFHV0060 were to spuriously open when operating Train B ESW, flow imbalance could occur, which will result in flow depletion and inoperability of essential PFSSD components.

Cables 11EFG05AA and 11EFG05AB are power and control cables associated with EFHV0051 and are run in area A-16 North. Cables 11EFG04AA and 11EFG04AB are power and control cables associated with EFHV0059 and are run in area A-16 North. A fire in area A-16 North will result in damage to these cables and the inability to control ESW flow to Train A CCW. However, Train B ESW valves are unaffected due to 20 feet of horizontal separation

with no intervening combustibles and suppression and detection. Therefore, Train B ESW will be used if the fire affects the North section.

Cables 14EFG05BA and 14EFG05BB are power and control cables associated with EFHV0052 and are run in area A-16 South. Cables 14EFG04BA and 14EFG04BB are power and control cables associated with EFHV0060 and are run in area A-16 South. A fire in area A-16 South will result in damage to these cables and the inability to control ESW flow to Train B CCW. However, Train A ESW valves are unaffected due to 20 feet of horizontal separation with no intervening combustibles and suppression and detection. Therefore, Train A ESW will be used if the fire affects the South section.

Based on the above discussion, at least one Train of ESW to CCW valves will be available if a fire occurs in area A-16.

References: E-15000, XX-E-013, E-1R1411, E-1R1413C, E-1R1423B, E-1R1423D, E-1R1431, E-1R1433A, E-1R1901, E-13EF04, E-13EF04A, E-13EF05, M-12EF02.

5.1.5 Component Cooling Water Pumps Pressure Transmitters

EGPT0077 is a pressure transmitter that monitors the discharge pressure on the Train A CCW pumps discharge header. EGPT0078 is a pressure transmitter that monitors the discharge pressure on the Train B CCW pumps discharge header. A low discharge pressure will automatically start the standby pump on the associated train. PFSSD requires that the pressure transmitter on the unaffected train be available.

Cable 11EGI13AA is associated with EGPT0077 and is run in area A-16 North. Cable 14EGI13BA is associated with EGPT0078 and is run in area A-16 South. Damage to these cables could cause the associated pressure transmitter to malfunction.

If a fire occurs in area A-16 North, EGPT0078 will be available. If a fire occurs in area A-16 South, EGPT0077 will be available. Therefore, pressure indication for the operating CCW pump will be available in the control room if a fire occurs in area A-16.

References: E-15000, XX-E-013, E-1R1411, E-1R1413B, E-1R1413C, E-1R1413D, E-1R1423A, E-1R1423C, E-1R1423D, E-13EG13, E-13RP07, E-13RP08, E-13RP09, M-12EG01.

5.1.6 Component Cooling Water Heat Exchanger Bypass Isolation Valves

EGTV0029 is the bypass isolation valve for the Train A CCW heat exchanger located in area A-16 North. This valve is air operated using solenoid valve EGTY0029A. With solenoid valve EGTY0029A energized (normal state), valve EGTV0029 is automatically modulated to maintain required CCW heat exchanger outlet temperature. Loss of power to the solenoid will fail valve EGTV0029 closed, which is the desired PFSSD position.

EGTV0030 is the bypass isolation valve for the Train B CCW heat exchanger located in area A-16 South. This valve is air operated using solenoid valve EGTY0030A. With solenoid valve EGTY0030A energized (normal state), valve EGTV0030 is automatically modulated to maintain required CCW heat exchanger outlet temperature. Loss of power to the solenoid will fail valve EGTV0030 closed, which is the desired PFSSD position.

Cable 11EGK16AA is associated with valve EGTV0029 and is run in area A-16 North. Cable 14EGK16BA is associated with valve EGTV0030 and is run in area A-16 South. Damage to either of these cables will either energize or de-energize the associated solenoid valve, causing the valve to modulate as designed or fail closed. Damage to either of these cables will not affect the available CCW train.

Cable 14EGK16BC is associated with the B Train CCW bypass isolation valve EGTV0030, but is run in area A-16 North (Train A side) of fire area A-16. This cable is run to EGTV0030 auxiliary relay 3XEG8 in Auxiliary Relay Rack RP331, which is also located in area A-16 North. Damage to this cable or relay will either de-energize or energize the solenoid valve, causing valve EGTV0030 to close or modulate, respectively.

Valve modulation is controlled mechanically by temperature detectors EGTIC0029 (Train A) and EGTIC0030 (Train B). Each temperature detector is located adjacent to its associated train CCW in either area A-16 North or South. The temperature detectors monitor outlet temperature of the CCW heat exchanger and adjust air pressure to the temperature control valves (EGTV0029 and EGTV0030) accordingly. This controls the amount of water that bypasses the CCW heat exchanger to maintain the outlet temperature at the desired level. Valve modulation will not affect PFSSD.

Based on the above discussion, CCW temperature control is satisfied if a fire occurs in area A-16.

References: E-15000, XX-E-013, M-12EG02, E-13EG16, E-1R1413A, E-1R1423A, E-1R1423B, E-1R1423C, E-1R1423D, E-1R1424, E-1R1443A, E-1R1443B.

5.1.7 Pressurizer Power Operated Relief Valves and Associated Block Valves

PFSSD requires that either the pressurizer power operated relief valve (PORV) or its associated block valve be closed. Cables and components associated with PORV BBPCV0456A and associated block valve BBHV8000B are located in area A-16 South.

BB008 is the DC contactor panel for PORV BBPCV0456A located in area A-16 South. Damage to this panel due to a fire in area A-16 South could cause PORV BBPCV0456A to spuriously open. Cables for PORV BBPCV0456A are also run in area A-16 South. Damage to these cables could also cause BBPCV0456A to spuriously open.

Valve BBHV8000B is located in a different fire area, however, cables for BBHV8000B are located in area A-16 South and could be damaged, causing the valve to be unresponsive to a close signal.

The pressurizer PORVs are not considered high/low pressure interfaces. The valves are supplied power by an ungrounded 125 VDC system. Therefore, based on GL 86-10, consideration of multiple proper polarity hot shorts is not required. A single proper polarity hot short still needs to be considered.

In the event a fire causes BBPCV0456A to open and damages BBHV8000B cables, Operators can close BBPCV0456A by placing hand switch BBHIS0456A, located on RL021, in the close position. Pressurizer level and RCS pressure indication are available to diagnose a failed open PORV using BBLI0459A and BBPI0405, respectively. In addition, pressurizer pressure indication is available using BBPI0455A and BBPI0457.

An instrument cable (12BBI16LB) associated with pressurizer pressure transmitter BBPT0456 is run in fire areas A-16 South and A-16 North. An instrument cable (13BBI16MB) associated with pressurizer pressure transmitter BBPT0457 is run in fire area A-16 North. An instrument cable (14BBI16NB) associated with pressurizer pressure transmitter BBPT0458 is run in fire area A-16 South. As discussed in Calculation XX-E-013, Appendix 1, the Ovation pressurizer pressure control system uses 4-channel verification from all four pressurizer pressure transmitters to operate the pressurizer PORVs. Failure of a single channel will not cause the spurious operation of the PORVs since the system uses the 2nd highest input as the validated signal. Damage to two channels will not cause the PORVs to open because both channels

would have to fail to the exact same value at the exact same time and therefore this failure mode is not credible, as discussed in XX-E-013.

Based on the above discussion, a fire in area A-16 North will have no impact on pressurizer PORVs BBPCV0455A and BBPCV0456A. A fire in area A-16 South could cause BBPCV0456A to open due to damage to the PORV control cables. In addition, a fire in area A-16 South could prevent block valve BBHV8000B from closing. The PORV can be closed using hand switch BBHIS0456A in the main control room.

References: E-15000, M-12BB02, E-13BB39, E-13BB40, E-13BB16, M-744-00028, M-761-02018, OFN KC-016, J-200-00207, CR 13079, DCP 12944, DCP 13324.

5.1.8 Component Cooling Water to Residual Heat Removal Heat Exchanger Control Valves

Valve EGHV0101 is the Train A CCW to RHR Heat Exchanger control valve. Valve EGHV0102 is the Train B CCW to RHR Heat Exchanger control valve. PFSSD requires that the valve on the operating train of CCW be closed until shutdown cooling mode is entered, at which time the valve on the operating train of RHR needs to be open.

Valve EGHV0101 is located in area A-16 North in room 1408. Valve EGHV0102 is located in area A-16 South in room 1402.

Cables 11EGG07AA and 11EGG07AB are associated with EGHV0101 and are run in area A-16 North. Consequently, a fire in this area will cause a loss of CCW A cooling to the A Train RHR heat exchanger. Damage to these cables would not cause the spurious opening of the valve. Valve EGHV0102 is unaffected by a fire in area A16 North.

Cables 14EGG07BA and 14EGG07BB are associated with EGHV0102 and are run in area A-16 South. Consequently, a fire in this area will cause a loss of CCW B cooling to the B Train RHR heat exchanger. Damage to these cables would not cause the spurious opening of the valve. Valve EGHV0101 is unaffected by a fire in area A16 South.

Based on the above discussion, a fire in area A-16 North could prevent operation of Train A RHR but Train B RHR is available. A fire in area A-16 South could prevent operation of Train B RHR but Train A RHR is available.

References: E-15000, XX-E-013, M-12EG02, E-1F9401A, E-1R1413B, E-1R1413D, E-1R1423C, E-13EG07

5.1.9 Component Cooling Water Common Header Return Valves

Valve EGHV0015 is the Train A CCW Common Header Return Valve. Valve EGHV0016 is the Train B CCW Common Header Return Valve. PFSSD requires that the valve on the operating CCW Train be open.

Valve EGHV0015 is located in area A-16 North in room 1408. Cables 11EGG05AA and 11EGG05AB are power and control cables, respectively, for EGHV0015 and are run in area A-16 North. Consequently, a fire in area A-16 North could cause a loss of the A Train CCW common header return valve but the B Train CCW common header return valve (EGHV0016) remains available.

Valve EGHV0016 is located in area A-16 South in room 1402. Cables 14EGG05BD, 14EGG05BE, 14EGG05BF and 14EGG05BG, associated with EGHV0016, are run in area A-16 South. These cables run to terminal box TB14109 which is also located in area A-16 South in room 1402. Cables 14EGG05BD and 14EGG05BE are also run in the combustible free zone between areas A-16 South and A-16 North as well as A-16 North. These cables are fire resistive and will not be affected by a postulated exposure fire. Cables 14EGG05BF and

14EGG05BG are not fire resistive and could be damaged by an exposure fire. Consequently, a fire in area A-16 South could cause a loss of the B Train CCW common header return valve but the A Train CCW common header return valve (EGHV0015) remains available.

It may not be possible to isolate one train from the other due to cable damage, but per calculation M-EG-24, the system will continue to operate with no damage to the pumps if the opposite train valve is not closed.

Based on the above discussion, a fire in this area will not adversely impact CCW common header return valve on the credited train.

References: E-15000, XX-E-013, E-13EG05A, E-1F9401A, E-1R1413B, E-1R1413D, E-1R1423C, M-12EG01, Calculation M-EG-24, CP 12418

5.1.10 Auxiliary Relay Rack RP210

RP210 is an Auxiliary Relay Rack located in room 1402. This relay rack houses PFSSD relays 3XBM9, 3XBM10, 3XBM11, 3XBM12 and 94XAB6. Relays 3XBM9, 3XBM10, 3XBM11 and 3XBM12 are associated with the Steam Generator Blowdown to Blowdown Flash Tank Isolation Valves BMHV0001, BMHV0002, BMHV0003 and BMHV0004, respectively. Relay 94XAB6 is associated with Main Steam Isolation Bypass Valves ABHV0012, ABHV0015, ABHV0018 and ABHV0021.

Redundant relay rack RP209 is located in a different fire area (A-8) and is unaffected by a fire in A-16. In addition, relay rack RP211 is located in fire area A-1 and is unaffected by a fire in A-16.

For an evaluation of the cables associated with these components, see Section 5.2.

References: E-15000, XX-E-013, E-1F9101

5.1.11 Auxiliary Relay Rack RP266

RP266 is an Auxiliary Relay Rack located in area A-16 North in room 1408. The PFSSD function of this panel is to support operation of the Turbine Driven Auxiliary Feedwater Pump (TDAFWP). A fire in area A-16 North will damage this panel and prevent operation of the TDAFWP. The Motor Driven Auxiliary Feedwater Pump A and associated cables are not run through A-16 and are available in the event of a fire in A-16.

For an evaluation of the cables associated with these components, see Section 5.2.

References: E-15000, XX-E-013, E-1F9422B

5.1.12 Reverse Isolation Relay Rack RP331

RP331 is the Reverse Isolation Relay Rack located in the North (Train A) section of area A-16 in room 1408. This relay rack houses PFSSD relays 3XEG8 and 95XGK08 associated with Train B components. Relay 3XEG8 and associated circuits are discussed in Section 5.1.6.

Relay 95XGK08 is an auxiliary relay for the Train B Class 1E Electrical Equipment Cooler SGK05B. This relay controls automatic shutdown of SGK05B prior to Halon actuation in the event of a fire in the Train B Class 1E switchgear rooms (Rooms 3302, 3404 and 3410). Damage to this relay could cause the SGK05B A/C unit to shut down.

Cables 14GKG13BE and 14GKG13BF are control cables for SGK05B and run to relay panel RP331 in area A-16 North. Damage to these cables could prevent automatic operation of SGK05B.

Cable 16GKK31DA is a control cable for fire signal isolation of SGK05B and runs to panel RP331 in area A-16 North. An open in cable 16GKK31DA will initiate a false fire isolation signal and shut down SGK05B. Cable 16RPK09PA provides 125 VDC power to relay 95XGK08 in panel RP331. Damage to this cable will de-energize the relay and cause SGK05B to shut down.

A fire in area A-16 North uses Train B equipment to achieve and maintain PFSSD and requires Train B Class 1E Electrical Equipment. If SGK05B automatically shuts down due to a fire in area A-16 North, the spurious fire isolation signal can be bypassed by placing GKHS0104 on panel RP068 in BYPASS and SGK05B can be started by rotating GKHIS0103 to the RUN position.

Train A Class 1E switchgear unit SGK05A is unaffected by a fire anywhere in area A-16. Cables associated with this unit are run in a separate fire area. If a fire occurs in area A-16 South, Train B components will be lost and Train A components will be used primarily for PFSSD. Therefore, SGK05A is available to supply room cooling to the Train A Class 1E switchgear rooms if the fire occurs in area A-16 South.

Based on the above discussion, a fire in area A-16 involving RP331 will not impact the ability to achieve and maintain PFSSD.

References: E-15000, E-1F9444, E-13GK13, E-13GK13A, E-13GK31, E-13RP09

5.1.13 Auxiliary Relay Rack RP333

RP333 is an Auxiliary Relay Rack located in area A-16 South in room 1408. This relay rack houses PFSSD relay 62TDENB03, Degraded Voltage Trip Block Relay. PFSSD requires that either this relay or relay K617 be available to ensure off-site power is available to NB02.

Relay K617 is located in panel SB032C in fire area C-27 (room 3605) and is unaffected by a fire in area A-16.

Based on Calculation XX-E-013, Appendix 2, off-site power is available using NB01 or NB02 for a fire in area A-16.

For an evaluation of the cables associated with this component, see Section 5.2.

References: E-15000, XX-E-013

5.1.14 Component Cooling Water to Nuclear Auxiliary Components

Valve EGHV0053 is the Train A CCW supply to the service loop. Valve EGHV0054 is the Train B CCW supply to the service loop. The valve on the operating CCW train is required to be open to ensure CCW flow to the seal water heat exchanger and thermal barrier cooling coils on all four reactor coolant pumps. The valve on the non-operating CCW train can remain open because check valves EGV0036 and EGV0061 will prevent flow diversion to the non-operating train.

If the fire occurs in A-16 North, valves EGHV0053 and EGHV0054 are unaffected. Cables 14EGG05DE and 14EGG05DF, associated with EGHV0054, are run in area A-16 North but these cables are fire resistance rated (see CP 12418) and have been tested to maintain their integrity during a postulated fire. Consequently, Train B CCW can be used, valve EGHV0054 can be opened and EGHV0053 can be closed.

If a fire occurs in area A-16 South, Train A CCW is credited. If a fire occurs in area A-16 North, Train B CCW is credited. Valves EGHV0053 and EGHV0054 are located in area A-16 South.

Therefore, a fire in area A-16 South could prevent operation or cause mal-operation of one or both valves. If the fire occurs in A-16 North, valves EGHV0053 and EGHV0054 are unaffected.

If the fire occurs in area A-16 South and Train A CCW is operating at the time of the fire, the valves will be in their proper lineup (EGHV0053 open and EGHV0054 closed) and damage to cables 11EGG05CA and 11EGG05CB will not cause EGHV0053 to close. If the fire occurs in area A-16 South and Train B CCW is operating at the time of the fire, it may be necessary for operators to swap to Train A CCW. However, valve EGHV0053 would be in the closed position and may not be operable because of cable damage. The Train A CCW system is unaffected but CCW flow to the seal water heat exchanger and RCP thermal barrier coolers may not be available.

Calculation BG-M-052 evaluated the case where CCW to the seal water heat exchanger is unavailable. Based on the results of the calculation, the CCP would remain operable as long as the seal return flowpath is isolated and CCW is available to the CCP oil cooler. In this scenario, the CCP is flowing minimum flow to the RCP seals and excess flow is re-circulating back to the pump suction. A fire in area A-16 South does not affect valve BGHV8112. Therefore, operators could isolate seal return using BGHIS8112 in the control room.

Based on the above discussion, a fire in area A-16 North will not adversely impact the ability to line up CCW to the nuclear auxiliary components. However, a fire in area A-16 South could prevent CCW flow to the seal water heat exchanger and RCP thermal barriers if Train B CCW is operating at the time of the fire. This is acceptable based on the discussion in the previous paragraph and due to the availability of RCP seal injection.

Based on the above discussion, a fire in area A-16 will not adversely impact the ability to achieve and maintain safe shutdown.

5.2 PFSSD CABLE EVALUATION

Table A-16-5 lists all the PFSSD cables (S. in E-15000) located in fire area A-16. The applicable evaluation section is listed in Table A-16-5.

5.2.1 Auxiliary Feedwater

The PFSSD design requires the use of one auxiliary feedwater pump (AFP) supplying water to at least two steam generators. The turbine driven auxiliary feedwater pump (TDAFP) is normally aligned to supply all four steam generators. The Train A motor driven auxiliary feedwater pump (MDAFP) is aligned to supply steam generators B and C. The Train B MDAFP is aligned to supply steam generators A and D.

The normal source of water to the AFPs is the condensate storage tank (CST). The emergency supply is from the essential service water (ESW) system. For commercial concerns, the CST is the preferred source and contains sufficient volume to supply the entire auxiliary feedwater (AFW) demand to achieve cold shutdown. However, as discussed in Section 5.2.3, the AFW supply could spuriously swap over to ESW.

A number of cables associated with various valves and components in the auxiliary feedwater (AFW) system are run through A-16 North. There are no AFW cables or components in fire area A-16 South. The cables in area A-16 North are associated with the TDAFP and the Train B MDAFP. Also, cables associated with ALPT0038 and ALPT0039 are run in fire area A-16 North. The impact of fire damage to ALPT0038 and ALPT0039 circuits is discussed in Section 5.2.3. The Train A MDAFP and associated suction and discharge valves are unaffected by a fire anywhere in area A-16.

Damage to the AFW cables in A-16 North could prevent operation of the TDAFP and the Train B MDAFP. The Train A MDAFP is unaffected by a fire in area A-16 North.

To prevent uncontrolled cooldown through the TDAFP, valves ABHV0005 and ABHV0006 or valves FCHV0312 or FCHV0313 are required to be closed. Valve FCHV0312 is located downstream of valves ABHV0005 and ABHV0006 in the 4-inch steam line to PAL02. This valve is normally closed and will prevent uncontrolled blowdown if valves ABHV0005 or ABHV0006 were to spuriously open. Valve FCHV0313 is located downstream of valve FCHV0312. This valve controls steam pressure entering the TDAFP turbine to control pump speed.

Cables associated with ABHV0005, ABHV0006, FCHV0312 and FCFV0313 are run in area A-16 North. Damage to cables associated with these valves could cause all four valves to spuriously open at the same time, causing uncontrolled blowdown through the TDAFP. If this occurs, the TDAFP will trip on high speed and valve FCFV0313 would mechanically shut, isolating the blowdown path.

Valve FCFV0310 is on a 1-inch line downstream of the steam trap. Damage to cables associated with this valve could prevent closing the valve from the control room. Uncontrolled blowdown through this 1-inch line will not cause unacceptable RCS cooldown and will not impact PFSSD.

Based on the above discussion, auxiliary feedwater is available if a fire occurs in area A-16 North using the Train A MDAFP to supply steam generators B and C. Auxiliary feedwater is unaffected by a fire in area A-16 South.

References: E-15000, XX-E-013, E-13AB01, E-13AB01A, E-13AL01B, E-13FC23, E-1F9101, M-12FC02, M-12AB02,

5.2.2 Steam Generator Main Steam Isolation Valves (MSIVs) and Bypass Valves

PFSSD requires the MSIVs and bypass valves be closed to prevent reactivity addition due to uncontrolled cooldown. The MSIVs and bypass valves are closed from the control room using all close hand switches ABHS0079 or ABHS0080.

Each MSIV is designed to utilize system fluid (main steam) as the motive force to open and close. The valve actuation (open or close) is accomplished through positioning a series of six electric solenoid pilot valves to either direct the system fluid to the Upper Piston Chamber (UPC) and/or the Lower Piston Chamber (LPC), or vent either or both piston chambers. The six solenoid pilot valves are divided into two trains (3 per train) that are independently powered and controlled. Either train can independently perform the PFSSD function to close the valve and isolate main steam. This is done by actuating either all close hand switch ABHS0079 (separation group 4) or ABHS0080 (separation group 1) to de-energize the associated solenoid valves.

The following table identifies the solenoids and associated control cables for each hand switch.

MSIV	ABHS0079 (Sep Group 4)		ABHS0080 (Sep Group 1)	
	Solenoids	Cable	Solenoids	Cable
ABHV0011	MV2, MV4, MV6	14ABK28BH	MV1, MV3, MV5	11ABK29BH
ABHV0014	MV2, MV4, MV6	14ABK29AH	MV1, MV3, MV5	11ABK28AH
ABHV0017	MV2, MV4, MV6	14ABK28AH	MV1, MV3, MV5	11ABK29AH
ABHV0020	MV2, MV4, MV6	14ABK29BH	MV1, MV3, MV5	11ABK28BH

All 4 cables associated with the 12 separation group 4 solenoid valves are run in area A-16 North. Cable damage due to a fire will likely result in disruption of power to the solenoids, which will close the valves. The four separation group 1 cables associated with hand switch ABHS0080 are unaffected by a fire in area A-16 North. Therefore, hand switch ABHS0080 is available to close the four MSIVs. Fire Area A-16 South has no cables associated with either hand switch.

Each MSIV bypass valve is normally closed and is required to remain closed for PFSSD. Two (2) redundant solenoid valves (one on each train) are installed on the air supply line and control air to the pneumatic actuator. The valves are normally closed with the solenoid valves de-energized. Actuation of either hand switch ABHS0079 or ABHS0080 will de-energize power to the solenoids to ensure they remain closed.

Cables associated with the 4 separation group 4 solenoids associated with each bypass valve are run in area A-16 North and South. Cables associated with the 4 separation group 1 solenoids associated with each bypass valve are unaffected by a fire in area A-16 North and South. Therefore, hand switch ABHS0080 is available to close the MSIV bypass valves.

Based on the above discussion, hand switch ABHS0080 is available to close the MSIVs and MSIV bypass valves in the event of a fire in area A-16.

References: E-15000, XX-E-013, E-13AB23A, E-13AB23B, E-13AB26, E-13AB27, E-13AB28, E-13AB29, E-1F9101, M-12AB02

5.2.3 Condensate Storage Tank

The preferred suction source for auxiliary feedwater (AFW) is the condensate storage tank (CST). This tank provides a clean source of water to the steam generators. On low auxiliary feedwater suction pressure (LSP), the suction source transfers to essential service water (ESW).

Three pressure transmitters are installed on the suction piping from the CST to the AFW pumps. These transmitters monitor auxiliary feedwater suction pressure from the CST and automatically transfer the AFW suction to ESW upon low pressure on two out of three pressure transmitters.

Circuits for two of the three pressure transmitters (ALPT0038 and ALPT0039) run through area A-16 North. Damage to these circuits could cause a spurious LSP signal on two pressure transmitters and swap the auxiliary feedwater source to ESW. This is acceptable for PFSSD since the ESW system is a credited source of AFW.

Based on the above discussion, a spurious auxiliary feedwater swapover from CST to ESW could occur if a fire occurs in area A-16 North. A fire in area A-16 South will not affect the swapover function.

References: E-15000, XX-E-013, E-1F9202, E-13AL08, M-12AL01

5.2.4 Safety Injection and Containment Spray

Calculation XX-E-013, Appendix 1 (PFSSD Support Section) provides a detailed discussion about the potential PFSSD impact of a spurious safety injection signal (SIS) and spurious containment spray actuation signal (CSAS). This section discusses the specific PFSSD impact if a fire occurs in this area.

Cables associated with GNPT0935 are run in area A-16 North. Cables associated with GNPT0936 are run in the North and South sections of area A-16. Consequently, a fire in area A-16 North could cause a spurious SIS and CSAS due to high containment pressure. A fire in area A-16 South will not cause a spurious CSAS since circuits for only one containment pressure transmitter are located in area A-16 South.

Cables associated with Train B containment spray isolation valve ENHV0012 are run in area A-16. Damage to these cables could cause the valve to spuriously open. However, as described below, a spurious CSAS can be mitigated from the control room. Therefore, spurious opening of this valve will not adversely impact PFSSD.

Cables associated with BBPT0456 are run in the North and South sections of area A-16. Cables associated with BBPT0457 are run in area A-16 North. Cables associated with BBPT0458 are run in area A-16 South. Consequently, a fire in either area A-16 North or South could cause a spurious SIS due to low pressurizer pressure.

Cables associated with steam line pressure transmitters ABPT0515, ABPT0516, ABPT0525, ABPT0526, ABPT0535, ABPT0536, ABPT0545 and ABPT0546 are run in area A-16 North. Area A-16 South does not contain cables associated with any of the steam line pressure transmitters. Consequently, a fire in area A-16 North could cause a spurious SIS due to damage to cables associated with two out of three steam line pressure transmitters on each steam loop.

Based on the above discussion, a fire in A-16 North could cause a spurious SIS and CSAS while a fire in area A-16 South could cause a spurious SIS.

Fire in A-16 North

A spurious SIS starts the charging sequence which starts the CCPs and opens the BIT flowpath valves. For a fire in area A-16 North, the B Train BIT flowpath valves could be affected and may not open on a SIS. The A Train BIT flowpath valves are unaffected by a fire in A-16 North. The RWST to CCP valves are unaffected and would open on a SIS. Also, the CCP mini flow valves are unaffected and Train B CCW flow to the seal water heat exchanger is unaffected to ensure cooling of the recirc flow, RCP seal return and CCP oil cooler. Therefore, there will be sufficient suction, discharge and cooling flow to ensure the charging pumps are not affected by a spurious SIS caused by a fire in this area.

A start of the credited CCW system (Train B) will not adversely impact the system. The Train B ESW system is unaffected and will start on a spurious SIS, providing necessary cooling water to the Train B CCW heat exchanger.

A start of the AFW pumps will not adversely impact PFSSD. The Train A AFW pump is credited for a fire in this area. Suction from the CST to the Train A AFW pump is unaffected. Discharge flow will either return to the CST or flow to the steam generators through the discharge control valves. Therefore, the Train A AFW pump is unaffected by a spurious SIS caused by a fire in area A-16 North.

A start of the RHR pumps due to a spurious SIS could adversely impact the A Train pump but the B Train pump is unaffected. The RWST supply to the pumps is not affected and the recirculation valves will remain in the open position. Train A CCW could be affected, preventing cooling to the Train A RHR heat exchanger. This could cause the Train A RHR pump to overheat while running on recirculation flow. Train B CCW is unaffected and is available to supply cooling water to the Train B RHR heat exchanger. Therefore, the Train B RHR pump will not be affected by a spurious SIS caused by a fire in area A-16 North.

A spurious CSAS could occur if a fire occurs in area A-16 North. If this occurs, operators can stop the CS pumps by placing pump control hand switches ENHIS0003 and ENHIS0009 in pull-to-lock. These switches are located on control room panel RL017.

Based on the above discussion, a spurious SIS and CSAS can occur if a fire occurs in this area. Credited PFSSD equipment will not be damaged by the spurious SIS. The CSAS can be terminated from the control room. Therefore, a spurious SIS and CSAS will not adversely impact PFSSD.

Fire in A-16 South

A spurious SIS starts the charging sequence which starts the CCPs and opens the BIT flowpath valves. For a fire in this area, the BIT flowpath valves are unaffected and would open on a SIS. The RWST to CCP valves are unaffected and would open on a SIS. Also, the CCP mini flow valves are unaffected and Train A CCW flow to the seal water heat exchanger is unaffected to ensure cooling of the recirc flow, RCP seal return and CCP oil cooler. Therefore, there will be sufficient suction, discharge and cooling flow to ensure the charging pumps are not affected by a spurious SIS caused by a fire in this area.

A start of the credited CCW system (Train A) will not adversely impact the system. The Train A ESW system is unaffected and will start on a spurious SIS, providing necessary cooling water to the Train B CCW heat exchanger.

A start of the AFW pumps will not adversely impact PFSSD. The Train A AFW pump is credited for a fire in this area. Suction from the CST to the Train A AFW pump is unaffected. Discharge flow will either return to the CST or flow to the steam generators through the

discharge control valves. Therefore, the Train A AFW pump is unaffected by a spurious SIS caused by a fire in area A-16 South.

A start of the RHR pumps due to a spurious SIS could adversely impact the B Train pump but the A Train pump is unaffected. The RWST supply to the pumps is not affected and the recirculation valves will remain in the open position. Train B CCW could be affected, preventing cooling to the Train B RHR heat exchanger. This could cause the Train B RHR pump to overheat while running on recirculation flow. Train A CCW is unaffected and is available to supply cooling water to the Train A RHR heat exchanger. Therefore, the Train A RHR pump will not be affected by a spurious SIS caused by a fire in area A-16 South.

Based on the above discussion, a spurious SIS can occur if a fire occurs in this area. Credited PFSSD equipment will not be damaged by the spurious SIS. Therefore, a spurious SIS will not adversely impact PFSSD.

References: E-15000, XX-E-013, E-1F9431, E-1F9433, E-13AB21, E-13BB16, E-13EM01, E-13EN01, E-13EN03, E-13GN05, M-12AB01, M-12BB02, M-12BN01, M-12EJ01, M-12EN01, M-12GN01, OFN KC-016

5.2.5 Steam Generator Atmospheric Relief Valves

Cables run in area A-16 associated with Steam Generator Atmospheric Relief Valves ABPV0002, ABPV0003 and ABPV0004 are evaluated in this section. Cables associated with Steam Generator Atmospheric Relief Valve ABPV0001 are not run in area A-16.

PFSSD requires at least two steam generator atmospheric relief valves (ARV) be controlled and the other two closed. The ARVs are normally closed and require air pressure to open. Each valve is controlled by a pressure transmitter input signal from a pressure transmitter installed on the outlet side of the steam generator. The relief valve opens when the pressure reaches a designated setpoint.

Because of the fail-close design of the valve, it is unlikely that spurious signals due to cable damage will cause the valves to open. In the unlikely event the valves open, air pressure can be removed by closing appropriate air and nitrogen supply valves to fail close the valves. These valves are not located in area A-16 and access to the valves can be gained without having to traverse area A-16.

Damage to the associated cables could prevent controlling two of the four ARVs from the control room. Local controllers ABFHC0002 and ABFHC0003, located in fire area A-23, can be used to control ARVs ABPV0002 and ABPV0003, respectively.

Based on the above discussion, manual actions exist to ensure a fire in area A-16 will not prevent the control of two Steam Generator Atmospheric Relief Valves and the closure of the remaining two. These are OMAs. Refer to E-1F9900 for details. Reference Attachment 4, MSO Evaluation Scenario ID PWROG 23.

References: E-15000, XX-E-013, E-1F9101, E-13AB20A, E-13AB20B, M-12AB01, M-12KA04, M-12KA05

5.2.6 Steam Generator Level Indication

The decay heat removal function for PFSSD requires the use of two RCS loops and two Steam Generators. Steam generator (SG) level indication is required to support this function. A fire anywhere in area A-16 uses MDAFW pump A, which is normally aligned to supply SGs B and C.

Cables 12AEI08GB, 12AEI12BB, 12AEI12CB, 13AEI08GB, 13AEI08HB, 13AEI08JB, 13AEI08KB run through area A-16 North (rooms 1406 and 1408). These cables are associated with SG level transmitters AELT0502 (SGB WR), AELT0552 (SGB NR), AELT0553 (SGC NR), AELT0503 (SGC WR), AELT0518 (SGA NR), AELT0528 (SGB NR) and AELT0538 (SGC NR), respectively. Consequently, these level transmitters may not be available if a fire occurs in area A-16 North.

Cables 14AEI08PB and 14AEI08QB run through area A-16 South (rooms 1402 and 1408). These cables are associated with SG level transmitters AELT0527 (SGB NR) and AELT0537 (SGC NR). Consequently, these level transmitters may not be available if a fire occurs in area A-16 South.

Cables 11AEI08BB and 11AEI08CB are associated with AELT0529 and AELT0539, respectively. These cables are not run in area A-16. Consequently, these level transmitters will be available to provide SG B and C level indication for a fire anywhere in area A-16.

Cable 14SBS16XA is associated with SG B Wide Range Level Indication on the RP118B panel. RP118B is only used for a Control Room fire and is not required for a fire in area A-16.

Steam Generator B and C level indication is assured for a fire in area A-16 by using narrow range level indicators AELI0529 and AELI0539. Alternatively, a fire in area A-16 North could use AELT0527 and AELT0537 because cables associated with these level transmitters are unaffected by a fire in area A-16 North. A fire in area A-16 South could use AELT0502, AELT0528, AELT0552, AELT0503 and AELT0538 because cables associated with these level transmitters are unaffected by a fire in area A-16 South.

Other PFSSD cables run through area A-16 associated with Steam Generator level indication are listed in Table A-16-5. Damage to these cables will not impact PFSSD because SG B and C level indication is assured.

Steam generator B and C level indication is assured if a fire occurs in area A-16.

References: E-15000, XX-E-013, E-1F9203, E-13AE08, E-13AE12, M-12AE02

5.2.7 Non-Class 1E 120 VAC Electrical Distribution System

Cable 14PNG01AE supplies 480 VAC power from NG002BBF1 to 480/120V transformer XPN08A. Damage to this cable due to a fire in area A-16 South will result in a loss of power to the transformer and loss of 120 VAC feed to PN08 from this power source. A fire in area A-16 North will not affect this cable.

The PFSSD function of the Non-Class 1E 120 VAC electrical distribution system is to supply 120 VAC power to Main Control Boards RL017/RL018 and RL021/RL022. The power is split at each MCB to supply specific PFSSD components.

The PFSSD components that depend on 120 VAC power from RL017/RL018 are Residual Heat Removal (RHR) discharge valves EJHCV0606 (Train A) and EJHCV0607 (Train B). Non-class 1E switchboard panel PN07 supplies power from switch PN0736 to valve positioner EJHY0606. Valve positioner EJHY0606 controls the position of EJHCV0606 using hand

controller EJHIC0606. Non-class 1E switchboard panel PN08 supplies power from switch PN0833 to valve positioner EJHY0607. Valve positioner EJHY0607 controls the position of EJHCV0607 using hand controller EJHIC0607.

The PFSSD components that depend on 120 VAC power from RL021/RL022 are temperature recorders BBTR0423, BBTR0433 and BBTR0443. Non-class 1E switchboard panel PN07 supplies power from switch PN0738 to temperature recorder BBTR0423. Non-class 1E switchboard panel PN08 supplies power from switch PN0835 to temperature recorders BBTR0433 and BBTR0443.

The redundant source of power to PN08 from PG20GER5 is unaffected by a fire in area A-16. Therefore, PN08 is available to supply its PFSSD loads if a fire occurs in fire area A-16. In addition, PN07 is unaffected by a fire in area A-16 and remains available to supply its respective PFSSD loads.

References: E-15000, XX-E-013, E-1F9421, E-13PN01

5.2.8 Source Range Monitoring

PFSSD requires source range (SR) flux monitoring to be available. Source range monitoring is provided by source range monitors SENE0031, SENE0032, SENY0060A & B, and SENY0061A & B. Cables run in fire area A-16 associated with these monitors are listed in Table A-16-5.

Cables for SENE0031 run in area A-16 North. A fire in area A-16 South will not affect cables associated with SENE0031 due to at least 20 feet of horizontal separation with no intervening combustibles. In addition, automatic suppression and detection is installed in the area. This configuration meets the separation requirements of 10CFR50, Appendix R Section III.G.2.b.

Cables for SENE0032 run in areas A-16 North and South. Therefore, SENE0032 is not available for a fire in area A-16.

Cables for SENY0060A & B run in area A-16 North. A fire in area A-16 South will not affect cables associated with SENY0060A & B due to at least 20 feet of horizontal separation with no intervening combustibles. In addition, automatic suppression and detection is installed in the area. This configuration meets the separation requirements of 10CFR50, Appendix R Section III.G.2.b.

Cable 14SES07BB is an indication circuit associated with SR monitor SENY0061A/B used for alternate PFSSD at remote shutdown panel RP118B. This cable is run in area A-16 North. A fire in this area does not use remote shutdown panel RP118B. Damage to this cable will not impact SR indication in the control room at panel RL020. Therefore, SR monitoring is available for a fire in area A-16 North using SENY061A/B.

A fire in area A-16 South can use SENE0031, SENY0060A/B, or SENY0061A/B.

For a more detailed evaluation on Source Range monitoring, see Calculation XX-E-013, Attachment 3.

References: E-15000, XX-E-013, E-13SE01, E-13SE02, E-13SE07, E-13SR14, E-1R1423B

5.2.9 Reactor Coolant System (RCS) Temperature Indication

PFSSD requires RCS temperature indication to be available. Cables associated with RCS Loop 2 cold leg wide range temperature indicator BBTI0423X and RCS loop 4 hot leg wide range temperature indicator BBTI0443A are run through fire area A-16. These cables are listed in Table A-16-5.

These components are located on the Auxiliary Shutdown Panel (RP118B) and are used for alternate shutdown in the event of a control room fire. Consequently, they are not required for a fire in area A-16. Damage to these cables will not affect RCS temperature indication in the control room.

References: E-15000, XX-E-013, E-13SB16

5.2.10 Reactor Head Vent Valves

PFSSD requires that one of the two reactor vessel head vent valves on each flow path (2 flow paths total) be closed to prevent uncontrolled depressurization of the RCS. Circuits for three of the four head vent valves run through area A-16. These cables are listed in Table A-16-5.

Cables for head vent valve BBHV8001A are not run through A-16 and are unaffected by a fire in A-16. Therefore, the cables for redundant head vent valve BBHV8002A can be damaged without any consequences on PFSSD.

Either BBHV8001B or BBHV8002B needs to be closed to prevent RCS depressurization through the separation group 4 head vent flow path. The separation requirements of 10CFR50, Appendix R are not satisfied for valves BBHV8001B and BBHV8002B. Less than 20 feet of horizontal separation exists between raceways carrying cables 14BBK30BA and 14BBK30DA.

Cable 14BBK30BA is run in conduit through area A-16. This conduit carries one other cable (14BGK48AB) which is a control cable for excess letdown isolation valve BGHV8153B and is normally de-energized. Therefore, the possibility of an inter-cable hot short that would cause valve BBHV8001B to open is not credible. An intra-cable short in cable 14BBK30BA would not cause the valve to open because this failure mode would not energize the control solenoid. Considering a ground fault equivalent hot short (GFEHS), a short to ground involving conductor 2 in cable 14BBK30BA coincident with a short to ground involving another +125 VDC conductor in another cable supplied from the same power source could open the head vent valve. This hot short has to occur prior to an intra-cable short occurring between conductors 2 and N2 in the associated cable because an intra-cable short between these conductors coincident with a GFEHS will open the circuit protective device and de-energize the control solenoid. Fire testing (NUREG/CR-7100) has shown that intra-cable shorting in thermoset cables occurs before inter-cable or GFEHS shorting. Therefore, there is reasonable assurance that inter-cable or GFEHS shorts will not cause two valves to open if a fire occurs in this area.

Based on the above discussion, there is reasonable assurance that cable damage, along with any combination of cable failures, will not cause two series valves in the head vent flow path to spuriously open in the event of a fire in area A-16.

References: E-15000, XX-E-013, E-1F9301, E-13BB30, E-1R1413D, E-1R1423A, E-1R1423C, E-1R1433A, E-1R1433B, M-12BB04

5.2.11 Reactor Coolant Pump Seal Injection

PFSSD requires RCP seal injection to provide a boron injection path, provide makeup to the RCS and provide cooling to the RCP seals. The redundant boron injection and makeup path is through the boron injection tank (BIT). The redundant seal cooling method uses thermal barrrier cooling. Boron injection tank flowpath availability is discussed in Section 5.2.26. Thermal barrier cooling is discussed in Section 5.2.24.

Cables 14BBG04AA, 14BBG04AB, 14BBG04BA, 14BBG04BB, 14BBG04CA, 14BBG04CB, 14BBG04DA and 14BBG04DB associated with RCP seal injection valves BBHV8351A, BBHV8351B, BBHV8351C and BBHV8351D are located in area A-16 South. Cables associated with these valves are not run in area A-16 North. The RCP seal injection valves are not high-low pressure interface valves, so consideration of a 3-phase proper polarity hot short is not required. A hot short, open circuit or short to ground involving these cables will not cause the valves to close. Therefore, RCP seal injection valves BBHV8351A, BBHV8351B, BBHV8351C and BBHV8351D will remain in their normally open position if a fire occurs anywhere in this area. Furthermore, the valves are de-energized so cable damage could not cause the valves to close.

Cable 14BGI51BA is associated with RCP seal total flow indicator BGFT0215B. Damage to this cable due to a fire in area A-16 South could prevent operation of the flow transmitter and could prevent operators from determining total RCP seal injection flow using flow indicator BGFI0215B. Flow indicator BGFI0215A is unaffected by a fire in area A-16 South and can be used by operators to determine if seal injection flow is functioning. Flow indicators BGFI0215A and BGFI0215B are unaffected by a fire in area A-16 North.

Based on the above discussion, RCP seal injection is available in the event of a fire in area A-16. Loss of the operating charging pump would be indicated by loss of flow to the RCP seals using flow indicator BGFI0215A if the fire is in A-16 North or South and BGFI0215B if the fire is in A-16 North.

References: E-15000, XX-E-013, E-13BB04, E-13BG51, E-1F9102, M-12BB03

5.2.12 Pressurizer Level Transmitters

PFSSD requires pressurizer level indication to be available. Pressurizer level indication is provided by level transmitters BBLT0459 and BBLT0460. Circuits for BBLT0459/BBLI0459A do not run through fire area A-16 and are unaffected by a fire in A-16. Cables for BBLT0460, that run through A-16 are summarized in Table A-16-5.

Pressurizer level indication is available for a fire in area A-16 using BBLT0459/BBLI0459A.

References: E-15000, E-1F9301, E-13BB16

5.2.13 Reactor Coolant System (RCS) Pressure Indication

The PFSSD design requires RCS pressure indication to be available. RCS pressure indication is provided in the control room using BBPI0405 or BBPI0406 on RL022.

Cable 14BBI16BA associated with BBPT0406 is run in fire area A-16 South. Cables associated with BBPT0405 and BBPT0406 are unaffected by a fire in area A-16 North.

Based on the above discussion, RCS pressure indication is available in the control room using BBPI0405 if a fire occurs in area A-16 South and both BBPI0405 and BBPI0406 if the fire is in A-16 North.

References: E-15000, XX-E-013, E-1F9201, E-13BB15, E-13BB16, M-12BB04

5.2.14 Residual Heat Removal (RHR)

Cold shutdown mode of PFSSD requires RHR taking suction from the RCS. RHR pump suction from the RCS is controlled by valves BBPV8702A and EJHV8701A (Train A) and BBPV8702B and EJHV8701B (Train B).

A fire in area A-16 North will cause a loss of Train A CCW and the inability to operate Train A RHR. Therefore, Train B RHR is required for a fire in area A-16 North.

A fire in area A-16 South will cause a loss of Train B CCW and the inability to operate Train B RHR. Therefore, Train A RHR is required for a fire in area A-16 South.

Damage to any of the cables associated with BBPV8702A and BBPV8702B could prevent opening the associated valve from the control room. Damage to cable 12BBI15NB associated with pressure transmitter BBPT0403 could send a false High-1 RCS pressure signal and open the contacts on relay K734 which would prevent remote opening of valves BBPV8702A and BBPV8702B. Since cable 12BBI15NB runs in the North and South sections, a fire anywhere in area A-16 would require a cold shutdown repair to be made within 72 hours per 10CFR50, Appendix R or a containment entry to manually open BBPV8702A or BBPV8702B.

The RHR heat exchanger discharge control valve on the operating train (EJHCV0606 (Train A) or EJHCV0607 (Train B)) needs to be available. Cable 16EJI12BA, which is associated with EJHCV0607, runs through area A-16 South. Damage to cable 16EJI12BA will result in the loss of control of valve EJHCV0607. Cables associated with valve EJHCV0606 run through a different fire area and are unaffected by a fire in area A-16. Therefore, Train A RHR heat exchanger outlet valve is available for a fire anywhere in area A-16 and Train B RHR heat exchanger outlet valve is available for a fire in area A-16 North.

The RHR pump discharge to RCS cold leg isolation valve (EJHV8809A or EJHV8809B) needs to be open on the operating train. Damage to cables 14EJG09BC and 14EJG09BD would likely result in valve EJHV8809B remaining in its as-is normally open position, which is the preferred PFSSD position. However, two proper intra-cable hot shorts in cable 14EJG09BD or one intra-cable hot short in cable 14EJG09BD combined with a short to ground on conductor U1 would spuriously close the valve. Cables for valve EJHV8809A are run in a separate fire area and are unaffected by a fire in area A-16. Therefore, Train A and Train B RHR pump discharge to RCS cold leg flow path is available for a fire anywhere in area A-16.

Based on the above discussion, the Train A RHR system is unaffected by a fire in area A-16 South and Train B RHR system is unaffected by a fire in area A-16 North. However, a cold shutdown repair or containment entry may be required to open BBPV8702A or BBPV8702B prior to initiating shutdown cooling.

References: E-15000, XX-E-013, E-1F9205, E-13BB12A, E-13BB12B, E-13EJ09C, E-13EJ12, M-12BB01, M-12EJ01, M-12EP01

5.2.15 RCS Hot and Cold Leg Temperature Elements

PFSSD requires RCS hot and cold leg temperature indication on at least one loop to verify flow through the steam generators. The temperature elements used for this purpose are listed in Table A-16-6.

The four cables associated with RCS temperature indication listed in Table A-16-5 run in the same raceway through the north and south portions of fire area A-16. A fire in either section could damage these cables and cause temperature indication on these four temperature

elements (BBTE0413B, BBTE0423B, BBTE0433A and BBTE0443A) to be unavailable. Consequently, temperature indication on at least one leg on each loop could be lost, which is not in accordance with the PFSSD methodology at Wolf Creek.

Table A-16-6
RCS Hot and Cold Leg Temperature Elements Used for PFSSD

COMPONENT	FUNCTION
BBTE0413A	RCS Hot Leg Temperature Element (WR) Loop 1
BBTE0413B	RCS Cold Leg Temperature Element (WR) Loop 1
BBTE0423A	RCS Hot Leg Temperature Element (WR) Loop 2
BBTE0423B	RCS Cold Leg Temperature Element (WR) Loop 2
BBTE0433A	RCS Hot Leg Temperature Element (WR) Loop 3
BBTE0433B	RCS Cold Leg Temperature Element (WR) Loop 3
BBTE0443A	RCS Hot Leg Temperature Element (WR) Loop 4
BBTE0443B	RCS Cold Leg Temperature Element (WR) Loop 4

EMG ES-04 provides alternate indication that may be used. One of these methods verifies that steam generator pressure is stable or decreasing. S/G “B” and S/G “C” pressure instruments ABPT524 and ABPT534 are unaffected by a fire in A-16 and can be used per EMG ES-04 to verify heat removal in loops 2 and 3.

The configuration is acceptable because, in the event of fire in fire area A-16, cooldown will be performed using RCS loops 2 and 3. RCS wide range hot and cold leg temperature elements (BBTE423A and BBTE433B) and ABPT524 and ABPT534 will provide indication.

References: E-15000, XX-E-013, E-1F9201, E-13BB15, M-12AB01, M-12BB01

5.2.16 Steam Generator Main Feedwater Isolation Valves

PFSSD requires that either the main feedwater isolation valves (MFIVs) be closed or the main feedwater pumps be stopped to prevent overfilling the steam generators. Flow diversion from auxiliary feedwater (AFW) to the main feedwater system piping is prevented by check valves AEV0420, AEV0421, AEV0422 and AEV0423. Closure of the main feedwater isolation valves is not required to prevent AFW flow diversion.

Each MFIV is designed to utilize system fluid (feedwater) as the motive force to open and close. The valve actuation (open or close) is accomplished through positioning a series of six electric solenoid pilot valves to either direct the system fluid to the Upper Piston Chamber (UPC) and/or the Lower Piston Chamber (LPC), or vent either or both piston chambers. The six solenoid pilot valves are divided into two trains (3 per train) that are independently powered and controlled. Either train can independently perform the PFSSD function to close the valve and isolate main feedwater. This is done by actuating either all close hand switch AEHS0080 (separation group 1) or AEHS0081 (separation group 4) to de-energize the associated solenoid valves.

The following table identifies the solenoids and associated control cables for each hand switch.

MFIV	AEHS0080 (Sep Group 1)		AEHS0081 (Sep Group 4)	
	Solenoids	Cable	Solenoids	Cable
AEFV0039	MV1, MV3, MV5	11AEK16AH	MV2, MV4, MV6	14AEK17AH
AEFV0040	MV1, MV3, MV5	11AEK17AH	MV2, MV4, MV6	14AEK16AH
AEFV0041	MV1, MV3, MV5	11AEK16BH	MV2, MV4, MV6	14AEK17BH
AEFV0042	MV1, MV3, MV5	11AEK17BH	MV2, MV4, MV6	14AEK16BH

All 4 cables associated with the 12 separation group 4 solenoid valves are run in area A-16 North. Cable damage due to a fire will likely result in disruption of power to the solenoids, which will close the valves. The four separation group 1 cables associated with hand switch AEHS0080 are unaffected by a fire in area A-16 North. Therefore, hand switch AEHS0080 is available to close the four MFIVs if a fire occurs in area A-16 North. Fire area A-16 South contains no cables associated wih the MFIVs. Therefore, either hand switch can be used to close the MFIVs in the event of a fire in area A-16 South.

Based on the above discussion, MFIV isolation is assured using hand switch AEHS0080 if a fire occurs in area A-16 North and hand switches AEHS0080 or AEHS0081 if a fire occurs in area A-16 South..

References: E-15000, XX-E-013, E-13AE14, E-13AE15, E-13AE16, E-13AE17, E-1F9201, M-12AE02

5.2.17 Charging Flow to Regenerative Heat Exchanger Isolation Valves

PFSSD requires charging flow to be directed to the RCP seals. To ensure adequate flow to the RCP seals, flow diversion to the regenerative heat exchanger needs to be prevented. Valves BGHV8105 and BGHV8106 are included in the PFSSD equipment list to accomplish this task. Manual valve BG8402B is also included to provide an alternate means of closing this flow path during alternate safe shutdown using OFN RP-017.

Cables associated with BGHV8105 are run in area A-16 North and could be damaged by a fire in this area, preventing valve BGHV8105 from being closed from the control room. However, cables associated with valve BGHV8106, and its hand switch (BGHIS8106), are unaffected by a fire in area A-16. Therefore, valve BGHV8106 can be used to isolate flow to the regenerative heat exchanger and therefore satisfy the PFSSD requirement.

References: E-15000, XX-E-013, E-1F9102, E-13BG11A, M-12BG03

5.2.18 Excess Letdown

PFSSD requires the excess letdown path be isolated to prevent uncontrolled depressurization of the RCS. To accomplish this, either normally closed valve BGHV8153A or BGHV8154A must be maintained closed and either normally closed valve BGHV8153B or BGHV8154B must be maintained closed. Cables associated with these valves are listed in Table A-16-5.

Circuits for BGHV8154A do not run through fire area A-16 and are unaffected by a fire in this area. Therefore, this valve remains closed.

The separation requirements of 10CFR50, Appendix R are not satisfied for valves BGHV8153B and BGHV8154B. Less than 20 feet of horizontal separation exists between raceways carrying cables 14BGK48AB and 14BGK48BB.

Cable 14BGK48AB is run in conduit through area A-16. This conduit carries one other cable (14BBK30BA) which is a control cable for RCS head vent valve BBHV8001B and is normally

de-energized. Therefore, a hot short that would cause valve BGHV8153B to open is not credible.

An intra-cable short in cable 14BGK48AB would not cause the valve to open because this failure mode would not energize the solenoid.

Based on this discussion, there is reasonable assurance that valve BGHV8153B will not spuriously open in the event of a fire in area A-16.

References: E-15000, XX-E-013, E-1F9301, E-13BG48, E-1R1413D, E-1R1423A, E-1R1423C, E-1R1433A, E-1R1433B, M-12BG01

5.2.19 Volume Control Tank (VCT) Discharge Valves

PFSSD requires isolation of the Volume Control Tank (VCT) discharge to charging pumps suction. Either valve BGLCVC0112B or BGLCV0112C needs to be closed. Cables run in area A-16 associated with valve BGLCV0112C are listed in Table A-16-5.

Damage to cables 14BGG12BA and 14BGG12BB will prevent closing valve BGLCV0112C from the control room. These cables are run in area A-16 North. Therefore, valve BGLCV0112C is unavailable due to a fire in area A-16 North.

Cable 14BGI51DA is an instrumentation cable for VCT level transmitter BGLT0185. This cable runs in area A-16 North. Damage to this cable could send a false VCT low-low level signal and close relay K647 on the close circuit for valve BGLCV0112C. This would fail the valve closed if all other permissives are met, which is the desired PFSSD position. In addition, valve BGLCV0112B is unaffected by a fire in this area. Therefore, damage to cable 14BGI51DA will have no adverse impact on the ability to isolate the VCT discharge flow path.

Power and control cables for BGLCV0112B are run in a separate fire area and are unaffected by a fire in area A-16. Therefore, valve BGLCV0112B is available for a fire anywhere in area A-16 and both valves BGLCV0112B and BGLCV0112C are available for a fire in area A-16 South.

References: E-15000, XX-E-013, E-1F9102, E-13BG12, E-13BG12A, E-13BG51, M-12BG03

5.2.20 Steam Generator Blowdown to Blowdown Flash Tank Isolation Valves

The reactivity control function requires the steam generator blowdown to blowdown flash tank valves (BMHV0001, BMHV0002, BMHV0003, and BMHV0004) be closed to prevent reactivity addition from uncontrolled cooldown. Cables run in area A-16 associated with these valves are listed in Table A-16-5.

Damage to cable 14RPK09AA could cause a loss of power to auxiliary relays 3XBM9, 3XBM10, 3XBM11 and 3XBM12, located in panel RP210, which will fail close valves BMHV0001, BMHV0002, BMHV0003 and BMHV0004, respectively.

An open circuit on cables 14BMK06AA, 14BMK06AC, 14BMK06BA, 14BMK06BC, 14BMK06CA, 14BMK06CC, 14BMK06DA or 14BMK06DC will fail the valves closed, which is the desired PFSSD position. A hot short on these cables could prevent the valves from being closed using hand switches BMHIS0001A, BMHIS0002A, BMHIS0003A and BMHIS0004A.

Redundant means for closing valves BMHV0001, BMHV0002, BMHV0003 and BMHV0004 are available and are unaffected by a fire in area A-16. This redundant means uses BMHIS0001C,

BMHIS0002C, BMHIS0003C and BMHIS0004C, located on the BM157 panel in the radwaste control room. Access to the radwaste control room can be gained from outside fire area A-16.

A fire in area A-16 will not prevent closing steam generator blowdown valves BMHV0001, BMHV0002, BMHV0003 and BMHV0004.

Thermal hydraulic analysis WCNOC-CP-002 shows insignificant impact on SG inventory even with all four blowdown valves open. Therefore, no E-1F9900 OMA is required to close blowdown valves to achieve and maintain hot standby. Reference Attachment 4, MSO Evaluation Scenario ID PWROG 34.

References: E-15000, XX-E-013, E-1F9101, E-13BM06A, E-13BM06D, M-12BM01

5.2.21 Refueling Water Storage Tank (RWST) and Containment Sump Isolation Valves

To prevent draindown of the RWST into the containment sump, PFSSD requires that either valve BNHV8812A or valve EJHV8811A and valve BNHV8812B or valve EJHV8811B be closed during hot standby. For cold shutdown, the operating train containment sump valve (EJHV8811A or EJHV8811B) must be closed to prevent flow diversion from the RCS to the containment sump. Valves BNHV8812A and BNHV8812B are normally open and valves EJHV8811A and EJHV8811B are normally closed.

PFSSD cables for valves BNHV8812A and BNHV8812B do not run through fire area A-16. If valve EJHV8811A or EJHV8811B were to spuriously open, valves BNHV8812A and BNHV8812B can be closed from the control room.

Cables for valve EJHV8811A do not run through fire area A-16. A spurious SIS is possible for a fire in area A-16 North or South, as discussed previously. However, only one RWST level transmitter could be affected by a fire in area A-16, so a spurious SIS coincident with a spurious low-low RWST level is not credible for a fire in area A-16 and valve EJHV8811A will not spuriously open due to a fire in area A-16.

Cables associated with EJHV8811B are run in area A-16 South. A fire in this area could damage these cables and cause valve EJHV8811B to spuriously open. If this occurs, valve BNHV8812B can be closed from the control room using BNHIS8812B.

RWST level indicators BNLI0930, BNLI0931 and BNLI0932 are unaffected by a fire in area A-16 South and will provide RWST level indication in the control room. If the RWST is losing inventory faster than expected, valves BNHV8812A and BNHV8812B can be closed from the control room.

Although valve EJHV8811B could spuriously open due to a fire in area A-16 South, valve BNHV8812B is unaffected and can be closed from the control room. Therefore, draindown of the RWST to the containment sump can be mitigated from the control room using BNHIS8812B. RWST level transmitters BNLI0930, BNLI0931 and BNLI0932 are available to diagnose the reducing RWST level if this occurs.

References: E-15000, XX-E-013, E-1F9205, E-13BN07, E-13EJ06A, E-13EJ06B, M-12BN01, M-12EJ01, E-1R1413B, E-1R1413D, E-1R1423A, E-1R1423B, E-1R1423D, E-1R1433A, E-1R1433B, M-10BN

5.2.22 Auxiliary Feedwater Pump Room Coolers

Cables associated with the Auxiliary Feedwater Pump B (AFPB) room cooler (SGF02B) are discussed in this section. Cables 14GFG01BA and 14GFG01BB are power and control cables, respectively, associated with SGF02B and run in area A-16 North. Damage to these cables will cause Auxiliary Feedwater Pump B room cooler motor DSGF02B to be inoperable. Consequently, AFPB is inoperable due to a fire in area A-16 North.

Cables associated with the Auxiliary Feedwater Pump A (AFPA) room cooler (SGF02A) are run in a different fire area and are unaffected by a fire anywhere in area A-16. Auxiliary Feedwater Pump A and associated room cooler is unaffected by a fire in area A-16. Therefore, the AFW Pump A flow path is available if a fire occurs in area A-16.

References: E-15000, XX-E-013, E-13GF01

5.2.23 Containment Coolers

PFSSD requires containment cooling to maintain the containment environment within EQ limits. Cables associated with Train B containment coolers are run in areas A-16 South and A-16 North. These circuits are listed in Table A-16-5.

Damage to these cables could prevent operation of the Train B containment coolers if a fire occurs in areas A-16 South or A-16 North. However, circuits for the Train A containment coolers are run in a separate fire area and are unaffected by a fire anywhere in area A-16. Power to the Train A containment coolers is available in the event of a fire in A-16, as discussed in Section 5.2.29. Train A ESW is unaffected by a fire in area A-16.

Based on the above discussion, the Train A containment coolers are available in the event of a fire in area A-16.

References: E-15000, XX-E-013, E-1F9441, E-13EF07, E-13EF08, E-13EF09, E-13GN02, E-13GN02A, E-03NG01, M-12EF02

5.2.24 Thermal Barrier Cooling

The Wolf Creek plant design provides two redundant methods of cooling the RCP seals, thermal barrier cooling (TBC) and RCP seal injection. The PFSSD methodology at Wolf Creek requires tripping the RCPs and performing a natural circulation cooldown upon loss of both TBC and RCP seal injection. If only one method is lost, continued operation of the RCP is allowed by present established procedures. In addition, as long as at least one seal cooling method (seal injection or thermal barrier cooling) is available and is unaffected by the fire, the CCW system can remain lined-up to the RCP thermal barriers with no adverse impact on PFSSD. However, if both methods are lost, it may be necessary to close the CCW return valves from the thermal barriers to prevent a water hammer in the CCW system.

A fire in area A-16 North may cause a loss of Train A CCW. If the Train B CCW system is operating at the time of the fire, then all components will be in their proper lineup and loss of TBC will not occur. If the Train A CCW system is operating at the time of the fire, operators may need to swap to Train B CCW to re-establish TBC. The swapover can be performed from the control room.

Cable 14EGI15AA is associated with flow transmitter EGFT0062 and runs in A-16 North. The flow transmitter monitors CCW outlet flow from the thermal barriers and automatically shuts valve EGHV0062 on a high flow signal. A fire could damage the cable, causing a spurious high flow signal and close the valve. If this occurs, CCW flow to the thermal barriers would be lost until operators open bypass valve EGHV0132 from the control room.

Cable 14EGI19BB is associated with CCW to RCPs flow transmitter EGFT0129 and runs in A-16 North. Damage to this cable could prevent operators from diagnosing a loss of CCW flow to the RCP thermal barriers using flow indicator EGFI0129. CCW to RCP flow indicator EGFI0128 is unaffected by a fire in area A-16 North and can be used to diagnose a loss of CCW flow to the RCP thermal barriers.

A fire in area A-16 South may cause a loss of Train B CCW. If the Train A CCW system is operating at the time of the fire, then all components will be in their proper lineup and loss of TBC will not occur. If the Train B CCW system is operating at the time of the fire, TBC may not be available because EGHV0053 will be in the closed position. A fire in area A-16 South could prevent operation of EGHV0053, which supplies CCW to the service loop, including the RCP thermal barriers. Therefore, a fire in area A-16 South could result in a loss of thermal barrier cooling. This is discussed in more detail in Section 5.1.14.

A fire in A-16 South can also cause the spurious closure of EGHV0062 due to damage to cables 14EGG10AC or 14EGG10AD. If this occurs, CCW flow to the thermal barriers would be lost until operators open bypass valve EGHV0132 from the control room.

If the fire is in area A-16 South, CCW to RCP flow indicators EGFI0128 and EGFI0129 are available to diagnose a loss of CCW flow to the RCP thermal barriers.

Based on the above discussion, thermal barrier cooling could be lost if a fire occurs in areas A-16 North or A-16 South. If the fire is in A-16 North, thermal barrier cooling can be restored from the control room. If the fire is in A-16 South, thermal barrier cooling may not be restorable from the control room. In both cases, RCP seal injection is available using the unaffected charging train as discussed in Section 5.2.11.

References: E-15000, XX-E-013, E-13EG09, E-13EG10, E-13EG15, E-13EG18, E-13EG19, E-1F9303, M-12EG03

5.2.25 RHR to RCS Hot Leg Loops 2 & 3 Isolation Valve

The cold shutdown mode of PFSSD requires isolation of hot leg recirculation. Valve EJHV8840 is used to isolate RHR flow to the RCS hot leg loops 2 and 3. This valve is normally closed and is required to be closed for cold shutdown. During hot standby, the valve can be in any position.

Cables associated with valve EJHV8840 run through area A-16. Damage to cables 14EJG09AC and 14EJG09AD would likely result in valve EJHV8840 remaining in its as-is normally closed position, which is the preferred PFSSD position. However, two proper intra-cable hot shorts in cable 14EJG09AD or one intra-cable hot short in cable 14EJG09AD combined with a short to ground on conductor U1 would spuriously open the valve.

As stated above, the position valve EJHV8840 (open or closed) will not affect hot standby. The valve needs to be closed for cold shutdown. The valve has been modified to address NRC IN 92-18 and can be closed manually prior to entering shutdown cooling mode. The torque and limit switches are not bypassed by postulated damage to these cables.

Based on the above discussion, valve EJHV8840 could spuriously open in the event of a fire in this area. This will not affect hot standby, however the valve will need to be locally closed prior to entering shutdown cooling mode.

References: E-15000, XX-E-013, E-1F9205, E-13EJ09C, M-12EJ01

5.2.26 Boron Injection Tank Flowpath

The Boron Injection Tank (BIT) flowpath is credited for reactivity control and reactor coolant makeup. For reactivity control, the BIT flowpath is credited as an alternate source of boration in the event RCP seal injection is unavailable. Based on Calculation XX-E-013, RCP seal injection will provide sufficient boration to achieve and maintain cold shutdown reactivity conditions. Therefore, the BIT flowpath is not required for reactivity control if RCP seal injection is available. Since RCP seal injection is limited to 5 gpm per seal or 20 gpm total injection to the RCS, an additional RCS charging flowpath is required for adequate RCS makeup during plant transition from hot standby to cold shutdown. The BIT injection path was selected as the additional RCS charging flowpath.

A fire in area A-16 does not affect letdown isolation valves BGLCV0459 and BGLCV0460. Also, excess letdown flow path isolation is unaffected by a fire in area A-16. Therefore, the BIT flowpath is not required to maintain hot standby but may be required for transition to cold shutdown.

Damage to cables 14EMG02BA or 14EMG02BB will prevent opening valve EMHV8803B from the control room. These cables run in area A-16 North. A fire in this area will damage cables associated with the A Train CCW and prevent supplying cooling water to the A CCP. Therefore, the B CCP is used for a fire in area A-16 North.

Cables 14EMG02DA and 14EMG02DB, associated with BIT outlet valve EMHV8801B, could also be damaged by a fire in area A-16 North. Cables associated with redundant BIT outlet valve EMHV8801A are unaffected. Therefore, makeup through the BIT is available for transition from hot standby to cold shutdown.

A fire in area A-16 South requires CCP A to be used due to damage to CCW Train B. Circuits for valve EMHV8803A do not run through area A-16 North or South and makeup through the BIT, using CCP A, is available if a fire occurs in area A-16 South.

Based on the above discussion, the BIT flowpath is available if a fire occurs in area A-16 South but may not be available if the fire is in A-16 North.

References: E-15000, XX-E-013, E-13EM02, E-13EM02B, M-12EM02, E-1F9302

5.2.27 Boron Injection Tank Flow Diversion

If charging flow through the BIT is used, flow diversion through the SIS test line should be avoided. Therefore, valves EMHV8843 and EMHV8882 need to be maintained closed. If either or both of these valves cannot be closed, then either valve EMHV8871 or EMHV8964 need to be closed.

Cables associated with EMHV8882 are not run in area A-16. Therefore, valve EMHV8882 is unaffected by a fire in A-16 and will not spuriously open.

Cable 14EMK04CA is a control cable for EMHV8843 run in area A-16 South. A +125 VDC external cable hot short in contact with conductor 2 in cable 14EMK04CA will energize the solenoid and open valve EMHV8843. The cable is run in raceways with cables carrying the proper voltage and polarity. The hot short would bypass the control room hand switch (EMHIS8843) on RL018 and control of this valve from the control room would be lost. Hand switch EMHS8843, located in room 1409, is unaffected by a fire in area A-16 and can be used to close valve EMHV8843 if this valve is unresponsive from the control room.

Cables for normally closed valve EMHV8964 are unaffected by a fire in area A-16. Consequently, valve EMHV8964 will remain closed and flow diversion through the SIS test line will be averted.

References: E-15000, XX-E-013, E-1F9302, E-13EM04, E-13EM04A, E-13EM05A, M-12EM02

5.2.28 Safety Injection Accumulator Isolation Valves

PFSSD requires isolation of the SI accumulators prior to reducing RCS pressure below the injection pressure to avoid unnecessary accumulator discharge. This is accomplished by closing valves EPHV8808A, EPHV8808B, EPHV8808C and EPHV8808D. These valves are normally open with the MCC breaker locked in the open position. Cables for valves EPHV8808B and EPHV8808D are run in area A-16 South and are listed in Table A-16-5.

Since the breakers for these valves are normally open, damage to these cables will not cause the valve to spuriously change position. However, damage to the cables will prevent closing the associated valve from the control room after power is restored.

The SI accumulators need to be isolated during cold shutdown, prior to the RCS reaching 1000 psig. If necessary, a containment entry can be made to manually close the valves.

A fire in area A-16 South may require a containment entry to close valves EPHV8808B and EPHV8808D if these valves are unresponsive from the control room.

References: E-15000, XX-E-013, E-13EP02A, M-12EP01

5.2.29 PFSSD Equipment Power Availability

PFSSD requires that one train of electrical systems required to power PFSSD components be available and be unaffected by a fire. Cable 14NBB14AD is a control cable for relay 62TDENB02 and is run in area A-16 South. Damage to this cable could cause a spurious degraded voltage signal which could result in a loss of off-site power to bus NB02. A fire in area A-16 North will not affect this cable due to separation in accordance with 10CFR50, Appendix R Section III.G.2.b. Therefore, Train B PFSSD equipment powered from bus NB02 is available if a fire occurs in area A-16 North. A fire in area A-16 South uses Train A equipment. Train A bus NB01 is unaffected by a fire in area A-16. As discussed in Section 5.2.33, the Train B EDG fuel oil transfer pump could be affected by a fire in area A-16 North, preventing transfer of fuel from the underground storage tank to the day tank. Therefore, the Train B Emergency Diesel Generator may not be available to power NB02 if a fire occurs in area A-16 North.

Cables 14NGG01AD and 14NGG01AE are power cables that supply power to 480 VAC MCC NG02B and are run in area A-16 South. Damage to these cables could cause a loss of power to 480 VAC MCC NG02B. A fire in area A-16 North will not affect these cables due to separation in accordance with 10CFR50, Appendix R Section III.G.2.b. Therefore, Train B PFSSD equipment powered from 480 VAC MCC NG02B is available if a fire occurs in area A-16 North. A fire in area A-16 South uses Train A equipment. Train A 480 VAC MCC NG01B is unaffected by a fire in area A-16 South.

Based on this discussion, a fire in area A-16 will not disrupt power to required PFSSD components.

5.2.30 Control Room Lock-Out Relays

Cables associated with control room lockout relays 86XRP5, 86XRP6 and 86XRP7 are run in area A-16. Equipment controlled by the relays is identified in the table below.

Relay #	Description
86XRP5	Train B MDAFP from CST and ESW Supply Valves (ALHV0034 and ALHV0030)
86XRP6	ESW to TDAFP Supply Valve (ALHV0033)
86XRP7	Train B MDAFP (PAL01B)

Damage to these cables could prevent operation of associated equipment. Train A equipment, located in a separate fire area, is available and is unaffected by the fire.

References: XX-E-013, E-15000, E-13AL01B, E-13AL02B, E-13AL04B, E-13RP12, E-13RP14, E-13RP15, E-093-00095, E-093-00096, E-1F9202, E-1F9204

5.2.31 Normal Pressurizer Spray

The normal pressurizer spray valves are included in the PFSSD design because spurious operation of pressurizer sprays can cause a decrease in pressure which can lead to boiling in the core. The pressurizer spray valves are part of the pressurizer pressure control system.

The pressurizer normal spray valves (BBPCV0455B and BBPCV0455C) operate off a signal from the Ovation pressurizer pressure control system. The operation of the pressure control system is discussed in Calculation XX-E-013.

An instrument cable (12BBI16LB) associated with pressurizer pressure transmitter BBPT0456 is run in fire areas A-16 South and A-16 North. An instrument cable (13BBI16MB) associated with pressurizer pressure transmitter BBPT0457 is run in fire area A-16 North. An instrument cable (14BBI16NB) associated with pressurizer pressure transmitter BBPT0458 is run in fire area A-16 South. As discussed in Calculation XX-E-013, Appendix 1, the Ovation pressurizer pressure control system uses 4-channel verification from all four pressurizer pressure transmitters to operate the pressurizer spray valves. Failure of a single channel will not cause the spurious operation of the pressurizer spray valves since the system uses the 2nd highest input as the validated signal. Damage to two channels will not cause the spray valves to open because both channels would have to fail to the exact same value at the exact same time and therefore this failure mode is not credible, as discussed in XX-E-013.

Based on the above discussion, the pressurizer spray valves will not spuriously open if a fire occurs in this area.

5.2.32 Control Room Air Conditioning

Cable 14GKG02BE is a control cable associated with control room A/C unit SGK04B. Damage to this cable due to a fire could prevent operation of Train B Control Room A/C unit.

Circuits for Train A control room A/C unit SGK04A do not run through area A-16 and are unaffected by a fire. Therefore, control room air conditioning is available using SGK04A.

References: XX-E-013, E-15000, E-13GK02D, E-1F9442, M-12GK01, M-622.1A-00007

5.2.33 Emergency Diesel Fuel Oil Transfer Pump

Emergency diesel fuel oil transfer pumps are required to transfer fuel oil from the underground storage tank to the aboveground day tank to support operation of the emergency diesel generator (EDG). Loss of the fuel oil transfer pump on the associated train will prevent operation of the associated EDG.

Cable 14JEG01BD is run in fire area A-16 North. A short to ground on this cable will blow the control power fuse and prevent operation of the Train B EDG fuel oil transfer pump. The EDG can operate for approximately 1 hour fully loaded on the contents of the day tank.

A fire in area A-16 North credits Train B components using off-site power to NB02. Therefore, loss of the Train B EDG due to a fire in this area will not affect PFSSD.

References: XX-E-013, E-15000, E-13JE01A, E-1F9411B

5.2.34 Load Center Feeder Breakers PA0105 and PA0206

Load center feeder breakers PA0105 and PA0206 are credited for PFSSD because they supply power to credited non-safety related loads. Cables associated with these breakers run in this area. PFSSD impact due to damage to these cables is discussed below.

Cable 15PGA10AA is a control cable associated with breaker PA0105 and runs in fire area A-16 South. An intra-cable hot short in this cable will trip PA0105. Breaker PA0105 supplies power to the following PFSSD components:

- PG11JFR2 – Main Steam Supply to 2nd Stage Reheat Valve ABHV0031
- PG11KBR3 – Auxiliary Steam System Control Valve FBHV0081

PG11JFR2 and PG11KBR3 supply power to components downstream of the MSIVs. The MSIVs are unaffected by a fire in this area and can be closed from the control room using hand switch ABHS0079. Therefore, the MSIV downstream components are not required if a fire occurs in this area.

The cable note in Setroute for cable 15PGA10AA states that the cable is located within a heat affected zone per M-663-00017A and requires further fire protection review if credited for PFSSD. The heat affected zone evaluation is discussed in M-663-00017A, Appendix B13, pages B-13-64 through B-13-69 and occurs where the cable passes between fire areas A-5 (Roomn 1119) and A-16 South (Room 1408). Since the cable traverses both fire areas and is not credited for a fire in either area, there will be no adverse impact on PFSSD if a fire occurs in areas A-5 or A-16 South.

Cable 16PGA10CA is a control cable associated with breaker PA0206 and runs in fire area A-16 South. An intra-cable hot short in this cable will trip PA0206. Breaker PA0206 supplies power to the following PFSSD components:

- PG12KAF4 – Main Steam Supply to 2nd Stage Reheat Valve ABHV0032
- PG12KAF5 – Main Steam Supply to Steam Seals Valve ABHV0046
- PG12KEF3 – Auxiliary Steam System Control Valve FBHV0080

PG12KAF4, PG12KAF5 and PG12KEF3 supply power to components downstream of the MSIVs. The MSIVs are unaffected by a fire in this area and can be closed from the control room using hand switch ABHS0079. Therefore, the MSIV downstream components are not required if a fire occurs in this area.

Based on the above discussion, loss of breakers PA0105 and PA0206 will have no adverse impact on PFSSD.

1.0 GENERAL AREA DESCRIPTION

Fire area A-17 is located on the 2026 elevation of the Auxiliary Building and includes the room listed in Table A-17-1.

Table A-17-1
Rooms Located in Fire Area A-17

ROOM #	DESCRIPTION
1409	South Electrical Penetration Room

Fire area A-17 is protected with an automatic Halon fire suppression system. In addition, automatic fire detection is installed throughout. The automatic suppression and detection system meets the requirements of 10CFR50, Appendix R, Section III.G.2.

2.0 PRIMARY EQUIPMENT USED FOR PFSSD

Table A-17-2 lists each system credited for post-fire safe shutdown and provides a discussion regarding the availability of the system to perform its Post Fire Safe Shutdown (PFSSD) function if a severe fire occurs in this area. For a summary of the area analysis results, see Section 8.0 of the Fire Area Analysis Narrative section.

Table A-17-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-17

System	System Name	PFSSD Function*	Comments
AB	Main Steam	R, M, H, P, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-17. All three steam generator pressure indicators on all four steam generators are available.
AC	Main Turbine	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-17.
AE	Main Feedwater	H, P	Steam generator level indication is available using AELI0501 (SGA WR), AELI0518 (SGA NR), AELI0551 (SGA NR), AELI0528 (SGB NR), AELI0529 (SGB NR), AELI0503 (SGC WR), AELI0538 (SGC NR), AELI0539 (SGC NR), AELI0548 (SGD NR) and AELI0554 (SGD NR)
AL	Aux. Feedwater System	H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-17.
AP	Condensate Storage System	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-17.
BB	Reactor Coolant System	R, M, H, P, S	All PFSSD functions associated with the reactor coolant system are satisfied. Cables associated with all four RCP seal injection valves could be affected but the damage will not cause the valves to close. Therefore, seal injection remains available. A spurious CISB due to 2/4 high containment pressures will isolate the CCW to/from RCP valves, which will isolate thermal barrier cooling. This is acceptable since RCP seal injection remains available. Loss of inventory through the head vent valves could occur due to spurious opening of BBHV8001B and BBHV8002B. The Train A CCP is available to charge through the BIT. Pressurizer level indication is available using BBLI0459A. RCS wide range hot leg temperature element BBTE423A (Steam Generator B) and wide range cold leg temperature element BBTE433B (Steam Generator C) are available. RCS pressure indication is available using BBPI0405. Pressurizer pressure indication is available using BBPI0455A and BBPI0457. A spurious SIS due to low pressurizer pressure on two out of four pressurizer pressure transmitters is averted by entering the EMG procedure network and, if necessary, placing EMHIS0004 and EMHIS0005 in pull-to-lock. When transferring to RHR, valve BBPV8702A may need to be manually opened to provide a suction source from the RCS to RHR pump A. Reactor coolant pumps C and D may not stop using the control room hand switch. RCP seal injection remains available. Therefore, the inability to stop the RCPs will have no adverse impact on PFSSD.

Table A-17-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-17

System	System Name	PFSSD Function*	Comments
BG	Chemical and Volume Control System	R, M, S	All PFSSD functions associated with the chemical and volume control system are satisfied. Train A centrifugal charging pump (CCP) is unaffected. Loss of inventory through the excess letdown path could occur due to spurious opening of BGHV8153B and BGHV8154B. The Train A CCP is available to charge through the BIT. RCP seal flow indication is available using BGFI0215A. RCP seal flow indicator BGFI0215B may be affected.
BM	Steam Generator Blowdown System	R, M, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-17.
BN	Borated Refueling Water Storage System	R, M, H	The RWST is available to provide a suction source to Centrifugal Charging Pump A via valve BNLCV0112D. Containment sump isolation valve EJHV8811B could spuriously open, causing a draindown path from the RWST to the containment sump. Valve BNHV8812B will automatically close, as designed, when EJHV8811B reaches full open position, mitigating draindown. However, if EJHV8811B stalls before reaching full open position, BNHV8812B will not automatically close. In this case, operators can close BNHV8812B using BNHIS8812B in the main control room. RWST level indicators BNLI0930, BNLI0931 and BNLI0932 are available. When initiating RHR, flow from the RWST to RHR pump A can be isolated using BNHV8812A.
EF	Essential Service Water System	H, S	All PFSSD functions associated with the Essential Service Water (ESW) system are satisfied. Train A ESW is available to supply cooling water to Auxiliary Feedwater Pump room cooler SGF02A, Containment Air Coolers SGN01A and SGN01C, Train A Component Cooling Water (CCW) Heat Exchanger, CCW A pump room cooler SGL11A, CCP A room cooler SGL12A and RHR A room cooler SGL10A. Train B ESW flow to containment coolers SGN01B and SGN01D may be affected. Train B ESW is available to supply cooling water to Auxiliary Feedwater Pump room cooler SGF02B, Train B Component Cooling Water (CCW) Heat Exchanger, CCW B pump room cooler SGL11B, CCP B room cooler SGL12B and RHR B room cooler SGL10B.
EG	Component Cooling Water System	S	The PFSSD support function associated with the Component Cooling Water (CCW) system is satisfied. Both trains of CCW are available to provide cooling to essential PFSSD components. A spurious CISB due to 2/4 high containment pressures will isolate the CCW to/from RCP valves, which will isolate thermal barrier cooling. This is acceptable since RCP seal injection remains available. CCW flow indicators EGFI0128 and EGFI0129 are unaffected.

Table A-17-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-17

System	System Name	PFSSD Function*	Comments
EJ	Residual Heat Removal System	M, H, P	All PFSSD functions associated with the Residual Heat Removal (RHR) system are satisfied. Containment sump isolation valve EJHV8811B could spuriously open, causing a draindown path from the RWST to the containment sump. Valve BNHV8812B will automatically close, as designed, when EJHV8811B reaches full open position, mitigating draindown. However, if EJHV8811B stalls before reaching full open position, BNHV8812B will not automatically close. In this case, operators can close BNHV8812B using BNHIS8812B in the main control room.
EM	High Pressure Coolant Injection	R, M	All PFSSD functions associated with the High Pressure Coolant Injection system are satisfied. A spurious SIS can be mitigated by entering EMG E-0 and terminating the spurious SIS.
EN	Containment Spray	R, M	A spurious containment spray actuation signal (CSAS) due to spurious signals on two out of four containment pressure transmitters can be terminated by placing pump control hand switches ENHIS0003 and ENHIS0009 on control room panel RL017 in pull-to-lock.
EP	Safety Injection Accumulators	H	The PFSSD Decay Heat Removal function associated with the Safety Injection Accumulators is satisfied. Accumulator injection lines can be isolated by closing valves EPHV8808A, EPHV8808B, EPHV8808C and EPHV8808D. It may be necessary to make a containment entry to manually close EPHV8808B and EPHV8808D.
FB	Auxiliary Steam	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-17.
FC	Auxiliary Turbines	R, H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-17.
GD	ESW Pump House HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-17.
GF	AFW Pump Room Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-17.
GK	Control Room and Class 1E Switchgear Room Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-17.
GL	Auxiliary Building HVAC	S	The PFSSD Support function associated with the Auxiliary Building HVAC system is satisfied. Electrical penetration room cooler SGL15B may be affected. Redundant Train A room cooler SGL15A is located in a separate fire area and is unaffected.
GM	Emergency Diesel Generator Room HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-17.

Table A-17-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-17

System	System Name	PFSSD Function*	Comments
GN	Containment Coolers	S	The PFSSD Support function associated with the Containment Coolers is satisfied. Train A (SGN01A and SGN01C) Containment Coolers are available. ESW Train A is available to supply cooling water to the containment coolers. Containment pressure indicators GNPI0935 and GNPI0937 are available.
JE	Diesel Fuel Oil	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-17.
KA	Instrument Air	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-17.
KC	Fire Protection	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-17.
KH	Service Gas	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-17.
KJ	Standby Diesel Engine	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-17.
MA	Main Generation	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-17.
MR	Startup Transformer	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-17.
NB	4.16 kV System	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-17.
NE	Standby Diesel Generator	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-17.
NF	Load Shed and Emergency Load Sequencing	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-17.
NG	480V Load Centers and MCCs	S	The PFSSD Support function associated with the 480 VAC system is satisfied. Train B 480 VAC MCC NG02B is affected. Train A 480 VAC load centers and MCCs are unaffected.
NK	125VDC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-17.
NN	120VAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-17.
PA	13.8kV	S	Breaker PA0206 could trip. This will not affect PFSSD since redundant capability exists.
PB	4.16kV	H, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-17.

Table A-17-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-17

System	System Name	PFSSD Function*	Comments
PG	480V Load Centers and MCCs	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-17.
PK	125VDC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-17.
PL	Local Instrument Panels	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-17.
PN	120VAC	S	The primary power supply to panel PN008 is affected. Redundant Train A 120 VAC distribution panel PN007 is unaffected.
QB	Standby AC Lighting	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-17.
QD	Emergency Lighting	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-17.
RL	Control Room MCB	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-17.
RP	Miscellaneous Control Panels	R, M, H, P, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-17.
SA	ESFAS	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-17.
SB	Reactor Protection System	R, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-17.
SC	Reactor Instrumentation	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-17.
SE	Ex-Core Neutron Monitoring	R, P	Source range monitoring is available using SENE0031 and SENY0060A & B.
SY	Switchyard	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-17.
UU	Supervisory System	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-17.

* R - Reactivity Control; M - Reactor Coolant Makeup; H - Decay Heat Removal; P - Process Monitoring; S - Support Function

3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD

This section describes operator actions that may need to be performed inside or outside the control room to achieve and maintain hot standby if a fire occurs in area A-17. This section also describes cold shutdown repairs that may need to be made to achieve and maintain cold shutdown conditions. Operator actions are proceduralized in OFN KC-016.

3.1 ACTIONS OUTSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

None

3.2 ACTIONS INSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

3.2.1 Containment Spray and Safety Injection

A spurious Safety Injection Signal (SIS) due to low pressurizer pressure and high containment pressure can be mitigated by consulting EMG E-0 and terminating the spurious SIS.

A spurious Containment Spray Actuation Signal (CSAS) can be mitigated by placing CS pump control hand switches ENHIS0003 and ENHIS0009 in pull-to-lock. These switches are located on control room panel RL017. Indication in the Control Room for SI and CS pump operation is unaffected by a fire in A-17.

3.2.2 Mitigation of RWST Draindown to Containment Sump

If a fire occurs in area A-17, it may be necessary to close valve BNHV8812B from the control room using BNHIS8812B to mitigate draindown of the RWST into the containment sump. This condition could occur due to EJHV8811B spuriously opening but stalling before reaching full open position, thereby not providing the permissive for BNHV8812B to close. RWST level indication is available using BNLI0930, BNLI0931 and BNLI0932.

3.2.3 Reactor Head Vent Valves

A fire involving containment penetrations ZSE233 and ZSE234 could cause both Train B reactor head vent valves to open. If this occurs, charging flow can be increased to make up for the inventory loss. Pressurizer level indication is available using BBLI0459A. RCS pressure indication is available using BBPI0405.

3.2.4 Excess Letdown

A fire involving containment penetrations ZSE233 and ZSE234 could cause both Train B excess letdown valves to open. If this occurs, charging flow can be increased to make up for the inventory loss. Pressurizer level indication is available using BBLI0459A.

3.3 ACTIONS TO ACHIEVE AND MAINTAIN COLD SHUTDOWN

3.3.1 RHR

Train B RHR may not be available. If valve BBPV8702A fails to respond when initiating RHR Train A for cold shutdown, make a containment entry to manually open the valve or perform a cold shutdown repair to fix the damaged circuit.

If valve EJHV8840 spuriously opens, close valve EJHV8716A to isolate RHR Train A flow to the hot leg.

3.3.2 Safety Injection Accumulators

It may be necessary to make a containment entry to close SI Accumulator injection valves EPHV8808B and EPHV8808D if these valves are unresponsive from the control room. Otherwise, nitrogen pressure can be relieved from the tanks to prevent injection. Valves EPHV8808A and EPHV8808C are unaffected.

4.0 CONCLUSION

With some exceptions, redundant Post-Fire Safe Shutdown capability exists if a severe fire occurs in this area. For those exceptions, feasible manual actions are available and are unaffected by the fire. Manual actions are documented in Section 3.0.

5.0 DETAILED ANALYSIS

This section describes the detailed component-by-component and cable-by-cable analysis for a fire in area A-17.

5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA A-17

PFSSD components (S. in E-15000) located in fire area A-17 are shown in Table A-17-3. An evaluation of each component and associated cables is provided in the sections that follow. The applicable evaluation section is listed in Table A-17-3.

Room #	PFSSD Equipment	Description	Evaluation Section	Comments

5.1.1 Electrical Penetration Room Cooler

A fire in area A-17 could disable the Train B electrical penetration room cooler (SGL15B). Motor Control Center (MCC) NG02BAF2, which provides power to the room cooler motor, is located in the area and could be damaged. Cable 14GLG12BA is a power cable that runs from the MCC to the room cooler motor and could be damaged.

Hand switch GLHS0035 is a local hand switch mounted on MCC NG02BAF2 that allows SGL15B to be locally started in the event of a fire in the control room. Damage to this switch could impact the ability to operate the unit.

Redundant Train A room cooler SGL15A is located in a separate fire area and is unaffected by a fire in area A-17.

References: E-15000, XX-E-013, E-13GL12A

5.1.2 Boron Injection Tank SIS Test Line

Valve EMHV8843 is normally closed and is required to be closed when injecting through the BIT to ensure adequate flow to the RCS. Local hand isolation switch EMHS8843 and associated cables 14EMK04CA and 14EMK04CD are located in area A-17. Damage to the hand switch or cables could cause the valve to spuriously open.

Cable 14EMK04EA, associated with valve EMHV8871, is located in area A-17. Valve EMHV8871 is located downstream of EMHV8843 and is an alternative means of isolating the SIS test line. Damage to this cable could result in EMHV8871 spuriously opening.

Redundant valve EMHV8964, located downstream of valves EMHV8843 and EMHV8871, is unaffected by a fire in area A-17. This valve is normally closed and will remain closed in the event valves EMHV8843 and EMHV8871 spuriously open. Therefore, the spurious opening of valves EMHV8843 and EMHV8871 will have no adverse impact on PFSSD.

References: E-15000, XX-E-013, E-13EM04, E-13EM04A, E-1F9302, M-12EM01, M-12EM02

5.1.3 Containment Cooling

Hand switches associated with containment coolers SGN01B and SGN01D are located in area A-17. These hand switches are located on MCCs NG02TAF1 and NG04TAF1. The hand switches allow local control of the Train B containment coolers from outside the control room.

Power and control cables associated with Train B containment coolers SGN01B and SGN01D are run in area A-17. Damage to these cables could prevent operation of the coolers.

Damage to the hand switches, MCCs or associated cables will result in a loss of Train B containment coolers. However, Train A containment coolers SGN01A and SGN01C are unaffected by a fire in area A-17 and will remain available to provide containment cooling.

References: E-15000, XX-E-013, E-13GN02A, E-1F9441

5.1.4 Train B 480 Volt Class 1E Auxiliary Building MCC NG02B

Motor Control Center (MCC) NG02B is located in area A-17. A number of PFSSD loads are supplied by this MCC. A fire in area A-17 could disrupt power to the MCC and prevent operation of the supplied loads. The following table identifies the PFSSD components that could be lost if this occurs and whether a redundant component on the opposite train is available.

480 VAC Motor Control Center NG02B		
MCC Breaker	**Description**	**Redundant Component**
NG02BAF1	Incoming Line From NG02	NG01
NG02BAF2	Penetration Room Cooler DSGL15B	DSGL15A
NG02BBF1	Primary Power Feed to PN08	PG20GER5

NG02BDR2	Valve EFHV0050	EFHV0049
NG02BEF1	Valve EGHV0127	EGHV0058
NG02BEF2	Valve EJHV8811B	See below
NG02BER1	Valve BBHV8157B	BBHV8157A
NG02BFR1	Relay Panel (EJHV8811B)	See below
NG02BGF3	Valve EPHV8808B	See below
NG02BHF1	Valve EGHV0133	EGHV0061
NG02BHF2	Valve EPHV8808D	See below
NG02BHF3	Valve EFHV0034	EFHV0033
NG02BHR2	Valve EFHV0046	EFHV0045

The power supply to both valves BBPV8702A and BBPV8702B (RCS to RHR pumps A and B) could be disrupted. For hot standby, this is acceptable since the power supply to these valves is normally de-energized at the MCC and the valves are maintained closed. For cold shutdown, however, the valves may not be able to be opened from the control room or from the MCC. If necessary, a cold shutdown repair could be performed to repair damage to the power supply or a containment entry could be made to open the appropriate valve.

Valve EJHV8840 is normally closed and is required to remain closed for PFSSD. Loss of power to the valve will not have an adverse impact on PFSSD since the valve is normally closed.

Valve EGHV0062 is normally open and will remain open if power is lost. PFSSD requires this valve to be open, or normally closed bypass valve EGHV0132 opened, when using CCW to maintain thermal barrier cooling. Valve EGHV0132 is unaffected by a fire in area A-17 and is available to be opened in the unlikely event valve EGHV0062 spuriously closes.

Valve EJHV8811B is normally closed and is required to remain closed for PFSSD. Loss of power to the valve will maintain it in its closed position. Therefore, loss of power to this valve will have no adverse impact on PFSSD.

NG02BFR1 is a relay panel section that houses relay 3XEJ19 associated with EJHV8811B. Loss of power to this relay will maintain the valve in its normally closed position, which is the desired PFSSD position.

Accumulator tank valves EPHV8808B and EPHV8808D are required to be closed prior to the RCS reaching @ 1,000 psi to prevent accidental accumulator injection. Loss of power to the valves will prevent them from being closed when necessary. The valves are closed when going to cold shutdown, so a cold shutdown repair is allowed. The power cable can either be repaired or nitrogen pressure can be relieved from the tanks to prevent injection. Otherwise, a containment entry can be made to close the valves.

Based on the above discussion, loss of power to NG02B will have no adverse impact on PFSSD.

5.1.5 Source Range Monitors

PFSSD requires source range (SR) flux monitoring to be available. Source range monitoring is provided by source range monitors SENE0031, SENE0032, SENY0060A & B, and SENY0061A & B.

Damage to SE32 or associated cables will prevent SENE0032 from operating. Damage to the cable associated with SENY0061A/B will prevent this source range monitor from operating. However, redundant source range monitors are available and are unaffected by a fire in area A-17.

For a more detailed evaluation on Source Range monitoring, see Calculation XX-E-013, Attachment 3.

References: E-15000, XX-E-013, E-1F9101, E-13SE01, E-13SE02, E-13SE07

5.1.6 Pressurizer Backup Group B Heaters

The pressurizer backup group B heaters are credited in procedure OFN RP-017 to control pressurizer pressure following a control room fire. The heaters are not required for post-fire safe shutdown following a fire in other areas of the plant.

Load center PG22, feeder breaker PG2201 and transformer XPG22 supply power to the heaters. These components were added to the PFSSD equipment list because they are required following a control room fire.

Damage to these components due to a fire in area A-17 could cause the spurious operation or mal-operation of the backup group B heaters. Calculation WCNOC-CP-002 shows that spurious operation or mal-operation of the heaters will not adversely impact the ability to achieve safe shutdown. Therefore, damage to this switch in the event of a fire in area A-17 will not affect safe shutdown.

5.2.1 Safety Injection and Containment Spray

Calculation XX-E-013, Appendix 1 (PFSSD Support Section) provides a detailed discussion about the potential PFSSD impact of a spurious safety injection signal (SIS) and spurious containment spray actuation signal (CSAS). This section discusses the specific PFSSD impact if a fire occurs in this area.

Containment pressure transmitters GNPT0934 and GNPT0936, and associated cables, are located in area A-17. Consequently, a spurious CSAS due to high containment pressure can occur if a fire occurs in area A-17. Also, a spurious SIS due to high containment pressure can occur since two of the three containment pressure SIS initiators are located in area A-17.

Cables associated with BBPT0456 and BBPT0458 are run in area A-17. Consequently, a fire in area A-17 can cause a spurious SIS due to low pressurizer pressure.

Power and control cables associated with containment spray isolation valve ENHV0012 are located in this area. Damage to these cables will not cause the valve to spuriously open. However, a CSAS will cause the valve to open. As described below, a spurious CSAS can be mitigated from the control room.

A spurious SIS starts the charging sequence which starts the CCPs and opens the BIT flowpath valves. For a fire in this area, the BIT flowpath valves are unaffected and would open on a SIS. The RWST valves are unaffected and would open on a SIS. Also, the CCP mini flow valves are unaffected and CCW flow to the seal water heat exchanger is unaffected to ensure cooling of the recirc flow, RCP seal return and CCP oil cooler. Therefore, the charging pumps will not be affected by a spurious SIS caused by a fire in this area.

A start of the credited CCW system (Train A) will not adversely impact the system. The Train A ESW system is unaffected and will start on a spurious SIS, providing necessary cooling water to the CCW heat exchanger.

A start of the AFW pumps will not adversely impact PFSSD. All three AFW pumps are unaffected by a fire in this area. Suction from the CST to the AFW pumps is unaffected. Discharge flow will either return to the CST or flow to the steam generators through the discharge control valves. Therefore, the AFW pumps are unaffected by a spurious SIS caused by a fire in this area.

A start of the RHR pumps due to a spurious SIS will not adversely impact either pump. The RWST supply to the pumps is not affected and the recirculation valves will remain in the open position. Component cooling water is available to both RHR heat exchangers. Operators will have time to terminate the spurious SIS and stop the pumps.

A spurious Containment Spray Actuation Signal (CSAS) due to spurious high containment pressure can be mitigated by placing CS pump control hand switches ENHIS0003 and ENHIS0009 in pull-to-lock. These switches are located on control room panel RL017. Indication in the Control Room for SI and CS pump operation is unaffected by a fire in A-17.

Based on the above discussion, a spurious SIS and CSAS can occur if a fire occurs in this area. Credited PFSSD equipment will not be damaged by the spurious SIS. The CSAS can be terminated from the control room. Therefore, a spurious SIS and CSAS will not adversely impact PFSSD.

References: E-15000, XX-E-013, E-13BB16, E-13EM01, E-13EN03, E-13GN05, E-1F9431, E-1F9432, E-1F9433

5.2.2 Steam Generator Level Indication

The decay heat removal function for PFSSD requires the use of two RCS loops and two Steam Generators. Steam generator (SG) level indication is required to support this function. A fire in area A-17 credits the Train A motor driven auxiliary feedwater pump (MDAFP), which is normally aligned to supply SGs B and C.

Each steam generator has 5 level indicators; one wide range and 4 narrow range. At least one of the 5 level transmitters needs to be available to satisfy the PFSSD function. Table A-17-4 lists the cables and associated level transmitters run in area A-17.

The following steam generator level transmitters are unaffected by a fire in area A-17:

Steam Generator A	AELT0501 (Wide Range) AELT0518 (Narrow Range) AELT0551 (Narrow Range)
Steam Generator B	AELT0528 (Narrow Range) AELT0529 (Narrow Range)
Steam Generator C	AELT0503 (Wide Range) AELT0538 (Narrow Range) AELT0539 (Narrow Range)
Steam Generator D	AELT0548 (Narrow Range) AELT0554 (Narrow Range)

Therefore, at least one level transmitter on each steam generator is available if a fire occurs in area A-17.

References: E-15000, XX-E-013, E-13AE08, E-13AE12, M-12AE02, E-1F9203

5.2.3 RCS Hot and Cold Leg Temperature Elements

PFSSD requires RCS hot and cold leg temperature indication on at least one loop to verify flow through the steam generators. The temperature elements used for this purpose are listed in Table A-17-5.

A fire in area A-17 could damage instrumentation cables associated with temperature elements BBTE0413B, BBTE0423B, BBTE0433A and BBTE0443A. Consequently, temperature indication on at least one leg on each loop could be lost, which is not in accordance with the PFSSD methodology at Wolf Creek.

Table A-17-5
RCS Hot and Cold Leg Temperature Elements Used for PFSSD

COMPONENT	FUNCTION
BBTE0413A	RCS Hot Leg Temperature Element (WR) Loop 1
BBTE0413B	RCS Cold Leg Temperature Element (WR) Loop 1
BBTE0423A	RCS Hot Leg Temperature Element (WR) Loop 2
BBTE0423B	RCS Cold Leg Temperature Element (WR) Loop 2
BBTE0433A	RCS Hot Leg Temperature Element (WR) Loop 3
BBTE0433B	RCS Cold Leg Temperature Element (WR) Loop 3

Table A-17-5 RCS Hot and Cold Leg Temperature Elements Used for PFSSD	
COMPONENT	**FUNCTION**
BBTE0443A	RCS Hot Leg Temperature Element (WR) Loop 4
BBTE0443B	RCS Cold Leg Temperature Element (WR) Loop 4

EMG ES-04 provides alternate indication that may be used. One of these methods verifies that steam generator pressure is stable or decreasing. S/G "B" and S/G "C" pressure instruments ABPT524 and ABPT534 are unaffected by a fire in A-17 and can be used per EMG ES-04 to verify heat removal in loops 2 and 3.

The configuration is acceptable because, in the event of fire in fire area A-17, cooldown will be performed using RCS loops 2 and 3. RCS wide range hot and cold leg temperature elements (BBTE0423A and BBTE0433B) and pressure transmitters ABPT0524 and ABPT0534 will provide indication.

References: E-15000, XX-E-013, E-1F9201, E-13BB15, M-12AB01, M-12BB01

5.2.4 Residual Heat Removal (RHR)

Cold shutdown mode of PFSSD requires RHR taking suction from the RCS. RHR pump suction from the RCS is controlled by valves BBPV8702A and EJHV8701A (Train A) and BBPV8702B and EJHV8701B (Train B).

Power and control cables associated with BBPV8702A and BBPV8702B run through area A-17. Damage to any of these cables could prevent opening the associated valve from the control room. During normal power operation, the MCC breaker for these valves is open which would prevent the valves from spuriously opening due to cable damage. However, since the valves are high-low pressure interface boundaries, consideration of 3-phase cable to cable hot shorts in the proper sequence is required. The cables are run in raceway with other 3-phase cables, which presents the possibility that a 3-phase hot short could occur, although unlikely due to the use of thermoset cables. In the unlikely event a hot short occurs such that the valves spuriously open, valves EJHV8701A and EJHV8701B are unaffected by the fire and will remain closed.

During normal power operation, RCS pressure is approximately 2,236 psig. An open permissive interlock relay (K734) prevents valves BBPV8702A and BBPV8702B from opening when RCS pressure is greater than 360 psig, as sensed by pressure transmitter BBPT0403. Damage to cable 12BBI15NB, associated with pressure transmitter BBPT0403, could send a false High-1 RCS pressure signal and maintain the contacts on relay K734 open, which would prevent remote opening of valves BBPV8702A and BBPV8702B. Also, damage to the cable could send a false low pressure signal, which would close the contact and provide the permissive to open the valve. As stated in the previous paragraph, spurious opening of the valves is mitigated by maintaining valves EJHV8701A and EJHV8701B closed.

A fire in area A-17 may cause the spurious opening of valves BBPV8702A and BBPV8702B, but redundant valves EJHV8701A and EJHV8701B will remain closed. When going to cold shutdown, a cold shutdown repair may be required to be made within 72 hours, per 10CFR50, Appendix R, or a containment entry to manually open BBPV8702A or BBPV8702B, depending on the RHR Train used.

5.2.5 Pressurizer Level Transmitters

PFSSD requires pressurizer level indication to be available. Pressurizer level indication is provided by level transmitters BBLT0459 and BBLT0460. Circuits for BBLT0460 are run in area A-17, so BBLT0460 may not be available. Circuits for BBLT0459/BBLI0459A do not run through fire area A-17 and are unaffected by a fire.

Pressurizer level indication is available for a fire in area A-17 using BBLT0459/BBLI0459A.

References: E-15000, E-1F9301, E-13BB16

5.2.6 Reactor Coolant Pump (RCP) Seal Injection

PFSSD requires RCP seal injection to provide a boron injection path, provide makeup to the RCS to maintain hot standby inventory and prevent damage to the RCP seals. The Component Cooling Water (CCW) system is an alternative means of cooling the RCP seals.

Cables 14BBG04AA, 14BBG04AB, 14BBG04BA, 14BBG04BB, 14BBG04CA, 14BBG04CB, 14BBG04DA and 14BBG04DB associated with normally open RCP seal injection valves BBHV8351A, BBHV8351B, BBHV8351C and BBHV8351D are located in area A-17. The RCP seal injection valves are not high-low pressure interface valves, so consideration of a 3-phase proper polarity hot short is not required. A hot short, open circuit or short to ground involving these cables will not cause the valves to close. Therefore, RCP seal injection valves BBHV8351A, BBHV8351B, BBHV8351C and BBHV8351D will remain in their normally open position if a fire occurs anywhere in this area. Furthermore, the valves are de-energized so cable damage could not cause the valves to close.

Both trains of charging are available if a fire occurs in this area. If the normal charging pump stops as a result of the fire, operators can start either charging pump, depending on the CCW train that is operating.

Cable 14BGI51BA is associated with RCP seal total flow indicator BGFT0215B. Damage to this cable could prevent operation of the flow transmitter and could prevent operators from determining total RCP seal flow using flow indicator BGFI0215B. Flow indicator BGFI0215A is unaffected by a fire in area A-17 and can be used by operators to determine if seal flow is functioning.

Based on the above discussion, there is reasonable assurance that the seal injection valves will remain open in the event of a fire in area A-17. Therefore, RCP seal injection is available to provide hot standby inventory control and seal cooling. Loss of the operating charging pump would be indicated by loss of flow to the RCP seals using flow indicator BGFI0215A.

References: E-15000, XX-E-013, E-13BB04, E-13BG51, E-1F9303

5.2.7 Pressurizer Power Operated Relief Valves and Associated Block Valves

PFSSD requires that either the pressurizer power operated relief valve (PORV) or its associated block valve be closed. Cables and components associated with PORV BBPCV0456A and associated block valve BBHV8000B are located in area A-17.

The pressurizer PORVs are not considered high/low pressure interfaces. The valves are supplied power by an ungrounded 125 VDC system. Therefore, based on GL 86-10, consideration of multiple proper polarity hot shorts is not required. A single proper polarity hot short still needs to be considered.

Cables 14BBK40BG and 14BBK40BJ associated with PORV BBPCV0456A are run in this area. Based on a review of drawing E-13BB40, it would take two concurrent proper polarity hot shorts to cause the PORV to spuriously open. Therefore, a fire in area A-17 is not postulated to open PORV BBPCV0456A due to damage to the control cables associated with the PORV.

Instrument cables 12BBI16LB and 14BBI16NB associated with pressurizer pressure transmitters BBPT0456 and BBPT0458, respectively, are run in fire area A-17. As discussed in Calculation XX-E-013, Appendix 1, the Ovation pressurizer pressure control system uses 4-channel verification from all four pressurizer pressure transmitters to operate the pressurizer PORVs. Failure of a single channel will not cause the spurious operation of the PORVs since the system uses the 2nd highest input as the validated signal. Damage to two channels will not cause the PORVs to open because both channels would have to fail to the exact same value at the exact same time and this failure mode is not credible, as discussed in XX-E-013.

Based on the above discussion, a fire in area A-17 will have no adverse impact on BBPCV0456A.

References: E-15000, XX-E-013, M-12BB02, E-13BB16, E-13BB39, E-13BB40, M-761-02018, OFN KC-016, J-200-00207, CR 13079, DCP 12944, DCP 13324

5.2.8 Reactor Coolant System (RCS) Pressure Indication

PFSSD requires RCS pressure indication to be available. RCS pressure indication is provided in the control room using BBPI0405 or BBPI0406.

Cable 14BBI16BA, associated with BBPT0406 runs through fire area A-17. Damage to this cable could prevent operation of the pressure transmitter and prevent pressure indication in the control room on BBPI0406.

Cables for BBPT0405 are run in a separate fire area and are unaffected by a fire in area A-17. Therefore, RCS pressure indication will be available using BBPI0405 if a fire occurs in area A-17.

References: E-15000, XX-E-013, E-1F9201, E-13BB15, E-13BB16, M-12BB04

5.2.9 Reactor Head Vent Valves

PFSSD requires that one of the two reactor vessel head vent valves on each flow path (2 flow paths total) be closed to prevent loss of inventory and uncontrolled depressurization of the RCS. Cables for two of the four head vent valves run through area A-17. The head vent valves are considered high-low pressure interfaces, so consideration of multiple proper polarity hot shorts is required.

Cables for head vent valves BBHV8001A and BBHV8002A are not run through A-17. Therefore, isolation of the separation group 1 flow path is assured. Either BBHV8001B or BBHV8002B needs to be closed to prevent RCS depressurization through the separation group 4 head vent flow path.

Cable 14BBK30BA associated with valve BBHV8001B is run in conduit through area A-17 and enters containment penetration assembly ZSE234. The conduit carries one other cable (14BGK48AB) which is a control cable for excess letdown isolation valve BGHV8153B and is normally de-energized. The containment penetration assembly contains multiple 125 VDC cables that could present a source of 125 VDC power to energize and open the valve. An intra-cable short in cable 14BBK30BA would not cause the valve to open because this failure mode would not energize the control solenoid. However, a fire that affects containment

penetration assembly ZSE234 could cause a single or multiple proper polarity inter-cable hot short that would open valve BBHV8001B.

Cable 14BBK30DA associated with valve BBHV8002B is run in cable tray through area A-17 and enters containment penetration assembly ZSE233. The cable tray and penetration assembly contain multiple 125 VDC cables that could present a source for 125 VDC power to energize the valve. An intra-cable short in cable 14BBK30DA would not cause the valve to open because this failure mode would not energize the control solenoid. However, a fire that affects the cable tray and containment penetration assembly ZSE233 could cause a single or multiple proper polarity inter-cable hot short that would open valve BBHV8002B.

Based on this discussion, the Train B reactor head vent valves could open if a fire occurs in area A-17. This would cause a loss of RCS inventory that is within the makeup capability of the charging pumps. Therefore, spurious opening of the Train B RCS head vent flowpath will not adversely impact PFSSD.

References: E-15000, XX-E-013, E-1F9301, E-13BB30, E-1R1413D, E-1R1423A, E-1R1423C, E-1R1433A, E-1R1433B, M-12BB04

5.2.10 Component Cooling Water

Component Cooling Water (CCW) is required for PFSSD to provide cooling flow to the CCP oil coolers, the seal water heat exchanger, the RHR pump seal coolers and the RHR heat exchangers. The CCW system is also redundant to the RCP seal injection system to provide RCP seal cooling through the thermal barrier.

All four CCW pumps and both essential service water pumps are available if a fire occurs in this area. A loss of off-site power to NB01 and NB02 will not occur if a fire occurs in this area. Therefore, the operating train of CCW will remain operating in the event of a fire.

A number of cables associated with EGHV0062, EGHV0127 and EGHV0133 are run in this area. Damage to cables associated with EGHV0127 and EGHV0133 will have no adverse impact because these valves are located in the bypass lines for valves EGHV0058 and EGHV0061, respectively. Valves EGHV0058 and EGHV0061 are unaffected by a fire in this area and will remain open.

Cables 14EGG10AA, 14EGG10AB, 14EGG10AC and 14EGG10AD associated with EGHV0062 are run in this area. Damage to cables 14EGG10AC or 14EGG10AD could cause the valve to spuriously close, preventing CCW flow to the thermal barrier heat exchangers. Bypass valve EGHV0132 is unaffected and can be opened from the control room to restore thermal barrier cooling. Flow indicators EGFI0128 and EGFI0129 are unaffected and can be used to diagnose a loss of CCW flow to the RCP thermal barriers.

Cables 14EFG05BA and 14EFG05BB, associated with Train B ESW to CCW heat exchanger valve EFHV0052, and cables 14EFG04BA and 14EFG04BB, associated with Train B ESW from CCW heat exchanger valve EFHV0060, are run in area A-17. Damage to the cables would not result in the valves spuriously operating but could prevent the valves from being operated from the control room. If the Train A CCW system is operating at the time of the fire, then all valves will be in their proper lineup. If the Train B CCW system is operating at the time of the fire, these valves will remain in their required PFSSD position and continued operation of the Train B CCW system is available.

Based on the above discussion, both trains of CCW are available to provide cooling to essential PFSSD components. Train A is the credited train if a fire occurs in this area and eventual swapover to train A CCW will be required if Train B CCW is operating at the time of the fire.

References: E-15000, XX-E-013, E-1F9303, E-13EF04A, E-13EG10, E-13EG17A, E-13EG18, E-13EG18A

5.2.11 Excess Letdown Isolation Valves

PFSSD requires the excess letdown path be isolated to prevent loss of inventory and uncontrolled depressurization of the RCS. To accomplish this, either normally closed valve BGHV8153A or BGHV8154A must be maintained closed and either normally closed valve BGHV8153B or BGHV8154B must be maintained closed. Valves BGHV8153A and BGHV8154A are unaffected by a fire in area A-17.

Cable 14BGK48AB associated with valve BGHV8153B is run in conduit through area A-17 and enters containment penetration assembly ZSE234. The conduit carries one other cable (14BBK30BA), which is a control cable for RCS head vent valve BBHV8001B and is normally de-energized. The containment penetration assembly contains multiple 125 VDC cables that could present a source of 125 VDC power to energize and open the valve. An intra-cable short in cable 14BGK48AB would not cause the valve to open because this failure mode would not energize the solenoid. However, a fire that affects containment penetration assembly ZSE234 could cause a single or multiple proper polarity inter-cable hot short that would open valve BGHV8153B.

Cable 14BGK48BB associated with valve BGHV8154B is run in cable tray through area A-17 and enters containment penetration assembly ZSE233. The cable tray and penetration assembly contain multiple 125 VDC cables that could present a source for 125 VDC power to energize the valve. An intra-cable short in cable 14BGK48BB would not cause the valve to open because this failure mode would not energize the control solenoid. However, a fire that affects the cable tray and containment penetration assembly ZSE233 could cause a single or multiple proper polarity inter-cable hot short that would open valve BGHV8154B.

Based on this discussion, the Train B excess letdown flow path could open if a fire occurs in area A-17. This would cause a loss of RCS inventory that is within the makeup capability of the charging pumps. Calculation WCNOC-CP-002 shows that a failed open excess letdown flowpath does not need to be mitigated. Therefore, spurious opening of the Train B excess letdown flow path will not adversely impact PFSSD.

References: E-15000, XX-E-013, E-1F9301, E-13BG48, E-1R1423A, M-12BG01, WCNOC-CP-002

5.2.12 Refueling Water Storage Tank (RWST)

The RWST level transmitters are interlocked with the containment sump isolation valves (EJHV8811A&B). In the event that two out of four low-low RWST level signals are received, co-incident with a SIS, valves EJHV8811A and EJHV8811B will open, draining the RWST into the containment sump. A spurious SIS is possible for a fire in area A-17, as discussed previously.

Cable 14BNI07FA, associated with RWST level transmitter BNLT0933, is run in area A-17. Circuits for the remaining three RWST level transmitters are not run in area A-17. A spurious low-low RWST level signal cannot occur due to a fire in area A-17 since circuits for at least two RWST level transmitters are not run in the area.

Power and control cables associated with containment sump isolation valve EJHV8811B are run in area A-17. A hot short within cable 14EJG06BT could cause the valve to spuriously open. In addition, there are other cable failure scenarios requiring multiple simultaneous shorts that could cause the valve to spuriously open. If valve EJHV8811B were to spuriously open

while valve BNHV8812B is open, the RWST would drain to the containment sump. However, cables associated with the automatic close permissive on valve BNHV8812B are unaffected by the fire and would result in closure of valve BNHV8812B when valve EJHV8811B is fully open. If valve EJHV8811B spuriously opens but stalls before reaching full open position, valve BNHV8812B will not automatically close. If this occurs, operators will recognize a decreasing RWST level using BNLI0930, BNLI0931 and/or BNLI0932 and take action to close BNHV8812B using BNHIS8812B in the main control room.

Based on the above discussion, there is reasonable assurance that a fire in area A-17 will not result in uncontrolled draindown of the RWST into the containment sump.

References: E-15000, XX-E-013, E-1F9205, E-13BN03A, E-13BN07, E-13EJ06A, E-13EJ06B, E-025-00007, M-10BN

5.2.13 Containment Coolers

PFSSD requires containment cooling to maintain the containment environment within EQ limits. Cables associated with the ESW supply to the Train B containment coolers are run in area A-17. These circuits are listed in Table A-17-4.

Damage to these cables could prevent operation of the Train B containment coolers due to spurious closure of one or more of the valves. However, circuits for the Train A containment coolers are run in a separate fire area and are unaffected by a fire in area A-17.

Therefore, the Train A containment coolers will remain available to provide containment cooling in the event of a fire in area A-17.

References: E-15000, XX-E-013, E-1F9441, E-13EF07, E-13EF08, E-13EF09, E-13GN02, E-13GN02A, E-13NG01, M-12EF02

5.2.14 RHR To RCS Hot and Cold Legs

During cold shutdown mode, PFSSD requires one RHR pump operating and discharging into the cold legs of either Loops 1 and 2 (Train A RHR) or 3 and 4 (Train B RHR). In addition, hot leg injection needs to be isolated.

Valve EJHV8840 is required to be closed to prevent injection through the hot leg of loops 2 and 3. Cables associated with this valve run through area A-17. In order for the valve to spuriously open, it would take two simultaneous hot shorts within the same multi-conductor cable. This is unlikely to occur since it would take the proper source conductor shorting to a specific target conductor without shorting to a different conductor or shorting to ground to cause the valve to open. In the unlikely event the valve spuriously opens, a cold shutdown repair can be performed, or valve EJHV8716A can be manually closed, to prevent flow from Train A RHR through this flow path. If Train B RHR is being used, then valve EJHV8716B can be closed to isolate this flow path.

Either EJHV8809A or EJHV8809B needs to be open when operating RHR pumps A or B, respectively. Cables associated with EJHV8809B run through area A-17 and could be damaged such that the valve spuriously closes. Cables associated with valve EJHV8809A are not run in area A-17. Consequently, valve EJHV8809A is unaffected if a fire occurs in area A-17.

Based on the above discussion, a flow path is available to ensure RHR flow to the RCS.

References: E-15000, XX-E-013, E-13EJ09A, E-1F9205, M-12EJ01

5.2.15 Safety Injection Accumulator Isolation Valves

PFSSD requires isolation of the SI accumulators prior to reducing RCS pressure below the injection pressure to avoid unnecessary accumulator discharge. This is accomplished by closing valves EPHV8808A, EPHV8808B, EPHV8808C and EPHV8808D. These valves are normally open with the MCC breaker locked in the open position. Cables for valves EPHV8808B and EPHV8808D are run in area A-17 and are listed in Table A-17-4.

Since the breakers for these valves are normally open, damage to these cables will not cause the valve to spuriously change position. However, damage to the cables will prevent closing the associated valve from the control room after power is restored.

The SI accumulators need to be isolated during cold shutdown, prior to the RCS reaching 1000 psig. If necessary, a containment entry can be made to manually close the valves or nitrogen pressure can be relieved from the tanks to prevent injection.

A fire in area A-17 may require a containment entry to close valves EPHV8808B and EPHV8808D if these valves are unresponsive from the control room.

References: E-15000, XX-E-013, E-13EP02A, M-12EP01

5.2.16 Reactor Coolant Pumps

The reactor coolant pumps are not credited in the PFSSD analysis. However, the capability to stop the pumps from the control room in the event of a loss of all seal cooling is credited. Westinghouse Technical Bulletin TB-04-22, Rev. 1 recommends that if all seal cooling is lost (RCP seal injection and thermal barrier heat exchanger flow), operators need to stop the pumps before a seal LOCA occurs.

Control cables associated with reactor coolant pumps C and D are run in fire area A-17. Damage to these cables in the event of a fire could prevent operators from stopping the C and D RCPs from the control room. However, a fire in A-17 will not cause a loss of all seal cooling since RCP seal injection remains available.

Based on the above discussion, the inability to trip the C and D RCPs from the control room will have no adverse impact on PFSSD. The pumps can continue to operate, providing forced flow circulation. If the pumps spuriously stop, natural circulation cooldown can be used.

References: E-15000, XX-E-013, E-13BB01, Westinghouse TB-04-22 Rev. 1

5.2.17 Load Center Feeder Breaker PA0206

Load center feeder breaker PA0206 is credited for PFSSD because it supplies power to credited non-safety related loads. Cable 16PGA10CA is a control cable associated with breaker PA0206. An intra-cable hot short in this cable will trip PA0206. Breaker PA0206 supplies power to the following PFSSD components:

- PG12KAF4 – Main Steam Supply to 2nd Stage Reheat Valve ABHV0032
- PG12KAF5 – Main Steam Supply to Steam Seals Valve ABHV0046
- PG12KEF3 – Auxiliary Steam System Control Valve FBHV0080

PG12KAF4, PG12KAF5 and PG12KEF3 supply power to components downstream of the MSIVs. The MSIVs are unaffected by a fire in this area and can be closed from the control room using either hand switch ABHS0079 or ABHS0080. Therefore, the MSIV downstream components are not required if a fire occurs in this area.

Based on the above discussion, loss of breaker PA0206 due to a fire in area A-17 will not adversely impact PFSSD.

References: XX-E-013, E-15000, E-13PG10, E-1F9424E

5.2.18 Normal Pressurizer Spray

The normal pressurizer spray valves are included in the PFSSD design because spurious operation of pressurizer sprays can cause a decrease in pressure which can lead to boiling in the core. The pressurizer spray valves are part of the pressurizer pressure control system.

The pressurizer normal spray valves (BBPCV0455B and BBPCV0455C) operate off a signal from the Ovation pressurizer pressure control system. The operation of the pressure control system is discussed in Calculation XX-E-013.

Instrument cables 12BBI16LB and 14BBI16NB associated with pressurizer pressure transmitters BBPT0456 and BBPT0458, respectively, are run in fire area A-17. As discussed in Calculation XX-E-013, Appendix 1, damage to one or more pressure input channels will not cause the spurious operation of the pressurizer spray valves due to the Ovation 4-channel validation logic. Therefore, a fire in area A-17 will not cause the spurious operation of pressurizer spray.

1.0 GENERAL AREA DESCRIPTION

Fire area A-18 is located on the 2026 elevation of the Auxiliary Building and includes the room listed in Table A-18-1.

Table A-18-1
Room Located in Fire Area A-18

ROOM #	DESCRIPTION
1410	North Electrical Penetration Room (Train A)

Fire area A-18 is protected with a total flooding Halon fire suppression system. In addition, automatic fire detection is installed throughout. The automatic suppression and detection system meets the intent of 10CFR50, Appendix R, Section III.G.2.c.

In some cases where redundant circuits are run through area A-18, circuits associated with one of the redundant components are wrapped with a raceway fire barrier material meeting the requirements for a 1-hour fire rating. This fire barrier along with automatic suppression and detection installed in the area meets Wolf Creek commitments to 10 CFR 50, Appendix R Section III.G.2(c) and provides reasonable assurance that PFSSD can be achieved.

2.0 PRIMARY EQUIPMENT USED FOR PFSSD

Table A-18-2 lists each system credited for post-fire safe shutdown and provides a discussion regarding the availability of the system to perform its Post Fire Safe Shutdown (PFSSD) function if a severe fire occurs in this area. For a summary of the area analysis results, see Section 8.0 of the Fire Area Analysis Narrative section.

Table A-18-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-18

System	System Name	PFSSD Function*	Comments
AB	Main Steam	R, M, H, P, S	All PFSSD functions associated with the main steam system are satisfied. Steam generator A, C and D ARVs are unaffected. It may be necessary to isolate SG B ARV using local control station ABFHC0002. Steam generator pressure indication is available using ABPI0514A, ABPI0524A, ABPI0526A, ABPI0534A, ABPI0536A, and ABPI0544A.
AC	Main Turbine	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-18.
AE	Main Feedwater	H, P	All PFSSD functions associated with the main feedwater system are satisfied. Steam generator A level indication is available using narrow range level transmitters AELT0517 and AELT0519. Steam generator D level indication is available using narrow range level indicators AELI0547 and AELI0549 and wide range level indicator AELI0504.
AL	Aux. Feedwater System	H, P	All PFSSD functions associated with the auxiliary feedwater system are satisfied. Train B MDAFP is available to supply S/Gs A and D. ALFT0001 and ALFT0007 are available to provide auxiliary feedwater flow indication from MDAFP B to SGs D and A, respectively. Condensate Storage Tank (CST) pressure indication is available.
AP	Condensate Storage System	H	The condensate storage system is available to supply water to Train B MDAFP.

Table A-18-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-18

System	System Name	PFSSD Function*	Comments
BB	Reactor Coolant System	R, M, H, P, S	All PFSSD functions associated with the reactor coolant system are satisfied. RCS pressure indication is available using BBPI0405 or BBPI0406. RCS wide range cold and hot leg temperature elements (BBTE413B and BBTE443A) and pressure transmitters ABPT0516 and ABPT0546 will provide indication that cooldown is being achieved. Pressurizer level indication is available using BBLI0460A. Pressurizer pressure indication is available using BBPI0456 and BBPI0458. A spurious start of the SI Pumps due to two out of four low pressurizer pressures can be mitigated by placing the pump control hand switches EMHIS0004 and EMHIS0005 on panel RL017 in pull-to-lock. Loss of RCS inventory through the RHR flow path is prevented by maintaining valves BBPV8702A and BBPV8702B closed. RCP thermal barrier cooling could be affected due to spurious closure of BBHV0013, BBHV0014, BBHV0015 and BBHV0016. Reactor coolant pumps A and B may not stop using the control room hand switch. RCP seal injection remains available. Therefore, the inability to stop the RCPs will have no adverse impact on PFSSD. Pressurizer spray valves BBPCV0455B and BBPCV0455C could spuriously open. If this occurs, pressurizer spray can be stopped by closing KAFV0029 using KAHIS0029 in the main control room. Loss of inventory through the head vent valves could occur due to spurious opening of BBHV8001A and BBHV8002A. The Train B CCP is available to charge through the BIT.
BG	Chemical and Volume Control System	R, M, S	All PFSSD functions associated with the chemical and volume control system are satisfied. Train B Centrifugal Charging Pump (CCP) is available to provide charging flow from the RWST to the RCP seals. Flow from the VCT can be isolated by closing BGLCV0112B. Loss of inventory through the excess letdown path could occur due to spurious opening of BGHV8153A and BGHV8154A. The Train B CCP is available to charge through the BIT. Charging flow through the BIT is assured. BGHV8106 may not respond to a close signal from the control room. Valve BGHV8105, and its hand switch (BGHIS8105), are unaffected by a fire in area A-18. Letdown isolation valves BGLCV0459 and BGLCV0460 and letdown orifice isolation valves BGHV8149A, BGHV8149B, and BGHV8149C may need to be failed closed by closing valve KAFV0029 using KAHIS0029 in the main control room.
BM	Steam Generator Blowdown System	R, M, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-18.

Table A-18-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-18

System	System Name	PFSSD Function*	Comments
BN	Borated Refueling Water Storage System	R, M, H	If containment sump isolation valve EJHV8811A spuriously opens and stalls before reaching full open position, BNHV8812A will not automatically close. In this case, operators can close BNHV8812A using BNHIS8812A in the main control room to mitigate draindown of the RWST into the containment sump.
EF	Essential Service Water System	H, S	All PFSSD functions associated with the Essential Service Water (ESW) system are satisfied. ESW flow to Train B Containment Air Coolers is available via valves EFHV0032, EFHV0034, EFHV0046 and EFHV0050.
EG	Component Cooling Water System	S	CCW flow to the RCP thermal barriers could be affected as discussed in BB System comments above. CCW flow indicators EGFI0128 and EGFI0129 are unaffected.
EJ	Residual Heat Removal System	M, H, P	All PFSSD functions associated with the Residual Heat Removal (RHR) system are satisfied. If valve EJHV8701B fails to respond when initiating RHR for cold shutdown, make a containment entry to manually open the valve or perform a cold shutdown repair to fix the damaged circuit. Containment sump isolation valve EJHV8811A could spuriously open, causing a draindown path from the RWST to the containment sump. Valve BNHV8812A will automatically close, as designed, when EJHV8811A reaches full open position, mitigating draindown. However, if EJHV8811A stalls before reaching full open position, BNHV8812A will not automatically close. In this case, operators can close BNHV8812A using BNHIS8812A in the main control room. Valve EJHV8811B is unaffected. RHR system flow diagnostic instrumentation is available using various available temperature indicators.
EM	High Pressure Coolant Injection	R, M	Charging flow from CCP B to the RCS is available through the BIT by opening valves EMHV8803B and EMHV8801B. Prevent flow diversion through the SIS test line when charging through the BIT by maintaining either valve EMHV8871 or valve EMHV8964 closed. A spurious SIS can be mitigated by entering EMG E-0 and terminating the spurious SIS.
EN	Containment Spray	R, M	A spurious containment spray actuation signal (CSAS) due to spurious signals on two out of four containment pressure transmitters can be terminated by placing pump control hand switches ENHIS0003 and ENHIS0009 on control room panel RL017 in pull-to-lock. Train A containment spray isolation valve ENHV0006 could spuriously open. Containment spray can be mitigated as described in the previous paragraph.
EP	Safety Injection Accumulators	H	A containment entry may be required to close SI Accumulator injection valves EPHV8808A and EPHV8808C if these valves are unresponsive from the control room. The SI accumulators need to be isolated during cold shutdown, prior to the RCS reaching 1000 psig.
FB	Auxiliary Steam	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-18.

Table A-18-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-18

System	System Name	PFSSD Function*	Comments
FC	Auxiliary Turbines	R, H, P	All PFSSD functions associated with the Auxiliary Turbines are satisfied. The Turbine Driven Auxiliary Feedwater Pump is not used for a fire in area A-18.
GD	ESW Pump House HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-18.
GF	AFW Pump Room Coolers	S	AFW Pump B room cooler is unaffected by a fire in area A-18.
GK	Control Room and Class 1E Switchgear Room Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-18.
GL	Auxiliary Building HVAC	S	The PFSSD Support function associated with the Auxiliary Building HVAC system is satisfied. Train B CCP room cooler SGL12B is available. Train B RHR pump room cooler SGL10B is available.
GM	Emergency Diesel Generator Room HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-18.
GN	Containment Coolers	S	Train B Containment Air Coolers SGN01B and SGN01D are available. Containment pressure indicators GNPI0934 and GNPI0936 are available.
JE	Diesel Fuel Oil	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-18.
KA	Instrument Air	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-18.
KC	Fire Protection	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-18.
KH	Service Gas	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-18.
KJ	Standby Diesel Engine	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-18.
MA	Main Generation	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-18.
MR	Startup Transformer	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-18.
NB	4.16 kV System	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-18.

Table A-18-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-18

System	System Name	PFSSD Function*	Comments
NE	Standby Diesel Generator	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-18.
NF	Load Shed and Emergency Load Sequencing	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-18.
NG	480V Load Centers and MCCs	S	Train B MCCs NG02B, NG02T and NG04T are not affected by a fire in area A-18.
NK	125VDC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-18.
NN	120VAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-18.
PA	13.8kV	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-18.
PB	4.16kV	H, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-18.
PG	480V Load Centers and MCCs	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-18.
PK	125VDC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-18.
PL	Local Instrument Panels	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-18.
PN	120VAC	S	One of the two sources of power to non-class 1E 120 VAC panel PN07 is affected by a fire in this area. The alternate power source is unaffected. In addition, non-class 1E 120 VAC panel PN08 is unaffected.
QB	Standby AC Lighting	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-18.
QD	Emergency Lighting	S	Emergency lighting for PFSSD outside the control room is provided by self-contained 8-hour battery powered lights. Emergency lighting in the control room is provided by 125 VDC emergency lighting distribution switchboard NK051A. The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-18.
RL	Control Room MCB	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-18.
RP	Miscellaneous Control Panels	R, M, H, P, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-18.

Table A-18-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-18

System	System Name	PFSSD Function*	Comments
SA	ESFAS	S	Status panel input for valves ABHV0005 and ABHV0006, associated with the TDAFP, may be affected. This is acceptable since the TDAFP is not used for a fire in area A-18.
SB	Reactor Protection System	R, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-18.
SC	Reactor Instrumentation	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-18.
SE	Ex-Core Neutron Monitoring	R, P	Source range monitoring is available for a fire in area A-18 using SR monitors SENE0032 and SENY0060A/B.
SY	Switchyard	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-18.
UU	Supervisory System	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-18.

* R - Reactivity Control; M - Reactor Coolant Makeup; H - Decay Heat Removal; P - Process Monitoring; S - Support Function

3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD

This section describes operator actions that may need to be performed inside or outside the control room to achieve and maintain hot standby if a fire occurs in area A-18. This section also describes cold shutdown repairs that may need to be made to achieve and maintain cold shutdown conditions. Operator actions are proceduralized in OFN KC-016.

3.1 ACTIONS OUTSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

Operator Manual Actions (OMAs) are those actions outside the main control room required to achieve and maintain hot standby. OMAs are identified in E-1F9900 and were determined from thermal hydraulic analysis WCNOC-CP-002. Applicable E-1F9900 OMAs are annotated herein. All other actions outside the control room are desirable for plant control in support of hot standby but not required to achieve and maintain hot standby.

3.1.1 Steam Generator ARVs

If damage occurs to cables associated with ABPV0002, local control station ABFHC0002, located in fire area A-23, can be used to close ARV ABPV0002.

3.2 ACTIONS INSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

3.2.1 Mitigation of RWST Draindown to Containment Sump

If a fire occurs in area A-18, it may be necessary to close valve BNHV8812A from the control room using BNHIS8812A to mitigate draindown of the RWST into the containment sump. This condition could occur due to EJHV8811A spuriously opening but stalling before reaching full open position, thereby not providing the permissive for BNHV8812A to close. RWST level indication is available using all four level indicators.

3.2.2 Containment Spray and Safety Injection

A spurious Safety Injection Signal (SIS) due to low pressurizer pressure and high containment pressure can be mitigated by consulting EMG E-0 and terminating the spurious SIS.

A spurious Containment Spray Actuation Signal (CSAS) can be mitigated by placing CS pump control hand switches ENHIS0003 and ENHIS0009 in pull-to-lock. These switches are located on control room panel RL017. Indication in the Control Room for SI and CS pump operation is unaffected by a fire in A-18.

3.2.3 Auxiliary Feedwater Pumps

It may be necessary to manually trip Train A MDAFP (PAL01A) using ALHIS0023A in the main control room due to possible loss of room cooler and loss of control of valves ALHV0009 and ALHV0011, which could lead to overfilling steam generators B and C.

3.2.4 Reactor Head Vent Valves

A fire in this area could cause both Train A reactor head vent valves to open. If this occurs, operators will need to increase charging flow to make up for the inventory loss. Pressurizer level indication is available using BBLI0460A. RCS pressure indication is available using BBPI0405 or BBPI0406.

3.2.5 Excess Letdown

A fire in this area could cause both Train A excess letdown valves to open. If this occurs, operators will need to increase charging flow to make up for the inventory loss. Pressurizer level indication is available using BBLI0460A.

3.2.6 Normal Pressurizer Spray

Pressurizer spray valves BBPCV0455B and BBPCV0455C could spuriously open. If this occurs, the spray can be stopped by isolating air to the valves. This can be accomplished by depressing the CLOSE push button on KAHIS0029 to close KAFV0029. KAHIS0029 is located on RL024. Pressurizer pressure indication is available using BBPI0456 and BBPI0458.

3.2.7 Isolation of Letdown

A fire in area A-18 could prevent valves BGLCV0459, BGLCV0460, BGHV8149A, BGHV8149B, and BGHV8149C from being closed using their associated control room hand switches. If this occurs, the valves can be closed by isolating air to the valves. This can be accomplished by depressing the CLOSE push button on KAHIS0029 to close KAFV0029. KAHIS0029 is located on RL024. Pressurizer level indication is available using BBLI0460A.

3.3 ACTIONS TO ACHIEVE AND MAINTAIN COLD SHUTDOWN

3.3.1 RHR

If valve EJHV8701B fails to respond when initiating RHR for cold shutdown, make a containment entry to manually open the valve or perform a cold shutdown repair to fix the damaged circuit.

3.3.2 SI Accumulators

A fire in area A-18 may require a containment entry to close SI Accumulator injection valves EPHV8808A and EPHV8808C if these valves are unresponsive from the control room. The SI accumulators need to be isolated during cold shutdown, prior to the RCS reaching 1000 psig.

4.0 CONCLUSION

With some exceptions, redundant Post-Fire Safe Shutdown capability exists if a severe fire occurs in this area. For those exceptions, feasible manual actions are available and are unaffected by the fire. Manual actions are documented in Section 3.0.

5.0 DETAILED ANALYSIS

This section describes the detailed component-by-component and cable-by-cable analysis for a fire in area A-18.

5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA A-18

PFSSD components (S. in E-15000) located in fire area A-18 are shown in Table A-18-3. An evaluation of each component and associated cables is provided in the sections that follow. The applicable evaluation section is listed in Table A-18-3.

Table A-18-3
PFSSD Equipment Located in Fire Area A-18

Room #	PFSSD Equipment	Description	Evaluation Section	Comments
1410	DSGL15A	North Electrical Penetration Room Cooler	5.1.1	
1410	EMHS8882	Local Hand Switch for Boron Injection Downstream Test Line Isolation Valve	5.1.2

5.1.1 North Electrical Penetration Room Cooler

A fire in area A-18 will result in the loss of the North Electrical Penetration Room cooler (DSGL15A). Cable 11GLG12AA, associated with this room cooler, will be damaged. The redundant South Electrical Penetration Room cooler is unaffected by a fire in area A-18 and will be used if a fire occurs in area A-18.

References: E-15000, XX-E-013

5.1.2 Boron Injection Downstrean Test Line Isolation Valves

To prevent CCP flow diversion through the SIS test line when charging through the BIT, valves EMHV8843 and EMHV8882 need to be closed. If either or both of these valves cannot be closed, then closing or maintaining closed either valve EMHV8871 or EMHV8964 will accomplish the PFSSD objective.

Cable 15EMK05EA is a control cable for EMHV8882. A +125 VDC external cable hot short in contact with conductor 2 in cable 15EMK05EA will energize the solenoid and open valve EMHV8882. The cable is run in raceways with cables carrying the proper voltage and polarity. The hot short would bypass the control room hand switch (EMHIS8882) on RL018 and control of this valve from the control room would be lost.

Cable 15EMK05EC is a control cable for EMHV8882. A short across the conductors in this cable will not have an impact on PFSSD since hand switch EMHS8882 is normally closed. An open on either conductor will de-energize the solenoid and close valve EMHV8882.

CCP flow diversion through the SIS test line is prevented by valves EMHV8871 or EMHV8964. Cables associated with EMHV8871 and EMHV8964 are run in a different fire area. Therefore, the flow path can be isolated using either EMHV8871 or EMHV8964.

5.1.3 Containment Cooler Fans A and C Hand Switches

GNHIS5A is the containment cooler fan A (DSGN01A) hand switch. This switch is located on NG01TAF1 in area A-18. GNHIS13A is the containment cooler fan C (DSGN01C) hand switch. This switch is located on NG03TAF1 in area A-18.

Damage to GNHIS5A and GNHIS13A, as well as associated cables, will prevent operation of containment coolers A and C. However, containment coolers B and D are unaffected by a fire in area A-18 and will be available to supply the needed containment cooling demand.

For a detailed evaluation, refer to the discussion on DSGN01A and DSGN01C in section 5.2.

References: E-15000, XX-E-013, E-1F9441

5.1.4 Containment Pressure Transmitters

Pressure transmitters GNPT0935 and GNPT0937 do not perform PFSSD functions. However, damage to these transmitters or associated cables could initiate a spurious Safety Injection Signal (SIS) or Containment Spray Actuation Signal (CSAS), which is not desired for PFSSD at Wolf Creek.

For a detailed cable analysis on spurious SIS or CSAS, see Section 5.2.

References: E-15000, XX-E-013, E-1F9431

5.1.5 Train A 480 VAC Motor Control Center

MCC NG01B supplies 480 VAC power to a number of Train A PFSSD components. A fire in area A-18 could cause loss of power to these loads. Damage to cables 11NGG01AD and 11NGG01AE will also cause loss of power to NG01B.

Redundant Train B components are powered from 480 VAC MCC NG02B. Therefore, loss of power to 480 VAC MCC NG01B will not affect PFSSD.

References: E-15000, XX-E-013, E-1F9424A, E-03NG01

5.1.6 Source Range Monitors

PFSSD requires source range (SR) flux monitoring to be available. Source range monitoring is provided by source range monitors SENE0031, SENE0032, SENY0060A & B, and SENY0061A & B.

Damage to SE31 or associated cable 11SES01BB will prevent SENE0031 from operating. However, redundant source range monitors are available and are unaffected by a fire in area A-18.

For a more detailed evaluation on Source Range monitoring, see Calculation XX-E-013, Attachment 3.

5.2.1 Steam Generator Atmospheric Relief Valves

PFSSD requires at least two steam generator atmospheric relief valves (ARVs) be controlled and the other two closed. The ARVs are normally closed and require air pressure to open. Each valve is controlled by a pressure transmitter input signal from a pressure transmitter installed on the outlet side of the steam generator. The relief valve opens when pressure reaches a designated setpoint.

Cables associated with Steam Generator Atmospheric Relief Valves ABPV0001, ABPV0002 and ABPV0004 are run in area A-18. Cables associated with Steam Generator Atmospheric Relief Valve ABPV0003 are not run in area A-18.

Cable 11ABI20EE runs through area A-18 from ABPY0001 in room 1508 to panel RP053AC in room 3605. Damage to this cable could cause the spurious opening of valve ABPV0001. This cable is run in raceways 111J3A1H and 111J1097, which have been wrapped with a 1-hour fire rated material. This fire wrap, along with automatic fire suppression and detection installed throughout the area, meets the separation requirement of 10CFR50, Appendix R, Section III.G.2.c. Therefore, ARV ABPV0001 is unaffected by a fire in area A-18.

Cable 14ABI20HH runs through area A-18 from ABPT0004 in room 1304 to RP147B in room 3302. Damage to this cable could cause the spurious opening of valve ABPV0004. This cable is run in raceway 114J3C1C, which has been wrapped with a 1-hour fire rated material. This fire wrap, along with automatic fire suppression and detection installed throughout the area, meets the separation requirement of 10CFR50, Appendix R, Section III.G.2.c. Therefore, ARV ABPV0004 is unaffected by a fire in area A-18.

Cable 12ABI20FE runs through area A-18 from ABPY0002 in room 1509 to panel RP147A in room 3302. Cable 12ABI20FH runs through area A-18 from ABPT0002 in room 1305 to RP147A in room 3302. If these cables are damaged, valve ABPV0002 could spuriously open.

If damage occurs to cables associated with ABPV0002, local controller ABFHC0002, located in fire area A-23, can be used to isolate ARV ABPV0002.

Based on the above discussion, manual actions are available to ensure a fire in area A-18 will not prevent the control of two Steam Generator Atmospheric Relief Valves and the closure of the remaining two.

Up to three ARVs can fail closed or open without impacting ability to achieve and maintain hot standby according to thermal hydraulic analysis WCNOC-CP-002. With at least one ARV unaffected, no E-1F9900 OMA is required to address ARV closure or control. Reference Attachment 4, MSO Evaluation Scenario ID PWROG 23.

References: E-15000, E-1R1443C, E-1R1444C, DCP 011038, XX-E-013

5.2.2 RCS Hot and Cold Leg Temperature Elements

PFSSD requires RCS hot and cold leg temperature indication on at least one loop to verify flow through the steam generators. The temperature elements used for this purpose are listed in Table A-18-5.

Cables 11BBI15HB (BBTE0413A), 11BBI15LB (BBTE0433B), 11BBI15JB (BBTE0423A) and 11BBI15KB (BBTE0443B) could be damaged by a fire in area A-18. This would cause the loss of at least one temperature indicator on each loop, which is not in accordance with the PFSSD design at Wolf Creek.

Table A-18-5 RCS Hot and Cold Leg Temperature Elements Used for PFSSD	
COMPONENT	**FUNCTION**
BBTE0413A	RCS Hot Leg Temperature Element (WR) Loop 1
BBTE0413B	RCS Cold Leg Temperature Element (WR) Loop 1
BBTE0423A	RCS Hot Leg Temperature Element (WR) Loop 2
BBTE0423B	RCS Cold Leg Temperature Element (WR) Loop 2
BBTE0433A	RCS Hot Leg Temperature Element (WR) Loop 3
BBTE0433B	RCS Cold Leg Temperature Element (WR) Loop 3
BBTE0443A	RCS Hot Leg Temperature Element (WR) Loop 4
BBTE0443B	RCS Cold Leg Temperature Element (WR) Loop 4

EMG ES-04, Attachment B, lists alternate indication that may be used to verify cooldown. S/G "A" and S/G "D" pressure instruments ABPT516 and ABPT546 are unaffected by a fire in A-18 due to 1-hour fire wrap provided around the conduit, and can be used per ES-04 to verify heat removal in loops 1 and 4.

The configuration is acceptable because, in the event of fire in fire area A-18, cooldown will be performed using RCS loops A and D. RCS wide range cold and hot leg temperature elements (BBTE413B and BBTE443A) and pressure transmitters ABPT0516 and ABPT0546 will provide indication that cooldown is being achieved.

References: E-15000, E-1R1441, XX-E-013

5.2.3 Steam Generator Level Indication

The decay heat removal function for PFSSD requires the use of two RCS loops and two Steam Generators. Steam generator (SG) level indication is required to support this function. A fire in A-18 uses MDAFW pump B, which is normally aligned to supply SGs A and D.

Steam generator A wide range level transmitter AELT0501 is unavailable due to a fire in area A-18. Steam generator A narrow range level transmitters AELT0518 and AELT0551 are unavailable due to a fire in area A-18. Steam generator A narrow range level transmitters AELT0517 and AELT0519 are unaffected by a fire in area A-18. Therefore, Steam Generator A level indication is assured.

Steam generator D narrow range level transmitters AELT0548 and AELT0554 are unavailable due to a fire in area A-18. Steam generator D narrow range level transmitters AELT0547 and AELT0549 are unaffected by a fire in area A-18. Also, steam generator D wide range level transmitter AELT0504 is unaffected by a fire in area A-18. Therefore, Steam Generator D level indication is assured.

References: E-15000, XX-E-013, E-1F9203

5.2.4 Motor Driven Auxiliary Feedwater Pump Discharge Valves

PFSSD for a fire in area A-18 relies on Motor Driven Auxiliary Feedwater Pump (MDAFP) B to provide feedwater to steam generators A and D. Circuits for all four MDAFP discharge valves are run through area A-18. However, circuits associated with ALHV0005 and ALHV0007 are wrapped with 1-hour fire rated material. In addition, area A-18 is provided with automatic detection and suppression throughout. This configuration meets the requirements of Wolf Creek's commitments to 10CFR50, Appendix R Section III.G.2.c.

Based on the above discussion, a fire in area A-18 will not affect the ability to supply auxiliary feedwater from MDAFP B through valves ALHV0007 and ALHV0005 to steam generators A and D, respectively.

References: E-15000, E-13AL03A, E-13AL03B, E-13AL09, DCP 011038

5.2.5 Pressurizer Power Operated Relief Valves and Associated Block Valves

PFSSD requires that either the pressurizer power operated relief valve (PORV) or its associated block valve be closed. Cables for PORV BBPCV0455A and its associated block valve BBHV8000A run through fire area A-18. Cables and components associated with PORV BBPCV0456A and associated block valve BBHV8000B are not located in area A-18.

The pressurizer PORVs are not considered high/low pressure interfaces. The valves are supplied power by an ungrounded 125 VDC system. Therefore, based on GL 86-10, consideration of multiple proper polarity hot shorts is not required. A single proper polarity hot short still needs to be considered.

Cables 11BBK40AG and 11BBK40AJ associated with PORV BBPCV0455A are run in this area. Based on a review of drawing E-13BB40, it would take two concurrent proper polarity hot shorts to cause the PORV to spuriously open. Therefore, a fire in area A-18 is not postulated to open PORV BBPCV0455A due to damage to the control cables associated with the PORV.

Instrument cables 11BBI16KB and 13BBI16MB associated with pressurizer pressure transmitters BBPT0455 and BBPT0457 are run in fire area A-18. As discussed in Calculation XX-E-013, Appendix 1, the Ovation pressurizer pressure control system uses 4-channel verification from all four pressurizer pressure transmitters to operate the pressurizer PORVs. Failure of a single channel will not cause the spurious operation of the PORVs since the system uses the 2nd highest input as the validated signal. Damage to two channels will not cause the PORVs to open because both channels would have to fail to the exact same value at the exact same time and therefore this failure mode is not credible.

Based on the above discussion, a fire in area A-18 will have no impact on the pressurizer PORVs.

References: E-15000, XX-E-013, E-13BB16, E-13BB39, E-13BB40, E-1F9301, M-12BB02, M-744-00028, M-761A-00063, CR 13079, DCP 12944, DCP 13324.

5.2.6 Safety Injection and Containment Spray

Calculation XX-E-013, Appendix 1 (PFSSD Support Section) provides a detailed discussion about the potential PFSSD impact of a spurious safety injection signal (SIS) and spurious containment spray actuation signal (CSAS). This section discusses the specific PFSSD impact if a fire occurs in this area.

Containment pressure transmitters GNPT0935 and GNPT0937 and associated cables are located in area A-18. Cables for containment pressure transmitters GNPT0934 and GNPT0936 are not run in area A-18. Consequently, a spurious CSAS due to high containment pressure can occur if a fire occurs in area A-18. A spurious SIS due to high containment pressure cannot occur since only one out of three containment pressure SIS initiators are located in area A-18.

Power and control cables associated with Train A containment spray isolation valve ENHV0006 are run in fire area A-18. Damage to these cables could cause the valve to spuriously open. As stated in the previous paragraph, a spurious CSAS is credible if a fire occurs in this area. Therefore, a spurious containment spray condition could occur.

Cables associated with BBPT0455 and BBPT0457 are run in area A-18. Cables associated with BBPT0456 and BBPT0458 are not run in area A-18. Consequently, a fire in area A-18 could cause a spurious SIS due to damage to cables associated with two of the four pressurizer pressure transmitters.

Cables associated with steam line pressure transmitters ABPT0515, ABPT0516, ABPT0525, ABPT0535, ABPT0545 and ABPT0546 are run in area A-18. Cables associated with ABPT0516 and ABPT0546 are wrapped with a 1-hour fire rated material. Consequently, the two out of three logic for low steam line pressure initiation of SIS cannot be satisfied if a fire occurs in area A-18.

A spurious SIS starts the charging sequence which starts the CCPs and opens the BIT flowpath valves. For a fire in this area, Train B CCP is credited for PFSSD since a number of Train A PFSSD components could be lost. Train B BIT flowpath valves EMHV8801B and EMHV8803B are unaffected and would open on a SIS. The Train B RWST to CCP suction header valve BNLCV0112B is unaffected and would open on a SIS. Also, the Train B CCP mini flow valve BGHV8111 is unaffected and Train B CCW flow to the seal water heat exchanger is unaffected to ensure cooling of the recirc flow, RCP seal return and CCP oil cooler. Therefore, the Train B charging pump will not be affected by a spurious SIS caused by a fire in this area.

A start of the credited CCW system (Train B) will not adversely impact the system. The Train B ESW system is unaffected and will start on a spurious SIS, providing necessary cooling water to the CCW heat exchanger.

A start of the AFW pumps will not adversely impact PFSSD. The Train B AFW pump is credited for a fire in this area. Suction from the CST to the Train B AFW pump is unaffected. Discharge flow will either return to the CST or flow to the steam generators through the discharge control valves. Therefore, the Train B AFW pump is unaffected by a spurious SIS caused by a fire in this area.

A start of the RHR pumps due to a spurious SIS will not adversely impact either pump. The RWST supply to the pumps is not affected unless Train A containment sump valve EJHV8811A spuriously opens, in which case BNHV8812A will automatically close, causing a loss of suction and damage to the Train A RHR pump. Train B containment sump valve EJHV8811B is unaffected and will not spuriously open. Component cooling water is available

to the Train B RHR heat exchanger. Therefore, the Train B RHR pump will not be affected by a spurious SIS caused by a fire in this area.

A spurious Containment Spray Actuation Signal (CSAS) due to spurious high containment pressure can be mitigated by placing CS pump control hand switches ENHIS0003 and ENHIS0009 in pull-to-lock. These switches are located on control room panel RL017. Indication in the Control Room for SI and CS pump operation is unaffected by a fire in A-18.

Based on the above discussion, a spurious SIS and CSAS can occur if a fire occurs in this area. Credited PFSSD equipment will not be damaged by the spurious SIS. The CSAS can be terminated from the control room. Therefore, a spurious SIS and CSAS will not adversely impact PFSSD.

References: E-15000, XX-E-013, E-13AB21, E-13BB16, E-13EM01, E-13EN01, E-13EN03, E-13GN05, E-1F9431, M-12AB01, M-12BB02, M-12BN01, M-12EJ01, M-12GN01, OFN KC-016

5.2.7 Pressurizer Level Transmitters

PFSSD requires pressurizer level indication to be available. Pressurizer level indication is provided by level transmitters BBLT0459 and BBLT0460. Cables associated with BBLT0459, that run through A-18, are summarized in Table A-18-4. Cables associated with BBLT0460 do not run through fire area A-18 and are unaffected by a fire in area A-18.

Therefore, pressurizer level indication is available for a fire in area A-18 using BBLT0460/BBLI0460A.

References: E-15000, E-1F9301, E-13BB16

5.2.8 Reactor Head Vent Valves

PFSSD requires that one of the two reactor vessel head vent valves on each flow path (2 flow paths total) be closed to prevent loss of inventory and uncontrolled depressurization of the RCS. Cables for two of the four head vent valves run through area A-18. The head vent valves are considered high-low pressure interfaces, so consideration of multiple proper polarity hot shorts is required.

Cables for head vent valves BBHV8001B and BBHV8002B are not run through A-18. Therefore, isolation of the separation group 4 flow path is assured. Either BBHV8001A or BBHV8002A needs to be closed to prevent RCS depressurization through the separation group 1 head vent flow path.

Cable 11BBK30AA is run in cable tray through area A-18 and enters containment penetration assembly ZNE277. The cable tray and penetration assembly contain multiple 125 VDC cables that could present a source for 125 VDC power to energize the valve. An intra-cable short in cable 11BBK30AA would not cause the valve to open because this failure mode would not energize the control solenoid. However, a fire that affects the cable tray and containment penetration assembly ZNE277 could cause a single or multiple proper polarity inter-cable hot short that would open valve BBHV8001A.

Cable 11BBK30CA associated with valve BBHV8002A is run in conduit through area A-18 and enters containment penetration assembly ZNE278. The conduit carries one other cable (11BGK48CB) which is a control cable for excess letdown isolation valve BGHV8153A and is normally de-energized. The containment penetration assembly contains multiple 125 VDC cables that could present a source of 125 VDC power to energize and open the valve. An intra-cable short in cable 11BBK30CA would not cause the valve to open because this failure

mode would not energize the control solenoid. However, a fire that affects containment penetration assembly ZNE278 could cause a single or multiple proper polarity inter-cable hot short that would open valve BBHV8002A.

Based on this discussion, the Train A reactor head vent valves could open if a fire occurs in area A-18. This would cause a loss of RCS inventory that is within the makeup capability of the charging pumps. Therefore, spurious opening of the Train A RCS head vent flowpath will not adversely impact PFSSD.

References: E-15000, E-1F9301, M-12BB04, E-13BB30, E-1R1413D, E-1R1423A, E-1R1423C, E-1R1433A, E-1R1433B

5.2.9 Charging Flow to Regenerative Heat Exchanger Isolation Valves

PFSSD requires charging flow to be directed to the RCP seals. To ensure adequate flow to the RCP seals, flow diversion to the regenerative heat exchanger needs to be prevented. Valves BGHV8105 and BGHV8106 are included in the PFSSD equipment list to accomplish this task. Manual valve BG8402B is also included to provide an alternate means of closing this flow path during alternate safe shutdown using OFN RP-017.

Cables associated with BGHV8106 are run in area A-18 and could be damaged by a fire in this area, preventing valve BGHV8106 from being closed from the control room. However, cables associated with valve BGHV8105, and its hand switch (BGHIS8105), are unaffected by a fire in area A-18. Therefore, valve BGHV8105 can be used to isolate flow to the regenerative heat exchanger and therefore satisfy the PFSSD requirement.

References: E-15000, XX-E-013, E-1F9102, E-13BG11A, M-12BG03

5.2.10 Excess Letdown Isolation Valves

PFSSD requires the excess letdown path be isolated to prevent loss of inventory and uncontrolled depressurization of the RCS. To accomplish this, either normally closed valve BGHV8153A or BGHV8154A must be maintained closed and either normally closed valve BGHV8153B or BGHV8154B must be maintained closed. Valves BGHV8153B and BGHV8154B are unaffected by a fire in area A-18.

Cable 11BGK48CB associated with valve BGHV8153A is run in conduit through area A-18 and enters containment penetration assembly ZNE278. The conduit carries one other cable (11BBK30CA), which is a control cable for RCS head vent valve BBHV8002A and is normally de-energized. The containment penetration assembly contains multiple 125 VDC cables that could present a source of 125 VDC power to energize and open the valve. An intra-cable short in cable 11BGK48CB would not cause the valve to open because this failure mode would not energize the solenoid. However, a fire that affects containment penetration assembly ZNE278 could cause a single or multiple proper polarity inter-cable hot short that would open valve BGHV8153A.

Cable 11BGK48DB associated with valve BGHV8154A is run in cable tray through area A-18 and enters containment penetration assembly ZNE277. The cable tray and penetration assembly contain multiple 125 VDC cables that could present a source for 125 VDC power to energize the valve. An intra-cable short in cable 11BGK48DB would not cause the valve to open because this failure mode would not energize the control solenoid. However, a fire that affects the cable tray and containment penetration assembly ZNE277 could cause a single or multiple proper polarity inter-cable hot short that would open valve BGHV8154A .

Based on this discussion, the Train A excess letdown flow path could open if a fire occurs in area A-18. This would cause a loss of RCS inventory that is within the makeup capability of

the charging pumps. Calculation WCNOC-CP-002 shows that a failed open excess letdown flowpath does not need to be mitigated. Therefore, spurious opening of the Train A excess letdown flow path will not adversely impact PFSSD.

References: E-15000, E-1F9301, M-12BG01, E-13BG48, E-1R1413D, E-1R1423A, E-1R1423C, E-1R1433A, E-1R1433B, WCNOC-CP-002

5.2.11 Containment Air Coolers

PFSSD requires at least one Train of containment air coolers. Valves EFHV0031, EFHV0033, EFHV0045 and EFHV0049 are associated with Train A containment air coolers SGN01A and SGN01C. All four valves are required to be open to ensure a supply of Essential Service Water (ESW) to the containment air coolers. As shown in Table A-18-4, circuits for all four valves are run in area A-18 and may be damaged by a fire, causing loss of control of these valves.

A fire in area A-18 uses train B containment air coolers SGN01B and SGN01D. Valves EFHV0032, EFHV0034, EFHV0046 and EFHV0050 control
ESW flow to the Train B containment air coolers. Circuits for these valves are run in a different fire area and are unaffected by a fire in area A-18. Therefore, ESW flow to/from Train B containment air coolers SGN01B and SGN01D will be available.

Power and control circuits for containment air coolers SGN01A and SGN01C are run in area A-18. Power and control circuits for containment air coolers SGN01B and SGN01D are run in a separate fire area and are unaffected by a fire in area A-18.

Based on the above discussion, Train B containment air coolers SGN01B and SGN01D are unaffected by a fire in area A-18.

References: E-15000, E-1F9403, E-1F9441, E-13EF07, E-13EF08, E-13EF09, E-13GN02

5.2.12 Thermal Barrier Cooling

The Wolf Creek plant design provides two redundant methods of cooling the RCP seals, thermal barrier cooling using CCW and seal injection using the CCP. The PFSSD methodology at Wolf Creek requires tripping the RCPs and performing a natural circulation cooldown upon loss of both thermal barrier cooling (TBC) and seal injection. If only one method is lost, continued operation of the RCP is allowed by present established procedures until the other method can be re-established.

Valves BBHV0013, BBHV0014, BBHV0015, BBHV0016, EGHV0058, EGHV0126 and EGHV0132 provide isolation capability for CCW flow to/from the RCP thermal barriers. Cables associated with these components are located in area A-18. If the valves fail to the open position, CCW would continue to flow to the RCP components, including the thermal barrier. This continued flow of water will not adversely impact PFSSD. If the valves fail to the closed position, CCW flow to the thermal barrier could be lost. This is acceptable since RCP seal injection is available.

Flow transmitters BBFT0017, BBFT0018, BBFT0019 and BBFT0020 are associated with valves BBHV0013, BBHV0014, BBHV0015 and BBHV0016, respectively. The flow transmitters monitor flow in the CCW piping and shut the valves on high CCW flow. Cables associated with these flow transmitters are run in this area. Damage to these cables could cause a spurious high CCW flow signal and close the valves. Damage to the valve cables could prevent re-opening the valves.

Loss of thermal barrier cooling would be indicated in the control room as a reduction in flow on flow indicators EGFI0128 and EGFI0129. Therefore, operators can diagnose a loss of thermal barrier cooling.

Based on the above discussion, a fire in area A-18 could affect CCW flow to/from the RCP thermal barriers. RCP seal injection is unaffected.

References: E-15000, XX-E-013, E-13BB03, E-13BB28, E-13EG09, E-13EG17A, E-13EG18, E-1F9303, M-12BB03, M-12EG03

5.2.13 RCS to RHR Isolation Valves

PFSSD requires isolation of the RCS to RHR pump flow path during hot standby and opening of this flow path when initiating RHR. RHR Train B is used for a fire in area A-18. Cables for EJHV8701A (Train A) and EJHV8701B (Train B) are run through area A-18. Damage to these cables could cause the associated valve to spuriously open or prevent operation of the valve from the control room.

During hot standby, redundant valves BBPV8702A and BBPV8702B are unaffected by a fire in area A-18 and are available to ensure the RCS to RHR flow path remains isolated. This will also ensure the RCS does not drain to the containment sump if valves EJHV8811A or EJHV8811B were to spuriously open.

When transitioning to RHR Train B for cold shutdown decay heat removal, valves EJHV8701B and BBPV8702B need to be open. Valve BBPV8702B is unaffected by the fire and can be opened from the control room. To open EJHV8701B, a cold shutdown repair is needed or a containment entry made to open the valve. Cold shutdown repairs and local operator actions performed within 72 hours are allowed per Wolf Creek's commitments to 10CFR50, Appendix R, Section III.G.1.

5.2.14 Containment Sump Isolation Valves

PFSSD requires that loss of inventory to the containment sump be prevented. Section 5.2.13 shows that loss of RCS inventory to the containment sump is prevented by maintaining valves BBPV8702A and BBPV8702B closed during hot standby.

Circuits for EJHV8811A are run through area A-18. Damage to these circuits could cause valve EJHV8811A to spuriously open. However, this valve is on the Train A side which is not used for a fire in area A-18. Valve BBPV8702A is maintained closed when operating the Train B RHR system. Therefore, loss of RCS inventory through valve EJHV8811A is prevented by maintaining valve BBPV8702A closed.

Draindown of the RWST to the containment sump also needs to be prevented. If valve EJHV8811A were to spuriously open and valve BNHV8812A stays open, the RWST will drain to the containment sump. Circuits for BNHV8812A are not run through area A-18. If valve EJHV8811A fully opens, valve BNHV8812A will automatically close, preventing draindown of the RWST to the containment sump. If valve EJHV8811A spuriously opens but stalls before reaching full open position, valve BNHV8812A will not automatically close. If this occurs, operators will recognize a decreasing RWST level using any of the four RWST level indicators and take action to close BNHV8812A using BNHIS8812A in the main control room.

Circuits for EJHV8811B are run in a separate fire area and are unaffected by a fire in area A-18. Therefore, loss of RCS and RWST inventory to the containment sump through valve EJHV8811B is prevented.

References: E-15000, E-13BN03, E-13EJ06A, E-13EJ06B, XX-E-013, M-12BN01, M-12EJ01, E-1F9205, E-1F9301

5.2.15 RHR Discharge Valves

PFSSD requires the discharge valves on the operating RHR Train be open to provide RHR flow to the RCS cold leg via the accumulator injection lines. Train B RHR is used for a fire in area A-18; therefore, valves EJHCV0607 and EJHV8809B need to be open during RHR.

Circuits for valve EJHV8809A (Train A) are run through area A-18. Circuits for EJHCV0607 and EJHV8809B are located in a different fire area and are unaffected by a fire in area A-18.

Therefore, RHR Train B outlet valves EJHCV0607 and EJHV8809B are available for a fire in area A-18.

References: E-15000, M-12EJ01, M-12EP01, E-13EJ09A

5.2.16 Boron Injection Tank Flowpath

The Boron Injection Tank (BIT) flowpath is credited for reactivity control and reactor coolant makeup. For reactivity control, the BIT flowpath is credited as an alternate source of boration in the event RCP seal injection is unavailable. Based on Calculation XX-E-013, RCP seal injection will provide sufficient boration to achieve and maintain cold shutdown reactivity conditions. Therefore, the BIT flowpath is not required for reactivity control if RCP seal injection is available. Since RCP seal injection is limited to 5 gpm per seal or 20 gpm total injection to the RCS, an additional RCS charging flowpath is required for adequate RCS makeup during plant transition from hot standby to cold shutdown. The BIT injection path was selected as the additional RCS charging flowpath.

A fire in area A-18 uses CCP B since circuits for CCP A may be affected by the fire. Also, a fire in area A-18 has the possibility to cause a loss of inventory through the letdown flow path until the letdown isolation valves can be failed closed. In addition, a loss of inventory could occur due to spurious opening of the Train A reactor head vent valves (Section 5.2.8) and the Train A excess letdown valves (Section 5.2.10). Therefore, charging through the BIT flow path may be required for hot standby. In addition, as discussed above, the BIT flowpath is required for transition to cold shutdown.

To ensure a flow path from CCP B is available, BIT inlet valve EMHV8803B must be open and either BIT outlet valve EMHV8801A or EMHV8801B must be open. Cables for valves EMHV8803B and EMHV8801B are not run through area A-18 and are unaffected by the fire.

Therefore, CCP B to RCS flow path through the BIT is assured for a fire in area A-18.

References: E-15000, E-13EM02, E-13EM02A, E-13EM02B, E-13EM02C, M-12EM02

5.2.17 Safety Injection Accumulator Isolation Valves

PFSSD requires isolation of the SI accumulators prior to reducing RCS pressure below the injection pressure to avoid unnecessary accumulator discharge. This is accomplished by closing valves EPHV8808A, EPHV8808B, EPHV8808C and EPHV8808D. These valves are normally open with the MCC breaker locked in the open position. Cables for valves EPHV8808A and EPHV8808C are run in area A-18 and are listed in Table A-18-4.

Since the breakers for these valves are normally open, damage to these cables will not cause the valve to spuriously change position. However, damage to the cables will prevent closing the associated valve from the control room after power is restored.

The SI accumulators need to be isolated during cold shutdown, prior to the RCS reaching 1000 psig. If necessary, a containment entry can be made to manually close the valves.

A fire in area A-18 may require a containment entry to close valves EPHV8808A and EPHV8808C if these valves are unresponsive from the control room.

References: E-15000, M-12EP01, E-13EP02A. XX-E-013

5.2.18 Auxiliary Feedwater Pump Room Coolers

PFSSD requires the operating train auxiliary feedwater pump room cooler to be available. A fire in area A-18 uses AFW Train B to supply feedwater to the steam generators.

Cables associated with Train A room cooler SGF02A are run through area A-18. Damage to these cables could prevent the operation of SGF02A. Cables associated with Train B room cooler SGF02B are run through a separate area and are unaffected by a fire in area A-18.

Auxiliary Feedwater Pump B room cooling is assured for a fire in area A-18 using SGF02B and Train B ESW.

References: E-15000, E-13GF01, M-12GF01

5.2.19 PFSSD Equipment Power Availability

PFSSD requires that one train of electrical systems required to power PFSSD components be available and unaffected by a fire. Cables that, if damaged, could result in a loss of power to the associated bus are run in fire area A-18.

Damage to cables 11NGG01AD and 11NGG01AE will cause a loss of power to 480 VAC MCC NG01B. Damage to cable 11NGG01AJ will cause a loss of power to 480 VAC MCC NG01T. Damage to cable 11NGG01BF will cause a loss of power to 480 VAC MCC NG03T. If this occurs, a number of Train A PFSSD components will be lost.

Cables for redundant Train B MCCs NG02B, NG02T and NG04T are unaffected by a fire in area A-18. Therefore, a fire in area A-18 will not disrupt power availability to required Train B PFSSD components.

Damage to cable 11PNG01AE will cause a loss of one of the two sources of power to non-class 1E 120 VAC distribution panel PN07. However, cables associated with the alternate power source from PG19GFR3 are unaffected. Therefore, PN07 will remain available to energize its respective PFSSD loads.

Both sources of power to non-class 1E 120 VAC distribution panel PN08 are unaffected by a fire in this area. Therefore, panel PN08 is available to supply its respective PFSSD loads.

References: E-15000, XX-E-013, E-1F9421, E-1F9426, E-03NG01, E-13PN01, E-13PN01A

5.2.20 Source Range Monitoring

PFSSD requires source range (SR) flux monitoring to be available. Source range monitoring is provided by source range monitors SENE0031, SENE0032, SENY0060A & B, and SENY0061A & B. Cables run in fire area A-18 associated with these monitors are listed in Table A-18-4.

Cables for SENE0031 and SENY0060A/B run in area A-18. Cables for SENE0032 and SENY0061A/B do not run in area A-18 and are unaffected by a fire in area A-18.

Source range monitoring is available for a fire in area A-18 using SR monitors SENE0032 and SENY0061A/B.

For a more detailed evaluation on Source Range monitoring, see Calculation XX-E-013, Attachment 3.

References: E-15000, E-13SE01, E-13SE07, XX-E-013

5.2.21 Turbine Driven Auxiliary Feedwater Pump (TDAFP)

To prevent uncontrolled cooldown through the TDAFP, valves ABHV0005 and ABHV0006 or valves FCHV0312 or FCHV0313 are required to be closed. Valve FCHV0312 is located downstream of valves ABHV0005 and ABHV0006 in the 4-inch steam line to PAL02. This valve is normally closed and will prevent uncontrolled blowdown if valves ABHV0005 or ABHV0006 were to spuriously open. Valve FCHV0313 is located downstream of valve FCHV0312. This valve controls steam pressure entering the TDAFP turbine to control pump speed.

Cables associated with ABHV0005, ABHV0006, FCHV0312 and FCFV0313 are run in area A-18. Damage to cables associated with these valves could cause all four valves to spuriously open at the same time, causing uncontrolled blowdown through the TDAFP. If this occurs, the TDAFP would trip on high speed and valve FCFV0313 would mechanically shut, isolating the blowdown path.

Uncontrolled blowdown through the TDAFP is avoided by FCFV0312 automatically closing due to TDAFP high speed.

References: E-15000, E-1F9101, M-12FC02, M-12AB02, E-13FC23, E-13AB01, E-13AB01A, E-13FC23, E-13FC24, E-13AL05A, E-13AL05B, E-13SA23, XX-E-013

5.2.22 Auxiliary Feedwater Pump Pressure Transmitters

PFSSD requires at least one train of AFW be available to supply feedwater to at least two steam generators. A fire in area A-18 uses Train B AFW pump. Cables associated with AFW pressure transmitters, run through area A-18, are discussed in this section.

The normal PFSSD supply of water to the AFW pumps is from the Condensate Storage Tank (CST). Three pressure transmitters (ALPT0037, ALPT0038 and ALPT0039) are located on the CST supply to the AFW pumps and are used to indicate CST pressure in the control room. In addition, these pressure transmitters initiate switchover to ESW if 2 out of 3 transmitters read low CST pressure. If necessary, CST level can be calculated manually using CST pressure.

Cables associated with pressure transmitter ALPT0037 are not run in area A-18. Cable 12ALI08BA is an instrument cable associated with pressure transmitter ALPT0038 and is run through area A-18. Damage to this cable will not prevent operation of the B Train AFW pump. Cable 14ALI08CA is an instrument cable associated with pressure transmitter ALPT0039. This cable is run in conduit 114J3C1C, which has been wrapped with a 1-hour fire rated material in area A-18. Consequently, there is reasonable assurance that a fire in area A-18 will not cause damage to cable 14ALI08CA and a spurious switchover to ESW will not occur.

Cable 12ALI07KD is an instrument cable associated with pressure transmitter ALPT0026. This pressure transmitter is located on the suction side of the TDAFP. A spurious signal on this pressure transmitter circuit will not prevent operation of the B Train AFW pump.

Cable 14ALI07HD is an instrument cable associated with pressure transmitter ALPT0024. This pressure transmitter is located on the suction side of the B MDAFP, which is required for a fire in area A-18. This cable is run in conduit 114J3C1C which has been wrapped with a 1-hour fire rated material. Consequently, there is reasonable assurance that a fire in area A-18 will not cause damage to cable 14ALI07HD.

Based on this discussion, damage to cables associated with ALPT0026 and ALPT0038 will not prevent AFW supply to the steam generators.

References: E-15000, XX-E-013, E-1F9202, E-1F9204, M-12AL01, E-13AL07B, E-13AL08

5.2.23 Auxiliary Feedwater Flow Transmitters

PFSSD requires flow to at least two steam generators be established. As stated previously, the Train B AFW flow path is available to supply feedwater to Steam Generators A and D.

Flow indication in the control room is necessary to ensure required flow to the steam generators. Flow transmitters ALFT0001 and ALFT0007 measure flow to Steam Generators D and A, respectively and indicate in the control room.

Cables associated with ALFT0001 and ALFT0007 are run in area A-18. These cables are run in conduit 114J3C1C in area A-18 which has been wrapped with a 1-hour fire rated material. In addition, area A-18 is provided with automatic detection and suppression throughout. This configuration meets the requirements of Wolf Creek's commitments to 10CFR50, Appendix R Section III.G.2.c.

A fire in area A-18 will not affect AFW to steam generator A and D flow transmitters ALFT0007 and ALFT0001 nor prevent AFW to steam generator flow indication in the control room.

References: E-15000, E-1F9204, M-12AL01, E-13AL07B, E-13AL09, DCP 011038

5.2.24 Letdown Isolation Valves

Letdown isolation valves BGLCV0459 and BGLCV0460 are isolation valves installed in series on the inlet side of the regenerative heat exchanger. PFSSD requires that either of these valves be closed.

15BGK10AA is a power/control cable for the BGLCV0459 solenoid valve (BGHY0459). Air supplied by an open (energized) solenoid valve will open valve BGLCV0459. A closed (de-energized) solenoid valve will cause loss of air pressure and closure of valve BGLCV0459.

15BGK10BA is a power/control cable for the BGLCV0460 solenoid valve (BGHY0460). Air supplied by an open (energized) solenoid valve will open valve BGLCV0460. A closed (de-energized) solenoid valve will cause loss of air pressure and closure of valve BGLCV0460.

Either BGLCV0459 or BGLCV0460 must be closed or letdown orifice isolation valves BGHV8149A, BGHV8149B, and BGHV8149C must be closed. The cables for BGLCV0459 and BGLCV0460 are routed in a common enclosure in cable trays. A hot short on the cables could cause the valves to open. A hot short on 15BGK10AA and 15BGK10BA prevents closing BGLCV0459 and BGLCV0460 from the control room. Other cables routed in the cable trays have the proper voltage for hot shorts. The hot shorts bypass MCB hand switches for BGLCV0459 and BGLCV0460. BGLCV0459 and BGLCV0460 constitute a high/low pressure interface, so multiple simultaneous hot shorts of the proper polarity was considered.

Letdown orifice isolation valves BGHV8149A, BGHV8149B, and BGHV8149C are listed as PFSSD components because of the interlock between these valves and BGLCV0459 and BGLCV0460. The interlock prevents closure of the letdown valves when any one or more orifice isolation valves are open. Cables associated with all three letdown orifice isolation valves are located in this fire area. Damage to these cables could prevent closure of the valves from the control room. Therefore, a fire in area A-18 will prevent closure of all three letdown orifice isolation valves (BGHV8149A, BGHV8149B, and BGHV8149C) as well as the two letdown isolation valves (BGLCV0459 and BGLCV0460).

BGHV8152 is located in the low-pressure piping rated for only 600 psi pressure down stream of BGLCV0459 and BGLCV0460. Isolating BGHV8152 with the reactor pressure above 600 psi will cause relief valve BGV8117 to open to protect the pipe, and discharge the water to the PRT. A maximum of 195 gpm can be passed through the three orifice isolation valves if they are all open. The centrifugal charging pump capacity is 150-gpm. Therefore approximately 45-gpm could be potentially lost while BGLCV0459 and BGLCV0460 remain open.

Valves BGLCV0459 and BGLCV0460 are air operated and fail in the closed position. The valves are located in containment. Instrument air to containment is controlled by valve KAFV0029, which is unaffected by a fire in area A-18. Therefore, hand switch KAHIS0029 can be used to close the valve from the control room and isolate instrument air to containment. Pressurizer level indication is available using BBLI0460A.

Based on the above discussion, letdown valves BGLCV0459 and BGLCV0460 can be closed from the control room if a fire occurs in area A-18.

References: E-15000, XX-E-013, E-13BG10, E-13BG35, E-13KA02, E-1R1444B, E-1R1444C, E-1F9301, M-12BG01, M-12KA01

5.2.25 Reactor Coolant Pumps

The reactor coolant pumps are not credited in the PFSSD analysis. However, the capability to stop the pumps from the control room in the event of a loss of all seal cooling is credited. Westinghouse Technical Bulletin TB-04-22, Rev. 1 recommends that if all seal cooling is lost (RCP seal injection and thermal barrier heat exchanger flow), operators need to stop the pumps before a seal LOCA occurs.

One control cable associated with reactor coolant pumps A and B is run in fire area A-18. Damage to these cables in the event of a fire could prevent operators from stopping the A and B RCPs from the control room. However, a fire in A-18 will not cause a loss of all seal cooling since RCP seal injection remains available.

Based on the above discussion, the inability to trip the A and B RCPs from the control room will have no adverse impact on PFSSD. The pumps can continue to operate, providing forced flow circulation. If the pumps spuriously stop, natural circulation cooldown can be used.

References: E-15000, XX-E-013, E-13BB01, Westinghouse TB-04-22 Rev. 1

5.2.26 Normal Pressurizer Spray

The normal pressurizer spray valves are included in the PFSSD design because spurious operation of pressurizer sprays can cause a decrease in pressure which can lead to boiling in the core. The pressurizer spray valves are part of the pressurizer pressure control system.

The pressurizer normal spray valves (BBPCV0455B and BBPCV0455C) operate off a signal from the Ovation pressurizer pressure control system. The operation of the pressure control system is discussed in Calculation XX-E-013.

Instrument cables 11BBI16KB and 13BBI16MB associated with pressurizer pressure transmitters BBPT0455 and BBPT0457 are run in fire area A-18. As discussed in Calculation XX-E-013, Appendix 1, the Ovation pressurizer pressure control system uses 4-channel verification from all four pressurizer pressure transmitters to operate the pressurizer spray system. Failure of a single channel will not cause the spurious operation of the spray valves since the system uses the 2nd highest input as the validated signal. Damage to two channels will not cause the spray valves to open because both channels would have to fail to the exact same value at the exact same time and therefore this failure mode is not credible.

Cable 15BBI19AA associated with pressurizer spray valve BBPCV0455B, and cable 15BBI19BA associated with pressurizer spray valve BBPCV0455C are run in this area. Damage to these cables could cause the spurious opening of the spray valves.

The pressurizer spray valves are electro/pneumatic operated and loss of air pressure will close the valves. The air supply comes from the compressed air system. Closing valve KAFV0029 using KAHIS0029 on RL024 will isolate compressed air to containment which will cause the pressurizer spray valves to close or prevent them from opening. Based on WCNOC-CP-002, spray flow needs to be stopped within 50 minutes. Since this is a control room action, this can be completed well within 50 minutes.

Based on the above discussion, the pressurizer spray valves could spuriously open if a fire occurs in this area. Pressurizer spray can be stopped by closing valve KAFV0029 from the main control room. Pressurizer pressure indication is available using BBPI0456 and BBPI0458.

1.0 GENERAL AREA DESCRIPTION

Fire area A-19 is located on the 2047 elevation of the Auxiliary Building and includes the rooms listed in Table A-19-1.

Table A-19-1
Rooms Located in Fire Area A-19

ROOM #	DESCRIPTION
1504	Containment Purge Exhaust & Mech Equipment Room
1506	Containment Purge Supply Air Handling Unit Room
1513	Control Building Ventilation Supply A/C Unit Room

Fire area A-19 has no fixed automatic suppression installed. The area is provided with automatic fire detection throughout.

2.0 PRIMARY EQUIPMENT USED FOR PFSSD

Table A-19-2 lists each system credited for post-fire safe shutdown and provides a discussion regarding the availability of the system to perform its Post Fire Safe Shutdown (PFSSD) function if a severe fire occurs in this area. For a summary of the area analysis results, see Section 8.0 of the Fire Area Analysis Narrative section.

Table A-19-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-19

System	System Name	PFSSD Function*	Comments
AB	Main Steam	R, M, H, P, S	Steam generator A ARV ABPV0001 could spuriously open. If necessary, fail the valve closed by closing valves KAV1435 (air) and KAV1364 (nitrogen) and bleeding air from the regulator.
AC	Main Turbine	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-19.
AE	Main Feedwater	H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-19.
AL	Aux. Feedwater System	H, P	Train A MDAFP may not be available. Train B MDAFP is available using either the CST or ESW as the suction source. The TDAFP is available using Train B ESW as the suction source. The suction from the CST and Train A ESW may be affected. The TDAFP can be lined up to any of the four steam generators.
AP	Condensate Storage System	H	The CST is available to supply AFW to the Train B MDAFP only.
BB	Reactor Coolant System	R, M, H, P, S	Power to valves BBPV8702A and BBPV8702B could be lost. If necessary, perform a cold shutdown repair to restore power or make a containment entry to manually open the required valve. RCP thermal barrier cooling could be affected due to spurious closure of BBHV0013, BBHV0014, BBHV0015 and BBHV0016. RCP seal injection is available.
BG	Chemical and Volume Control System	R, M, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-19.
BM	Steam Generator Blowdown System	R, M, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-19.
BN	Borated Refueling Water Storage System	R, M, H	Level transmitters BNLT0930, BNLT0931 and BNLT0932 may be affected. Level transmitter BNLT0933 is available. A fire-induced SIS will not occur so a spurious low-low level in the RWST will not cause a draindown of the RWST into the containment sump.
EF	Essential Service Water System	H, S	Both trains of ESW are available except that the Train A ESW to Train A CCW heat exchanger flowpath may be affected.

Table A-19-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-19

System	System Name	PFSSD Function*	Comments
EG	Component Cooling Water System	S	The Train A CCW system may be affected. The Train B CCW system is unaffected by a fire in this area. Valves EGHV0061, EGHV0127 and EGHV0133 could be affected, potentially causing a loss of thermal barrier cooling. CCW flow indicators EGFI0128 and EGFI0129 are unaffected. Valve EGHV0101 could spuriously open or may not open when operating Train A RHR. Valve EGHV0102 is unaffected.
EJ	Residual Heat Removal System	M, H, P	The Train A RHR system may be affected. The Train B RHR system is unaffected by a fire in this area. Containment sump isolation valves EJHV8811A and EJHV8811B could spuriously open, causing a draindown path from the RWST to the containment sump. Valves BNHV8812A and BNHV8812B will automatically close, as designed, when EJHV8811A and EJHV8811B, respectively, reach full open position, mitigating draindown. However, if either EJHV8811A or EJHV8811B stall before reaching full open position, BNHV8812A or BNHV8812B will not automatically close. In this case, operators can close BNHV8812A and BNHV8812B using BNHIS8812A and BNHIS8812B, respectively, in the main control room.
EM	High Pressure Coolant Injection	R, M	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-19.
EN	Containment Spray	R, M	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-19.
EP	Safety Injection Accumulators	H	Power to SI accumulator tank valves EPHV8808B and EPHV8808D could be affected. Prior to the RCS reaching 1000 psi, it may be necessary to make a containment entry to close the valves or bleed nitrogen from the accumulator to prevent injection.
FB	Auxiliary Steam	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-19.
FC	Auxiliary Turbines	R, H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-19.
GD	ESW Pump House HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-19.
GF	AFW Pump Room Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-19.
GK	Control Room and Class 1E Switchgear Room Coolers	S	Train A control room A/C unit SGK04A may be affected. Train B control room A/C unit SGK04B is unaffected by a fire in this area.

Table A-19-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-19

System	System Name	PFSSD Function*	Comments
GL	Auxiliary Building HVAC	S	Train A CCW room cooler SGL11A may be affected. Train B CCW room cooler SGL11B is unaffected by a fire in this area.
GM	Emergency Diesel Generator Room HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-19.
GN	Containment Coolers	S	Train B containment coolers could be affected. Train A containment coolers are unaffected. Containment pressure transmitter GNPT0934 may be affected. The remaining containment pressure transmitters are unaffected.
JE	Diesel Fuel Oil	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-19.
KA	Instrument Air	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-19.
KC	Fire Protection	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-19.
KH	Service Gas	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-19.
KJ	Standby Diesel Engine	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-19.
MA	Main Generation	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-19.
MR	Startup Transformer	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-19.
NB	4.16 kV System	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-19.

3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD

This section describes operator actions that may need to be performed inside or outside the control room to achieve and maintain hot standby if a fire occurs in area A-19. This section also describes cold shutdown repairs that may need to be made to achieve and maintain cold shutdown conditions. Operator actions are proceduralized in OFN KC-016.

3.1 ACTIONS OUTSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

Operator Manual Actions (OMAs) are those actions outside the main control room required to achieve and maintain hot standby. OMAs are identified in E-1F9900 and were determined from thermal hydraulic analysis WCNOC-CP-002. Applicable E-1F9900 OMAs are annotated herein. All other actions outside the control room are desirable for plant control in support of hot standby but not required to achieve and maintain hot standby.

3.1.1 Steam Generator Atmospheric Relief Valves

It may be necessary to fail close steam generator ARV ABPV0001 by closing valves KAV1435 (air) and KAV1364 (nitrogen) and bleeding air from the regulator.

3.2 ACTIONS INSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

3.2.1 Auxiliary Feedwater

It may be necessary to line up AFW using the TDAFP, supplied by Train B ESW or using the Train B MDAFP supplied by either the CST or ESW. Since ARV ABPV0001 may be affected, it may be necessary to use the TDAFP in order to cooldown using at least two steam generators.

3.2.2 Mitigation of RWST Draindown to Containment Sump

If a fire occurs in area A-19, it may be necessary to close valves BNHV8812A and BNHV8812B from the control room using BNHIS8812A and BNHIS8812B, respectively, to mitigate draindown of the RWST into the containment sump. This condition could occur due to EJHV8811A and/or EJHV8811B spuriously opening but stalling before reaching full open position, thereby not providing the permissive for BNHV8812A and BNHV8812B to close. RWST level indication is available using level indicator BNLI0933.

3.2.3 Component Cooling Water

Train A CCW could be affected by a fire in this area. If this occurs, swap to Train B CCW using normal operating procedures.

3.3 ACTIONS TO ACHIEVE AND MAINTAIN COLD SHUTDOWN

3.3.1 Residual Heat Removal System

It may be necessary to repair damage to the NG02B incoming power cables 14NGG01AD and 14NGG01AE to restore power to BBPV8702A and BBPV8702B prior to starting RHR, or a containment entry should be made to open the desired valve.

3.3.2 SI Accumulator Isolation

It may be necessary to repair damage to the NG02B incoming power cables 14NGG01AD and 14NGG01AE to restore power to valves EPHV8808B and EPHV8808D to allow them to be isolated prior to the RCS reaching ≅ 1,000 psi. Otherwise, nitrogen pressure can be relieved from tanks B and D to prevent injection. Valves EPHV8808A and EPHV8808C are unaffected.

4.0 CONCLUSION

With some exceptions, redundant Post-Fire Safe Shutdown capability exists if a severe fire occurs in this area. For those exceptions, feasible manual actions are available and are unaffected by the fire. Manual actions are documented in Section 3.0.

5.0 DETAILED ANALYSIS

This section describes the detailed cable-by-cable analysis for a fire in area A-19.

5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA A-19

There is no PFSSD equipment located in area A-19. The area only contains cables associated with PFSSD equipment located in a different fire area. For an evaluation of the PFSSD cables located in area A-19, see Section 5.2.

5.2 PFSSD CABLE EVALUATION

Table A-19-3 lists all the PFSSD cables (S. in E-15000) located in fire area A-19. The applicable evaluation section is also listed in Table A-19-3.

Table A-19-3

5.2.1 Steam Generator Atmospheric Relief Valves

PFSSD requires at least two steam generator atmospheric relief valves (ARV) be controlled and the other two closed. The ARVs are normally closed and require air pressure to open. Each valve is controlled by a pressure transmitter input signal from a pressure transmitter installed on the outlet side of the steam generator. The relief valve opens when pressure reaches a designated setpoint.

One cable associated with Steam Generator ARV ABPV0001 runs in area A-19. Cables associated with Steam Generator ARVs ABPV0002, ABPV0003 and ABPV0004 are not run in area A-19.

Cable 11ABI20EE runs through area A-19 from ABPY0001 in room 1508 to panel RP053AC in room 3605. Damage to this cable could cause the spurious opening of valve ABPV0001. If this occurs, an operator would have to close the ARV by isolating air and nitrogen to the valve and bleeding air from the regulator to fail the valve closed. This is done by closing valves KAV1435 (air) and KAV1364 (nitrogen) which can be accessed without having to enter fire area A-19.

Based on the above discussion, manual actions are available to ensure a fire in area A-19 will not prevent the control of two Steam Generator Atmospheric Relief Valves and the closure of the remaining two.

Up to three ARVs can fail closed or open without impacting ability to achieve and maintain hot standby according to thermal hydraulic analysis WCNOC-CP-002. With at least one ARV unaffected, no E-1F9900 OMA is required to address ARV closure or control. Reference Attachment 4, MSO Evaluation Scenario ID PWROG 23.

5.2.2 Auxiliary Feedwater

Power and control cables associated with certain auxiliary feedwater control valves are run in area A-19. Damage to these cables could prevent operation, or cause maloperation, of the associated motor operated valve.

Train A motor driven auxiliary feedwater pump (MDAFP) suction isolation valves from both the condensate storage tank (CST) (ALHV0035) and the essential service water system (ESW) (ALHV0031) could spuriously operate or fail to operate. This would prevent a suction source to the Train A MDAFP and would prevent operation of the pump.

The Train A ESW suction source to the turbine driven auxiliary feedwater pump (TDAFP) could be prevented due to damage to cables associated with valve ALHV0032. The CST suction source to the TDAFP could be prevented due to damage to cables associated with ALHV0036. The Train B ESW suction supply to the TDAFP is unaffected, since cables associated with ALHV0033 are run in a different fire area.

The Train B MDAFP suction sources from ESW and CST are unaffected by the fire, since cables associated with ALHV0030 (ESW) and ALHV0034 (CST) are run in a different fire area.

Based on the above discussion, both the Train B MDAFP and the TDAFP are available to provide auxiliary feedwater to the steam generators.

References: E-15000, XX-E-013, E-13AL02A, E-13AL04A, M-12AL01

5.2.3 Refueling Water Storage Tank

Cables associated with refueling water storage tank (RWST) level transmitters BNLT0930, BNLT0931 and BNLT0932 are run in area A-19. Damage to these cables could prevent proper operation of the level indicators in the control room. Cables associated with RWST level transmitter BNLT0933 are unaffected by the fire, since they are run in a different fire area. Consequently, RWST level indication is available if a fire occurs in area A-19.

A low-low RWST level signal on two out of four level transmitters will provide a permissive for containment sump isolation valves EJHV8811A and EJHV8811B to open. If this occurs coincident with a safety injection signal (SIS), the containment sump isolation valves will open, causing the RWST to drain to the sump. As stated in Section 5.2.9, a spurious SIS is not credible for a fire in area A-19. Therefore, the open permissive signal will not occur for valves EJHV8811A and EJHV8811B.

Cable 11EJG06AT, associated with containment sump isolation valve EJHV8811A, is run in this area. Damage to this cable could cause the valve to open, momentarily causing the RWST to drain to the containment sump due to normally open valve BNHV8812A. Cables associated with BNHV8812A are unaffected by a fire in this area.

If valve EJHV8811A fully opens, valve BNHV8812A will automatically close, preventing draindown of the RWST to the containment sump. If valve EJHV8811A spuriously opens but stalls before reaching full open position, valve BNHV8812A will not automatically close. If this occurs, operators will recognize a decreasing RWST level using RWST level indicator BNLI0933 and take action to close BNHV8812A using BNHIS8812A in the main control room.

Cable 14EJG06BT, associated with containment sump isolation valve EJHV8811B, is run in this area. Damage to this cable could cause the valve to open, momentarily causing the RWST to drain to the containment sump due to normally open valve BNHV8812B. Cables associated with BNHV8812B are unaffected by a fire in this area.

If valve EJHV8811B fully opens, valve BNHV8812B will automatically close, preventing draindown of the RWST to the containment sump. If valve EJHV8811B spuriously opens but stalls before reaching full open position, valve BNHV8812B will not automatically close. If this occurs, operators will recognize a decreasing RWST level using RWST level indicator BNLI0933 and take action to close BNHV8812B using BNHIS8812B in the main control room.

Based on the above discussion, damage to cables associated with valves EJHV8811A and EJHV8811B and RWST level transmitters BNLT0930, BNLT0931 and BNLT0932 will not adversely impact safe shutdown.

5.2.4 Component Cooling Water

Component Cooling Water (CCW) is required for PFSSD to provide cooling flow to the CCP oil coolers, the seal water heat exchanger, the RHR pump seal coolers and the RHR heat exchangers. The CCW system is also redundant to the RCP seal injection system to provide RCP seal cooling through the thermal barrier.

Cables associated with both Train A and Train B ESW to CCW heat exchanger valves are run in area A-19. However, as discussed below, Train B CCW remains available.

Cables 14EFG04BA and 14EFG04BB, associated with valve EFHV0060, are run in area A-19. Valve EFHV0060 is normally closed and is required to remain closed when operating the Train B CCW system for PFSSD. If this valve were to spuriously open, then a flow imbalance will occur in the Train B ESW system that could prevent the proper ESW flow to essential PFSSD components. Damage to these cables (hot short, open circuit or short to ground) will not cause the valve to spuriously open. The only failure in the control circuit for this valve that could cause the valve to open would be a short within cable 14EFG04BC, which is not run in area A-19. Therefore, there are no credible circuit failures that would cause valve EFHV0060 to spuriously open.

Cables 14EFG05BA and 14EFG05BB, associated with valve EFHV0052, are run in area A-19. Valve EFHV0052 is normally open and is required to remain open when operating the Train B CCW system for PFSSD. If this valve were to spuriously close, then the Train B CCW heat exchanger would have no cooling flow from the ESW system. Damage to these cables (hot short, open circuit or short to ground) will not cause the valve to spuriously close. The only failure in the control circuit for this valve that could cause the valve to close would be a short within cable 14EFG05BC, which is not run in area A-19. Therefore, there are no credible circuit failures that would cause valve EFHV0052 to spuriously close.

Train A ESW to/from CCW heat exchanger valves EFHV0051 and EFHV0059 could spuriously operate. Therefore, the Train A CCW system cannot be relied on for PFSSD if a fire occurs in area A-19.

Power and control cables associated with a number of Train A CCW valves are run in area A-19. The cables and associated components are listed in Table A-19-3. Damage to these cables will prevent operation of the Train A CCW system.

Power and control cables associated with CCW to thermal barrier cooling coil supply and return valves are run in area A-19. Valves BBHV0013, BBHV0014, BBHV0015, BBHV0016, EGHV0061, EGHV0127 and EGHV0133 could be affected by a fire in this area. A fire in this area does not affect RCP seal injection, so thermal barrier cooling is not required. Isolation of the CCW return line from the thermal barrier is not required as long as seal injection is maintained. Seal injection is unaffected by a fire in this area. Flow indicators EGFI0128 and EGFI0129 are unaffected and can be used to diagnose a loss of thermal barrier cooling.

A control cable associated with Train A CCW pump room cooler motor DSGL11A is run in area A-19. Damage to this cable could prevent operation of the room cooler. Cables associated with Train B CCW room cooler SGL11B are not run in area A-19. Therefore, the Train B CCW room cooler is available.

Based on the above discussion, Train B CCW is available in the event of a fire in area A-19. However, RCP thermal barrier cooling could be affected. This is acceptable since RCP seal injection is available.

5.2.5 Residual Heat Removal System

PFSSD requires one train of residual heat removal (RHR) to be available for shutdown cooling. The RHR system is not used for hot standby.

Power and control cables associated with valve EJHV8804A are run in area A-19. This valve is required to remain closed for PFSSD when operating the Train A RHR system. Maintaining the valve closed will prevent flow diversion from the RCS to the CVCS.

Valve EGHV0101 is the Train A CCW to RHR Heat Exchanger control valve. Valve EGHV0102 is the Train B CCW to RHR Heat Exchanger control valve. The valves are normally closed during power operation. PFSSD requires that the valve on the operating train of CCW be closed until shutdown cooling mode is entered, at which time the valve on the operating train of RHR needs to be open. As stated in Section 5.2.4, the Train A CCW system may not be available to supply cooling water to the Train A RHR heat exchanger.

The Train B CCW system is available to supply cooling water to the Train B RHR heat exchanger. Cables associated with valves EGHV0102 and EJHV8804B are not run in area A-19. Therefore, the Train B RHR system is available to provide decay heat removal if a fire occurs in area A-19.

References: E-15000, XX-E-013, E-13EG07, E-13EJ04A, M-12EJ01

5.2.6 Control Room A/C Units

Power and control cables associated with Train A control room A/C unit SGK04A are run in area A-19. In addition, power and control cables associated with SGK04A supply and return dampers GKHZ0029B and GKHZ0029A, respectively, are run in area A-19. Damage to these cables could prevent operation of SGK04A.

Cables associated with Train B control room A/C unit SGK04B and associated dampers are run in a different fire area and are unaffected by a fire in area A-19. Therefore, control room A/C is available if a fire occurs in area A-19.

References: E-15000, XX-E-013, E-13GK02A, E-13GK02B, E-13GK02C, E-13SA19, M-12GK01

5.2.7 480 VAC Power Distribution

Main power feeder cables to both Train A and Train B 480 VAC motor control centers located in the Auxiliary Building run in area A-19. Damage to these cables could prevent operation of a number of components on both trains. Loss of power to Train A components served by these cables is acceptable since a number of other Train A components are affected by a fire in this area. Loss of power to Train B components served by these cables may impact the ability to achieve and maintain safe shutdown following a fire in this area. The following paragraphs discuss the consequences of a loss of 480 VAC power to affected Train B components.

Motor control center NG02B could lose power due to damage to cables 14NGG01AD and 14NGG01AE. The following table lists each PFSSD component that is supplied 480 VAC power from NG02B and the consequences of a loss of power to the component.

480 VAC Motor Control Center NG02B		
MCC Breaker	**Description**	**Consequences**
NG02BAF2	South Electrical Penetration Room Cooler DSGL15B	Since NG02B is located in the South Electrical Penetration Room (A-17), loss of power to NG02B will significantly reduce the heat load within the room. As stated in the remainder of this table, loss of power to NG02B will not adversely impact the ability to achieve and maintain PFSSD. Excessive temperature in the room will not cause the valves to move to an undesired position. Therefore, loss of power to the Train B electrical penetration room cooler will not affect the ability to achieve and maintain PFSSD. Therefore, no adverse impact.
NG02BBF1	Power Feed to XPN08A	PG20GER5 remains available to supply power to PN08. Therefore, no adverse impact.
NG02BBF3	Valve BBPV8702B	Valve is normally de-energized and closed. When transitioning to RHR for cold shutdown, a repair would be necessary to restore power and open the valve or a containment entry made to open the valve. Therefore, no adverse impact.
NG02BBR2	Valve EJHV8809B	Valve is normally open and is required to be open when operating RHR Train B. Loss of power will fail the valve in the open position. Therefore, no adverse impact.
NG02BBR3	Valve EJHV8840	Valve is normally closed and is required to remain closed when operating RHR. Loss of power will fail the valve in the closed position. Therefore, no adverse impact.
NG02BCF2	Valve BBPV8702A	Valve is normally de-energized and closed. When transitioning to RHR for cold shutdown, a repair would be necessary to restore power and open the valve or a containment entry made to open the valve. Therefore, no adverse impact.
NG02BDF1	Valve BBHV8000B	Valve is normally open and is required to be closed or pressurizer PORV BBPCV0456A is required to remain closed. Loss of power will prevent closing BBHV8000B but the PORV is unaffected by the fire and will remain closed. Therefore, no adverse impact.
NG02BDF3	Valve EGHV0062	Valve is normally open and would remain open if power is lost. If a loss of all seal cooling occurs due to the fire, then valve EGHV0061 or this valve is required to be closed to protect the CCW piping. Seal injection is unaffected by the fire, so the position of this valve is of no consequence. Therefore, no adverse impact.
NG02BDR1	Valve EFHV0032	Valve is required to be open when operating the Train B containment air coolers. The valve is normally open and will remain open if power is lost. Therefore, no adverse impact.
NG02BDR2	Valve EFHV0050	Valve is required to be open when operating the Train B containment air coolers. The valve is normally open and will remain open if power is lost. Therefore, no adverse impact.
NG02BEF1	Valve EGHV0127	Valve is normally closed and can remain closed for PFSSD. Loss of power will maintain valve in a closed position. Therefore, no adverse impact.
NG02BEF2	Valve EJHV8811B	Valve is normally closed and is required to remain closed for PFSSD. Loss of power will maintain valve in closed position. Therefore, no adverse impact.
NG02BFR1	Relay Panel (EJHV8811B)	This is a relay panel section that houses relay 3XEJ19 associated with EJHV8811B. Loss of power to this relay will maintain the valve in its normally closed position, which is the desired PFSSD position. Therefore, no adverse impact.

480 VAC Motor Control Center NG02B		
MCC Breaker	**Description**	**Consequences**
NG02BGF3 NG02BHF2	Valve EPHV8808B Valve EPHV8808D	Accumulator tank valves EPHV8808B and EPHV8808D are required to be closed prior to the RCS reaching @ 1,000 psi to prevent accidental accumulator injection. Loss of power to the valves will prevent them from being closed when necessary. The valves are closed when going to cold shutdown, so a cold shutdown repair is allowed. The power cable can either be repaired or nitrogen pressure can be relieved from the tanks to prevent injection. Therefore, no adverse impact.
NG02BHF1	Valve EGHV0133	Valve is normally closed and can remain closed for PFSSD. Loss of power will maintain valve in a closed position. Therefore, no adverse impact.
NG02BHF3	Valve EFHV0034	Valve is required to be open when operating the Train B containment air coolers. The valve is normally open and will remain open if power is lost. Therefore, no adverse impact.
NG02BHR2	Valve EFHV0046	Valve is required to be open when operating the Train B containment air coolers. The valve is normally open and will remain open if power is lost. Therefore, no adverse impact.

MCCs NG02T and NG04T could lose power due to damage to cables 14NGG01AJ and 14NGG01BF, respectively. These MCCs supply power to containment coolers SGN01B and SGN01D. Loss of power to these MCCs will cause a loss of power to the Train B containment coolers. Train A containment coolers are unaffected by a fire in area A-19.

References: E-15000, XX-E-013, E-11NG20, E-13NG01A, E-1F9424A, M-12GN01

5.2.8 Main Steam Isolation Valve (MSIV) Downstream Components

Control cables for several components downstream of the MSIVs are run in area A-19. These components are required to function (close) in the event the MSIVs cannot be closed due to the fire. A fire in area A-19 will not prevent the closure of the MSIVs or the MSIV bypass valves. Therefore, cable damage to the components downstream of the MSIVs will not adversely impact the ability to achieve and maintain PFSSD.

References: E-15000, XX-E-013, E-13AB08, E-13AB11A, E-13AB11B, E-13AB11C, E-1F9101, E-1F9103

5.2.9 Safety Injection and Containment Spray

A spurious safety injection signal (SIS) could cause the safety injection pumps to operate. During operation and hot standby, where the RCS is greater than 1,000 psi, the SI pumps will operate on minimum flow and re-circulate water back to the RWST. Therefore, a spurious start of the SI pumps will not impact PFSSD, but should be stopped for cold shutdown.

A spurious containment spray actuation signal (CSAS) could cause the containment spray pumps to operate, depleting inventory in the RWST. Mitigation of a spurious CSAS should occur prior to the RWST volume going below the minimum necessary to achieve cold shutdown conditions.

Safety injection (SI) is initiated automatically by any of the following conditions:

1. Two out of three high containment pressures monitored by pressure transmitters GNPT0934, GNPT0935 and GNPT0936.
2. Two out of four low pressurizer pressures monitored by pressure transmitters BBPT0455, BBPT0456, BBPT0457 and BBPT0458.

3. Two out of three low steam line pressures on any steam generator monitored by ABPT0514, ABPT0515 and ABPT0516 on SG A; ABPT0524, ABPT0525 and ABPT0526 on SG B; ABPT0534, ABPT0535 and ABPT0536 on SG C; and, ABPT0544, ABPT0545 and ABPT0546 on SG D. Two out of three logic must be satisfied on a single steam generator line. Low pressure on a single pressure transmitter co-incident with low pressure on another pressure transmitter on a different steam generator line will not initiate SIS.

Containment spray (CS) is initiated automatically by two out of four high containment pressures monitored by pressure transmitters GNPT0934, GNPT0935, GNPT0936 and GNPT0937.

Cables associated with GNPT0935, GNPT0936 and GNPT0937 are not run in area A-19. Only one cable associated with GNPT0934 is run in area A-19. Therefore, a fire in area A-19 will not cause a spurious SIS or CSAS due to high containment pressure.

References: E-15000, XX-E-013, E-13GN05, E-1F9431, M-12GN01

5.2.10 Source Range Monitoring

PFSSD requires source range (SR) flux monitoring to be available. Source range monitoring is provided by source range monitors SENE0031, SENE0032, SENY0060A & B, and SENY0061A & B.

One cable associated with SENY0061A/B runs in area A-19. Cables for the remaining source range monitors are run outside area A-19 and would be unaffected by a fire. Therefore, source range monitoring remains available if a fire occurs in area A-19.

For a more detailed evaluation on Source Range monitoring, see Calculation XX-E-013, Attachment 3.

1.0 GENERAL AREA DESCRIPTION

Fire area A-20 is located on the 2047 elevation of the Auxiliary Building and includes the rooms listed in Table A-20-1.

Table A-20-1
Rooms Located in Fire Area A-20

ROOM #	DESCRIPTION
1502	Train B CCW Surge Tank Area
1503	Train A CCW Surge Tank Area
1505	Corridor
1507	Personnel Access Hatch Area

Fire area A-20 has partial automatic fire detection installed. There is no automatic suppression in this area.

2.0 PRIMARY EQUIPMENT USED FOR PFSSD

Table A-20-2 lists each system credited for post-fire safe shutdown and provides a discussion regarding the availability of the system to perform its Post Fire Safe Shutdown (PFSSD) function if a severe fire occurs in this area. For a summary of the area analysis results, see Section 8.0 of the Fire Area Analysis Narrative section.

Table A-20-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-20

System	System Name	PFSSD Function*	Comments
AB	Main Steam	R, M, H, P, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-20.
AC	Main Turbine	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-20.
AE	Main Feedwater	H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-20.
AL	Aux. Feedwater System	H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-20.
AP	Condensate Storage System	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-20.
BB	Reactor Coolant System	R, M, H, P, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-20.
BG	Chemical and Volume Control System	R, M, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-20.
BM	Steam Generator Blowdown System	R, M, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-20.
BN	Borated Refueling Water Storage System	R, M, H	Level transmitters BNLT0930, BNLT0931 and BNLT0932 may be affected. Level transmitter BNLT0933 is available.
EF	Essential Service Water System	H, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-20.
EG	Component Cooling Water System	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-20.
EJ	Residual Heat Removal System	M, H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-20.
EM	High Pressure Coolant Injection	R, M	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-20.
EN	Containment Spray	R, M	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-20.

Table A-20-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-20

System	System Name	PFSSD Function*	Comments
EP	Safety Injection Accumulators	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-20.
FB	Auxiliary Steam	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-20.
FC	Auxiliary Turbines	R, H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-20.
GD	ESW Pump House HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-20.

3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD

This section describes operator actions that may need to be performed inside or outside the control room to achieve and maintain hot standby if a fire occurs in area A-20. This section also describes cold shutdown repairs that may need to be made to achieve and maintain cold shutdown conditions. Operator actions are proceduralized in OFN KC-016.

3.1 ACTIONS OUTSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

None

3.2 ACTIONS INSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

None

3.3 ACTIONS TO ACHIEVE AND MAINTAIN COLD SHUTDOWN

None

4.0 CONCLUSION

Redundant Post-Fire Safe Shutdown capability exists if a severe fire occurs in this area.

5.0 DETAILED ANALYSIS

This section describes the detailed component-by-component and cable-by-cable analysis for a fire in area A-20.

5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA A-20

PFSSD components (S. in E-15000) located in fire area A-20 are shown in Table A-20-3. An evaluation of each component and associated cables is provided in the sections that follow. The applicable evaluation section is listed in Table A-20-3.

Table A-20-3
PFSSD Equipment Located in Fire Area A-20

Room #	PFSSD Equipment	Description	Evaluation Section	Comments
1502	EGLG0008	Train B CCW Surge Tank Level Glass	5.1.1	Mechanical device – no cables
1502	TEG01B	Train B CCW Surge Tank	5.1.1	Mechanical device – no cables
1503	EGLG0007	Train A CCW Surge Tank Level Glass	5.1.1	Mechanical device – no cables
1503	TEG01A	Train A CCW Surge Tank	5.1.1	Mechanical device – no cables

5.1.1 Component Cooling Water Surge Tanks

Both trains of CCW surge tanks are located in area A-20, separated by a partial dividing wall. The tanks are used for volume expansion in the closed loop CCW system and provide a constant suction head for the CCW pumps. The tanks are mechanical devices that require no electrical input to operate. Therefore, they are not subject to failure in the event of a fire. The Fire Hazards Analysis (E-1F9905) provides a discussion of the fire protection features and combustible loading in area A-20.

The sight glasses are also mechanical and do not transmit tank level to the control room. The sight glasses are used by operations in their normal rounds to record the level in the tanks. The sight glasses are not subject to damage by fire.

A fire in area A-20 will not affect operation of either CCW surge tank.

5.2 PFSSD CABLE EVALUATION

Table A-20-4 lists all the PFSSD cables (S. in E-15000) located in fire area A-20. The applicable evaluation section is also listed in Table A-20-4.

Table A-20-4
PFSSD Cables Located in Fire Area A-20

Cable #	Location	Primary PFSSD Equipment	Cable Function (P) Power (C) Control (I) Instrumentation	Evaluation Section	Comments
11BNI07CA	1507	BNLT0930	I	5.2.1	RWST Level Transmitter
12BNI07DA	1507	BNLT0931	I	5.2.1	RWST Level Transmitter
13BNI07EC	1507	BNLT0932	I	5.2.1	RWST Level Transmitter
14GNI05DA	1507	GNPT0934	I	5.2.2	Containment Pressure Transmitter
14SES07AC	1507	SENY0061A/B	I	5.2.3	Source Range Monitor

5.2.1 Refueling Water Storage Tank

The RWST is credited in the PFSSD analysis as the primary source of borated water to achieve cold shutdown. The Wolf Creek Technical Specifications ensure the minimum quantity and boron concentration is maintained to achieve cold shutdown. Therefore, RWST level transmitters, indicators and circuits are not evaluated for level control.

The RWST level transmitters and associated circuits are included in the PFSSD analysis because of the automatic functions they perform. In particular, a low level in the RWST on 2 out of 4 RWST level transmitters, coincident with a safety injection signal (SIS), will initiate a swapover, which is not desired for PFSSD because it could cause the RWST to drain to the containment sump.

Cables associated with refueling water storage tank (RWST) level transmitters BNLT0930, BNLT0931 and BNLT0932 are run in area A-20. Damage to these cables could initiate a spurious low-low RWST level signal. A spurious SIS is not credible if a fire occurs in area A-20 per Section 5.2.2. Therefore, the open permissive will not occur for valves EJHV8811A and EJHV8811B. Consequently, a spurious RWST draindown is not credible if a fire occurs in this area.

Based on the above discussion, the RWST is available if a fire occurs in area A-20.

References: E-15000, XX-E-013, E-13BN07, E-13EJ06A, E-13EJ06B, M-12BN01, M-12EJ01

5.2.2 Safety Injection and Containment Spray

A spurious safety injection signal (SIS) could cause the safety injection pumps to operate. During operation and hot standby, where the RCS is greater than 1,000 psi, the SI pumps will operate on minimum flow and re-circulate water back to the RWST. Therefore, a spurious start of the SI pumps will not impact PFSSD, but should be stopped for cold shutdown.

A spurious containment spray actuation signal (CSAS) could cause the containment spray pumps to operate, depleting inventory in the RWST. Mitigation of a spurious CSAS should occur prior to the RWST volume going below the minimum necessary to achieve cold shutdown conditions.

Safety injection (SI) is initiated automatically by any of the following conditions:

1. Two out of three high containment pressures monitored by pressure transmitters GNPT0934, GNPT0935 and GNPT0936.
2. Two out of four low pressurizer pressures monitored by pressure transmitters BBPT0455, BBPT0456, BBPT0457 and BBPT0458.
3. Two out of three low steam line pressures on any steam generator monitored by ABPT0514, ABPT0515 and ABPT0516 on SG A; ABPT0524, ABPT0525 and ABPT0526 on SG B; ABPT0534, ABPT0535 and ABPT0536 on SG C; and, ABPT0544, ABPT0545 and ABPT0546 on SG D. Two out of three logic must be satisfied on a single steam generator line. Low pressure on a single pressure transmitter co-incident with low pressure on another pressure transmitter on a different steam generator line will not initiate SIS.

Containment spray (CS) is initiated automatically by two out of four high containment pressures monitored by pressure transmitters GNPT0934, GNPT0935, GNPT0936 and GNPT0937.

Cables associated with GNPT0935, GNPT0936 and GNPT0937 are not run in area A-20. Only one cable associated with GNPT0934 is run in area A-20. Therefore, a fire in area A-20 will not cause a spurious SIS or CSAS due to high containment pressure.

5.2.3 Source Range Monitoring

PFSSD requires source range (SR) flux monitoring to be available. Source range monitoring is provided by source range monitors SENE0031, SENE0032, SENY0060A & B, and SENY0061A & B.

One cable associated with SENY0061A/B runs in area A-20. Cables for the remaining source range monitors are run outside area A-20 and would be unaffected by a fire. Therefore, source range monitoring remains available if a fire occurs in area A-20.

For a more detailed evaluation on Source Range monitoring, see Calculation XX-E-013, Attachment 3.

1.0 GENERAL AREA DESCRIPTION

Fire area A-21 is located on the 2047'-6" elevation of the Auxiliary Building and includes the room listed in Table A-21-1.

Table A-21-1
Room Located in Fire Area A-21

ROOM #	DESCRIPTION
1501	Train B Control Room A/C Unit

Fire area A-21 has no installed automatic suppression system but is provided with automatic fire detection throughout.

2.0 PRIMARY EQUIPMENT USED FOR PFSSD

Table A-21-2 lists each system credited for post-fire safe shutdown and provides a discussion regarding the availability of the system to perform its Post Fire Safe Shutdown (PFSSD) function if a severe fire occurs in this area. For a summary of the area analysis results, see Section 8.0 of the Fire Area Analysis Narrative section.

Table A-21-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-21

System	System Name	PFSSD Function*	Comments
AB	Main Steam	R, M, H, P, S	All PFSSD functions associated with the main steam system are satisfied. Steam generators B and C are controlled and steam generators A and D are isolated. Hand switch ABHS0080 is available to close the MSIVs and bypass valves. ABPV0004 (S/G D) may need to be manually closed by isolating and venting air and nitrogen lines. Steam generator B and C level indication is available.
AC	Main Turbine	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-21.
AE	Main Feedwater	H, P	All PFSSD functions associated with the main feedwater system are satisfied. Isolate all four main feedwater isolation valves using hand switch AEHS0080.
AL	Aux. Feedwater System	H, P	All PFSSD functions associated with the auxiliary feedwater system are satisfied. Train A MDAFP is available to supply S/Gs B and C. ALFT0009 and ALFT0011 are available to provide auxiliary feedwater flow indication from MDAFP A to SGs B and C, respectively. Condensate Storage Tank (CST) pressure indication is available using pressure transmitters ALPT0037 and ALPT0038 and MDAFP A suction pressure transmitter ALPT0025.
AP	Condensate Storage System	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-21.
BB	Reactor Coolant System	R, M, H, P, S	All PFSSD functions associated with the reactor coolant system are satisfied. All four RCP seal injection valves will remain open. Loss of inventory through the head vent valves is prevented by maintaining valves BBHV8001A or BBHV8002A and BBHV8002B closed. When transferring to RHR, valve BBPV8702A may need to be manually opened to provide a suction source from the RCS to RHR pump A.
BG	Chemical and Volume Control System	R, M, S	All PFSSD functions associated with the chemical and volume control system are satisfied. Train A Centrifugal Charging Pump (CCP) is available to provide charging flow from the RWST through the RCP seals and BIT. Vave BGHV8106 is available to isolate normal charging. VCT discharge valve BGLCV0112B is available to isolate the VCT from the charging pump suction header. Excess letdown is isolated using BGHV8154B and either BGHV8153A or BGHV8154A.

Table A-21-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-21

System	System Name	PFSSD Function*	Comments
BM	Steam Generator Blowdown System	R, M, H	All PFSSD functions associated with the steam generator blowdown system are satisfied. Steam generator blowdown is isolated by closing valves BMHV0001, BMHV0002, BMHV0003 and BMHV0004 using BMHIS0001C, BMHIS0002C, BMHIS0003C and BMHIS0004C, located on the BM157 panel in the radwaste control room.
BN	Borated Refueling Water Storage System	R, M, H	The RWST is available to provide a suction source to Centrifugal Charging Pump A via valve BNLCV0112D. RWST level indicators BNLI0930, BNLI0932 and BNLI0933 are available. When initiating RHR, flow from the RWST to RHR pump A can be isolated using BNHV8812A.
EF	Essential Service Water System	H, S	All PFSSD functions associated with the Essential Service Water (ESW) system are satisfied. Train A ESW is available to supply cooling water to Auxiliary Feedwater Pump room cooler SGF02A, Containment Air Coolers SGN01A and SGN01C, Train A Component Cooling Water (CCW) Heat Exchanger, CCW A pump room cooler SGL11A, CCP A room cooler SGL12A and RHR A room cooler SGL10A.
EG	Component Cooling Water System	S	All PFSSD functions associated with the Component Cooling Water (CCW) system are satisfied. Train A CCW is available to provide cooling water to the RHR A heat exchanger, the CCP A oil cooler, the seal water heat exchanger and the RHR pump A seal cooler. Either CCW pumps PEG01A or PEG01C are available. Temperature control valve EGTV0029 is unaffected by the fire. CCW flow to the RCP thermal barrier could be temporarily disrupted due to closure of valves EGHV0062 and EGHV0071. Bypass valves EGHV0126 and EGHV0132 can be opened from the control room to restore CCW flow to the thermal barriers. RCP seal injection is unaffected. CCW to RCP flow indicator EGFI0129 could be affected. CCW to RCP flow indicator EGFI0128 is unaffected. Valve EGHV0102 could spuriously open or may not open when operating Train B RHR. Valve EGHV0101 is unaffected.
EJ	Residual Heat Removal System	M, H, P	All PFSSD functions associated with the Residual Heat Removal (RHR) system are satisfied. Loss of RCS inventory through the RHR flow path is prevented by maintaining valves EJHV8701A and EJHV8701B closed. RHR Train A is available via RCS suction valve EJHV8701A and discharge valves EJHCV0606 and EJHV8809A. RHR pump A mini-flow valve EJFCV0610 is available. Containment sump isolation valve EJHV8811B could spuriously open, causing a draindown path from the RWST to the containment sump. Valve BNHV8812B will automatically close, as designed, when EJHV8811B reaches full open position, mitigating draindown. However, if EJHV8811B stalls before reaching full open position, BNHV8812B will not automatically close. In this case, operators can close BNHV8812B using BNHIS8812B in the main control room.

Table A-21-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-21

System	System Name	PFSSD Function*	Comments
EM	High Pressure Coolant Injection	R, M	All PFSSD functions associated with the High Pressure Coolant Injection system are satisfied. Valves EMHV8801A and EMHV8803A are available to ensure a charging flow path from the Train A CCP to the BIT.
EN	Containment Spray	R, M	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-21.
EP	Safety Injection Accumulators	H	The PFSSD Decay Heat Removal function associated with the Safety Injection Accumulators is satisfied. Accumulator injection lines can be isolated by closing valves EPHV8808A, EPHV8808B, EPHV8808C and EPHV8808D. It may be necessary to make a containment entry to manually close EPHV8808B and EPHV8808D.
FB	Auxiliary Steam	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-21.
FC	Auxiliary Turbines	R, H, P	The TDAFP steam trap valve FCFV0310 may be affected. Steam loss through this valve will not affect PFSSD.
GD	ESW Pump House HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-21.
GF	AFW Pump Room Coolers	S	The PFSSD Support function associated with the AFW Pump Room Coolers is satisfied. Train B MDAFP room cooler SGF02B may be affected. Train A MDAFP room cooler SGF02A is available.
GK	Control Room and Class 1E Switchgear Room Coolers	S	The PFSSD Support function associated with the Control Room and Class 1E Switchgear Room Coolers is satisfied. Control room A/C unit SGK04A is not affected by a fire in area A-21. Train A Class 1E Switchgear Room Cooler SGK05A is unaffected by a fire in area A-21.
GL	Auxiliary Building HVAC	S	The PFSSD Support function associated with the Auxiliary Building HVAC system is satisfied. Train A CCW pump room cooler SGL11A is available.
GM	Emergency Diesel Generator Room HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-21.
GN	Containment Coolers	S	The PFSSD Support function associated with the Containment Coolers is satisfied. Train A (SGN01A and SGN01C) Containment Coolers are available. ESW Train A is available to supply cooling water to the containment coolers.
JE	Diesel Fuel Oil	S	Diesel fuel oil transfer pump PJE01B could be affected.

Table A-21-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-21

System	System Name	PFSSD Function*	Comments
KA	Instrument Air	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-21.
KC	Fire Protection	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-21.
KH	Service Gas	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-21.
KJ	Standby Diesel Engine	S	Diesel fuel oil transfer pump PJE01B could be affected, preventing operation of the Train B EDG.
MA	Main Generation	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-21.
MR	Startup Transformer	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-21.
NB	4.16 kV System	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-21.
NE	Standby Diesel Generator	S	Diesel fuel oil transfer pump PJE01B could be affected, preventing operation of the Train B EDG.
NF	Load Shed and Emergency Load Sequencing	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-21.
NG	480V Load Centers and MCCs	S	Train A Load Centers NG01, NG03 and MCC NG05E are available to supply 480 VAC PFSSD loads.
NK	125VDC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-21.
NN	120VAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-21.
PA	13.8kV	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-21.
PB	4.16kV	H, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-21.
PG	480V Load Centers and MCCs	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-21.
PK	125VDC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-21.
PL	Local Instrument Panels	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-21.

Table A-21-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-21

System	System Name	PFSSD Function*	Comments
PN	120VAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-21.
QB	Standby AC Lighting	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-21.
QD	Emergency Lighting	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-21.
RL	Control Room MCB	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-21.
RP	Miscellaneous Control Panels	R, M, H, P, S	Train B control room lockout relays are affected. Train A components are available and can be controlled from the control room.
SA	ESFAS	S	Status panel SA066B monitoring of SGK04B and associated components may be affected. Status panel SA066A is unaffected.
SB	Reactor Protection System	R, S	Indication at RP118B for several RPS devices may be lost. This will not affect indication in the main control room.
SC	Reactor Instrumentation	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-21.
SE	Ex-Core Neutron Monitoring	R, P	Source Range monitors SENE0031, SENE0032 and SENY0060A/B are available.
SY	Switchyard	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-21.
UU	Supervisory System	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-21.

* R - Reactivity Control; M - Reactor Coolant Makeup; H - Decay Heat Removal; P - Process Monitoring; S - Support Function

3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD

This section describes operator actions that may need to be performed inside or outside the control room to achieve and maintain hot standby if a fire occurs in area A-21. This section also describes cold shutdown repairs that may need to be made to achieve and maintain cold shutdown conditions. Operator actions are proceduralized in OFN KC-016.

3.1 ACTIONS OUTSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

Operator Manual Actions (OMAs) are those actions outside the main control room required to achieve and maintain hot standby. OMAs are identified in E-1F9900 and were determined from thermal hydraulic analysis WCNOC-CP-002. Applicable E-1F9900 OMAs are annotated herein. All other actions outside the control room are desirable for plant control in support of hot standby but not required to achieve and maintain hot standby.

3.1.1 Isolation of SGK04B

A fire could cause spurious operation of SGK04B. If this occurs, operators can isolate power to the unit by opening breaker NG0205 located in fire area C-10 (Room 3302).

3.1.2 Steam Generator Atmospheric Relief Valve ABPV0004

Steam Generator ARV ABPV0004 could spuriously open. If necessary, operators can fail the ARV closed by closing the air and nitrogen supply valves KAV1429 and KAV1365, respectively. These valves are located in fire area A-23 and access is available without having to traverse area A-21.

3.1.3 Steam Generator Blowdown to Blowdown Flash Tank Isolation

If a fire occurs in area A-21, cables for BMHIS0001A, BMHIS0002A, BMHIS0003A and BMHIS0004A may be damaged by the fire. Therefore, use BMHIS0001C, BMHIS0002C, BMHIS0003C and BMHIS0004C located on the BM157 panel in the Radwaste Control room to close valves BMHV0001, BMHV0002, BMHV0003, and BMHV0004.

3.2 ACTIONS INSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

3.2.1 Thermal Barrier Cooling

CCW flow to the thermal barrier cooling coils could be lost due to the spurious closure of valves EGHV0062 and EGHV0071. If this occurs, operators could open bypass valves EGHV0126 and EGHV0132 to restore thermal barrier cooling. Otherwise, operators should close EGHV0061 using EGHIS0061 to prevent a steam bubble from damaging the CCW piping. CCW to RCP flow indicator EGFI0128 is available to diagnose a loss of CCW flow to the RCP thermal barriers.

3.2.2 Main Steam Isolation Valves (MSIVs) and MSIV Bypass Valves

Cables for hand switch ABHS0079 may be damaged by the fire. Cables for redundant hand switch ABHS0080 are unaffected. Use ABHS0080 to close the MSIVs and MSIV bypass valves.

3.2.3 Main Feedwater Isolation Valves (MFIVs)

Cables for hand switch AEHS0081 may be damaged. Cables for redundant hand switch AEHS0080 are unaffected. Use AEHS0080 to close the MFIVs.

3.2.4 Mitigation of RWST Draindown to Containment Sump

If a fire occurs in area A-21, it may be necessary to close valve BNHV8812B from the control room using BNHIS8812B to mitigate draindown of the RWST into the containment sump. This condition could occur due to EJHV8811B spuriously opening but stalling before reaching full open position, thereby not providing the permissive for BNHV8812B to close. RWST level indication is available using level indicators BNLI0930, BNLI0932 and BNLI0933.

3.2.5 Component Cooling Water

Train B CCW could be affected by a fire in this area. If this occurs, swap to Train A CCW using normal operating procedures if Train A CCW is not already running.

3.3 ACTIONS TO ACHIEVE AND MAINTAIN COLD SHUTDOWN

3.3.1 RHR

It may be necessary to repair damage to the NG02B incoming power cables 14NGG01AD and 14NGG01AE to restore power to NG02B to allow opening of either valve BBPV8702A or BBPV8702B. Otherwise, a containment entry could be made to open the appropriate valve.

3.3.2 Accumulator Tank Isolation

It may be necessary to repair damage to the NG02B incoming power cables 14NGG01AD and 14NGG01AE to restore power to valves EPHV8808B and EPHV8808D to allow them to be isolated prior to the RCS reaching @ 1,000 psi. Otherwise, nitrogen pressure can be relieved from tanks B and D to prevent injection. Valves EPHV8808A and EPHV8808C are unaffected.

4.0 CONCLUSION

With some exceptions, redundant Post-Fire Safe Shutdown capability exists if a severe fire occurs in this area. For those exceptions, feasible manual actions are available and are unaffected by the fire. Manual actions are documented in Section 3.0.

5.0 DETAILED ANALYSIS

This section describes the detailed component-by-component and cable-by-cable analysis for a fire in area A-21.

5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA A-21

PFSSD components (S. in E-15000) located in fire area A-21 are shown in Table A-21-3. An evaluation of each component and associated cables is provided in the sections that follow. The applicable evaluation section is listed in Table A-21-3.

1501	TB15204	Fire Cable Termination Box	5.2.17	

5.1.1 Control Room A/C Unit SGK04B

Control room air conditioning is required to be available to satisfy the PFSSD support function. Two redundant and independent air conditioning units (SGK04A and SGK04B) are provided to satisfy this function. At least one unit is required to be available for PFSSD.

Train B control room A/C unit SGK04B and associated power and control panels (GK199A, GK199B and GK199C) are located in fire area A-21. In addition, power and control cables associated with this unit are also run in this area. A fire could damage cables and equipment associated with SGK04B, which would prevent operation of the unit or cause the unit to spuriously operate.

Hand switch GKHS0040 is located in area A-21. The hand switch is used to locally start the unit and isolate the control circuits from the control room. Damage to this switch or associated cables could prevent operation of the unit or cause the unit to spuriously operate.

Spurious operation of the unit can be mitigated by opening breaker NG0205 located in fire area C-10 (Room 3302).

Control room A/C unit SGK04B inlet and outlet dampers GKHZ0040A and GKHZ0040B and associated control cables are located in the area. Damage to the cables or equipment due to a fire could prevent operation of the dampers, which would prevent operation of SGK04B.

Redundant Train A control room A/C unit SGK04A and associated cables and equipment are located in a different fire area and are separated by minimum 3-hour rated fire barriers. Therefore, there is reasonable assurance that control room ventilation will be available using Train A control room A/C unit SGK04A. Therefore, no E-1F9900 OMA is required to address SGK04B function.

5.1.2 Class 1E Elec Equip A/C Unit SGK05B

The PFSSD support function requires Class 1E electrical equipment air conditioning on the operating train of equipment. Class 1E electrical equipment air conditioning is provided by units SGK05A (Train A) and SGK05B (Train B). Both units are normally operating, providing cooling to their associated train of equipment.

Hand switch GKHS0103 is used in OFN RP-017 in response to a control room fire. Operation of the handswitch from NORMAL to ISO/RUN position isolates SGK05B control circuits from the control room and starts the unit. Damage to this switch or associated cables (14GKG13BF, 14GKG13BK, 14GKG13BL and 14GKG13BM) could prevent operation of the unit or cause the unit to spuriously start.

Cable 14GKG13BE is a control cable for SGK05B and runs to relay panel RP331 in area A-16 North. Damage to this cable could prevent automatic operation of SGK05B. Cable 14SAZ20PA is a control cable that monitors the control power supply status for SGK05B. A shor to ground on this cable will blow the control power fuse and disrupt control power to SGK05B.

In the event SGK05B is affected by the fire Class 1E A/C unit SGK05A is available to provide room cooling for required Train A Class 1E equipment. Therefore, loss of SGK05B will have no adverse impact on PFSSD.

5.1.3 Train B 480 VAC Motor Control Center NG04C

Motor Control Center (MCC) NG04C is located in area A-21. Several Train B PFSSD components could be affected if the fire damages NG04C and disrupts power to those components.

Redundant Train A equipment, powered by Train A 480 VAC Motor Control Centers NG01A, NG01B and NG03C are located in a separate fire area and are unaffected by the fire.

Cubicle NG04CPF2 is the power supply for valve BGHV8104. Valve BGHV8104 is included in the PFSSD design for cold shutdown after a control room fire. The valve is used in OFN RP-017A to establish long term boration for cold shutdown. The valve is not credited for hot standby. Cables associated with the valve are not included in the PFSSD design because the valve can be de-energized and manually opened if needed. A fire in this area that affects valve BGHV8104 will not adversely impact PFSSD.

For further discussion of the cables associated with Train B 480 VAC MCC NG04C that run through area A-21, see Section 5.2.

5.1.4 Source Range Monitoring

PFSSD requires source range (SR) flux monitoring to be available. Source range monitoring is provided by source range monitors SENE0031, SENE0032, SENY0060A & B, and SENY0061A & B. Source range monitor SENY0061A/B is located in area A-21 and may be unavailable.

Source range monitors SENE0031, SENE0032 and SENY0060A/B are unaffected by a fire in area A-21. Therefore, source range monitoring is available if a fire occurs in area A-21.

For a more detailed evaluation on Source Range monitoring, see Calculation XX-E-013, Attachment 3.

5.2 PFSSD CABLE EVALUATION

Table A-21-4 lists all the PFSSD cables (S. in E-15000) located in fire area A-21. The applicable evaluation section is also listed in Table A-21-4.

Table A-21-4

5.2.1 Refueling Water Storage Tank

The RWST is credited in the PFSSD analysis as the primary source of borated water to achieve cold shutdown. The Wolf Creek Technical Specifications ensure the minimum quantity and boron concentration is maintained to achieve cold shutdown. Therefore, RWST level transmitters, indicators and circuits are not evaluated for level indication.

The RWST level transmitters and associated circuits are included in the PFSSD analysis because of the automatic functions they perform. A low level in the RWST on 2 out of 4 RWST level transmitters, coincident with a safety injection signal, will initiate a swapover, which is not desired for PFSSD because it could cause the RWST to drain to the containment sump.

A cable associated with refueling water storage tank (RWST) level transmitter BNLT0931 runs in fire area A-21. Cables for the remaining RWST level transmitters are unaffected. Therefore, a spurious low-low level in the RWST is not credible if a fire occurs in this area.

Based on the above discussion, the RWST is available if a fire occurs in area A-21.

References: E-15000, XX-E-013, E-13BN07, E-13EJ06A, E-13EJ06B, E-1F9102, E-1F9205, E-1F9302, M-12BN01, M-12EJ01, M-767-00162, M-767-00165, M-767-00168, M-767-00189

5.2.2 Steam Generator Atmospheric Relief Valves

Cables associated with Steam Generator Atmospheric Relief Valve ABPV0004 are run in area A-21. Cables associated with Steam Generator Atmospheric Relief Valves ABPV0001, ABPV0002 and ABPV0003 are not run in area A-21.

PFSSD requires at least two steam generator atmospheric relief valves (ARV) be controlled and the other two closed. The ARVs are normally closed and require air pressure to open. Each valve is controlled by a pressure transmitter input signal from a pressure transmitter installed on the outlet side of the steam generator. The relief valve opens when the pressure reaches a designated setpoint.

Damage to the instrument cables associated with pressure transmitter ABPT0004 or I/P converter ABPY0004 could provide a false high steamline pressure signal and open ARV ABPV0004. Since cables associated with the other three ARVs are not run in area A-21, they will remain closed. A single open ARV is bounded by the main steamline break analysis and will not adversely impact PFSSD. If necessary, operators can fail the ARV closed by closing the air and nitrogen supply valves KAV1429 and KAV1365, respectively. These valves are located in fire area A-23 and access is available without having to traverse area A-21.

Based on the above discussion, a fire in area A-21 will not prevent the control of two Steam Generator Atmospheric Relief Valves and the closure of the remaining two.

Up to three ARVs can fail closed or open without impacting ability to achieve and maintain hot standby according to thermal hydraulic analysis WCNOC-CP-002. With at least one ARV unaffected, no E-1F9900 OMA is required to address ARV closure or control. Reference Attachment 4, MSO Evaluation Scenario ID PWROG 23.

References: E-15000, XX-E-013, E-13AB20B, E-1F9101, M-12AB01, M-12KA04, M-12KA05

5.2.3 Safety Injection and Containment Spray

A spurious safety injection signal (SIS) could cause the safety injection pumps to operate. During operation and hot standby, where the RCS is greater than 1,000 psi, the SI pumps will operate on minimum flow and re-circulate water back to the RWST. Therefore, a spurious start of the SI pumps will not impact PFSSD, but should be stopped for cold shutdown.

A spurious containment spray actuation signal (CSAS) could cause the containment spray pumps to operate, depleting inventory in the RWST. Mitigation of a spurious CSAS should occur prior to the RWST volume going below the minimum necessary to achieve cold shutdown conditions.

Safety injection (SI) is initiated automatically by any of the following conditions:

1. Two out of three high containment pressures monitored by pressure transmitters GNPT0934, GNPT0935 and GNPT0936.
2. Two out of four low pressurizer pressures monitored by pressure transmitters BBPT0455, BBPT0456, BBPT0457 and BBPT0458.
3. Two out of three low steam line pressures on any steam generator monitored by ABPT0514, ABPT0515 and ABPT0516 on SG A; ABPT0524, ABPT0525 and ABPT0526 on SG B; ABPT0534, ABPT0535 and ABPT0536 on SG C; and, ABPT0544, ABPT0545 and ABPT0546 on SG D. Two out of three logic must be satisfied on a single steam generator line. Low pressure on a single pressure transmitter co-incident with low pressure on another pressure transmitter on a different steam generator line will not initiate SIS.

Containment spray (CS) is initiated automatically by two out of four high containment pressures monitored by pressure transmitters GNPT0934, GNPT0935, GNPT0936 and GNPT0937.

Cables run through fire area A-21 associated with these pressure transmitters are summarized in Table A-21-4.

Cables associated with GNPT0935, GNPT0936 and GNPT0937 are not run in area A-21. Only cables associated with GNPT0934 are run in area A-21. Therefore, a fire in area A-21 will not cause a spurious SIS or CSAS due to high containment pressure.

Cables associated with all four pressurizer pressure transmitters are not run in area A-21. Therefore, a spurious SIS due to low pressurizer pressure is not credible for a fire in area A-21.

Cables associated with steam line pressure transmitters ABPT0516 and ABPT0546 are run in area A-21. Cables associated with the remaining steam line pressure transmitters are not run in area A-21. Therefore, a spurious SIS due to low steam line pressure is not credible for a fire in area A-21.

Based on the above discussion, a spurious SIS or CSAS is not credible if a fire occurs in fire area A-21.

References: E-15000, XX-E-013, E-13AB21, E-13GN05, E-1F9431, M-12AB01, M-12GN01

5.2.4 Main Steam Isolation Valves Downstream Components

Cables for several valves located downstream of the main steam isolation valves (MSIV) are located in this area. These valves are used for PFSSD to isolate the main steam lines in the event the MSIVs or MSIV bypass valves fail to close.

As discussed in Section 5.2.5, the MSIVs and the MSIV bypass valves can be isolated using hand switch ABHS0080 if a fire occurs in area A-21. Cables associated with hand switch ABHS0080 are run in a different fire area and are unaffected by a fire in area A-21. Therefore, these downstream isolation valves can fail open with no adverse impact on PFSSD.

References: E-15000, XX-E-013, E-13AB08, E-13AB11A, E-13AB11B, E-13AB11C, E-1F9101, E-1F9103, M-12AB02, M-12AB03

5.2.5 Steam Generator Main Steam Isolation Valves (MSIVs) and Bypass Valves

PFSSD requires the MSIVs and bypass valves be closed to prevent reactivity addition due to uncontrolled cooldown. The MSIVs and bypass valves are closed from the control room using all close hand switches ABHS0079 or ABHS0080.

Each MSIV is designed to utilize system fluid (main steam) as the motive force to open and close. The valve actuation (open or close) is accomplished through positioning a series of six electric solenoid pilot valves to either direct the system fluid to the Upper Piston Chamber (UPC) and/or the Lower Piston Chamber (LPC), or vent either or both piston chambers. The six solenoid pilot valves are divided into two trains (3 per train) that are independently powered and controlled. Either train can independently perform the PFSSD function to close the valve and isolate main steam. This is done by actuating either all close hand switch ABHS0079 (separation group 4) or ABHS0080 (separation group 1) to de-energize the associated solenoid valves.

The following table identifies the solenoids and associated control cables for each hand switch.

MSIV	ABHS0079 (Sep Group 4)		ABHS0080 (Sep Group 1)	
	Solenoids	Cable	Solenoids	Cable
ABHV0011	MV2, MV4, MV6	14ABK28BH	MV1, MV3, MV5	11ABK29BH
ABHV0014	MV2, MV4, MV6	14ABK29AH	MV1, MV3, MV5	11ABK28AH
ABHV0017	MV2, MV4, MV6	14ABK28AH	MV1, MV3, MV5	11ABK29AH
ABHV0020	MV2, MV4, MV6	14ABK29BH	MV1, MV3, MV5	11ABK28BH

All 4 cables associated with the 12 separation group 4 solenoid valves are run in area A-21. Cable damage due to a fire will likely result in disruption of power to the solenoids, which will close the valves. The four separation group 1 cables associated with hand switch ABHS0080 are unaffected by a fire in area A-21. Therefore, hand switch ABHS0080 is available to close the four MSIVs.

Each MSIV bypass valve is normally closed and is required to remain closed for PFSSD. Two (2) redundant solenoid valves (one on each train) are installed on the air supply line and control air to the pneumatic actuator. The valves are normally closed with the solenoid valves de-energized. Actuation of either hand switch ABHS0079 or ABHS0080 will de-energize power to the solenoids to ensure they remain closed.

Cables associated with the 4 separation group 4 solenoids associated with each bypass valve are run in area A-21. Cables associated with the 4 separation group 1 solenoids associated with each bypass valve are unaffected by a fire in area A-21. Therefore, hand switch ABHS0080 is available to close the MSIV bypass valves.

Based on the above discussion, hand switch ABHS0080 is available to close the MSIVs and MSIV bypass valves in the event of a fire in area A-21.

References: E-15000, XX-E-013, E-13AB23A, E-13AB23B, E-13AB26, E-13AB27, E-13AB28, E-13AB29, E-1F9101, M-12AB02

5.2.6 Emergency Diesel Fuel Oil Transfer Pump

Emergency diesel fuel oil transfer pumps are required to transfer fuel oil from the underground storage tank to the aboveground day tank to support operation of the emergency diesel generator (EDG). Loss of the fuel oil transfer pump on the associated train will prevent operation of the associated EDG.

Cable 14JEG01BD is run in fire area A-21. A short to ground on this cable will blow the control power fuse and prevent operation of the Train B EDG fuel oil transfer pump. The Train B EDG can operate for approximately 1 hour fully loaded on the contents of the day tank.

A fire in area A-21 credits Train A components using off-site and on-site power to NB01. Therefore, loss of the Train B EDG due to a fire in this area will not affect PFSSD.

References: XX-E-013, E-15000, E-13JE01A, E-1F9411B

5.2.7 Steam Generator Main Feedwater Isolation Valves

PFSSD requires that either the main feedwater isolation valves (MFIVs) be closed or the main feedwater pumps be stopped to prevent overfilling the steam generators. Flow diversion from auxiliary feedwater (AFW) to the main feedwater system piping is prevented by check valves AEV0420, AEV0421, AEV0422 and AEV0423. Closure of the main feedwater isolation valves is not required to prevent AFW flow diversion.

Each MFIV is designed to utilize system fluid (feedwater) as the motive force to open and close. The valve actuation (open or close) is accomplished through positioning a series of six electric solenoid pilot valves to either direct the system fluid to the Upper Piston Chamber (UPC) and/or the Lower Piston Chamber (LPC), or vent either or both piston chambers. The six solenoid pilot valves are divided into two trains (3 per train) that are independently powered and controlled. Either train can independently perform the PFSSD function to close the valve and isolate main feedwater. This is done by actuating either all close hand switch AEHS0080 (separation group 1) or AEHS0081 (separation group 4) to de-energize the associated solenoid valves.

The following table identifies the solenoids and associated control cables for each hand switch.

MFIV	AEHS0080 (Sep Group 1)		AEHS0081 (Sep Group 4)	
	Solenoids	Cable	Solenoids	Cable
AEFV0039	MV1, MV3, MV5	11AEK16AH	MV2, MV4, MV6	14AEK17AH
AEFV0040	MV1, MV3, MV5	11AEK17AH	MV2, MV4, MV6	14AEK16AH
AEFV0041	MV1, MV3, MV5	11AEK16BH	MV2, MV4, MV6	14AEK17BH
AEFV0042	MV1, MV3, MV5	11AEK17BH	MV2, MV4, MV6	14AEK16BH

All 4 cables associated with the 12 separation group 4 solenoid valves are run in area A-21. Cable damage due to a fire will likely result in disruption of power to the solenoids, which will close the valves. The four separation group 1 cables associated with hand switch AEHS0080 are unaffected by a fire in area A-21. Therefore, hand switch AEHS0080 is available to close the four MFIVs if a fire occurs in area A-21.

Based on the above discussion, MFIV isolation is assured using hand switch AEHS0080 if a fire occurs in area A-21.

References: E-15000, XX-E-013, E-13AE14, E-13AE15, E-13AE16, E-13AE17, E-1F9201, M-12AE02

5.2.8 Auxiliary Feedwater

The PFSSD design requires the use of one auxiliary feedwater pump supplying water to at least two steam generators. The turbine driven auxiliary feedwater pump (TDAFP) is normally aligned to supply all four steam generators. The Train A motor driven auxiliary feedwater pump (MDAFP) is aligned to supply steam generators B and C. The Train B MDAFP is aligned to supply steam generators A and D.

Based on Table A-21-4, cables for several components associated with Train B MDAFP and the TDAFP are run in area A-21. The suction source from both the CST and the ESW system to the B Train MDAFP could be disrupted due to spurious closure of the suction valves (ALHV0030 and ALHV0034). The Train B MDAFP discharge valves to SGs A and D (ALHV0007 and ALHV0005) could spuriously close due to cable damage. Also, damage to cable 14ALB01BM could cause the Train B MDAFP to spuriously stop. Therefore, the Train B MDAFP is unavailable to supply AFW for decay heat removal.

The Train B ESW supply to the TDAFP may be affected by the fire due to damage to cables associated with ALHV0033. The CST and the Train A ESW supplies remain available. The TDAFP may not be capable of supplying AFW to SGs B and C due to damage to cables associated with valves ALHV0010 and ALHV0012. The TDAFP supply to SGs A and D, through valves ALHV0008 and ALHV0006, respectively, is unaffected by the fire. However, as stated in Section 5.2.2 above, steam generator D ARV ABPV0004 may be affected by the fire and may not function as required.

Cables associated with AFW to SG D flow transmitter ALFT0001 and AFW to SG A flow transmitter ALFT0007 are run in area A-21. Damage to these cables could provide false flow indication to operators in the control room.

Cables associated with MDAFP B suction pressure transmitter ALPT0024 are run in area A-21. this transmitter provides suction pressure indication in the control room. False low suction pressure due to cable damage will generate a signal to open the ESW supply source. This will not prevent achieving PFSSD.

Cables for Train A MDAFP and associated suction and discharge valves and transmitters are run in a separate fire area and are unaffected. Consequently, MDAFP A is available in the event of a fire in area A-21. Damage to cables associated with B Train MDAFP and the TDAFP will not prevent auxiliary feedwater flow to at least two steam generators.

Cables associated with Train B MDAFP room cooler SGF02B are run in area A-21. Damage to these cables could prevent operation of the room cooler which would result in inoperability of the Train B MDAFP.

Cables associated with Train A MDAFP room cooler SGF02A are run in a different fire area. Therefore, the Train A MDAFP room cooler is unaffected by a fire in area A-21.

References: E-15000, XX-E-013, E-1F9204, E-13AL01B, E-13AL03B, E-13AL05A, E-13AL05B, E-13AL07B, E-13AL09, E-13GF01

5.2.9 Condensate Storage Tank Suction Pressure

The preferred suction source for auxiliary feedwater (AFW) is the condensate storage tank (CST). This tank provides a clean source of water to the steam generators. Upon low CST pressure, the suction source transfers to essential service water (ESW).

Three pressure transmitters are installed on the suction piping from the CST to the AFW pumps. These transmitters indicate CST pressure in the control room and automatically transfer the AFW suction to ESW upon low pressure on two out of three pressure transmitters.

Circuits for one of the three pressure transmitters (ALPT0039) run through area A-21. Damage to these circuits could prevent the pressure transmitter from functioning. Circuits for the remaining pressure transmitters (ALPT0037 and ALPT0038) are not run through area A-21. Therefore, CST level indication is available in the control room and a spurious transfer to the ESW system is avoided.

A fire in area A-21 will not affect CST level indication and will not actuate a spurious low AFW suction pressure signal.

References: E-15000, XX-E-013, E-1F9202, E-13AL08, M-12AL01

5.2.10 Reactor Coolant Pump (RCP) Seal Injection

PFSSD requires RCP seal injection to provide a boron injection path, provide makeup to the RCS to maintain hot standby inventory and prevent damage to the RCP seals. The Component Cooling Water (CCW) system is an alternative means of cooling the RCP seals.

A fire in area A-21 could damage power and control cables associated with all four RCP seal injection valves (BBHV8351A, BBHV8351B, BBHV8351C and BBHV8351D). The seal injection valves are normally open and de-energized with the circuit breaker maintained in the OFF position. The valves are not high/low pressure interface valves so three-phase hot shorts do not have to be considered and, consequently, damage to the power cables will not cause the valves to spuriously close. Damage to the control cables will not cause the valves to close because the power and control circuits are de-energized. Therefore, a fire in this area will not cause the seal injection valves to close.

Based on the above discussion, RCP seal injection is available.

References: E-15000, XX-E-013, E-1F9303, E-13BB04

5.2.11 Reactor Head Vent Valves

PFSSD requires that one of the two reactor vessel head vent valves on each flow path (2 flow paths total) be closed to prevent uncontrolled depressurization of the RCS. A cable (14BBK30BA) associated with one of the four head vent valves (BBHV8001B) runs through area A-21.

Cables for remaining head vent valves BBHV8001A, BBHV8002A and BBHV8002B are not run through A-21 and are unaffected by the fire. Therefore, at least one valve on each flow path can be controlled and spurious opening of BBHV8001B will have no adverse impact on PFSSD.

References: E-15000, XX-E-013, E-1F9301, E-13BB30, M-12BB04

5.2.12 Charging Flow to Regenerative Heat Exchanger Isolation Valves

PFSSD requires charging flow to be directed to the RCP seals. To ensure adequate flow to the RCP seals, flow diversion to the regenerative heat exchanger needs to be prevented. Valves BGHV8105 and BGHV8106 are included in the PFSSD equipment list to accomplish this task. Manual valve BG8402B is also included to provide an alternate means of closing this flow path during alternate safe shutdown using OFN RP-017.

Cables associated with BGHV8105 are run in area A-21 and could be damaged by a fire, preventing valve BGHV8105 from being closed from the control room. However, cables associated with valve BGHV8106, and its hand switch (BGHIS8106), are unaffected by a fire in area A-21. Therefore, valve BGHV8106 can be used to isolate flow to the regenerative heat exchanger and therefore satisfy the PFSSD requirement.

References: E-15000, XX-E-013, E-1F9102, E-13BG11A, M-12BG03

5.2.13 Volume Control Tank (VCT) Discharge Valves

PFSSD requires isolation of the Volume Control Tank (VCT) discharge to charging pumps suction. Either valve BGLCVC0112B or BGLCV0112C needs to be closed. Cables run in area A-21 associated with valve BGLCV0112C are listed in Table A-21-4.

Damage to cables 14BGG12BA and 14BGG12BB will prevent closing valve BGLCV0112C from the control room. Therefore, valve BGLCV0112C is unavailable to perform its PFSSD function if a fire occurs in area A-21. Damage to these cables will not cause the valve to spuriously close. A three-phase hot short is not required to be considered since the valve is not a high-low pressure interface. Therefore, damage to the operating charging pump due to spurious closure of this valve is not credible.

Cable 14BGI51DA is an instrumentation cable for VCT level transmitter BGLT0185. Damage to this cable could send a false VCT low-low level signal and close relay K647 on the close circuit for valve BGLCV0112C. This would fail the valve closed if all other permissives are met, which is the desired PFSSD position. Therefore, damage to this cable will have no impact on the ability to close the valve. Redundant VCT level transmitter BGLT0112 is unaffected by a fire in area A-21 and remains available to provide reliable VCT level indication in the control room.

Power and control cables for BGLCV0112B are run in a separate fire area and are unaffected by a fire in area A-21. Therefore, VCT isolation can be accomplished using BGLCV0112B.

References: E-15000, XX-E-013, E-1F9102, E-13BG12, E-13BG12A, E-13BG51, M-12BG03

5.2.14 Excess Letdown

PFSSD requires the excess letdown path be isolated to prevent uncontrolled depressurization of the RCS. To accomplish this, either normally closed valve BGHV8153A or BGHV8154A must be maintained closed and either normally closed valve BGHV8153B or BGHV8154B must be maintained closed.

Only one cable associated with valve BGHV8153B is run in area A-21. Cables associated with the remaining three excess letdown isolation valves are not run in area A-21. Therefore, excess letdown is assured using BGHV8154B and either BGHV8153A or BGHV8154A.

References: E-15000, XX-E-013, E-1F9301, E-13BG48, M-12BG01

5.2.15 Steam Generator Blowdown to Blowdown Flash Tank Isolation Valves

The reactivity control function requires the steam generator blowdown to blowdown flash tank valves (BMHV0001, BMHV0002, BMHV0003, and BMHV0004) be closed to prevent reactivity addition from uncontrolled cooldown. Cables run in area A-21 associated with these valves are listed in Table A-21-4.

A hot short within cables 14BMK06AA, 14BMK06BA, 14BMK06CA and14BMK06DA will not cause the valves to spuriously open due to the absence of a +125 VDC source conductor. However, the cables are run in raceway that could contain other cables carrying 125 VDC that, if an inter-cable hot short occurs, could spuriously open the valves and prevent them from being closed using hand switches BMHIS0001A, BMHIS0002A, BMHIS0003A and BMHIS0004A. Although this is unlikely due to the use of thermoset cables, it is postulated to occur for the purposes of this analysis.

Redundant means for closing valves BMHV0001, BMHV0002, BMHV0003 and BMHV0004 are available and are unaffected by a fire in area A-21. This redundant means uses BMHIS0001C, BMHIS0002C, BMHIS0003C and BMHIS0004C, located on the BM157 panel in the radwaste control room. Access to the radwaste control room is available from outside fire area A-21.

Based on the above discussion, a fire in area A-21 will not prevent closing steam generator blowdown valves BMHV0001, BMHV0002, BMHV0003 and BMHV0004.

Thermal hydraulic analysis WCNOC-CP-002 shows insignificant impact on SG inventory even with all four blowdown valves open. Therefore, no E-1F9900 OMA is required to close blowdown valves to achieve and maintain hot standby. Reference Attachment 4, MSO Evaluation Scenario ID PWROG 34.

5.2.16 Essential Service Water to/from Component Cooling Water Valves

EFHV0052 is the Essential Service Water (ESW) Train B to CCW Train B heat exchanger supply isolation valve and is required to be open when using Train B for PFSSD. EFHV0060 is the return isolation valve from CCW Train B heat exchanger to the Ultimate Heat Sink (UHS). PFSSD requires that EFHV0060 be closed when using Train B CCW for plant shutdown following a fire and that valve EFV0090 be maintained in a locked throttled position to provide the minimum required ESW water flow. If valve EFHV0060 were to spuriously open when operating Train B ESW, flow imbalance could occur, which will result in flow depletion and inoperability of essential PFSSD components.

Cables 14EFG05BA, 14EFG05BB and 14EFG05BC are power and control cables associated with EFHV0052. Cables 14EFG04BA, 14EFG04BB and 14EFG04BC are power and control cables associated with EFHV0060. A fire in area A-21 will result in damage to these cables and the inability to control ESW flow to Train B CCW.

Hand switch EFHS0052 is the control room isolation switch associated with valve EFHV0052. Hand switch EFHS0060 is the control room isolation switch associated with valve EFHV0060. Damage to either of these switches could prevent operation of the associated valves from the control room or could cause spurious operation of the valves.

Cables associated with Train A ESW to/from CCW valves are run in a different fire area and are unaffected by a fire in area A-21.

Based on the above discussion, at least one Train of ESW to CCW valves will be available if a fire occurs in area A-21.

References: E-15000, XX-E-013, E-13EF04, E-13EF04A, E-13EF05, M-12EF02

5.2.17 Component Cooling Water

The component cooling water system is required for PFSSD to provide cooling water to the CCP oil coolers, seal water heat exchanger, RHR heat exchanger, RHR pump seal cooler and RCP thermal barriers (to maintain RCP seal cooling in the event RCP seal injection is lost). In addition, the CCW system provides cooling to the RCP thermal barriers and is credited as a backup to RCP seal injection for maintaining seal cooling.

Cables associated with components on the Train B CCW system run through area A-21. Damage to these cables due to a fire could prevent operation of the associated equipment and prevent operation of Train B CCW. Cables associated with redundant Train A CCW are run in a different fire area and are unaffected by the fire.

To ensure an operable CCW flow path, either valves EGHV0071 or EGHV0126 must be open and either EGHV0058 or EGHV0127 must be open. In addition, either valves EGHV0062 or EGHV0132 must be open and either EGHV0061 or EGHV0133 must be open. Also, valves EGHV0015 and EGHV0053 need to be open when operating the Train A CCW system and valves EGHV0016 and EGHV0054 need to be open when operating the Train B CCW system to ensure a flow path to and from the service loop.

Cables associated with valves EGHV0054, EGHV0071, EGHV0127 and EGHV0133 run through area A-21. In addition, cable 14EGI15AA, associated with flow transmitter EGFT0062, runs in fire area A-21. The flow transmitter monitors CCW outlet flow from the thermal barriers and automatically shuts valve EGHV0062 on a high flow signal. Cables associated with other thermal barrier cooling flow path valves are unaffected by the fire.

If the fire affects cables associated with flow transmitter EGFT0062 or valve EGHV0071, valves EGHV0062 or EGHV0071 may spuriously close. If this occurs and it is desired to have CCW flow to the thermal barriers, Operators would need to open valves EGHV0126 or EGHV0132. Valves EGHV0126 and EGHV0132 are unaffected by the fire.

Cable 14EGI19BB is associated with CCW to RCP flow transmitter EGFT0129. Damage to this cable could prevent operators from diagnosing a loss of CCW flow to the RCP thermal barriers using flow indicator EGFI0129. CCW to RCP flow indicator EGFI0128 is unaffected by a fire in area A-21 and can be used to diagnose a loss of CCW flow to the RCP thermal barriers.

Cables associated with Train B CCW pump room cooler SGL11B are run in area A-21. Damage to these cables could cause a loss of capability to cool the Train B CCW pumps. The Train A CCW pump room cooler is unaffected by the fire since cables for this unit are not run in area A-21.

As discussed in Section 5.2.10, RCP seal injection is unaffected by a fire in area A-21. Therefore, loss of thermal barrier cooling will have no adverse impact on PFSSD.

Based on the above discussion, Train A CCW is available to provide cooling to essential PFSSD components. Loss of CCW flow to the RCP thermal barriers can be diagnosed using flow indicator EGFI0128. RCP seal injection remains available.

References: E-15000, XX-E-013, E-13EG05A, E-13EG05B, E-13EG05D, E-13EG07, E-13EG09, E-13EG15, E-13EG16, E-13EG18, E-13EG18A, E-13EG19, E-13GL06, E-1F9303

5.2.18 Boron Injection Tank Flowpath

The Boron Injection Tank (BIT) flowpath is credited for reactivity control and reactor coolant makeup. For reactivity control, the BIT flowpath is credited as an alternate source of boration in the event RCP seal injection is unavailable. Based on Calculation XX-E-013, RCP seal injection will provide sufficient boration to achieve and maintain cold shutdown reactivity conditions. Therefore, the BIT flowpath is not required for reactivity control if RCP seal injection is available. Since RCP seal injection is limited to 5 gpm per seal or 20 gpm total injection to the RCS, an additional RCS charging flowpath is required for adequate RCS makeup during plant transition from hot standby to cold shutdown. The BIT injection path was selected as the additional RCS charging flowpath.

As stated in Section 5.2.10, RCP seal injection is available in the event of a fire in area A-21. In addition, the letdown and excess letdown flowpaths can be isolated if a fire occurs in this area. Therefore, boration and inventory control through the BIT is not required to ensure PFSSD.

Damage to cables 14EMG02BA, 14EMG02BB or 14EMG02BC will prevent opening valve EMHV8803B from the control room. Damage to cables 14EMG02DA, 14EMG02DB or 14EMG02DE will prevent opening valve EMHV8801B from the control room.

As stated throughout this report, the Train A CCP is the protected charging pump if a fire occurs in area A-21. BIT inlet valve EMHV8803A and outlet valve EMHV8801A are unaffected by the fire. These valves can be opened using the associated hand switches in the control room. Therefore, boration and inventory control is available using the Train A CCP and injecting through the BIT. However, this may not be necessary due to the availability of RCP seal injection.

5.2.19 TDAFP Steam Trap Drain Valve

Valve FCFV0310 is on a 1-inch line downstream of the steam trap. Damage to cables associated with this valve could prevent closing the valve from the control room. Uncontrolled blowdown through this 1-inch line will not cause unacceptable RCS cooldown and will not impact PFSSD.

References: E-15000, XX-E-013, E-1F9202, M-12FC02, E-13FC21

5.2.20 480 VAC Motor Control Center NG02B

A fire in area A-21 could damage the main incoming power cable from load center NG02 to motor control center (MCC) NG02B. If this occurs, power to all Train B PFSSD loads fed by NG02B would be lost. The following table identifies the PFSSD components that could be lost if this occurs and whether a redundant component on the opposite train is available.

480 VAC Motor Control Center NG02B		
MCC Breaker	**Description**	**Redundant Component**
NG02BAF2	Penetration Room Cooler DSGL15B	DSGL15A
NG02BBF1	Power Feed to XPN08A	PG20GER5
NG02BBF3	Valve BBPV8702B	See below
NG02BBR2	Valve EJHV8809B	EJHV8809A
NG02BBR3	Valve EJHV8840	See below
NG02BCF2	Valve BBPV8702A	See below

480 VAC Motor Control Center NG02B		
MCC Breaker	**Description**	**Redundant Component**
NG02BCR1	Valve BGHV8100	BGHV8112
NG02BDF1	Valve BBHV8000B	BBPCV0456A
NG02BDF3	Valve EGHV0062	See below
NG02BDR1	Valve EFHV0032	EFHV0031
NG02BDR2	Valve EFHV0050	EFHV0049
NG02BEF1	Valve EGHV0127	EGHV0058
NG02BEF2	Valve EJHV8811B	See below
NG02BFR1	Relay Panel (EJHV8811B)	See below
NG02BGF3	Valve EPHV8808B	See below
NG02BHF1	Valve EGHV0133	EGHV0061
NG02BHF2	Valve EPHV8808D	See below
NG02BHF3	Valve EFHV0034	EFHV0033
NG02BHR2	Valve EFHV0046	EFHV0045

The power supply to both valves BBPV8702A and BBPV8702B (RCS to RHR pumps A and B) could be disrupted. For hot standby, this is acceptable since the power supply to these valves is normally de-energized at the MCC and the valves are maintained closed. For cold shutdown, however, the valves may not be able to be opened from the control room or from the MCC due to damage to the NG02B incoming power cables. If necessary, a cold shutdown repair could be performed to repair damage to the power supply or a containment entry could be made to open the appropriate valve.

Valve EJHV8840 is normally closed and is required to remain closed for PFSSD. Loss of power to the valve will not have an adverse impact on PFSSD since the valve is normally closed.

Valve EGHV0062 is normally open and will remain open if power is lost. PFSSD requires this valve to be open, or normally closed bypass valve EGHV0132 opened, when using CCW to maintain thermal barrier cooling. Therefore, loss of power to valve EGHV0062 will not adversely impact PFSSD. As discussed in Section 5.2.17, CCW flow to the thermal barrier heat exchangers could be lost, but CCW could be restored quickly from the control room. If CCW is not restored, then it may be necessary to isolate CCW from the thermal barrier to prevent a steam bubble from forming in the CCW piping, which could result in water hammer and damage to the CCW system. Valve EGHV0061 is unaffected by the fire and can be closed from the control room to isolate CCW from the RCP thermal barrier, if necessary.

Valve EJHV8811B is normally closed and is required to remain closed for PFSSD. Loss of power to the valve will maintain it in its closed position. Therefore, loss of power to this valve will have no impact on PFSSD.

NG02BFR1 is a relay panel section that houses relay 3XEJ19 associated with EJHV8811B. Loss of power to this relay will maintain the valve in its normally closed position, which is the desired PFSSD position.

Accumulator tank valves EPHV8808B and EPHV8808D are required to be closed prior to the RCS reaching @ 1,000 psi to prevent accidental accumulator injection. Loss of power to the valves will prevent them from being closed when necessary. The valves are closed when going to cold shutdown, so a cold shutdown repair is allowed. The power cable can either be repaired or nitrogen pressure can be relieved from the tanks to prevent injection.

References: E-15000, XX-E-013, E-13EJ06B, E-13NG01, E-1F9424A, E-1F9424B, E-1F9424D, M-12AL01, M-12BB01, M-12BG01, M-12BG03, M-12EF02, M-12EG03, M-12EM02, M-12EP01

5.2.21 Containment Coolers

Power and control cables associated with Train B containment coolers SGN01B and SGN01D are run through area A-21. Damage to these cables could prevent operation of the coolers. The containment coolers are required to maintain EQ environmental conditions within the containment during normal operations and to reduce the effects of a LOCA.

Train A containment coolers SGN01A and SGN01C are unaffected by the fire. Therefore, containment cooling will be available if a fire occurs in area A-21.

References: E-15000, XX-E-013, E-13GN02A, E-13NG01A, E-1F9441

5.2.22 Control Room Lock-Out Relays

Cables associated with control room lockout relays 86XRP5, 86XRP6 and 86XRP7 are run in area A-21. Equipment controlled by the relays is identified in the table below.

Relay #	Description
86XRP5	Train B MDAFP from CST and ESW Supply Valves (ALHV0034 and ALHV0030)
86XRP6	ESW to TDAFP Supply Valve (ALHV0033)
86XRP7	Train B MDAFP (PAL01B)

Damage to these cables could prevent operation of associated equipment. Train A equipment, located in a separate fire area, is available and is unaffected by the fire.

References: XX-E-013, E-15000, E-13AL01B, E-13AL02B, E-13AL04B, E-13RP12, E-13RP14, E-13RP15, E-093-00095, E-093-00096, E-1F9202, E-1F9204

5.2.23 Auxiliary Shutdown Panel RP118B Process Instruments

Several instrument cables associated with process indication at auxiliary shutdown panel RP118B are run through area A-21. If these instrument cables are damaged, indication at the auxiliary shutdown panel would be lost. A fire in area A-21 does not use the auxiliary shutdown panel to shutdown the plant. Process indication located in the main control room is unaffected.

References: E-15000, XX-E-013, E-13SB16

5.2.24 Containment Sump Isolation Valves

Cable 14EJG06BT, associated with containment sump isolation valve EJHV8811B, is run in this area. Damage to this cable could cause the valve to open, momentarily causing the RWST to drain to the containment sump due to normally open valve BNHV8812B. Cables associated with BNHV8812B are unaffected by a fire in this area.

If valve EJHV8811B fully opens, valve BNHV8812B will automatically close, preventing draindown of the RWST to the containment sump. If valve EJHV8811B spuriously opens but stalls before reaching full open position, valve BNHV8812B will not automatically close. If this occurs, operators will recognize a decreasing RWST level using RWST level indicators BNLI0930, BNLI0932 and BNLI0933 and take action to close BNHV8812B using BNHIS8812B in the main control room.

Based on the above discussion, damage to cables associated with valve EJHV8811B will not adversely impact safe shutdown.

References: E-15000, XX-E-013, E-13EJ06B

5.2.25 Residual Heat Removal System

PFSSD requires one train of residual heat removal (RHR) to be available for shutdown cooling. The RHR system is not used for hot standby.

Valve EGHV0101 is the Train A CCW to RHR Heat Exchanger control valve. Valve EGHV0102 is the Train B CCW to RHR Heat Exchanger control valve. PFSSD requires that the valve on the operating train of CCW be closed until shutdown cooling mode is entered, at which time the valve on the operating train of RHR needs to be open. As stated in Section 5.2.17, the Train B CCW system may not be available to supply cooling water to the Train B RHR heat exchanger.

The Train A CCW system is available to supply cooling water to the Train A RHR heat exchanger. Cables associated with valves EGHV0101 are not run in area A-21. Therefore, the Train A RHR system is available to provide decay heat removal if a fire occurs in area A-21.

5.2 PFSSD CABLE EVALUATION 12

1.0 GENERAL AREA DESCRIPTION

Fire area A-22 is located on the 2047 elevation of the Auxiliary Building and includes the rooms listed in Table A-22-1.

Table A-22-1
Rooms Located in Fire Area A-22

ROOM #	DESCRIPTION
1512	Train A Control Room A/C Unit

Fire area A-22 has no installed automatic suppression system but is provided with automatic fire detection throughout.

2.0 PRIMARY EQUIPMENT USED FOR PFSSD

Table A-22-2 lists each system credited for post-fire safe shutdown and provides a discussion regarding the availability of the system to perform its Post Fire Safe Shutdown (PFSSD) function if a severe fire occurs in this area. For a summary of the area analysis results, see Section 8.0 of the Fire Area Analysis Narrative section.

Table A-22-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-22

System	System Name	PFSSD Function*	Comments
AB	Main Steam	R, M, H, P, S	Steam generator A ARV ABPV0001 could spuriously open. If necessary, fail the valve closed by closing valves KAV1435 (air) and KAV1364 (nitrogen) and bleeding air from the regulator.
AC	Main Turbine	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-22.
AE	Main Feedwater	H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-22.
AL	Aux. Feedwater System	H, P	Train A MDAFP may not be available. Train B MDAFP is available using either the CST or ESW as the suction source. The TDAFP is available using Train B ESW as the suction source. The suction from the CST and Train A ESW may be affected.
AP	Condensate Storage System	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-22.
BB	Reactor Coolant System	R, M, H, P, S	RCP thermal barrier cooling could be affected due to spurious closure of BBHV0013, BBHV0014, BBHV0015 and BBHV0016.
BG	Chemical and Volume Control System	R, M, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-22.
BM	Steam Generator Blowdown System	R, M, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-22.
BN	Borated Refueling Water Storage System	R, M, H	Level transmitters BNLT0930 and BNLT0932 may be affected, causing a spurious low-low level in the RWST. A SIS is not credible if a fire occurs in this area so containment sump isolation valves will not open and the RWST will not drain to the sump.
EF	Essential Service Water System	H, S	The Train A ESW system may be affected due to the potential full opening of EFHV0059 causing a flow imbalance in the system. The Train B ESW system is unaffected by a fire in this area.
EG	Component Cooling Water System	S	The Train A CCW system may be affected. The Train B CCW system is unaffected by a fire in this area. CCW flow to the RCP thermal barriers could be affected as discussed in BB System comments above. CCW flow indicators EGFI0128 and EGFI0129 are unaffected. RCP seal injection remains available throughout the event. Valve EGHV0101 could spuriously open or may not open when operating Train A RHR. Valve EGHV0102 is unaffected.

Table A-22-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-22

System	System Name	PFSSD Function*	Comments
EJ	Residual Heat Removal System	M, H, P	The Train A RHR system may be affected. The Train B RHR system is unaffected by a fire in this area. Containment sump isolation valves EJHV8811A and EJHV8811B could spuriously open, causing a draindown path from the RWST to the containment sump. Valves BNHV8812A and BNHV8812B will automatically close, as designed, when EJHV8811A and EJHV8811B, respectively, reach full open position, mitigating draindown. However, if either EJHV8811A or EJHV8811B stall before reaching full open position, BNHV8812A or BNHV8812B will not automatically close. In this case, operators can close BNHV8812A and BNHV8812B using BNHIS8812A and BNHIS8812B, respectively, in the main control room.
EM	High Pressure Coolant Injection	R, M	All PFSSD functions associated with the High Pressure Coolant Injection System are satisfied. Valves EMHV8801A and EMHV8803A are available to ensure a charging flow path from the Train A CCP to the RCS.
EN	Containment Spray	R, M	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-22.
EP	Safety Injection Accumulators	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-22.
FB	Auxiliary Steam	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-22.
FC	Auxiliary Turbines	R, H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-22.
GD	ESW Pump House HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-22.
GF	AFW Pump Room Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-22.
GK	Control Room and Class 1E Switchgear Room Coolers	S	The PFSSD Support function associated with the Control Room and Class 1E Switchgear Room Coolers is satisfied. Control room A/C unit SGK04B is not affected by a fire in area A-22. Train B Class 1E Switchgear Room Cooler SGK05B is unaffected by a fire in area A-22.
GL	Auxiliary Building HVAC	S	Train A CCW Pump Room Cooler (SGL11A) could be affected. Train B CCW Pump Room Cooler (SGL11B) is unaffected by a fire in this area.
GM	Emergency Diesel Generator Room HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-22.
GN	Containment Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-22.

Table A-22-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-22

System	System Name	PFSSD Function*	Comments
JE	Diesel Fuel Oil	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-22.
KA	Instrument Air	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-22.
KC	Fire Protection	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-22.
KH	Service Gas	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-22.
KJ	Standby Diesel Engine	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-22.
MA	Main Generation	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-22.
MR	Startup Transformer	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-22.
NB	4.16 kV System	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-22.
NE	Standby Diesel Generator	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-22.
NF	Load Shed and Emergency Load Sequencing	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-22.
NG	480V Load Centers and MCCs	S	Train A motor control center NG03C could be affected by the fire. Redundant Train B MCCs NG02A, NG02B and NG04C are unaffected by the fire.
NK	125VDC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-22.
NN	120VAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-22.
PA	13.8kV	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-22.
PB	4.16kV	H, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-22.
PG	480V Load Centers and MCCs	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-22.
PK	125VDC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-22.

Table A-22-2 Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-22			
System	**System Name**	**PFSSD Function***	**Comments**
PL	Local Instrument Panels	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-22.
PN	120VAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-22.

3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD

This section describes operator actions that may need to be performed inside or outside the control room to achieve and maintain hot standby if a fire occurs in area A-22. This section also describes cold shutdown repairs that may need to be made to achieve and maintain cold shutdown conditions. Operator actions are proceduralized in OFN KC-016.

3.1 ACTIONS OUTSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

Operator Manual Actions (OMAs) are those actions outside the main control room required to achieve and maintain hot standby. OMAs are identified in E-1F9900 and were determined from thermal hydraulic analysis WCNOC-CP-002. Applicable E-1F9900 OMAs are annotated herein. All other actions outside the control room are desirable for plant control in support of hot standby but not required to achieve and maintain hot standby.

3.1.1 Isolation of SGK04A

A fire could cause spurious operation of SGK04A. If this occurs, operators can isolate power to the unit by opening breaker NG0105 located in fire area C-9 (Room 3301).

3.1.2 Steam Generator Atmospheric Relief Valves

It may be necessary to fail close steam generator ARV ABPV0001 by closing valves KAV1435 (air) and KAV1364 (nitrogen) and bleeding air from the regulator.

3.2 ACTIONS INSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

3.2.1 Auxiliary Feedwater

It may be necessary to line up AFW using the TDAFP, supplied by Train B ESW or using the Train B MDAFP supplied by either the CST or ESW. Since ARV ABPV0001 may be affected, it may be necessary to use the TDAFP in order to cooldown using at least two steam generators.

3.2.2 Mitigation of RWST Draindown to Containment Sump

If a fire occurs in area A-22, it may be necessary to close valves BNHV8812A and BNHV8812B from the control room using BNHIS8812A and BNHIS8812B, respectively, to mitigate draindown of the RWST into the containment sump. This condition could occur due to EJHV8811A and/or EJHV8811B spuriously opening but stalling before reaching full open position, thereby not providing the permissive for BNHV8812A and BNHV8812B to close. RWST level indication is available using level indicators BNLI0931 and BNLI0933.

3.2.3 Component Cooling Water

Train A CCW could be affected by a fire in this area. If this occurs, swap to Train B CCW using normal operating procedures if Train B CCW is not already running.

3.3 ACTIONS TO ACHIEVE AND MAINTAIN COLD SHUTDOWN

None

4.0 CONCLUSION

With some exceptions, redundant Post-Fire Safe Shutdown capability exists if a severe fire occurs in this area. For those exceptions, feasible manual actions are available and are unaffected by the fire. Manual actions are documented in Section 3.0.

5.0 DETAILED ANALYSIS

This section describes the detailed component-by-component and cable-by-cable analysis for a fire in area A-22.

5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA A-22

PFSSD components (S. in E-15000) located in fire area A-22 are shown in Table A-22-3. An evaluation of each component and associated cables is provided in the sections that follow. The applicable evaluation section is listed in Table A-22-3.

Table A-22-3
PFSSD Equipment Located in Fire Area A-22

Room #	PFSSD Equipment	Description	Evaluation Section	Comments
1512	GK198A	Control Room A/C Unit SKG04A Control Panel	5.1.1

1512	TB15205	TB for RWST Level Transmitter BNLT0932	5.2.3	

5.1.1 Control Room A/C Unit SGK04A

Train A control room A/C unit SGK04A and associated power and control panels (GK198A, GK198B and GK198C) are located in fire area A-22. In addition, power and control cables associated with this unit are also run in the area. A fire could damage cables and equipment associated with SGK04A, which would prevent operation of the unit or cause the unit to spuriously operate.

Spurious operation of the unit can be mitigated by opening breaker NG0105 located in fire area C-9 (Room 3301).

Control room A/C unit SGK04A inlet and outlet dampers GKHZ0029A and GKHZ0029B and associated control cables are located in the area. Damage to the cables or equipment due to a fire could prevent operation of the dampers, which would prevent operation of SGK04A.

Redundant Train B control room A/C unit SGK04B and associated cables and equipment are located in a different fire area and are separated by minimum 3-hour rated fire barriers. Therefore, there is reasonable assurance that control room ventilation will be available using Train B control room A/C unit SGK04B. Therefore, no E-1F9900 OMA is required to address SGK04A function.

5.1.2 Train A 480 VAC Motor Control Center NG03C

Motor Control Center (MCC) NG03C is located in area A-22. Several Train A PFSSD components could be affected if the fire damages NG03C and disrupts power to those components.

Redundant Train B equipment, powered by Train B 480 VAC Motor Control Centers NG02A, NG02B and NG04C are located in a separate fire area and are unaffected by the fire.

For further discussion of the cables associated with Train A 480 VAC MCC NG03C that run through area A-22, see Section 5.2.

5.2.1 Steam Generator Atmospheric Relief Valves

Cable 11ABI20EE, associated with steam generator atmospheric relief valve (ARV) ABPV0001 runs in area A-22. Cables associated with the remaining ARVs do not run in area A-22.

Damage to cable 11ABI20EE could cause a false signal that would open ABPV0001. If this occurs, operators may not be able to close the valve from the control room. A single failed open ARV is bounded by the main steamline break analysis, so this condition would not impact the ability to safely shut down. Motor driven auxiliary feedwater pump B is available to supply auxiliary feedwater to steam generators A and D. In addition, the turbine driven auxiliary feedwater pump (TDAFP) is available to supply auxiliary feedwater to all four steam generators.

If ABPV0001 spuriously opens, it can be failed closed by isolating the air and nitrogen supplies and bleeding air from the regulator. Air and nitrogen are isolated by closing valves KAV1435 (air) and KAV1364 (nitrogen). These valves are located in fire area A-23 (room 1508) and access is available without having to traverse area A-22. Cooldown can then be accomplished using the TDAFP supplying any two of steam generators B, C or D.

Based on the above discussion, redundant capability exists or manual actions are available to control at least two steam generators and close the remaining two. Therefore, steam generator atmospheric control can be achieved.

Up to three ARVs can fail closed or open without impacting ability to achieve and maintain hot standby according to thermal hydraulic analysis WCNOC-CP-002. With at least one ARV unaffected, no E-1F9900 OMA is required to address ARV closure or control. Reference Attachment 4, MSO Evaluation Scenario ID PWROG 23.

References: E-15000, XX-E-013, E-13AB20A, E-1F9101

5.2.2 Auxiliary Feedwater

The PFSSD design requires the use of one auxiliary feedwater pump supplying water to at least two steam generators. The turbine driven auxiliary feedwater pump (TDAFP) is normally aligned to supply all four steam generators. The Train A motor driven auxiliary feedwater pump (MDAFP) is aligned to supply steam generators B and C. The Train B MDAFP is aligned to supply steam generators A and D.

Several cables associated with Train A auxiliary feedwater (AFW) components are run in area A-22. Damage to these cables could impair both suction sources (CST and ESW) to the Train A MDAFP and prevent the CST and Train A ESW from supplying the TDAFP.

Cables associated with Train B AFW components are unaffected by the fire. The Train B CST and ESW source is available to supply the Train B MDAFP. The Train B ESW source is available to supply the TDAFP.

Based on the above discussion, the Train B MDAFP is available to supply AFW to steam generators A and D. However, as stated in Section 5.2.1, steam generator A ARV may have to be failed closed. The TDAFP is available to supply AFW to all four steam generators.

References: E-15000, XX-E-013, E-1F9202, E-1F9204

5.2.3 Refueling Water Storage Tank

The RWST is credited in the PFSSD analysis as the primary source of borated water to achieve cold shutdown. The Wolf Creek Technical Specifications ensure the minimum quantity and boron concentration is maintained to achieve cold shutdown. Therefore, RWST level transmitters, indicators and circuits are not evaluated for level indication.

The RWST level transmitters and associated circuits are included in the PFSSD analysis because of the automatic functions they perform. In particular, a low level in the RWST on 2 out of 4 RWST level transmitters, coincident with a safety injection signal, will initiate a swapover, which is not desired for PFSSD because it could cause the RWST to drain to the containment sump.

Cables associated with refueling water storage tank (RWST) level transmitters BNLT0930 and BNLT0932 are run in fire area A-22. Damage to these cables could initiate a spurious low-low RWST level signal. A spurious SIS is not credible if a fire occurs in area A-22. Therefore, the open permissive will not occur for valves EJHV8811A and EJHV8811B. Consequently, a spurious RWST draindown is not credible if a fire occurs in this area.

Based on the above discussion, the RWST is available if a fire occurs in area A-22.

5.2.4 Essential Service Water to/from Component Cooling Water Valves

Valve EFHV0051 is the Train A essential service water (ESW) to Train A component cooling water (CCW) heat exchanger supply isolation valve and is required to be open when using Train A for PFSSD. Valve EFHV0059 is the return valve from Train A CCW heat exchanger to the ultimate heat sink (UHS). PFSSD requires that EFHV0059 be closed when using Train A CCW for plant shutdown following a fire and that valve EFV0058 be maintained in a locked throttled position to provide the minimum required ESW water flow. If valve EFHV0059 were to spuriously open when operating Train A ESW, flow imbalance could occur, which will result in flow depletion and inoperability of essential PFSSD components.

Power and control cables associated with EFHV0051 and EFHV0059 run in area A-22. A fire in area A-22 will result in damage to these cables and the inability to control ESW flow to Train A CCW.

Cables associated with Train B ESW to/from CCW valves are run in a different fire area and are unaffected by a fire in area A-22. Therefore, Train B ESW is available to supply the necessary cooling flow to the CCW Train B heat exchanger.

References: E-15000, XX-E-013, E-13EF04, E-13EF05, M-12EF02

5.2.5 Component Cooling Water

For PFSSD, the component cooling water (CCW) system is used to provide cooling to the centrifugal charging pump (CCP) oil cooler, the seal water heat exchanger, the RHR heat exchangers and the RHR pump seal coolers. In addition, the CCW system provides cooling to the RCP thermal barriers and is credited as a backup to RCP seal injection for maintaining seal cooling.

Power and control cables associated with Train A CCW valves EGHV0015, EGHV0053 and EGHV0061 run through area A-22. In addition, an instrument cable associated with pressure transmitter EGPT0077 (CCW pumps A and C discharge pressure) runs through area A-22. Damage to these cables due to a fire could prevent operation of the associated equipment and prevent operation of Train A CCW. Cables associated with redundant Train B CCW components are run in a different fire area and are unaffected by the fire.

Power and control cables associated with valves BBHV0013, BBHV0014, BBHV0015 and BBHV0016 could be affected by a fire in this area. Cable damage could cause the valves to spuriously close. If this occurs, CCW flow to the RCP thermal barriers would be lost. In addition, if valve EGHV0061 were to spuriously close, CCW flow to the RCP thermal barriers would be lost. This is acceptable since RCP seal injection remains available to cool the seals.

Loss of thermal barrier cooling would be indicated in the control room as a reduction in flow on flow indicators EGFI0128 and EGFI0129. Therefore, operators can diagnose a loss of thermal barrier cooling.

Cables associated with CCW pump room cooler SGL11A are run in area A-22. Damage to these cables could prevent operation of the cooler. Train B CCW pump room cooler SGL11B is unaffected by the fire and will be available to provide room cooling for the Train B CCW pumps.

Based on the above discussion, Train A CCW could be affected by a fire in this area but Train B CCW is available. CCW flow to the RCP thermal barriers could be affected, but RCP seal injection remains available.

References: E-15000, XX-E-013, E-13BB03, E-13EG05B, E-13EG05C, E-13EG07, E-13EG09A, E-13GL06, E-1F9303, E-1F9401A, E-1F9444

5.2.6 Residual Heat Removal System

PFSSD requires one train of residual heat removal (RHR) to be available for shutdown cooling. The RHR system is not used for hot standby.

Power and control cables associated with valve EJHV8804A are run in area A-22. This valve is required to remain closed for PFSSD when operating the Train A RHR system. Maintaining the valve closed will prevent flow diversion from the RCS to the CVCS.

Valve EGHV0101 is the Train A CCW to RHR Heat Exchanger control valve. Valve EGHV0102 is the Train B CCW to RHR Heat Exchanger control valve. These valves are normally closed during power operation. PFSSD requires that the valve on the operating train of CCW be closed until shutdown cooling mode is entered, at which time the valve on the operating train of RHR needs to be open. As stated in Section 5.2.5, the Train A CCW system may not be available to supply cooling water to the Train A RHR heat exchanger. Cables 11EGG07AA, 11EGG07AB and 11EGG07AC are associated with valve EGHV0101. Damage to the cables could prevent operation of EGHV0101 and damage to cable 11EGG07AC could cause the valve to spuriously open. Valve EGHV0102 is unaffected by a fire in this area.

The Train B CCW system is available to supply cooling water to the Train B RHR heat exchanger. Cables associated with valves EGHV0102 and EJHV8804B are not run in area A-22. Therefore, the Train B RHR system is available to provide decay heat removal if a fire occurs in area A-22.

References: E-15000, XX-E-013, E-13EG07, E-13EJ04A, M-12EJ01

5.2.7 Main Steam Isolation Valve (MSIV) Downstream Components

Control cables for several components downstream of the MSIVs are run in area A-22. These components are required to function (close) in the event the MSIVs cannot be closed due to the fire. A fire in area A-22 will not prevent the closure of the MSIVs or the MSIV bypass valves. Therefore, cable damage to the components downstream of the MSIVs will not adversely impact the ability to achieve and maintain PFSSD.

References: E-15000, XX-E-013, E-13AB08, E-13AB11A, E-13AB11B, E-13AB11C, E-1F9101, E-1F9103

5.2.8 Containment Sump Isolation Valves

Cable 11EJG06AT, associated with containment sump isolation valve EJHV8811A, is run in this area. Damage to this cable could cause the valve to open, momentarily causing the RWST to drain to the containment sump due to normally open valve BNHV8812A. Cables associated with BNHV8812A are unaffected by a fire in this area.

If valve EJHV8811A fully opens, valve BNHV8812A will automatically close, preventing draindown of the RWST to the containment sump. If valve EJHV8811A spuriously opens but stalls before reaching full open position, valve BNHV8812A will not automatically close. If this occurs, operators will recognize a decreasing RWST level using RWST level indicators BNLI0931 and BNLI0933 and take action to close BNHV8812A using BNHIS8812A in the main control room.

Cable 14EJG06BT, associated with containment sump isolation valve EJHV8811B, is run in this area. Damage to this cable could cause the valve to open, momentarily causing the RWST to drain to the containment sump due to normally open valve BNHV8812B. Cables associated with BNHV8812B are unaffected by a fire in this area.

If valve EJHV8811B fully opens, valve BNHV8812B will automatically close, preventing draindown of the RWST to the containment sump. If valve EJHV8811B spuriously opens but stalls before reaching full open position, valve BNHV8812B will not automatically close. If this occurs, operators will recognize a decreasing RWST level using RWST level indicator BNLI0931 and BNLI0933 and take action to close BNHV8812B using BNHIS8812B in the main control room.

Based on the above discussion, damage to cables associated with valves EJHV8811A and EJHV8811B will not adversely impact safe shutdown.

References: E-15000, XX-E-013, E-13EJ06A

5.2.9 Boron Injection Tank (BIT) Flowpath

The Boron Injection Tank (BIT) flowpath is credited for reactivity control and reactor coolant makeup. For reactivity control, the BIT flowpath is credited as an alternate source of boration in the event RCP seal injection is unavailable. Based on Calculation XX-E-013, RCP seal injection will provide sufficient boration to achieve and maintain cold shutdown reactivity conditions. Therefore, the BIT flowpath is not required for reactivity control if RCP seal injection is available.

The power and control cables for the RCP seal injection valves (BBHV8351A, BBHV8351B, BBHV8351C and BBHV8351D) are not routed in area A-22 and cannot be damaged by an area A-22 fire. Thus, RCP seal injection will be available in the event of a fire in area A-22. Therefore, boration and inventory control through the BIT is not required to ensure PFSSD.

Since RCP seal injection is limited to 5 gpm per seal or 20 gpm total injection to the RCS, an additional RCS charging flowpath is required for adequate RCS makeup during plant transition from hot standby to cold shutdown. The BIT injection path is the additional RCS charging flowpath.

Damage to cable 14EMG02DE will prevent opening the BIT outlet valve EMHV8801B from the control room. Train A CCP is unaffected if a fire occurs in area A-22. BIT inlet valve EMHV8803A and outlet valve EMHV8801A are also unaffected by the fire. These valves can be opened using the associated hand switches in the control room. Therefore, boration and inventory control is available using the Train A CCP and injecting through the BIT. However, this may not be necessary due to the availability of RCP seal injection.

1.0 GENERAL AREA DESCRIPTION

Fire area A-23 is located on the 2026 and 2047 elevation of the Auxiliary Building and includes the rooms listed in Table A-23-1.

Table A-23-1
Rooms Located in Fire Area A-23

ROOM #	DESCRIPTION
1411	Main Feedwater Room No. 1 West
1412	Main Feedwater Room No. 2 East
1508	Main Steam Isolation Valve Room No. 1 West
1509	Main Steam Isolation Valve Room No. 2 East

Rooms 1508 and 1509 have infrared flame detectors installed. There is no automatic fire suppression in fire area A-23. A 2-foot thick barrier separates the east and west compartments within this area. The wall is not fire rated due to the presence of large doorway and vent openings which are necessary for communication between rooms and to prevent over-pressurization of the compartment. The level of protection was found acceptable by the NRC as documented in the Wolf Creek Safety Evaluation Report, Supplement 5, Section 9.5.1.4.

2.0 PRIMARY EQUIPMENT USED FOR PFSSD

Table A-23-2 lists each system credited for post-fire safe shutdown and provides a discussion regarding the availability of the system to perform its Post Fire Safe Shutdown (PFSSD) function if a severe fire occurs in this area. For a summary of the area analysis results, see Section 8.0 of the Fire Area Analysis Narrative section.

Table A-23-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-23

System	System Name	PFSSD Function*	Comments
AB	Main Steam	R, M, H, P, S	A fire in the East compartment (Rooms 1412 and 1509) may require ARVs ABPV0002 and ABPV0003 to be failed closed by opening switches NN0208 and NN0307. Cooldown can be controlled using steam generators A and D ARVs ABPV0001 and ABPV0004. A fire in the West compartment (Rooms 1411 and 1508) may require ARVs ABPV0001 and ABPV0004 to be failed closed by opening switches NN0116 and NN0416. Cooldown can be controlled using steam generators B and C ARVs ABPV0002 and ABPV0003. Main steam isolation valves and bypass valves may not be isolable from the control room. Isolation valves located downstream of the MSIVs and bypass valves are unaffected by the fire and can be closed from the control room. Main steamline pressure transmitters ABPT0524, ABPT0525, ABPT0526, ABPT0534, ABPT0535 and ABPT0536 may be affected by a fire in the east compartment and may cause a spurious SI. Steamline pressure indication remains available on steam generators A and D using ABPI0514A, ABPI0515A, ABPI0516A, ABPI0544A, ABPI0545A, and ABPI0546A. Main steamline pressure transmitters ABPT0514, ABPT0515, ABPT0516, ABPT0544, ABPT0545 and ABPT0546 may be affected by a fire in the west compartment and may cause a spurious SI. Steamline pressure indication remains available on steam generators A and D using ABPI0524A, ABPI0525A, ABPI0526A, ABPI0534A, ABPI0535A, and ABPI0536A.
AC	Main Turbine	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-23.
AE	Main Feedwater	H, P	All four main feedwater isolation valves may not close using either hand switch AEHS0080 or AEHS0081. Main feedwater flow can be stopped from the control room using FCHS0018A, FCHS0018B, FCHS0118A, FCHS0118B and AEHIS0104. All steam generator level indicators on all four steam generators are available.
AL	Aux. Feedwater System	H, P	A fire in the East compartment (Rooms 1412 and 1509) could impact operability of the TDAFP. Both MDAFPs are available following a fire in this area. All three AFW pumps are available if a fire occurs in the West compartment (Rooms 1411 and 1508).
AP	Condensate Storage System	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-23.
BB	Reactor Coolant System	R, M, H, P, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-23. RCS pressure indication is available using BBPI0405 or BBPI0406. Pressurizer level indication is available using BBLI0459A or BBLI0460A.

Table A-23-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-23

System	System Name	PFSSD Function*	Comments
BG	Chemical and Volume Control System	R, M, S	A safety injection signal caused by a sporadic low steamline pressure signal will cause both trains of charging pumps to operate, isolate normal charging and close the VCT outlet valves. This will not adversely impact PFSSD as this is the desired position for these components.
BM	Steam Generator Blowdown System	R, M, H	Blowdown valves BMHV0001, BMHV0002, BMHV0003 and BMHV0004 may have to be failed closed by opening breaker NK4411 in room 3404 (fire area C-15).
BN	Borated Refueling Water Storage System	R, M, H	A safety injection signal caused by a sporadic low steamline pressure signal will cause the RWST to align to the charging suction header. This will not adversely impact PFSSD.
EF	Essential Service Water System	H, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-23.
EG	Component Cooling Water System	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-23.
EJ	Residual Heat Removal System	M, H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-23.
EM	High Pressure Coolant Injection	R, M	A safety injection signal caused by a sporadic low steamline pressure signal will cause the safety injection pumps to operate. This can be mitigated by entering the EMG procedure network and, if necessary, place SI pump control hand switches EMHIS0004 and EMHIS0005 on RL017 in pull-to-lock.
EN	Containment Spray	R, M	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-23.
EP	Safety Injection Accumulators	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-23.
FB	Auxiliary Steam	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-23.
FC	Auxiliary Turbines	R, H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-23.
GD	ESW Pump House HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-23.
GF	AFW Pump Room Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-23.

Table A-23-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-23

System	System Name	PFSSD Function*	Comments
GK	Control Room and Class 1E Switchgear Room Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-23.
GL	Auxiliary Building HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-23.
GM	Emergency Diesel Generator Room HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-23.
GN	Containment Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-23. Containment pressure indicators GNPI0934, GNPI0935, GNPI0936 and GNPI0937 are available.
JE	Diesel Fuel Oil	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-23.
KA	Instrument Air	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-23.

3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD

This section describes operator actions that may need to be performed inside or outside the control room to achieve and maintain hot standby if a fire occurs in area A-23. This section also describes cold shutdown repairs that may need to be made to achieve and maintain cold shutdown conditions. Operator actions are proceduralized in OFN KC-016.

3.1 ACTIONS OUTSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

Operator Manual Actions (OMAs) are those actions outside the main control room required to achieve and maintain hot standby. OMAs are identified in E-1F9900 and were determined from thermal hydraulic analysis WCNOC-CP-002. Applicable E-1F9900 OMAs are annotated herein. All other actions outside the control room are desirable for plant control in support of hot standby but not required to achieve and maintain hot standby.

3.1.1 Steam Generator Blowdown

If a fire occurs in the east compartment (Rooms 1412/1509), blowdown valves BMHV0002 and BMHV0003 may have to be failed closed by opening breaker NK4411 in room 3404 (fire area C-15). This will also fail BMHV0001 and BMHV0004 closed.

If a fire occurs in the west compartment (Rooms 1411/1508), blowdown valves BMHV0001 and BMHV0004 may have to be failed closed by opening breaker NK4411 in room 3404 (fire area C-15). This will also fail BMHV0002 and BMHV0003 closed.

3.1.2 Steam Generator Atmospheric Relief Valves

If a fire occurs in the east compartment (Rooms 1412 and 1509) isolate steam generators B and C ARVs by opening switches NN0208 and NN0307. These switches are located in rooms 3410 (Area C-15) and 3414 (Area C-16), respectively. Access is available without traversing area A-23 and emergency lighting is provided in the area.

If a fire occurs in the west compartment (Rooms 1411 and 1508) isolate steam generators A and D ARVs by opening switches NN0116 and NN0416. These switches are located in rooms 3408 (Area C-16) and 3404 (Area C-15), respectively. Access is available without traversing area A-23 and emergency lighting is provided in the area.

3.2 ACTIONS INSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

3.2.1 Main Steam Isolation

MSIVs ABHV0011, ABHV0014, ABHV0017 and ABHV0020 may not close and MSIV bypass valves ABHV0012, ABHV0015, ABHV0018 and ABHV0021 could spuriously open. Operators may need to isolate redundant components located downstream of the MSIVs using hand switches in the main control room.

3.2.2 Safety Injection

A spurious Safety Injection Signal (SIS) due to low steamline pressure can be mitigated by consulting EMG E-0 and terminating the spurious SIS.

3.2.3 Main Feedwater Isolation

All four main feedwater isolation valves may not close using either hand switch AEHS0080 or AEHS0081. Main feedwater flow can be stopped from the control room using FCHS0018A, FCHS0018B, FCHS0118A, FCHS0118B and AEHIS0104.

3.3 ACTIONS TO ACHIEVE AND MAINTAIN COLD SHUTDOWN

None specific to PFSSD

4.0 CONCLUSION

With some exceptions, redundant Post Fire Safe Shutdown capability exists if a severe fire occurs in area A-23. For those exceptions, feasible manual actions are available and are unaffected by the fire. Manual actions are documented in Section 3.0.

5.0 DETAILED ANALYSIS

This section describes the detailed component-by-component and cable-by-cable analysis for a fire in area A-23.

5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA A-23

PFSSD components (S. in E-15000) located in fire area A-23 are shown in Table A-23-3. An evaluation of each component and associated cables is provided in the sections that follow. The applicable evaluation section is listed in Table A-23-3.

5.1.1 Steam Generator Main Steam Isolation Valves (MSIVs) and Bypass Valves

PFSSD requires the MSIVs and bypass valves be closed to prevent reactivity addition due to uncontrolled cooldown. The MSIVs and bypass valves are closed from the control room using all close hand switches ABHS0079 or ABHS0080. Alternatively, components located downstream of the MSIVs can be closed to isolate main steam flow. These include the steam dumps, the main steam drain valves, main feed pump turbine valves and others as indicated on E-1F9103.

Each MSIV is designed to utilize system fluid (main steam) as the motive force to open and close. The valve actuation (open or close) is accomplished through positioning a series of six electric solenoid pilot valves to either direct the system fluid to the Upper Piston Chamber (UPC) and/or the Lower Piston Chamber (LPC), or vent either or both piston chambers. The six solenoid pilot valves are divided into two trains (3 per train) that are independently powered and controlled. Either train can independently perform the PFSSD function to close the valve and isolate main steam. This is done by actuating either all close hand switch ABHS0079 (separation group 4) or ABHS0080 (separation group 1) to de-energize the associated solenoid valves.

The following table identifies the solenoids and associated control cables for each hand switch.

MSIV	ABHS0079 (Sep Group 4)		ABHS0080 (Sep Group 1)	
	Solenoids	Cable	Solenoids	Cable
ABHV0011	MV2, MV4, MV6	14ABK28BH	MV1, MV3, MV5	11ABK29BH
ABHV0014	MV2, MV4, MV6	14ABK29AH	MV1, MV3, MV5	11ABK28AH
ABHV0017	MV2, MV4, MV6	14ABK28AH	MV1, MV3, MV5	11ABK29AH
ABHV0020	MV2, MV4, MV6	14ABK29BH	MV1, MV3, MV5	11ABK28BH

A fire in the east compartment may affect the ability to close MSIVs ABHV0017 and ABHV0020 and may cause MSIV bypass valves ABHV0018 and ABHV0021 to spuriously open. A fire in the west compartment may affect the ability to close MSIVs ABHV0011 and ABHV0014 and may cause MSIV bypass valves ABHV0012 and ABHV0015 to spuriously open. If this occurs, operators will need to isolate redundant components located downstream of the MSIVs using hand switches in the main control room.

Based on the above discussion, a fire in area A-23 could affect the ability to close the MSIVs and bypass valves, due to the valves and circuits located in the area. However, the downstream components are unaffected by the fire and can be closed from the control room.

References: E-15000, XX-E-013, E-13AB23A, E-13AB23B, E-13AB26, E-13AB27, E-13AB28, E-13AB29, E-1F9101, M-12AB02

5.1.2 Safety Injection and Containment Spray

Calculation XX-E-013, Appendix 1 (PFSSD Support Section) provides a detailed discussion about the potential PFSSD impact of a spurious safety injection signal (SIS) and spurious containment spray actuation signal (CSAS). This section discusses the specific PFSSD impact if a fire occurs in this area.

Main steamline pressure transmitters ABPT0524, ABPT0525, ABPT0526, ABPT0534, ABPT0535 and ABPT0536 may be affected by a fire in the east compartment and may cause a spurious SI. Main steamline pressure transmitters ABPT0514, ABPT0515, ABPT0516, ABPT0544, ABPT0545 and ABPT0546 may be affected by a fire in the west compartment and may cause a spurious SI.

A fire in this area will not cause a spurious CSAS.

A spurious SIS starts the charging sequence which starts the CCPs and opens the BIT flowpath valves. For a fire in this area, the BIT flowpath valves are unaffected and would open on a SIS. The RWST valves are unaffected and would open on a SIS. Also, the CCP mini flow valves are unaffected and CCW flow to the seal water heat exchanger is unaffected to ensure cooling of the recirc flow, RCP seal return and CCP oil cooler. Therefore, the charging pumps will not be affected by a spurious SIS caused by a fire in this area.

A start of the CCW system will not adversely impact the system. Both trains of ESW are unaffected and will start on a spurious SIS, providing necessary cooling water to the CCW heat exchangers.

A start of the AFW pumps will not adversely impact PFSSD. All three AFW pumps are unaffected by a fire in the west compartment in this area. Both motor driven AFW pumps are unaffected by a fire in the east compartment in this area. Suction from the CST to the AFW pumps is unaffected. Discharge flow will either return to the CST or flow to the steam generators through the discharge control valves. Therefore, the AFW pumps are unaffected by a spurious SIS caused by a fire in this area.

A start of the RHR pumps due to a spurious SIS will not adversely impact either pump. The RWST supply to the pumps is not affected and the recirculation valves will remain in the open position. Component cooling water is available to both RHR heat exchangers. Operators will have time to terminate the spurious SIS and stop the pumps.

Based on the above discussion, a spurious SIS can occur if a fire occurs in this area. Credited PFSSD equipment will not be damaged by the spurious SIS. Therefore, a spurious SIS will not adversely impact PFSSD.

References: E-15000, XX-E-013, E-13AB21, E-1F9431, E-1F9432, M-12AB01

5.1.3 Steam Generator Atmospheric Relief Valves

All four steam generator ARVs are located in this area. Two ARVs are located on the east side of the shield wall and the other two are located on the west side. The PFSSD design requires all four ARVs to be controlled. Damage to the ARVs and associated cables is discussed in the following paragraphs.

For the purpose of this analysis, it is assumed that direct flame impingement on the ARV, in the absence of cable damage, will not cause the valve to spuriously open. The valves require air pressure to open. The current to pneumatic (I/P) converter receives an open signal from the control panel via a 2/c STP #16 AWG instrument cable.

Cables associated with steam generator pressure transmitters ABPT0001, ABPT0002, ABPT0003 and ABPT0004 are not run in area A-23. Therefore, a spurious high pressure signal is not credible. However, instrument cables that run to the I/P converter for each ARV are run in this area. Damage to these cables could cause the associated ARV to open.

Since the air and nitrogen supply valves for all four ARVs, as well as the local control stations for ARVs ABPV0002 and ABPV0003, are located in this area, a spuriously open ARV will need to be mitigated by de-energizing the I/P device. This can be done by opening the associated 120 VAC power supply switch shown in the following table.

ARV	SWITCH	REFERENCE DRAWINGS
ABPV0001	NN0116	J-110-00583, J-110-00584, J-110-00587
ABPV0002	NN0208	J-110-00588, J-110-00590
ABPV0003	NN0307	J-110-00588, J-110-00591
ABPV0004	NN0416	J-110-00592, J-110-00593, J-110-00596

A fire in the West compartment (Rooms 1411 and 1508) may require de-energizing ABPV0001 and ABPV0004. As discussed in Section 5.1.5, all three AFW pumps are available if a fire occurs in these rooms. Opening switches NN0116 and NN0416 will affect the following additional components:

Switch	Affected Components
NN0116	ACPT0233 - Main Steam Ctrl Valve 1 Pressure ALFT0002 - AFW to Steam Generator A Flow Transmitter ALFT0009 - AFW to Steam Generator B Flow Transmitter for ALHV0009 Control ALFT0011 - AFW to Steam Generator C Flow Transmitter for ALHV0011 Control ALHV0006 - TDAFP to SG D Isolation Valve (Valve Fails Open) ALHV0008 - TDAFP to SG A Isolation Valve (Valve Fails Open) ALHV0009 - MDAFP A to SG B Flow Control Valve ALHV0011 - MDAFP A to SG C Flow Control Valve ALLSL0025 - CST Low Level Switch ALPT0025 - MDAFP A Suction Pressure BNTE0002 - RWST Temperature EFFT0053 - ESW A Flow to Powerblock EFPDS0019 - ESW A Self-Cleaning Strainer Pressure Differential Switch EGFT0107 - CCW to Radwaste Building Flow (Train A) EGLV0001 - CCW Surge Tank A Makeup Valve from Demineralized Water EGTSH0031 - CCW A Heat Exchanger Outlet Temperature EJLSH0007 - Containment Recirc Sump A Level GKAE0003 - Control Room Chlorine Monitor GMTC0001 - Diesel Generator A Ventilation Supply Fan GNTE0062 - Containment Cooler C Temperature GTRE0059 - Containment Radiation Monitor JELT0001 - Diesel Generator A Day Tank Level JELT0012 - Diesel Generator A Day Tank Level LFLIT0009 - Containment Normal Sump Level
NN0416	ALFT0007 - AFW to Steam Generator A Flow Transmitter ALHV0005 - MDAFP B to SG D Flow Control Valve ALHV0007 - MDAFP B to SG A Flow Control Valve ALHV0010 - TDAFP to SG B Isolation Valve (Valve Fails Open) ALHV0012 - TDAFP to SG C Isolation Valve (Valve Fails Open) ALLSL0024 - CST Low Level Switch ALPT0024 - MDAFP B Suction Pressure BNTE0005 - RWST Temperature EFFT0054 - ESW B Flow to Powerblock EFPDS0020 - ESW B Self-Cleaning Strainer Pressure Differential Switch EGFT0108 - CCW to Radwaste Building Flow (Train B) EGFT0062 – CCW from RCPs Flow Transmitter EGLV0002 - CCW Surge Tank B Makeup Valve from Demineralized Water EGTE0032 - CCW B Heat Exchanger Outlet Temperature EJLR0006 – Containment Recirc Sump B Level Recorder EJLSH0008 - Containment Recirc Sump B Level GKAE0002 - Control Room Chlorine Monitor GMTC0011 - Diesel Generator B Ventilation Supply Fan GNTE0061 – Containment Cooler B Temperature GTRE0060 - Containment Radiation Monitor JELT0021 - Diesel Generator B Day Tank Level LFLIT0010 - Containment Normal Sump Level

The components listed in the above table will fail to the required PFSSD position or are not required for PFSSD. For a fire in rooms 1411/1508 the TDAFP can be used to supply AFW to steam generators B and C and ARVs ABPV0002 and ABPV0003 can be used to control cooldown.

A fire in the East compartment (Rooms 1412 and 1509) may require de-energizing ABPV0002 and ABPV0003. As discussed in Section 5.1.5, the two MDAFW pumps are available if a fire occurs in this room. Opening switches NN0208 and NN0307 will affect the following additional components:

Switch	Affected Components
NN0208	ACPT0231 - Main Steam Ctrl Valve 3 Pressure ALPT0026 – TDAFP Suction Pressure ALPT0038 – ESFAS Aux Feedwater LSP Initiator NKEY0002 – E/E Converter in Cab RP053DA for NK02 DC Bus Voltage Monitoring NKIY0004 – Battery NK12 E/E Converter for Battery Monitoring
NN0307	ACPT0232 - Main Steam Ctrl Valve 2 Pressure ALFT0004 - AFW to Steam Generator C Flow Transmitter NKEY0003 - E/E Converter in Cab RP053DB for NK03 DC Bus Voltage Monitoring NKIY0006 - Battery NK13 E/E Converter for Battery Monitoring

Loss of the components identified in the above table will have no adverse impact on PFSSD since redundant capability exists. For a fire in rooms 1412/1509 the Train B MDAFP can be used to supply AFW to steam generators A and D and ARVs ABPV0001 and ABPV0004 can be used to control cooldown.

Up to three ARVs can fail closed or open without impacting ability to achieve and maintain hot standby according to thermal hydraulic analysis WCNOC-CP-002. With at least one ARV unaffected, no E-1F9900 OMA is required to address ARV closure or control. Reference Attachment 4, MSO Evaluation Scenario ID PWROG 23.

5.1.4 Steam Generator Main Feedwater Isolation Valves

PFSSD requires that either the main feedwater isolation valves (MFIVs) be closed or the main feedwater pumps be stopped to prevent overfilling the steam generators. Flow diversion from auxiliary feedwater (AFW) to the main feedwater system piping is prevented by check valves AEV0420, AEV0421, AEV0422 and AEV0423. Closure of the main feedwater isolation valves is not required to prevent AFW flow diversion.

Each MFIV is designed to utilize system fluid (feedwater) as the motive force to open and close. The valve actuation (open or close) is accomplished through positioning a series of six electric solenoid pilot valves to either direct the system fluid to the Upper Piston Chamber (UPC) and/or the Lower Piston Chamber (LPC), or vent either or both piston chambers. The six solenoid pilot valves are divided into two trains (3 per train) that are independently powered and controlled. Either train can independently perform the PFSSD function to close the valve and isolate main feedwater. This is done by actuating either all close hand switch AEHS0080 (separation group 1) or AEHS0081 (separation group 4) to de-energize the associated solenoid valves.

The following table identifies the solenoids and associated control cables for each hand switch.

MFIV	AEHS0080 (Sep Group 1)		AEHS0081 (Sep Group 4)	
	Solenoids	Cable	Solenoids	Cable
AEFV0039	MV1, MV3, MV5	11AEK16AH	MV2, MV4, MV6	14AEK17AH
AEFV0040	MV1, MV3, MV5	11AEK17AH	MV2, MV4, MV6	14AEK16AH
AEFV0041	MV1, MV3, MV5	11AEK16BH	MV2, MV4, MV6	14AEK17BH
AEFV0042	MV1, MV3, MV5	11AEK17BH	MV2, MV4, MV6	14AEK16BH

All 8 cables associated with the 24 solenoid valves are run in area A-23. However, a shield wall is installed between the two compartments in this room. This shield wall is credited to prevent propagation of hot gases between compartments and provides reasonable assurance that a fire in one compartment will not affect cables or equipment in the other compartment.

Valves AEFV0039 and AEFV0042, and associated cables, are located in the west compartment. Valves AEFV0040 and AEFV0041, and associated cables, are located in the east compartment. Consequently, a fire in this area could prevent closing at least two of the four MFIVs.

As discussed in Section 5.1.1, the MSIVs may not close due to a fire in this area but the downstream MSIV components are unaffected. The steam driven main feedwater pumps and the motor driven feedwater pump can be stopped from the control room.

Based on the above discussion, steam generator overfilling can be prevented by stopping all three main feedwater pumps from the control room.

References: E-15000, XX-E-013, E-13AE16, E-13AE17, E-1F9201, E-1R1353C, E-1R1354, E-1R1914, E-1R1915, M-12AE02

5.1.5 Auxiliary Feedwater

Cables and components associated with Train A and Train B motor driven auxiliary feedwater pumps are not located in area A-23. Therefore, either motor driven auxiliary feedwater pump can be used if a fire occurs in this area.

The main steam supply valves to the turbine driven auxiliary feedwater pump (TDAFP) (ABHV0005 and ABHV0006) are located in the east compartment in this area. Damage to these valves or associated cables could prevent the valves from opening, which would prevent operation of the TDAFP. A fire in the west compartment will not affect these valves, since associated cables are not located in this compartment.

If a fire occurs in the west compartment, all three auxiliary feedwater pumps will be available. If a fire occurs in the east compartment, the two motor driven auxiliary feedwater pumps will be available. Check valves AEV0420, AEV0421, AEV0422 and AEV0423 will ensure AFW flow is directed to the appropriate steam generator.

References: E-15000, XX-E-013, E-13AB01, E-13AB01A, E-1F9101, E-1F9202, M-12AB02, M-12AE02

5.1.6 Steam Generator Blowdown to Blowdown Flash Tank Valves

The reactivity control function requires the steam generator blowdown to blowdown flash tank valves (BMHV0001, BMHV0002, BMHV0003, and BMHV0004) be closed to prevent reactivity addition from uncontrolled cooldown. The air operated valves are normally open and each valve is controlled by three solenoid valves. All three solenoid valves are required to be energized to open the valve. If any one solenoid is de-energized, the associated valve will close or remain closed. Only two of the three solenoids for each valve are considered in the PFSSD analysis, so the third solenoid is assumed energized throughout the event.

All four valves and associated cables are located in area A-23. Valves BMHV0001 and BMHV0004 are located in the west compartment while BMHV0002 and BMHV0003 are located in the east compartment. Cables associated with each valve are located in the same compartment as the valve, so a fire in one compartment will not affect the valves in the other compartment.

The control room handswitch (BMHIS0001A, BMHIS0002A, BMHIS0003A and BMHIS0004A) associated with each valve is unaffected by a fire in this area. When the close button on the handswitch is depressed, the associated solenoid is de-energized and the valve will close. However, an external (inter-cable) +125 VDC hot short could cause the affected valves to open. The cables are run in raceway carrying the proper voltage such that a single +125 VDC inter-cable hot short is postulated to occur.

In the unlikely event that cable damage described above occurs, the blowdown valves can be failed closed by opening breaker NK4411 in room 3404 (fire area C-15). Access to this room is available without having to pass through area A-23 and emergency lighting is available.

Thermal hydraulic analysis WCNOC-CP-002 shows insignificant impact on SG inventory even with all four blowdown valves open. Therefore, no E-1F9900 OMA is required to close blowdown valves to achieve and maintain hot standby. Reference Attachment 4, MSO Evaluation Scenario ID PWROG 34.

5.2 PFSSD CABLE EVALUATION

Table A-23-4 lists all the PFSSD cables (S. in E-15000) located in fire area A-23. The applicable evaluation section is also listed in Table A-23-4. Since all cables in this area terminate at their associated component, there are no evaluations in Section 5.2. All cable evaluations are documented in Section 5.1, along with their associated component.

1.0 GENERAL AREA DESCRIPTION

Fire area A-24 is located on the 2000 elevation of the Auxiliary Building and includes the rooms listed in Table A-24-1.

Table A-24-1
Rooms Located in Fire Area A-24

ROOM #	DESCRIPTION
1323	North Pipe Penetration Room
N/A	Duct chase from 2000 elevation to 2026 elevation

Fire area A-24 has automatic fire detection installed throughout, except within the duct chase. There is no automatic fire suppression installed. The area is separated from other areas by minimum 3-hour fire rated construction.

2.0 PRIMARY EQUIPMENT USED FOR PFSSD

Table A-24-2 lists each system credited for post-fire safe shutdown and provides a discussion regarding the availability of the system to perform its Post Fire Safe Shutdown (PFSSD) function if a severe fire occurs in this area. For a summary of the area analysis results, see Section 8.0 of the Fire Area Analysis Narrative section.

Table A-24-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-24

System	System Name	PFSSD Function*	Comments
AB	Main Steam	R, M, H, P, S	ARV ABPV0003 may need to be isolated using local controller ABFHC0003 in area A-23. Main steam to TDAFP valves ABHV0005 and ABHV0006 may be affected.
AC	Main Turbine	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-24.
AE	Main Feedwater	H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-24.
AL	Aux. Feedwater System	H, P	The turbine auxiliary feedwater pump is affected. Train B auxiliary feedwater pump PAL01B is available to supply auxiliary feedwater to steam generators A and D but cable damage could cause valves ALHV0005 and ALHV0007 to fail full open. Train A auxiliary feedwater pump PAL01A is available to supply auxiliary feedwater to steam generators B and C, but ARV ABPV0003 may need to be locally controlled.
AP	Condensate Storage System	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-24.
BB	Reactor Coolant System	R, M, H, P, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-24.
BG	Chemical and Volume Control System	R, M, S	Valves BGHV8105 and BGHV8106 may be affected and may not respond to a close signal from the control room. Operators can mitigate this by maintaining the auxiliary pressurizer spray valve (BGHV8145) closed, tripping the RCPs and cycling the charging pump as needed to maintain pressurizer level.
BM	Steam Generator Blowdown System	R, M, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-24.
BN	Borated Refueling Water Storage System	R, M, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-24.
EF	Essential Service Water System	H, S	Valves EFHV0031 and EFHV0049 associated with Train A ESW to/from the Train A containment coolers may be affected. Valves associated with Train B containment coolers are located in a separate fire area and are unaffected by a fire in this area.
EG	Component Cooling Water System	S	Valves EGHV0058, EGHV0061, EGHV0071, EGHV0126, EGHV0127 and EGHV0133 in the CCW to/from RCP auxiliaries flowpath may be affected. The damage would not result in the valves spuriously operating but could prevent operation from the control room. Valves EGHV0062 and EGHV0132 are unaffected.
EJ	Residual Heat Removal System	M, H, P	Cables associated with EJHV8809A are located in this area but damage will not result in the valve spuriously closing. Both trains of RHR are available if a fire occurs in this area.

Table A-24-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-24

System	System Name	PFSSD Function*	Comments
EM	High Pressure Coolant Injection	R, M	Boron injection tank (BIT) outlet isolation valves EMHV8801A and EMHV8801B could be affected. Reactor coolant pump seal injection is available for boration and inventory control. For transition to cold shutdown, one of these valves may need to be manually opened to provide additional makeup using Train B CCP.
EN	Containment Spray	R, M	Train A containment spray isolation valve ENHV0006 could spuriously open. A spurious CSAS is not credible for a fire in this area and the Train A containment spray pump will not spuriously start. Therefore, spurious opening of ENHV0006 will not result in an actual containment spray.
EP	Safety Injection Accumulators	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-24.
FB	Auxiliary Steam	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-24.
FC	Auxiliary Turbines	R, H, P	The TDAFP mechanical trip and throttle valve FCHV0312 and the speed governing valve FCFV0313 may be affected. The Train A motor driven auxiliary feedwater pump is available.
GD	ESW Pump House HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-24.
GF	AFW Pump Room Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-24.
GK	Control Room and Class 1E Switchgear Room Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-24.
GL	Auxiliary Building HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-24.
GM	Emergency Diesel Generator Room HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-24.
GN	Containment Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-24.
JE	Diesel Fuel Oil	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-24.
KA	Instrument Air	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-24.
KC	Fire Protection	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-24.

Table A-24-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-24

System	System Name	PFSSD Function*	Comments
KH	Service Gas	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-24.
KJ	Standby Diesel Engine	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-24.
MA	Main Generation	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-24.
MR	Startup Transformer	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-24.
NB	4.16 kV System	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-24.
NE	Standby Diesel Generator	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-24.
NF	Load Shed and Emergency Load Sequencing	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-24.
NG	480V Load Centers and MCCs	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-24.
NK	125VDC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-24.
NN	120VAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-24.
PA	13.8kV	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-24.
PB	4.16kV	H, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-24.
PG	480V Load Centers and MCCs	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-24.
PK	125VDC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-24.
PL	Local Instrument Panels	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-24.
PN	120VAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-24.
QB	Standby AC Lighting	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-24.

Table A-24-2 Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-24			
System	**System Name**	**PFSSD Function***	**Comments**
QD	Emergency Lighting	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-24.
RL	Control Room MCB	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-24.
RP	Miscellaneous Control Panels	R, M, H, P, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-24.
SA	ESFAS	S	The status panel (SA066C) input for valves ABHV0005 and ABHV0006, associated with the TDAFP, could be affected. This is acceptable since the TDAFP is affected by a fire in area A-24.
SB	Reactor Protection System	R, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-24.
SC	Reactor Instrumentation	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-24.
SE	Ex-Core Neutron Monitoring	R, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-24.
SY	Switchyard	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-24.
UU	Supervisory System	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-24.

* R - Reactivity Control; M - Reactor Coolant Makeup; H - Decay Heat Removal; P - Process Monitoring; S - Support Function

3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD

This section describes operator actions that may need to be performed inside or outside the control room to achieve and maintain hot standby if a fire occurs in area A-24. This section also describes cold shutdown repairs that may need to be made to achieve and maintain cold shutdown conditions. Operator actions are proceduralized in OFN KC-016.

3.1 ACTIONS OUTSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

Operator Manual Actions (OMAs) are those actions outside the main control room required to achieve and maintain hot standby. OMAs are identified in E-1F9900 and were determined from thermal hydraulic analysis WCNOC-CP-002. Applicable E-1F9900 OMAs are annotated herein. All other actions outside the control room are desirable for plant control in support of hot standby but not required to achieve and maintain hot standby.

3.1.1 Steam Generator Atmospheric Relief Valves

ARV ABPV0003 may need to be controlled using local controller ABFHC0003 in area A-23. Emergency lighting is available and access is available without having to traverse area A-24.

3.2 ACTIONS INSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

3.2.1 Charging

Valves BGHV8105 and BGHV8106 may be affected and may not respond to a close signal from the control room. Operators can mitigate this by maintaining the auxiliary pressurizer spray valve (BGHV8145) closed, tripping the RCPs and cycling the charging pump as needed to maintain pressurizer level.

3.3 ACTIONS TO ACHIEVE AND MAINTAIN COLD SHUTDOWN

3.3.1 Boron Injection Tank Flowpath

It may be necessary to manually open either EMHV8801A or EMHV8801B in order to establish a BIT flowpath.

3.3.2 CCW to Excess Letdown Flowpath

It may be necessary to manually open EGHV0059 to establish a flowpath from CCW to the excess letdown heat exchanger.

4.0 CONCLUSION

With some exceptions, redundant Post Fire Safe Shutdown capability exists if a severe fire occurs in area A-24. For those exceptions, feasible manual actions are available and are unaffected by the fire. Manual actions are documented in Section 3.0.

5.0 DETAILED ANALYSIS

This section describes the detailed component-by-component and cable-by-cable analysis for a fire in area A-24.

5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA A-24

PFSSD components (S. in E-15000) located in fire area A-24 are shown in Table A-24-3. An evaluation of each component and associated cables is provided in the sections that follow. The applicable evaluation section is listed in Table A-24-3.

Table A-24-3
PFSSD Equipment Located in Fire Area A-24

Room #	PFSSD Equipment	Description	Evaluation Section	Comments
1323	BGHV8105	Charging Pumps To Regenerative HX/CTMT Iso Valve	5.1.1	
1323	BGHV8106	Charging Pumps To Regenerative HX Iso Valve	5.1.1

1323	EMHV8801A	BIT Outlet Iso Valve to RCS	5.1.5	
1323	EMHV8801B	BIT Outlet Iso Valve to RCS	5.1.5	
1323	EMHV8964	SI Test Line System Outside CTMT Iso Valve	5.1.5	
1323	EMHY8964	SI Test Line/Containment Iso Valve Solenoid	5.1.5	
1323	ENHV0006	Containment Spray Pump A Disch Iso Valve	5.2.2	

5.1.1 Charging to Regen Heat Exchanger Isolation Valves

The Post Fire Safe Shutdown methodology requires isolation of charging flow to the regenerative heat exchanger. Two motor operated valves (BGHV8105 and BGHV8106) and one manual valve (BG8402B) installed on the discharge line are credited in the PFSSD analysis to ensure the charging flowpath can be isolated.

Valves BGHV8105 and BGHV8106, and associated power and control cables, are located in area A-24. Damage to these cables and valves could prevent closing the valves from the control room.

Calculation WCNOC-CP-002 Scenario 5.3 documents the thermal hydraulic plant response where the normal charging pump continues to operate, the charging flow control valve goes full open and the normal charging line cannot be isolated. Based on the calculation, PFSSD can be achieved by maintaining the auxiliary pressurizer spray valve (BGHV8145) closed, tripping the RCPs and cycling the charging pump as needed to maintain pressurizer level.

Cables for the normal charging pump (PBG04) and both centrifugal charging pumps (PBG05A and PBG05B) are unaffected by a fire in this area. Therefore, the pumps can be controlled from the control room.

Cables for BGHV8145 are unaffected by a fire in this area. Therefore, the auxiliary spray valve will not spuriously open if a fire occurs in this area or, if the valve is open, it can be closed from the control room.

Cables associated with the reactor coolant pumps are unaffected by a fire in this area. Therefore, the RCPs can be tripped from the control room if a fire occurs in this area.

The NCP and valve BGHV8145 are not PFSSD components and the cables for these components are not PFSSD. However, a Setroute review was performed and it was determined that the cables are not located in fire area A-24. Cables that were reviewed are as follows.

Cable	Component	Function	Routing
15BGK37AA	DPBG04	Control Cable for the NCP	TURBINE, CC-1, C-21
15PBK12AA	DPBG04	Control Power	TURBINE
15PBK12AB	DPBG04	Control Power	TURBINE
15BGK19AA	BGHV8145	Control Cable	A-1, A-11, A-18, C-7, C-12, C-18, C-21, C-24, C-27
15BGK19AB	BGHV8145	Control Cable	RB

Based on the above discussion and Calculation WCNOC-CP-002, PFSSD can be achieved if the fire prevents isolation of normal charging.

5.1.2 Containment Cooling

At least one train of containment cooling is required for PFSSD to maintain the containment atmosphere within EQ limits.

Valves EFHV0031 and EFHV0049, and associated power and control cables, are located in area A-24. These valves are in the flowpath from Train A ESW to/from the Train A containment coolers. Damage to these valves and cables could cause the valves to spuriously close, isolating ESW to the train A containment coolers.

Valves associated with Train B containment coolers are located in a separate fire area and are unaffected by a fire in this area. Therefore, Train B containment coolers are available to maintain the containment atmosphere if a fire occurs in this area.

References: XX-E-013, E-15000, E-13EF07, E-13EF08, E-1F9403, M-12EF02

5.1.3 Thermal Barrier Cooling

The Wolf Creek plant design provides two redundant methods of cooling the RCP seals, thermal barrier cooling using CCW and seal injection using the CCP. The PFSSD methodology at Wolf Creek requires tripping the RCPs and performing a natural circulation cooldown upon loss of both thermal barrier cooling (TBC) and seal injection. If only one method is lost, continued operation of the RCP is allowed by present established procedures until the other method can be re-established.

Valves EGHV0058, EGHV0061 and EGHV0071 are normally open valves in the flowpath from CCW to/from the RCP thermal barriers. These valves, as well as associated power and control cables, are located in this fire area. Damage to the cables would result in the valves remaining in the open position and would prevent closure of the valves from the control room. The cable damage would not cause the valves to spuriously close.

Valves EGHV0126, EGHV0127 and EGHV0133 are normally closed bypass valves in the flowpath from CCW to/from the RCP thermal barriers. These valves, as well as associated power and control cables, are located in this fire area. Damage to the cables would result in the valves remaining in the closed position and would prevent opening of the valves from the control room.

Based on the above discussion, CCW flow to the RCP thermal barriers is unaffected by a fire in this area.

References: E-15000, XX-E-013, E-13EG09, E-13EG09A, E-13EG10, E-13EG17A, E-13EG18, E-13EG18A, M-12EG03, E-1F9303

5.1.4 Residual Heat Removal

For cold shutdown, the RHR pump discharge to RCS cold leg isolation valve (EJHV8809A or EJHV8809B) needs to be open on the operating train. Valve EJHV8809A, and associated cables, are located in area A-24.

Damage to cables 11EJG09CA and 11EJG09CB will result in valve EJHV8809A remaining in its as-is normally open position, which is the preferred PFSSD position. There is no postulated cable failures that would cause the valve to close. Cables associated with Train B valve EJHV8809B do not run in area A-24. Therefore, both Trains A and B RHR pump discharge to RCS cold leg flow paths are available for a fire in area A-24.

References: E-15000, XX-E-013, E-13EJ09A, E-1F9205, M-12EJ01

5.1.5 Boron Injection Tank Flowpath

The Boron Injection Tank (BIT) flowpath is credited for reactivity control and reactor coolant makeup. For reactivity control, the BIT flowpath is credited as an alternate source of boration in the event RCP seal injection is unavailable. Based on Calculation XX-E-013, RCP seal injection will provide sufficient boration to achieve and maintain cold shutdown reactivity conditions. Therefore, the BIT flowpath is not required for reactivity control if RCP seal injection is available. Since RCP seal injection is limited to 5 gpm per seal or 20 gpm total injection to the RCS, an additional RCS charging flowpath is required for adequate RCS makeup during plant transition from hot standby to cold shutdown. The BIT injection path was selected as the additional RCS charging flowpath.

BIT outlet valves EMHV8801A and EMHV8801B, and associated cables, are located in this fire area. Damage to the valves and cables due to a fire could prevent opening the valves from the control room. For hot standby, RCP seal injection is available for boration and inventory control. When transitioning to cold shutdown, it may be necessary to locally open either EMHV8801A or EMHV8801B to establish additional RCS makeup.

Valve EMHV8964 and associated cables are located in this area. Either this valve or valve EMHV8871 is required to be closed when charging through the BIT to prevent flow diversion through the SI test line. Cables for valve EMHV8871 do not run in this area and the valve will remain closed throughout the event. Therefore, if EMHV8964 spuriously opens, it will not adversely impact PFSSD.

References: E-15000, XX-E-013, E-13EM02, E-13EM02A, E-13EM12, E-1F9302, M-12EM01, M-12EM02

5.1.6 CCW From RCP Containment Isolation Valve

Valve EGHV0059 is included in the PFSSD equipment list to ensure availability of CCW to the excess letdown heat exchanger during cold shutdown. For hot standby, the position of this valve (open or closed) will not impact PFSSD. Since this valve is only credited for cold shutdown, cables associated with the valve are not considered in the PFSSD analysis. If the valve is required for cold shutdown, it can be repaired, if necessary, and manually opened. Based on the above discussion, a fire in this area that affects EGHV0059 will not adversely impact PFSSD.

5.2.1 Steam Generator Atmospheric Relief Valves

Cables associated with steam generator atmospheric relief valves (ARVs) ABPV0002, ABPV0003 and ABPV0004 are run in area A-24. The effects of fire damage to these cables are discussed in the following paragraphs.

Cable 12ABI20FE provides a signal from ARV ABPV0002 controller to pressure transducer ABPY0002. Cable 12ABI20FH provides a signal from ABPT0002 to ARV ABPV0002 controller. The transducer signals the position controller (ABZC0002) on ABPV0002 to open whenever steamline pressure reaches a designated setpoint. The cables are run in raceway that has been protected with a 3-hour fire rated barrier. Therefore, the cables will remain free of fire damage in the event of a fire in this area and ARV ABPV0002 can be controlled from the control room.

Cable 13ABI20GE provides a signal from ARV ABPV0003 controller to pressure transducer ABPY0003. Cable 13ABI20GA provides a signal from ABPT0003 to ARV ABPV0003 controller. The transducer signals the position controller (ABZC0003) on ABPV0003 to open whenever steamline pressure reaches a designated setpoint. Damage to the cables due to a fire could cause a spurious signal which could open the ARV. Damage to cable 13ABI20GE could prevent manual operation of the valve from the control room.

Cable 14ABI20HH provides a signal from ABPT0004 to ARV ABPV0004 controller and opens the valve when steamline pressure reaches a designated setpoint. The cable is run in raceway that has been protected with a 3-hour fire rated barrier. Therefore, the cable will remain free of fire damage in the event of a fire in this area.

Based on the above discussion, ARVs ABPV0001 and ABPV0004 can be controlled from the control room if using Train B MDAFP. If Train A MDAFP is used, ARV ABPV0002 can be controlled from the control room while ARV ABPV0003 may need to be controlled using local controller ABFHC0003 in area A-23. See Section 5.2.3 for a discussion on auxiliary feedwater availability.

Up to three ARVs can fail closed or open without impacting ability to achieve and maintain hot standby according to thermal hydraulic analysis WCNOC-CP-002. With at least one ARV unaffected, no E-1F9900 OMA is required to address ARV closure or control. Reference Attachment 4, MSO Evaluation Scenario ID PWROG 23.

5.2.2 Safety Injection and Containment Spray

A spurious safety injection signal (SIS) could cause the safety injection pumps to operate. A spurious containment spray actuation signal (CSAS) could cause the containment spray pumps to operate, depleting inventory in the RWST. These conditions are not desirable for PFSSD at Wolf Creek.

Safety injection (SI) is initiated automatically by any of the following conditions:

1. Two out of three high containment pressures monitored by pressure transmitters GNPT0934, GNPT0935 and GNPT0936.
2. Two out of four low pressurizer pressures monitored by pressure transmitters BBPT0455, BBPT0456, BBPT0457 and BBPT0458.
3. Two out of three low steam line pressures on any steam generator monitored by ABPT0514, ABPT0515 and ABPT0516 on SG A; ABPT0524, ABPT0525 and ABPT0526 on SG B; ABPT0534, ABPT0535 and ABPT0536 on SG C; and, ABPT0544, ABPT0545 and ABPT0546 on SG D. Two out of three logic must be satisfied on a single steam generator line. Low pressure on a single pressure

transmitter co-incident with low pressure on another pressure transmitter on a different steam generator line will not initiate SIS.

Containment spray (CS) is initiated automatically by two out of four high containment pressures monitored by pressure transmitters GNPT0934, GNPT0935, GNPT0936 and GNPT0937.

Only cables associated with steam line pressure transmitters ABPT0515, ABPT0516, ABPT0525, ABPT0526, ABPT0535, ABPT0536, ABPT0545 and ABPT0546 are run in area A-24. Cables associated with ABPT0515, ABPT0516 ABPT0525, ABPT0535, ABPT0545 and ABPT0546 are installed in raceway that has been protected with a 3-hour fire rated barrier. Therefore, the cables will remain free of fire damage in the event of a fire in this area. Consequently, two out of three logic for low steam line pressure initiation of SIS cannot be satisfied if a fire occurs in area A-24.

Cables associated with containment pressure transmitters and pressurizer pressure transmitters are not located in this fire area. Consequently, a spurious CSAS and SIS is not credible if a fire occurs in area A-24.

Containment spray valve ENHV0006 and associated power and control cables are located in this fire area. Damage to the control cables could cause the valve to spuriously open. However, as stated in the previous paragraph, a spurious CSAS is not credible if a fire occurs in this area. In addition, control cables associated with the Train A containment spray pump are located outside fire area A-24. Therefore, the Train A containment spray pump will not spuriously start if a fire occurs in area A-24.

Based on the above discussion, a spurious SIS and CSAS is not credible if a fire occurs in area A-24. In addition, containment spray will not occur if valve ENHV0006 spuriously opens.

References: E-15000, XX-E-013, E-13AB21, E-13EN03, E-106-00027, E-1F9431, E-1F9432, E-1F9433, E-1R1343C, E-1R1911, M-12AB01, M-12EN01, DCP 07037

5.2.3 Auxiliary Feedwater

Several cables associated with auxiliary feedwater are run in this area. The following paragraphs describe the effects of fire damage on PFSSD.

Cables 12ABK01AF and 12ABK01BF are control cables associated with main steam to turbine driven auxiliary feedwater pump (TDAFP) supply valves ABHV0005 and ABHV0006, respectively. Damage to these cables could cause the valves to fail closed, although this is unlikely due to the fail safe design of the circuit (valve fails open on loss of power). In addition, several other cables associated with various components for the TDAFP are run in this area and could be damaged. Therefore, the TDAFP is not available in the event of a fire in area A-24.

Cables 12SAZ23AA and 12SAZ23BA provide status panel indication of the position of valves ABHV0005 and ABHV0006, respectively. Damage to these cables could cause false position indication in the main control room. As stated above, the TDAFP is unavailable if a fire occurs in this area and, therefore, damage to these cables will not adversely impact PFSSD.

Cables associated with several valves in the auxiliary feedwater system are run in this area. These valves include the Train B motor driven auxiliary feedwater pump (MDAFP) to steam generators A and D valves ALHV0005 and ALHV0007 and the TDAFP to steam generators B and C valves ALHV0010 and ALHV0012. A majority of these cables are run in raceway that has been wrapped with a 3-hour fire rated material. In addition, cables associated with flow transmitters ALFT0001 and ALFT0007 are run in raceway that has been wrapped with a 3-hour fire rated material. These flow transmitters provide a signal to modulate valves ALHV0005 and ALHV0007 in response to flow going to steam generators D and A, respectively.

Two cables (14ALY09AB and 14ALY09BB) associated with ALHV0005 and ALHV0007 are not protected and could be damaged. These are power cables associated with the Modutronic controller. Valves ALHV0005 and ALHV0007 are normally full open and fail full open on loss of power to the controllers. This could cause a loss of control of these valves but would not prevent flow of auxiliary feedwater to steam generators A and D.

Cables associated with two of the three pressure transmitters that initiate an AFW low suction pressure (LSP) signal run in this area. Cable 12ALI08BA is associated with pressure transmitter ALPT0038. Cable 14ALI08CA is associated with pressure transmitter ALPT0039. Damage to these cables could cause a spurious LSP signal (2/3 logic) and initiate auxiliary feedwater suction swapover to the ESW system. Both cables are run in raceway that has been wrapped with a 3-hour fire rated material. Therefore, the cables will remain free of fire damage in the event of a fire in this area and a spurious LSP signal will not occur.

Cable 14ALI07HD is associated with MDAFP B suction pressure transmitter ALPT0024. This cable is run in raceway that has been wrapped with a 3-hour fire rated material. Therefore, this cable is unaffected by a fire and ALPT0024 is available.

Based on the above discussion, auxiliary feedwater is available using Train B MDAFP supplying steam generators A and D through valves ALHV0005 and ALHV0007.

1.0 GENERAL AREA DESCRIPTION

Fire area A-25 is located on the 2000 elevation of the Auxiliary Building and includes the room listed in Table A-25-1.

Table A-25-1
Room Located in Fire Area A-25

ROOM #	DESCRIPTION
1322	Pipe Penetration Room B

Fire area A-25 is protected with automatic fire detection throughout. There is no automatic fire suppression installed. The area is separated from other areas by minimum 3-hour fire rated construction.

2.0 PRIMARY EQUIPMENT USED FOR PFSSD

Table A-24-2 lists each system credited for post-fire safe shutdown and provides a discussion regarding the availability of the system to perform its Post Fire Safe Shutdown (PFSSD) function if a severe fire occurs in this area. For a summary of the area analysis results, see Section 8.0 of the Fire Area Analysis Narrative section.

Table A-25-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-25

System	System Name	PFSSD Function*	Comments
AB	Main Steam	R, M, H, P, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-25.
AC	Main Turbine	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-25.
AE	Main Feedwater	H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-25.
AL	Aux. Feedwater System	H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-25.
AP	Condensate Storage System	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-25.
BB	Reactor Coolant System	R, M, H, P, S	Cables associated with pressure transmitter BBPT0403 could be damaged, causing a false High-1 RCS pressure signal. This would prevent remote opening of BBPV8702A and BBPV8702B. A cold shutdown repair or containment entry may be required to open valves BBPV8702A or BBPV8702B when aligning RHR for cold shutdown.
BG	Chemical and Volume Control System	R, M, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-25.
BM	Steam Generator Blowdown System	R, M, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-25.
BN	Borated Refueling Water Storage System	R, M, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-25.
EF	Essential Service Water System	H, S	Valves EFHV0032 and EFHV0050 associated with Train B ESW to/from the Train B containment coolers may be affected. Valves associated with Train A containment coolers are unaffected.
EG	Component Cooling Water System	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-25.
EJ	Residual Heat Removal System	M, H, P	As stated in System BB above, the suction source for RHR could be affected. All other components of the RHR system are unaffected, or the effects of fire damage to the cables will have no adverse impact on PFSSD.
EM	High Pressure Coolant Injection	R, M	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-25.

Table A-25-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-25

System	System Name	PFSSD Function*	Comments
EN	Containment Spray	R, M	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-25.
EP	Safety Injection Accumulators	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-25.
FB	Auxiliary Steam	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-25.
FC	Auxiliary Turbines	R, H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-25.
GD	ESW Pump House HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-25.
GF	AFW Pump Room Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-25.
GK	Control Room and Class 1E Switchgear Room Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-25.
GL	Auxiliary Building HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-25.
GM	Emergency Diesel Generator Room HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-25.
GN	Containment Coolers	S	ESW to Train B containment coolers may be affected as described in System EF above. ESW to Train A containment coolers is unaffected.
JE	Diesel Fuel Oil	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-25.
KA	Instrument Air	S	Valve KAV0201 is located in this fire area. This valve is used as an alternate means to isolate letdown. The ability to isolate letdown from the control room is unaffected. Therefore, valve KAV0201 is not required for PFSSD if a fire occurs in this area. Valve KAFV0029 could be affected by a fire in this area. This will have no adverse impact on PFSSD.
KC	Fire Protection	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-25.
KH	Service Gas	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-25.

Table A-25-2

3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD

This section describes operator actions that may need to be performed inside or outside the control room to achieve and maintain hot standby if a fire occurs in area A-25. This section also describes cold shutdown repairs that may need to be made to achieve and maintain cold shutdown conditions. Operator actions are proceduralized in OFN KC-016.

3.1 ACTIONS OUTSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

None

3.2 ACTIONS INSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

None specific to PFSSD

3.3 ACTIONS TO ACHIEVE AND MAINTAIN COLD SHUTDOWN

3.3.1 Residual Heat Removal

A cold shutdown repair or containment entry may be required to open valves BBPV8702A or BBPV8702B, depending on the RHR train used for cold shutdown.

4.0 CONCLUSION

Post Fire Safe Shutdown is assured for a fire in fire area A-25. Redundant capability exists for achieving and maintaining PFSSD if a fire occurs in area A-25.

5.0 DETAILED ANALYSIS

This section describes the detailed component-by-component and cable-by-cable analysis for a fire in area A-25.

5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA A-25

PFSSD components (S. in E-15000) located in fire area A-25 are shown in Table A-25-3. An evaluation of each component and associated cables is provided in the sections that follow. The applicable evaluation section is listed in Table A-25-3.

Table A-25-3
PFSSD Equipment Located in Fire Area A-25

Room #	PFSSD Equipment	Description	Evaluation Section	Comments
1322	BBHV8351A	RCP A Seal Water Supply	5.1.1	
1322	BBHV8351B	RCP B Seal Water Supply	5.1.1	
1322	BBHV8351C	RCP C Seal Water Supply	5.1.1	
1322	BBHV8351D	RCP D Seal Water Supply	5.1.1	
1322	EFHV0032	ESW B to Containment Air Coolers	5.1.2

1322	KAV0201	AUX Bldg To RX Bldg Instrument Air Outside CTMT Iso	5.1.4	
1322	TB13303	RCS Wide Range Pressure Transmitter BBPT0403	5.1.3	

5.1.1 Reactor Coolant Pump (RCP) Seal Injection

RCP seal injection is required to provide a boron injection path, provide makeup to the RCS and prevent damage to the RCP seals. Seal injection valves BBHV8351A, BBHV8351B, BBHV8351C and BBHV8351D, and associated power and control cables, are located in this area. In order to ensure seal injection, these valves are required to remain in their normally open position.

The seal injection valves are maintained de-energized with the circuit breaker in the OFF position. Therefore, damage to the control cables will not cause the valves to close. The valves are not high-low pressure interface valves so consideration of a 3-phase hot short is not required. Therefore, damage to the power cables will not cause the valves to close.

Based on the above discussion, RCP seal injection is unaffected by a fire in area A-25.

References: E-15000, XX-E-013, E-13BB04, E-1F9102, E-1F9303, M-12BB03

5.1.2 Containment Cooling

At least one train of containment cooling is required for PFSSD to maintain the containment atmosphere within EQ limits.

Valves EFHV0032 and EFHV0050, and associated power and control cables, are located in this area. These valves are in the flowpath from Train B ESW to/from the Train B containment coolers. Damage to these valves and cables could cause the valves to spuriously close, isolating ESW to the Train B containment coolers.

Valves associated with Train A containment coolers are located in a separate fire area and are unaffected by a fire in this area. Therefore, Train A containment coolers are available to maintain the containment atmosphere if a fire occurs in this area.

References: XX-E-013, E-15000, E-13EF07, E-13EF08, E-1F9403, M-12EF02

5.1.3 Residual Heat Removal

For cold shutdown, the RHR pump discharge to RCS cold leg isolation valve (EJHV8809A or EJHV8809B) needs to be open on the operating train. In addition, the hot leg recirculation valve EJHV8840 is required to remain closed. Valves EJHV8809B and EJHV8840, and associated cables, are located in area A-25.

Damage to cables 14EJG09BA and 14EJG09BB will result in valve EJHV8809B remaining in its as-is normally open position, which is the preferred PFSSD position. There are no postulated cable failures that would cause the valve to close. Cables associated with Train A valve EJHV8809A do not run in area A-25. Therefore, both Trains A and B RHR pump discharge to RCS cold leg flow paths are available for a fire in area A-25.

Damage to cables 14EJG09AA and 14EJG09AB will result in valve EJHV8840 remaining in its as-is normally closed position, which is the required PFSSD position. There are no postulated cable failures that would cause the valve to open. Therefore, valve EJHV8840 will remain closed if a fire occurs in this area.

Hot shutdown mode of PFSSD requires isolation of the RCS to RHR flow path by maintaining either BBPV8702A or EJHV8701A closed and either BBPV8702B or EJHV8701B closed. Cold shutdown mode of PFSSD requires RHR taking suction from the RCS. RHR pump suction from the RCS is controlled by valves BBPV8702A and EJHV8701A (Train A) and BBPV8702B and EJHV8701B (Train B).

Terminal Box TB13303 contains cables 12BBI15NA and 12BBI15NB. Damage to cables 12BBI15NA and 12BBI15NB, associated with pressure transmitter BBPT0403, could initiate a false High-1 RCS pressure signal and open the contacts on relay K734. This false High-1 pressure signal would prevent remote opening of valves BBPV8702A and BBPV8702B. Since cables 12BBI15NA and 12BBI15NB run through area A-25, a fire may require a cold shutdown repair or a containment entry to open valves BBPV8702A or BBPV8702B, depending on the RHR train used for cold shutdown.

References: E-15000, XX-E-013, E-13BB12A, E-13BB12B, E-13BB15, E-13EJ09A, E-1F9205, M-12BB04, M-12EJ01

5.1.4 Containment Instrument Air Supply

The containment instrument air supply provides the motive force for a number of air operated valves in containment. The instrument air system is not credited for PFSSD because loss of instrument air will fail the valves in their desired position. Isolation valves for the containment instrument air supply are credited for PFSSD because, in the event of a fire in certain areas, it may be necessary to close the valves to fail certain valves closed.

Manual isolation valve KAV0201 and air operated valve KAFV0029 are credited in the PFSSD analysis in the event of a fire in certain areas. These valves are used to isolate air to letdown isolation valves BGLCV0459 and BGLCV0460 and pressurizer spray valves BBPCV0455B and BBPCV0455C to fail the valves closed. Valves KAV0201 and KAFV0029 are diverse means for closing BGLCV0459, BGLCV0460, BBPCV0455B and BBPCV0455C if the fire prevents closing the valves using their respective control room hand switches. Only one of these valves is required to be closed to isolate instrument air to containment.

Cable 11KAK02AA is a control cable associated with valve KAFV0029. Damage to this cable could prevent closure of the valve from the control room or could cause the valve to spuriously close. If the valve spuriously closes, PFSSD will not be affected as documented in E-1F9900.

A fire in area A-25 does not require closure of the air supply to containment to achieve PFSSD. Letdown isolation valves BGLCV0459 and BGLCV0460 and pressurizer spray valves BBPCV0455B and BBPCV0455C are unaffected by a fire in this area and can be closed from the control room.

Based on the above discussion, damage to cable 11KAK02AA will have no adverse impact on the ability to achieve and maintain safe shutdown following a fire in this area. In addition, valves KAV0201 and KAFV0029 are not credited for a fire in area A-25.

14ENG03BB	1322	ENHV0012	C	5.2.1	CTMT Spray Train B Disch Iso Valve

5.2.1 Containment Pressure Transmitters

Containment pressure transmitters initiate a Safety Injection Signal (SIS) on two out of three high containment pressures monitored by pressure transmitters GNPT0934, GNPT0935 and GNPT0936. In addition, a Containment Spray Actuation Signal (CSAS) is activated by two out of four high containment pressures monitored by pressure transmitters GNPT0934, GNPT0935, GNPT0936 and GNPT0937.

A cable associated with pressure transmitter GNPT0936 is run in area A-25. Cables associated with the remaining pressure transmitters are located in a separate fire area. Therefore, a spurious SIS or CSAS will not occur due to a fire in area A-25.

Cables 14ENG03BA and 14ENG03BB are associated with valve ENHV0012. Valve ENHV0012 and associated cables were added to the PFSSD equipment list to mitigate a spurious containment spray if a fire occurs in area C-10. A fire in area A-25 will not result in a spurious CSAS. Therefore, the valve is not required to function if a fire occurs in area A-25 and damage to cables 14ENG03BA and 14ENG03BB will have no adverse impact on safe shutdown.

1.0 GENERAL AREA DESCRIPTION

Fire area A-26 is located on the 2026 elevation of the Auxiliary Building and includes the rooms listed in Table A-26-1.

Table A-26-1
Rooms Located in Fire Area A-26

ROOM #	DESCRIPTION
1405	Chemical Storage Area
1415	I & C Hot Shop

Fire area A-26 is protected with an automatic fire detection system throughout. The area is bounded on all sides by minimum 3-hour fire rated construction.

2.0 PRIMARY EQUIPMENT USED FOR PFSSD

Table A-26-2 lists each system credited for post-fire safe shutdown and provides a discussion regarding the availability of the system to perform its Post Fire Safe Shutdown (PFSSD) function if a severe fire occurs in this area. For a summary of the area analysis results, see Section 8.0 of the Fire Area Analysis Narrative section.

Table A-26-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-26

System	System Name	PFSSD Function*	Comments
AB	Main Steam	R, M, H, P, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-26.
AC	Main Turbine	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-26.
AE	Main Feedwater	H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-26.
AL	Aux. Feedwater System	H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-26.
AP	Condensate Storage System	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-26.
BB	Reactor Coolant System	R, M, H, P, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-26.
BG	Chemical and Volume Control System	R, M, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-26.
BM	Steam Generator Blowdown System	R, M, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-26.
BN	Borated Refueling Water Storage System	R, M, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-26.
EF	Essential Service Water System	H, S	All PFSSD functions associated with the Essential Service Water (ESW) system are satisfied. The ability to operate Train B valves EFHV0052 and EFHV0060 from the control room may be affected. The valves will not spuriously operate. Train A ESW is unaffected.
EG	Component Cooling Water System	S	All PFSSD functions associated with the Component Cooling Water (CCW) system are satisfied. Bypass valves EGHV0127 and EGHV0133 may be affected. This will not affect the ability to supply CCW to the RCP thermal barriers.
EJ	Residual Heat Removal System	M, H, P	Containment sump isolation valve EJHV8811B could spuriously open, causing a draindown path from the RWST to the containment sump. Valve BNHV8812B will automatically close, as designed, when EJHV8811B reaches full open position, mitigating draindown. However, if EJHV8811B stalls before reaching full open position, BNHV8812B will not automatically close. In this case, operators can close BNHV8812B using BNHIS8812B in the main control room.

Table A-26-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-26

System	System Name	PFSSD Function*	Comments
EM	High Pressure Coolant Injection	R, M	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-26.
EN	Containment Spray	R, M	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-26.
EP	Safety Injection Accumulators	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-26.

3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD

This section describes operator actions that may need to be performed inside or outside the control room to achieve and maintain hot standby if a fire occurs in area A-26. This section also describes cold shutdown repairs that may need to be made to achieve and maintain cold shutdown conditions. Operator actions are proceduralized in OFN KC-016.

3.1 ACTIONS OUTSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

None

3.2 ACTIONS INSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

3.2.1 Mitigation of RWST Draindown to Containment Sump

If a fire occurs in area A-26, it may be necessary to close valve BNHV8812B from the control room using BNHIS8812B to mitigate draindown of the RWST into the containment sump. This condition could occur due to EJHV8811B spuriously opening but stalling before reaching full open position, thereby not providing the permissive for BNHV8812B to close. RWST level indication is available using all four level indicators.

3.3 ACTIONS TO ACHIEVE AND MAINTAIN COLD SHUTDOWN

None

4.0 CONCLUSION

Post-Fire Safe Shutdown capability is assured if a severe fire occurs in this area.

5.0 DETAILED ANALYSIS

This section describes the detailed component-by-component and cable-by-cable analysis for a fire in area A-26.

5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA A-26

There are no PFSSD components located in area A-26. This fire area only contains cables associated with PFSSD equipment located in other areas.

5.2 PFSSD CABLE EVALUATION

Table A-26-3 lists all the PFSSD cables (S. in E-15000) located in fire area A-26. The applicable evaluation section is also listed in Table A-26-3.

Table A-26-3
PFSSD Cables Located in Fire Area A-26

Cable #	Location	Primary PFSSD Equipment	Cable Function (P) Power (C) Control (I) Instrumentation	Evaluation Section	Comments
14EFG04BA	1405, 1415	EFHV0060	P	5.2.1	ESW return to UHS from CCW B Hx
14EFG04BB	1405, 1415	EFHV0060	C	5.2.1	ESW return to UHS from CCW B Hx
14EFG05BA	1405, 1415	EFHV0052	P	5.2.1	ESW to CCW B Heat Exchanger
14EFG05BB	1405, 1415	EFHV0052	C	5.2.1	ESW to CCW B Heat Exchanger
14EGG18BA	1415	EGHV0127	P	5.2.1	Thermal Barrier Cooling
14EGG18BB	1415	EGHV0127	C	5.2.1	Thermal Barrier Cooling
14EGG18DA	1415	EGHV0133	P	5.2.1	Thermal Barrier Cooling
14EGG18DB	1415	EGHV0133	C	5.2.1	Thermal Barrier Cooling
14EJG06BT	1405	EJHV8811B	C	5.2.3	CTMT Recirc Sump To RHR Pump B
14GLG06BA	1405	DSGL11B	P	5.2.1	Train B CCW Pumps B and D Room Cooler
14GLG06BC	1405	DSGL11B	C	5.2.1	Train B CCW Pumps B and D Room Cooler
14NGG01AD	1405	NG02B	P	5.2.2	Incoming Power Feed to NG02B from NG0207
14NGG01AE	1405	NG02B	P	5.2.2	Incoming Power Feed to NG02B from NG0207
14NGG01AJ	1405	DSGN01B	P	5.2.2	Incoming Power Feed to NG02T from NG0208
14NGG01BF	1405	DSGN01D	P	5.2.2	Incoming Power Feed to NG04T from NG0405

5.2.1 Essential Service Water and Component Cooling Water

For PFSSD, component cooling water (CCW) relies on essential service water (ESW) to provide cooling to the CCW heat exchanger. When operating Train A CCW, valve EFHV0051 is required to remain open (throttled) and valve EFHV0059 is required to remain closed with manual bypass valve EFV0058 throttled. When operating Train B CCW, valve EFHV0052 is required to remain open (throttled) and valve EFHV0060 is required to remain closed with manual bypass valve EFV0090 throttled. If valves EFHV0059 or EFHV0060 were to open, a flow imbalance will occur in the associated ESW Train such that sufficient ESW flow may not reach other PFSSD components.

Cables 14EFG04BA and 14EFG04BB, associated with valve EFHV0060, are run in area A-26. Damage to these cables (hot short, open circuit or short to ground) will not cause the valve to spuriously open. The only failure in the control circuit for this valve that could cause the valve to open would be a short within cable 14EFG04BC, which is not run in area A-26. Therefore, there are no credible circuit failures that would cause valve EFHV0060 to spuriously open.

Cables 14EFG05BA and 14EFG05BB, associated with valve EFHV0052, are run in area A-26. Damage to these cables (hot short, open circuit or short to ground) will not cause the valve to spuriously close. The only failure in the control circuit for this valve that could cause the valve to close would be a short within cable 14EFG05BC, which is not run in area A-26. Therefore, there are no credible circuit failures that would cause valve EFHV0052 to spuriously close.

Train A ESW to/from CCW heat exchanger valves EFHV0051 and EFHV0059 are unaffected by a fire in area A-26. Therefore, the Train A CCW system is available if a fire occurs in area A-26.

Cables 14EGG18BA and 14EGG18BB, associated with normally closed valve EGHV0127, are run in area A-26. Cables 14EGG18DA and 14EGG18DB, associated with normally closed valve EGHV0133, are run in area A-26. Valves EGHV0127 and EGHV0133 are required to ensure thermal barrier cooling if valves EGHV0058 and EGHV0061 are affected by a fire. Valves EGHV0058 and EGHV0061 are unaffected by a fire in area A-26, so the position of valves EGHV0127 and EGHV0133 has no adverse impact on PFSSD. In addition, a fire in this area does not affect RCP seal injection, so thermal barrier cooling is not required.

Power and control cables 14GLG06BA and 14GLG06BC, associated with Train B CCW pump room cooler motor DSGL11B, are run in fire area A-26. Damage to these cables could prevent operation of the room cooler. Loss of the Train B CCW pump room cooler will not result in an immediate loss of the Train B CCW system. Therefore, if the Train B CCW system is operating at the time of the fire, it can continue to operate until the Train A CCW system is lined up. Cables associated with Train A CCW room cooler SGL11A are not run in area A-26. Therefore, the Train A CCW room cooler is available.

Based on the above discussion, Train A and Train B CCW and ESW are available if a fire occurs in area A-26.

References: E-15000, XX-E-013, E-13EF04A, E-13EF05, E-13EG18, E-13EG18A, E-13GL06, E-1F9303, E-1F9403, E-1F9444, M-12EF02, M-12EG03

5.2.2 Class 1E 480 Volt AC Power

Motor control center (MCC) NG02B could lose power due to damage to cables 14NGG01AD and 14NGG01AE. If this occurs, power to a number of Train B PFSSD components could be lost. Train A MCCs are unaffected by a fire in area A-26 and are available to supply power to redundant Train A PFSSD components.

MCCs NG02T and NG04T could lose power due to damage to cables 14NGG01AJ and 14NGG01BF, respectively. These MCCs supply power to Train B containment coolers SGN01B and SGN01D. Train A containment coolers SGN01A and SGN01C are unaffected by a fire in area A-26 and are available to provide required containment cooling.

Based on the above discussion, loss of power to NG02B, NG02T and NG04T will not adversely impact the ability to achieve and maintain safe shutdown following a fire in area A-26.

References: E-15000, XX-E-013, E-11NG20, E-13NG01A, E-1F9424A, E-1F9424B, M-12GN01

5.2.3 Containment Sump Isolation Valves

Cable 14EJG06BT, associated with containment sump isolation valve EJHV8811B, is run in this area. Damage to this cable could cause the valve to open, momentarily causing the RWST to drain to the containment sump due to normally open valve BNHV8812B. Cables associated with BNHV8812B are unaffected by a fire in this area.

If valve EJHV8811B fully opens, valve BNHV8812B will automatically close, preventing draindown of the RWST to the containment sump. If valve EJHV8811B spuriously opens but stalls before reaching full open position, valve BNHV8812B will not automatically close. If this occurs, operators will recognize a decreasing RWST level using any of the four RWST level indicators and take action to close BNHV8812B using BNHIS8812B in the main control room.

Based on the above discussion, damage to cables associated with valve EJHV8811B will not adversely impact safe shutdown.

5.2 PFSSD CABLE EVALUATION 22

1.0 GENERAL AREA DESCRIPTION

Fire area A-27 is located on the 2026 elevation of the Auxiliary Building and includes the room listed in Table A-27-1.

Table A-27-1
Room Located in Fire Area A-27

ROOM #	DESCRIPTION
1403	Rod Drive/MG Set Room

Fire area A-27 is protected with a total flooding Halon fire suppression system. In addition, automatic fire detection is installed throughout. The automatic suppression and detection system meets the intent of 10CFR50, Appendix R, Section III.G.2.c.

2.0 PRIMARY EQUIPMENT USED FOR PFSSD

Table A-27-2 lists each system credited for post-fire safe shutdown and provides a discussion regarding the availability of the system to perform its Post Fire Safe Shutdown (PFSSD) function if a severe fire occurs in this area. For a summary of the area analysis results, see Section 8.0 of the Fire Area Analysis Narrative section.

Table A-27-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-27

System	System Name	PFSSD Function*	Comments
AB	Main Steam	R, M, H, P, S	All PFSSD functions associated with the main steam system are satisfied. Steam generator A and D ARVs can be controlled from the control room. Local control stations ABFHC0002 and ABFHC0003 may be required to close steam generator B and C atmospheric relief valves ABPV0002 and ABPV0003. ABHS0080 is available to close the MSIVs and MSIV bypass valves. A spurious safety injection signal (SIS) due to low steam line pressure on two out of three steam line pressure transmitters is averted by entering the EMG procedure network and, if necessary, placing EMHIS0004 and EMHIS0005 in pull-to-lock. Control of main steam flow to the TDAFP using ABHV0005 and ABHV0006 may be lost. Steam generator pressure indication is available using ABPI0514A, ABPI0516A, ABPI0524A, ABPI0534A, ABPI0544A and ABPI0545A.
AC	Main Turbine	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-27.
AE	Main Feedwater	H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-27. Steam generator A wide range level indicator AELI0501 and narrow range level indicator AELI0551 are available. Steam generator D narrow range level indicator AELI0554 is available.
AL	Aux. Feedwater System	H, P	All PFSSD functions associated with the auxiliary feedwater system are satisfied. Motor Driven Auxiliary Feedwater Pump (MDAFP) A is available to supply feedwater to SGs B and C. However, steam generator B and C ARVs ABPV0002 and ABPV0003 may need to be controlled locally. Motor Driven Auxiliary Feedwater Pump (MDAFP) B is available to supply feedwater to SGs A and D. The TDAFP may be affected.
AP	Condensate Storage System	H	The condensate storage tank is available to supply water to Train B MDAFP.

Table A-27-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-27

System	System Name	PFSSD Function*	Comments
BB	Reactor Coolant System	R, M, H, P, S	All PFSSD functions associated with the reactor coolant system are satisfied. Loss of inventory through the head vent valves is prevented by maintaining valves BBHV8001A and BBHV8001B closed. Pressurizer level indication is available using level indicator BBLI0459A. Pressurizer pressure indication is available using BBPI0455A located on RL002. RCS pressure indication is available using BBPI0405 on RL022. A spurious SIS due to low pressurizer pressure on two out of four pressurizer pressure transmitters is mitigated by entering EMG E-0 and terminating the spurious SIS. When transferring to RHR, valve BBPV8702B may need to be manually opened to provide a suction source from the RCS to RHR pump B. Pressurizer PORV BBPCV0456A may open and block valve BBHV8000B may not close. If this occurs Operators can close the PORV by placing BBHIS0456A in the CLOSE position. To mitigate a spurious opening of PORV BBPCV0455A, close block valve BBHV8000A using BBHIS8000A. All four reactor coolant pumps may not stop using the control room hand switch. RCP seal injection remains available. Therefore, the inability to stop the RCPs will have no adverse impact on PFSSD. A spurious CISB due to 2/4 high containment pressures will isolate the CCW to/from RCP valves, which will isolate thermal barrier cooling. This is acceptable since RCP seal injection remains available.
BG	Chemical and Volume Control System	R, M, S	All PFSSD functions associated with the chemical and volume control system are satisfied. Train A centrifugal charging pump (CCP) may be unavailable due to the potential loss of Train A component cooling water (CCW) which supplies cooling to the CCP oil cooler. Train B CCP is available to provide charging flow from the RWST to the RCP seals. Flow from the VCT can be isolated by closing either BGLCV0112B or BGLCV0112C. Valves BGHV8154A and BGHV8153B are maintained closed to isolate excess letdown. Non-Class 1E 125 VDC power to valves BGLCV0459, BGLCV0460, BGHV8149A, BGHV8149B and BGHV8149C could be affected. If this occurs, the valves will fail closed which is the desired PFSSD position. Valves BGLCV0459, BGLCV0460, BGHV8149A, BGHV8149B and BGHV8149C may not automatically close on a low pressurizer level signal. The valves can be closed by isolating air to containment using KAHIS0029 in the control room. Pressurizer level is available using BBLI0459A. RCP seal flow indication is available using BGFI0215A. RCP seal flow indicator BGFI0215B may be affected.

Table A-27-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-27

System	System Name	PFSSD Function*	Comments
BM	Steam Generator Blowdown System	R, M, H	All PFSSD functions associated with the steam generator blowdown system are satisfied. Steam generator blowdown is isolated by closing valves BMHV0001, BMHV0002, BMHV0003 and BMHV0004 using BMHIS0001C, BMHIS0002C, BMHIS0003C and BMHIS0004C, located on the BM157 panel in the radwaste control room.
BN	Borated Refueling Water Storage System	R, M, H	The RWST is available to provide a suction source to Centrifugal Charging Pump B via valve BNLCV0112E. RWST level indicators BNLI0930, BNLI0931 and BNLI0932 are available.
EF	Essential Service Water System	H, S	All PFSSD functions associated with the Essential Service Water (ESW) system are satisfied. Train A ESW is available to supply cooling water to Train A Diesel Engine Coolers and Train A Containment Air Coolers SGN01A and SGN01C. Train B ESW is available to supply cooling to the Train B Diesel Engine Coolers, Train B Component Cooling Water (CCW) Heat Exchanger, Train B Motor Driven Auxiliary Feedwater (MDAFW) pump room cooler, CCW B pump room cooler SGL11B, Train B Centrifugal Charging Pump (CCP) room cooler SGL12B and Train B Residual Heat Removal (RHR) pump room cooler SGL10B.
EG	Component Cooling Water System	S	Train B CCW is available. Train A pumps could be lost due to damage to the power cables. It may be necessary to either perform a cold shutdown repair or manually open valve EGHV0102 when transitioning to RHR Train B. A spurious low discharge pressure on Train B discharge pressure transmitter may cause transfer to the standby CCW pump on Train B. If this occurs, both pumps will continue to operate. Since the pressure transmitter may be lost, it may be necessary to have an operator monitor the discharge pressure using a local pressure indicator. Train B temperature control valve EGTV0030 may not close as desired for PFSSD. However, this valve is designed to modulate based on CCW outlet temperature, which is acceptable for PFSSD. A spurious CISB due to 2/4 high containment pressures will isolate the CCW to/from RCP valves, which will isolate thermal barrier cooling. This is acceptable since RCP seal injection remains available. CCW flow indicators EGFI0128 and EGFI0129 are unaffected.

Table A-27-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-27

System	System Name	PFSSD Function*	Comments
EJ	Residual Heat Removal System	M, H, P	All PFSSD functions associated with the Residual Heat Removal (RHR) system are satisfied. Loss of RCS inventory through the RHR flow path is prevented by maintaining valves EJHV8701A and EJHV8701B closed. Valve EJHCV0607 may need to be manually re-opened if the fire causes the valve to close. Valve EJHV8840 could spuriously open. This will not affect hot standby but the valve will need to be closed prior to shutdown cooling. Valve EJHV8809B may spuriously close. This will not affect hot standby but the valve would need to be opened for shutdown cooling. RHR system flow diagnostic instrumentation is available using various available temperature indicators.
EM	High Pressure Coolant Injection	R, M	All PFSSD functions associated with the High Pressure Coolant Injection system are satisfied. A spurious SI signal is averted by entering the EMG procedure network and, if necessary, placing EMHIS0004 and EMHIS0005 in pull-to-lock.
EN	Containment Spray	R, M	All PFSSD functions associated with the Containment Spray system are satisfied. A spurious containment spray actuation signal (CSAS) due to spurious signals on two out of four containment pressure transmitters can be avoided by entering the EMG procedure network and, if necessary, placing the pump control hand switches ENHIS0003 and ENHIS0009 on control room panel RL017 in pull-to-lock.
EP	Safety Injection Accumulators	H	The PFSSD Decay Heat Removal function associated with the Safety Injection Accumulators is satisfied. Accumulator injection lines can be isolated by closing valves EPHV8808A, EPHV8808B, EPHV8808C and EPHV8808D. It may be necessary to make a containment entry to manually close EPHV8808B and EPHV8808D.
FB	Auxiliary Steam	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-27.
FC	Auxiliary Turbines	R, H, P	All PFSSD functions associated with the Auxiliary Turbines are satisfied. The Turbine Driven Auxiliary Feedwater Pump is not used for a fire in area A-27. Valves FCHV0312 and FCFV0313 may open. The TDAFP should trip on overspeed if this occurs. Valve FCFV0105 may be affected. The MSIVs can be closed using all-close hand switch ABHS0080.
GD	ESW Pump House HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-27.
GF	AFW Pump Room Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-27.

Table A-27-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-27

System	System Name	PFSSD Function*	Comments
GK	Control Room and Class 1E Switchgear Room Coolers	S	Class 1E electrical equipment A/C units SGK05A and SGK05B may stop due to a spurious fire isolation signal. The spurious signal can be bypassed by placing GKHS0101 (SGK05A) or GKHS0104 (SGK05B) located on panel RP068 in BYPASS then rotate GKHIS0100 (SGK05A) or GKHIS0103 (SGK05B) to the RUN position.
GL	Auxiliary Building HVAC	S	Train B CCW pump room cooler SGL11B may not be available. Loss of this cooler is acceptable based on PIR 2000-2646.
GM	Emergency Diesel Generator Room HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-27.
GN	Containment Coolers	S	The PFSSD Support function associated with the Containment Coolers is satisfied. Train A (SGN01A and SGN01C) Containment Coolers are available. ESW Train A is available to supply cooling water to the containment coolers. Containment pressure indicators GNPI0934 and GNPI0937 are available.
JE	Diesel Fuel Oil	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-27.
KA	Instrument Air	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-27.
KC	Fire Protection	S	A spurious fire signal could occur due to damage to cables associated with the fire detection system in Halon protected ESF switchgear rooms, causing SGK05A and SGK05B to shut down. See GK system above for further information.
KH	Service Gas	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-27.
KJ	Standby Diesel Engine	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-27.
MA	Main Generation	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-27.
MR	Startup Transformer	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-27.
NB	4.16 kV System	S	Offsite power from NB01 and NB02 may be lost. Both emergency diesel generator trains are available.
NE	Standby Diesel Generator	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-27.

Table A-27-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-27

System	System Name	PFSSD Function*	Comments
NF	Load Shed and Emergency Load Sequencing	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-27.
NG	480V Load Centers and MCCs	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-27.
NK	125VDC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-27.
NN	120VAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-27.
PA	13.8kV	S	Breakers PA0105, PA0106, PA0206 and PA0207 could fail, causing loss of power to associated PFSSD equipment. Redundant capability is available.
PB	4.16kV	H, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-27.
PG	480V Load Centers and MCCs	S	Both MCCs PG19G and PG20G could be lost. Alternate power sources are available to supply the PFSSD loads associated with these MCCs.
PK	125VDC	S	Power to 125VDC non-Class 1E distribution switchboards PK51, PK52 and PK61 could be lost. Loss of power to the associated PFSSD loads is acceptable since the components fail in the desired position.
PL	Local Instrument Panels	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-27.
PN	120VAC	S	The PFSSD Support function associated with the 120VAC system is satisfied. Both power feeds to PN08 could be damaged. The alternate power feed to panel PN07 could be affected. The primary power feed to PN07 is unaffected.
QB	Standby AC Lighting	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-27.
QD	Emergency Lighting	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-27.

Table A-27-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-27

System	System Name	PFSSD Function*	Comments
RL	Control Room MCB	S	The alternate non-Class 1E 120 VAC power to RL017/RL018 could be affected. The primary source of power is unaffected. Non-Class 1E 125 VDC power to RL013/RL014 and RL017/RL018 could be affected. This will not adversely impact PFSSD. Non-Class 1E 120 VAC power to RL023/RL024 could be affected. Loss of power will fail open several steam isolation valves located downstream of the MSIVs. The MSIVs are unaffected by a fire in this area and can be closed from the main control room. Non-Class 1E 125 VDC power to RL001/RL002 could be affected. The PFSSD components that are affected are the letdown isolation valves and the letdown orifice valves. These valves fail closed on loss of power, which is the desired PFSSD position.
RP	Miscellaneous Control Panels	R, M, H, P, S	Several components associated with the RP system could be affected. However, PFSSD is assured.
SA	ESFAS	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-27.
SB	Reactor Protection System	R, S	Both trains of reactor trip switchgear could be damaged. If necessary, the control rods can be inserted by de-energizing rod drive motor generators SF001 and SF002 by opening PA0106 and PA0207 using hand switches PGHIS0002 and PGHIS0003 on RL016.
SC	Reactor Instrumentation	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-27.
SE	Ex-Core Neutron Monitoring	R, P	Source Range monitor SENY0061A/B is available to provide source range monitoring.
SY	Switchyard	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-27.
UU	Supervisory System	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-27.

* R - Reactivity Control; M - Reactor Coolant Makeup; H - Decay Heat Removal; P - Process Monitoring; S - Support Function

3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD

This section describes operator actions that may need to be performed inside or outside the control room to achieve and maintain hot standby if a fire occurs in area A-27. This section also describes cold shutdown repairs that may need to be made to achieve and maintain cold shutdown conditions. Operator actions are proceduralized in OFN KC-016.

3.1 ACTIONS OUTSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

Operator Manual Actions (OMAs) are those actions outside the main control room required to achieve and maintain hot standby. OMAs are identified in E-1F9900 and were determined from thermal hydraulic analysis WCNOC-CP-002. Applicable E-1F9900 OMAs are annotated herein. All other actions outside the control room are desirable for plant control in support of hot standby but not required to achieve and maintain hot standby.

3.1.1 Component Cooling Water Pressure

If necessary, locally monitor the Train B CCW pump discharge pressure using EGPI0026 or EGPI0028 due to damage to pressure transmitter EGPT0078 cable.

3.1.2 Steam Generator Atmospheric Relief Valves

Cables associated with SGARVs ABPV0002 and ABPV0003 may be damaged, preventing control of these valves from the control room. Local controllers ABFHC0002 and ABFHC0003, located in fire area A-23, can be used to close ARVs ABPV0002 and ABPV0003, respectively.

3.1.3 Steam Generator Blowdown to Blowdown Flash Tank Isolation

If a fire occurs in area A-27, cables for BMHIS0001A, BMHIS0002A, BMHIS0003A and BMHIS0004A may be damaged by the fire. Therefore, use BMHIS0001C, BMHIS0002C, BMHIS0003C and BMHIS0004C located on the BM157 panel in the Radwaste Control Room to close valves BMHV0001, BMHV0002, BMHV0003, and BMHV0004.

3.2 ACTIONS INSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

3.2.1 Pressurizer PORV/Block Valve

Pressurizer PORV BBPCV0455A could spuriously open due to control cable damage. If this occurs, operators can close the PORV using BBHIS455A or close block valve BBHV8000A using BBHIS8000A. Pressurizer pressure indication is available using BBPI0455A located on RL002.

3.2.2 Reactor Trip Switchgear

A fire in this area could affect both trains of reactor trip switchgear. If the reactor does not trip using SBHS0001 or SBHS0042, it will be necessary to insert the control rods by de-energizing rod drive motor generators SF001 and SF002 by opening breakers PA0106 and PA0207 using PGHIS0002 and PGHIS0003 on panel RL016.

3.2.3 Component Cooling Water Pumps

Train A component cooling water pumps could be unavailable due to damage to power cables. If Train A CCW is operating when the fire occurs, it may be necessary to transfer to Train B CCW.

Train B CCW pump discharge pressure transmitter circuit may spuriously indicate low discharge pressure, which would start the standby pump. If this occurs, single pump operation can be achieved by locking out one of the two pumps. Otherwise, both pumps would operate.

3.2.4 Steam Generator Atmospheric Relief Valves

Use steam generators A and D to control cooldown. SGARVs ABPV0001 and ABPV0004 are available and can be controlled from the control room.

3.2.5 MSIVs and MSIV Bypass Valves

The MSIV bypass valves may spuriously open. Cables for hand switch ABHS0079 may be damaged by the fire. Cables for redundant hand switch ABHS0080 are unaffected. Use ABHS0080 to close the MSIVs and MSIV bypass valves.

3.2.6 Safety Injection and Containment Spray

A spurious Safety Injection Signal (SIS) due to low steamline pressure, low pressurizer pressure and high containment pressure can be mitigated by consulting EMG E-0 and terminating the spurious SIS.

A spurious start of the CS pumps due to two out of four low containment pressures can be mitigated by placing the pump control hand switches ENHIS0003 and ENHIS0009 on control room panel RL017 in pull-to-lock.

3.2.7 Class 1E Switchgear Room Coolers SGK05A and SGK05B

If SGK05A and SGK05B spuriously stop or cannot be started due to loss of power to the associated fire signal isolation relay, operators can bypass the spurious signal by placing GKHS0101 (SGK05A) or GKHS0104 (SGK05B) located on panel RP068 in BYPASS then rotate GKHIS0100 (SGK05A) or GKHIS0103 (SGK05B) to the RUN position. Indication is available for SGK05A and SGK05B on RP068.

3.2.8 Isolation of Letdown

Letdown valves BGLCV0459 and BGLCV0460 and letdown orifice isolation valves BGHV8149A, BGHV8149B and BGHV8149C may not close as a result of low pressurizer level signal. Operators can attempt to close the valves using their respective hand switches in the main control room. If this does not work, Operators can isolate instrument air to containment, using KAHIS0029, to fail the valves closed.

3.3 ACTIONS TO ACHIEVE AND MAINTAIN COLD SHUTDOWN

3.3.1 Residual Heat Removal (RHR) Train B

It may be necessary to either perform a cold shutdown repair or manually open valve EGHV0102 in fire area A-16 when transitioning to RHR Train B.

It may be necessary to either perform a cold shutdown repair or manually open valve BBPV8702B in fire area RB-1 when transitioning to RHR Train B.

It may be necessary to either perform a cold shutdown repair or manually open valve EJHCV0607 in fire area A-9 when transitioning to RHR Train B.

Valve EJHV8840 could spuriously open in the event of a fire in this area. This will not affect hot standby, however the valve will need to be locally closed prior to entering shutdown cooling mode.

Valve EJHV8809B could spuriously close and may need to be manually opened prior to entering shutdown cooling mode of operation.

4.0 CONCLUSION

With some exceptions, redundant Post-Fire Safe Shutdown capability exists if a severe fire occurs in this area. For those exceptions, feasible manual actions are available and are unaffected by the fire. Manual actions are documented in Section 3.0.

5.0 DETAILED ANALYSIS

This section describes the detailed component-by-component and cable-by-cable analysis for a fire in area A-27.

5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA A-27

PFSSD components (S. in E-15000) located in fire area A-27 are shown in Table A-27-3. An evaluation of each component and associated cables is provided in the sections that follow. The applicable evaluation section is listed in Table A-27-3.

5.1.1 Pressurizer Power Operated Relief Valves and Associated Block Valves

PFSSD requires that either the pressurizer power operated relief valve (PORV) or its associated block valve be closed. Cables and components associated with PORVs BBPCV0455A and BBPCV0456A and block valve BBHV8000B are located in area A-27. A fire in this area could result in PORVs BBPCV0455A and BBPCV0456A spuriously opening and block valve BBHV8000B not responding to a close signal. Block valve BBHV8000A is unaffected by a fire in area A-27.

Panel BB07 is the DC contactor panel for PORV BBPCV0455A. Damage to this panel or associated cables due to a fire in area A-27 could cause PORV BBPCV0455A to spuriously open.

Instrument cables 12BBI16LB, 13BBI16MB and 14BBI16NB associated with pressurizer pressure transmitters BBPT0456, BBPT0457 and BBPT0458, respectively, are run in fire area A-27. As discussed in Calculation XX-E-013, Appendix 1, the Ovation pressurizer pressure control system uses 4-channel verification from all four pressurizer pressure transmitters to operate the pressurizer PORVs. Failure of a single channel will not cause the spurious operation of the PORVs since the system uses the 2nd highest input as the validated signal. Damage to two channels will not cause the PORVs to open because both channels would have to fail to the exact same value at the exact same time and therefore this failure mode is not credible.

The pressurizer PORVs are not considered high/low pressure interfaces. The valves are supplied power by an ungrounded 125 VDC system. Therefore, based on GL 86-10, consideration of multiple proper polarity hot shorts is not required. A single proper polarity hot short still needs to be considered.

A spuriously open PORV BBPCV0455A can be mitigated by either closing block valve BBHV8000A using BBHIS8000A in the control room or closing the PORV using BBHIS0455A . Pressurizer level and RCS pressure indication are available to diagnose a failed open PORV using BBLI0459A and BBPI0405, respectively. In addition, pressurizer pressure indication is available using BBPI0455A.

If a fire causes BBPCV0456A to open and damages BBHV8000B cables, Operators can close BBPCV0456A by placing hand switch BBHIS0456A, located on RL021, in the close position. Pressurizer level and RCS pressure indication are available to diagnose a failed open PORV using BBLI0459A and BBPI0405, respectively. In addition, pressurizer pressure indication is available using BBPI0455A.

Based on the above discussion, a fire in area A-27 could cause PORVs BBPCV0455A and BBPCV0456A to open due to damage to the PORV control cables. In addition, a fire in area A-27 could prevent block valve BBHV8000B from closing. The PORV can be re-closed using their respective hand switches in the control room. Also, block valve BBHV8000A can be closed from the control room using BBHIS8000A.

References: E-15000, XX-E-013, E-13BB16, E-13BB39, E-13BB40, E-1R1421, E-1R1424, J-200-00207, M-12BB02, M-761-02018, M-761A-00063, OFN KC-016, CR 13079, DCP 12944, DCP 13324

5.1.2 480VAC Non-Class 1E Auxiliary Building MCC PG19G (Separation Group 5)

Motor Control Center (MCC) PG19G, located in area A-27, supplies power to PFSSD components PN03 (10 kVA Inverter and Bypass Transformer), RL023/RL024 (Misc MCB Power Circuits), and XPN07D (Instr. Bus Transformer Alternate Feed). A fire in this area could disrupt power to PG19G, which would result in a loss of power to the PFSSD components described above.

MCC PG19G main power feeder cables 15PGG02AF and 15PGG02AX are run in a different fire area before they penetrate the floor of area A-27, directly below PG19G. The cables do not run in area A-27, except within the MCC cabinet.

MCC Cubicle PG19GCF3 supplies 480 VAC power to inverter PN03 (via cable 15PNG02AA). Redundant source of power to PN03 is from PK0105 (via cables 15PNK02AA and 15PNK02AB). Inverter PN03 supplies power to 120 VAC distribution panel PN310 (via cables 15PNY02AA and 15PNY02AB), which in turn supplies redundant 120 VAC power to NSSS control cabinets RP043 and RP047. For PFSSD, cabinet RP043 houses relays BGLCV0459X and BGLCV0460X, which are associated with letdown isolation valves BGLCV0459 and BGLCV0460, respectively. Cabinet RP047 includes controls for pressurizer PORVs and pressurizer spray.

A normally closed contact on relays BGLCV0459X and BGLCV0460X will open when the relay is energized following a low pressurizer level signal, causing the letdown isolation valves to close. This prevents loss of inventory through the normal letdown path if the pressurizer level is low. Loss of power to cabinet RP043 will prevent automatic closure of the letdown valves on low pressurizer level.

As discussed in Section 5.1.3, loss of the alternate source of power to RP043 and RP047, through PN04, can also occur if a fire occurs in area A-27. Therefore, a complete loss of power to RP043 and RP047 can occur if a fire occurs in this area.

Loss of power to RP043 will prevent the relays from performing their function but will not prevent PFSSD. If power is lost and the relays cannot be energized the letdown flow path can be closed by isolating air to containment using KAHIS0029 in the control room. Cables associated with KAFV0029 are unaffected by a fire in this area.

Cable 15PNY01AR is an alternate power feed from XPN07D to switchboard PN07, located in room 3409 (North Non-Essential Switchgear Room). Panel PN07 supplies power to main control board RL017 and RL018 through switch PN0736. The primary power to PN07 is from MCC NG01A located in room 3301 (North ESF Switchgear Room) and is unaffected by a fire in area A-27. Therefore, damage to cable 15PNY01AR, resulting in a loss of alternate power feed to PN07, will not affect PFSSD.

Cable 15RLY01HA supplies 120VAC power to MCB RL023/RL024 miscellaneous circuits from PG19GCR217. Several loads are supplied by this power supply, but only eight are PFSSD components. These are ABLV0051, ABLV0053, ABFV0023, ABFV0025, ABFV0027, ABFV0029, ABHIS0032 and FCHV0003 which are components downstream of the Main Steam Isolation Valves (MSIVs). Loss of power to ABLV0051, ABLV0053, ABFV0023, ABFV0025, ABFV0027, ABFV0029 and FCHV0003 will fail the valves open, which is not desired for PFSSD. Loss of power to ABHIS0032 will cause a loss of hand switch indicator lights. However, a fire in area A-27 does not affect the ability to close the MSIVs and MSIV bypass valves using hand switch ABHS0080 in the main control room. Therefore, the MSIV downstream components can fail in an undesired position without any consequence on PFSSD.

Based on the above discussion, a fire in area A-27 resulting in a loss of MCC PG19G will not impact the ability to achieve and maintain safe shutdown.

References: E-15000, XX-E-013, E-11PG20, E-11PG21, E-11PK01, E-11PN01, E-13AB02C, E-13BG10, E-13BG35, E-13PA02, E-13PG02, E-13PN01A, E-13RL07, E-13SC12, E-1F9421, E-1R1321, M-12BG01, M-761-00046, M-761-00174, M-761-02297, DCP 013324

5.1.3 480VAC Non-Class 1E Auxiliary Building MCC PG20G (Separation Group 6)

Motor Control Center (MCC) PG20G, located in area A-27, supplies power to PFSSD components RL023/RL024 (Misc MCB Power Circuits), XPN08D (Instr. Bus Transformer Alternate Feed), 10 kVA Inverter and Bypass Transformer PN04. A fire in this area could disrupt power to PG20G, which would result in a loss of power to the PFSSD components described above.

Load center transformer XPG020 is supplied 13.8kV power via cables 16PGG04AB and 16PGG04AC. These cables supply power from PG1400 to PG2400 and from PG2400 to PG2000, respectively. Damage to any of these cables will result in a loss of power to 480VAC load center PG20, which supplies power to PG20G. Cables 16PGG04AG and 16PGG04AR supply power from PG20 to PG20G. Damage to any of these cables will result in loss of power to PG20G.

Cable 16PNY01AR supplies non-class 1E 480 VAC power from PG20GER5 to transformer XPN08D. Cable 14PNG01AE supplies class 1E 480 VAC power from NG02BBF1 to NG02ADF1, which supplies 480 VAC to transformer XPN08A. Transformers XPN08A and XPN08D are the only sources of power to non-class 1E switchboard PN08. The PFSSD function of PN08 is to supply power from switch PN0833 to valve positioner EJHY0607 via RL017/RL018. Valve positioner EJHY0607 controls the position of Train B Residual Heat Removal (RHR) discharge valve EJHCV0607 using hand controller EJHIC0607. Both the primary and alternate power feeds to PN08 could be disrupted due to damage to cables 14PNG01AE and 16PNY01AR.

Panel PN08 also supplies non-class 1E 120 VAC power from switch PN0835 to RCS temperature recorders BBTR0433 and BBTR0443 via RL021/RL022. Loss of these temperature recorders will prevent indication of temperature on loop 3 (hot and cold legs) and loop 4 cold leg.

As discussed in Section 5.1.2, the primary power feed to non-class 1E switchboard panel PN07 is unaffected by a fire in area A-27. Panel PN07 supplies power from switch PN0736 to valve positioner EJHY0606. Valve positioner EJHY0606 controls the position of Train A Residual Heat Removal (RHR) discharge valve EJHCV0606 using hand controller EJHIC0606. Also, panel PN07 supplies power from switch PN0738 to temperature recorder BBTR0423. Therefore, loss of power to PN08 will have no adverse impact on PFSSD.

Cable 16RLY01GA supplies 120 VAC power to MCB RL023 miscellaneous circuits from PG20GBR217. Several loads are supplied by this power supply but only three are PFSSD components. These are FCHV0103, ABLV0050 and ABLV0052, which are main steam header to steam dump trap bypass valves. Loss of power to the solenoids associated with these valves will fail the valve open, which is not desired for PFSSD. However, a fire in area A-27 does not affect the ability to close the Main Steam Isolation Valves (MSIVs) and MSIV bypass valves using hand switch ABHS0080 in the main control room. Therefore, the MSIV downstream components can fail in an undesired position without any consequence on PFSSD.

MCC Cubicle PG20GAF4 supplies 480 VAC power to inverter PN04 (via cable 16PNG02AA). Redundant source of power to PN04 is from PK0407 (via cables 16PNK02AA and 16PNK02AB). Inverter PN04 supplies power to 120 VAC distribution panel PN410 (via cables 16PNY02AA and 16PNY02AB), which in turn supplies redundant 120 VAC power to NSSS control cabinets RP043 and RP047. For PFSSD, cabinet RP043 houses relays BGLCV0459X and BGLCV0460X, which are associated with letdown isolation valves BGLCV0459 and BGLCV0460, respectively. Cabinet RP047 includes controls for pressurizer PORVs and pressurizer spray.

A normally closed contact on relays BGLCV0459X and BGLCV0460X will open when the relay is energized following a low pressurizer level signal, causing the letdown isolation valves to close. This prevents loss of inventory through the normal letdown path if the pressurizer level is low. Loss of power to cabinet RP043 will prevent automatic closure of the letdown valves on low pressurizer level.

As discussed in Section 5.1.2, loss of the alternate source of power to RP043 and RP047, through PN03, can also occur if a fire occurs in area A-27. Therefore, a complete loss of power to RP043 and RP047 can occur if a fire occurs in this area.

Loss of power to RP043 will prevent the relays from performing their function but will not prevent PFSSD. If power is lost and the relays cannot be energized the letdown flow path can be closed by isolating air to containment using KAHIS0029 in the control room. Cables associated with KAFV0029 are unaffected by a fire in this area.

Based on the above discussion, a fire in area A-27 resulting in a loss of MCC PG20G will not impact the ability to achieve and maintain safe shutdown.

References: E-15000, XX-E-013, E-11PG20, E-11PG21, E-13AB18, E-13BG10, E-13BG35, E-13PG04, E-13PN01, E-13RL07, E-13SC12, E-1F9421, E-1R1421, J-200-00121, DCP 13324

5.1.4 125VDC Non-Class 1E Distribution Switchboard PK51 (Separation Group 5)

Switchboard PK51 supplies power to a number of PFSSD components. Cables supplying power to PK51 are run through area A-27 and could be damaged by a fire, resulting in the loss of power to PK51 and associated PFSSD loads. Cables 15PKK01AL and 15PKK01AM supply 125VDC power to PK5100 from 125VDC bus PK01. These cables are run on the North end of the area from the Communications Corridor to PK51. There are five breakers associated with PFSSD components on PK51. These are PK5113, PK5117, PK5123, PK5126 and PK5129. The consequences due to loss of power to these breakers is discussed below.

Breaker PK5113 supplies power to panel RP060 via cable 15RPK09RA. The PFSSD function of RP060 is to allow isolation of off-site power to NB01 and NB02 in the event of a fire in areas C-9 and C-10, respectively. Loss of power to RP060 will not adversely impact the ability to achieve and maintain PFSSD in the event of a fire in area A-27.

Breaker PK5117 supplies power to several non-safety components on panel RL001/RL002 via cable 15RLK01AA. Some of these components are credited for PFSSD. Those components are BGLCV0459, BGLCV0460, BGHV8149A, BGHV8149B and BGHV8149C.

Valves BGLCV0459 and BGLCV0460 are letdown isolation valves. Either valve is required to be closed for PFSSD. Loss of power to PK5117 will de-energize the associated control solenoid and fail the valves closed, which is the desired PFSSD position.

Valves BGHV8149A, BGHV8149B and BGHV8149C are letdown orifice isolation valves. Loss of power to PK5117 will de-energize the associated control solenoid and fail the valves closed, which is the desired PFSSD position.

Breaker PK5123 supplies power to steam generator blowdown control panel BM157 located in the Radwaste control room. The steam generator blowdown panel (BM157) is used as an alternate means for isolating steam generator blowdown. The normal means uses hand switches located on RL024 in the main control room. Loss of power to BM157 will de-energize solenoid valves associated with BMHV0001, BMHV0002, BMHV0003 and BMHV0004 and will fail the valves closed, which is the desired PFSSD position.

Breaker PK5126 supplies power, via cable 15RPK09NA, to relay 95XGK07 in relay rack RP330, as well as other non-PFSSD relays. Relay 95XGK07 is the automatic fire signal isolation relay for SGK05A. This relay is normally energized and, upon loss of power, SGK05A

will shut down. Power to the relay will be lost if a fire detection signal in any one of the Train A Halon protected Class 1E electrical switchgear rooms is received or damage to breaker PK5126 or cable 15RPK09NA occurs. Also, an intra-cable short in cables 16KCQ21FA and 16KCQ21JA will cause a false fire detection signal, initiate Halon release and shut down SGK05A. A fire in area A-27 could also damage cable 15GKK31CA, causing a loss of power to relay 95XGK07 and subsequent shutdown of SGK05A. If power to relay 95XGK07 is lost, operators can bypass the spurious shutdown signal by placing GKHS0101 on RP068 in BYPASS then rotate GKHIS0100 to the RUN position.

Breaker PK5129 supplies power to auxiliary relay rack RP211 via cable 15RPK09EA. The only PFSSD relay within RP211 is 3XBM46, which is the blowdown and sample process isolation signal relay. This relay is normally de-energized, so loss of power to this relay will not affect PFSSD.

Based on the above discussion, a fire in area A-27 that affects 125VDC Non-Class 1E Distribution Switchboard PK51 will not impact the ability to achieve and maintain safe shutdown.

References: E-15000, XX-E-013, E-11PK01, E-13BG10, E-13BG40, E-13BM16, E-13EG16, E-13GK13, E-13GK13A, E-13GK31, E-13KC21, E-13RL01, E-13RL02, E-13RP09, E-1R1421, M-12BG03

5.1.5 125VDC Non-Class 1E Distribution Switchboard PK52 (Separation Group 6)

Cables supplying power to PK52 are run through area A-27 and could be damaged by a fire, resulting in a loss of power to PK52 and associated PFSSD loads. Cables 16PKK02AN and 16PKK02AP supply 125VDC power to PK5200 from 125VDC bus PK02. There is one breaker (PK5213) associated with PFSSD components on PK52. The consequences due to loss of power to this breaker is discussed below.

Breaker PK5213 supplies power to reverse isolation relay rack RP331. This relay rack houses two relays (3XEG08 and 95XGK08) used for PFSSD. Relay 3XEG08 is the CCW heat exchanger B temperature valve (EGTV0030) auxiliary relay. Power to this relay originates from RL019/RL020 and is unaffected by a fire in area A-27.

Relay 95XGK08 is the automatic fire signal isolation relay for SGK05B. This relay is normally energized and, upon loss of power, SGK05B will shut down. Power to the relay will be lost if a fire detection signal in any one of the Train B Halon protected Class 1E electrical switchgear rooms is received or damage to breaker PK5213 or cable 16RPK09PA occurs. Also, an intra-cable short in cables 16KCQ21EA and 16KCQ21HA will cause a false fire detection signal, initiate Halon release and shut down SGK05B. A fire in area A-27 could also damage cables 16GKK31DA and 16GKK31DB, causing a loss of power to relay 95XGK08 and subsequent shutdown of SGK05B. If power to relay 95XGK08 is lost, operators can bypass the spurious shutdown signal by placing GKHS0104 on RP068 in BYPASS then rotate GKHIS0103 to the RUN position.

Based on the above discussion, a fire in area A-27 affecting 125VDC Non-Class 1E Distribution Switchboard PK52 will not impact the ability to achieve and maintain safe shutdown.

5.1.6 125VDC Non-Class 1E Distribution Switchboard PK61 (Separation Group 5)

Cables supplying power to PK61 are run through area A-27 and could be damaged by a fire, resulting in a loss of power to PK61 and associated PFSSD loads. Cables 15PKK01AJ and 15PKK01AW supply 125VDC power to PK6100 from 125VDC bus PK01. These cables are run on the North end of the area from the Communications Corridor to PK61. There are five breakers associated with PFSSD components on PK61. These are PK6106, PK6107, PK6108, PK6115, and PK6116. The consequences due to loss of power to these breakers is discussed below.

Breaker PK6106 supplies control power to MA104E via cables 15MRK10AB and 15MRK10AC. Loss of power to MA104E would cause a loss of fault protection for the startup transformer but would not cause the transformer to trip. Loss of power would annunciate on RK045C2. Consequently, loss of power to this breaker will not impact PFSSD.

Breaker PK6108 supplies control power to MA104F via cable 15NBK10AA. Loss of power to MA104F would cause a loss of fault protection for ESF transformer XNB01 but would not cause the transformer to trip. Loss of power would annunciate on RK045C2. Consequently, loss of power to this breaker will not impact PFSSD.

Breaker PK6115 supplies power to panel RL013/RL014 via cable 15RLK01CA. The PFSSD function of RL013/RL014 is to allow isolation of off-site power to NB01 and NB02 in the event of a fire in areas C-9 and C-10, respectively. Loss of power to RL013/RL014 will not adversely impact the ability to achieve and maintain PFSSD in the event of a fire in area A-27.

Breaker PK6116 supplies power to a number of 125VDC loads on RL017/RL018 via cable 15RLK01DA. The only PFSSD load supplied by PK6116 is the control solenoid for valve EMHV8882. Valve EMHV8882 is the boron injection downstream test line and is required to be closed for PFSSD. De-energizing the control solenoid closes EMHV8882. Therefore, loss of power to the solenoid will not impact PFSSD.

A fire in area A-27 affecting 125VDC Non-Class 1E Distribution Switchboard PK61 will not impact the ability to achieve and maintain safe shutdown.

5.1.7 Reactor Trip Switchgear Cabinets SB102A and SB102B

Both trains of reactor trip switchgear are located in fire area A-27. There is no physical separation between the two cabinets. A fire in this area could damage both trains of switchgear and associated cables such that the reactor cannot be tripped using SBHS0001 or SBHS0042 in the control room.

Cables 11SBS10AB, 11SBS12AC, 14SBS10BB and 14SBS12BC are associated with the reactor trip switchgear and are run through area A-27. Damage to any of these cables could prevent tripping the reactor from the control room.

If the reactor does not trip automatically or manually using SBHS0001 or SBHS0042, it will be necessary to insert the control rods by de-energizing rod drive motor generators SF001 and SF002. Breakers PG1902 and PG2002 supply 480 VAC power to SF001 and SF002, respectively. However, these breakers are only locally controlled. Breakers PG1901 and PG2001 are the feeder breakers for PG19 and PG20, respectively. Breaker PG1901 is located in fire area A-8. However, control power for this breaker is from PK6101 which is located in fire area A-27 and could be affected by the fire. Therefore, PG1901 may not respond to an open signal from control room hand switch PGHIS0016. Load center PG20 is located in fire area A-27 so PG2001 may not open in response to a signal from control room hand switch PGHIS0018.

In order to de-energize the rod drive motor generators, breakers PA0106 and PA0207 can be opened. These breakers are located in the turbine building and are unaffected by a fire in area A-27. Control power for PA0106 and PA0207 is from PK4103 and PK6204, respectively, which are located in the Turbine Building. Control circuits associated with PA0106 and PA0207 are unaffected by a fire in area A-27. Control power cables are unaffected by a fire in area A-27. Therefore, PA0106 and PA0207 can be opened using hand switches PGHIS0002 and PGHIS0003, respectively, located on RL016.

Opening PA0106 will de-energize load centers PG15, PG17 and PG19. Opening PA0207 will de-energize load centers PG14, PG18, PG20 and PG24. These load centers are not credited for a fire in area A-27 so loss of power will not adversely affect PFSSD in the event of a fire in this area.

Based on the above discussion, a fire in area A-27 involving reactor trip switchgear cabinets SB102A and SB102B will not prevent PFSSD. Diverse means are available to trip the reactor in the event the reactor cannot be manually tripped from the control room. Therefore, the configuration is acceptable.

5.1.8 Source Range Monitoring

PFSSD requires source range (SR) flux monitoring to be available. Source range monitoring is provided by source range monitors SENE0031, SENE0032, SENY0060A/B, and SENY0061A/B.

Source range monitor SENY0060A/B and associated cables are located in fire area A-27. Also, cables for SENE0031 and SENE0032 run through area A-27. A fire in area A-27 could cause source range monitors SENY0060A/B, SENE0031 and SENE0032 to be inoperable. Source range monitor SENE0061A/B is available to provide source range monitoring and is unaffected by a fire in area A-27.

A fire in area A-27 can use SENY0061A/B for source range monitoring.

For a more detailed evaluation on Source Range monitoring, see Calculation XX-E-013, Attachment 3.

5.2.1 Reactor Head Vent Valves

PFSSD requires that one of the two reactor vessel head vent valves on each flow path (2 flow paths total) be closed to prevent uncontrolled depressurization of the RCS. Circuits for three of the four head vent valves run through area A-27. These cables are listed in Table A-27-4.

Cables for head vent valve BBHV8001A are not run through A-27 and are unaffected by a fire in A-27. Therefore, the cables for redundant head vent valve BBHV8002A can be damaged without any consequences on PFSSD.

Either BBHV8001B or BBHV8002B needs to be closed to prevent RCS depressurization through the separation group 4 head vent flow path. The separation requirements of 10CFR50, Appendix R are not satisfied for valves BBHV8001B and BBHV8002B. Less than 20 feet of horizontal separation and intervening combustibles exist between raceways carrying cables 14BBK30BA and 14BBK30DA.

Cable 14BBK30BA is run in conduit through area A-27. This conduit carries one other cable (14BGK48AB) which is a control cable for excess letdown isolation valve BGHV8153B and is normally de-energized. Therefore, the possibility of an inter-cable hot short that would cause valve BBHV8001B to open is not credible. An intra-cable short in cable 14BBK30BA would not cause the valve to open because this failure mode would not energize the control solenoid. Considering a ground fault equivalent hot short (GFEHS), a short to ground involving conductor 2 in cable 14BBK30BA coincident with a short to ground involving another +125 VDC conductor in another cable supplied from the same power source could open the head vent valve. This hot short has to occur prior to an intra-cable short occurring between conductors 2 and N2 in the associated cable because an intra-cable short between these conductors coincident with a GFEHS will open the circuit protective device and de-energize the control solenoid. Fire testing (NUREG/CR-7100) has shown that intra-cable shorting in thermoset cables occurs before inter-cable or GFEHS shorting. Therefore, there is reasonable assurance that inter-cable or GFEHS shorts will not cause two valves to open if a fire occurs in this area.

Based on this discussion, there is reasonable assurance that cable damage, along with any combination of cable failures, will not cause valve BBHV8001B to spuriously open in the event of a fire in area A-27. Therefore, both head vent valve flow paths will be isolated.

References: E-15000, XX-E-013, E-1F9301, E-13BB30, E-1R1423A, M-12BB04

5.2.2 Excess Letdown Isolation Valves

PFSSD requires the excess letdown path be isolated to prevent uncontrolled depressurization of the RCS. To accomplish this, either normally closed valve BGHV8153A or BGHV8154A must be maintained closed and either normally closed valve BGHV8153B or BGHV8154B must be maintained closed. Cables associated with these valves are listed in Table A-27-4.

Circuits for BGHV8154A do not run through fire area A-27 and are unaffected by a fire in this area. Therefore, this valve remains closed.

The separation requirements of 10CFR50, Appendix R are not satisfied for valves BGHV8153B and BGHV8154B. Less than 20 feet of horizontal separation and intervening combustibles exist between raceways carrying cables 14BGK48AB and 14BGK48BB.

Cable 14BGK48AB is run in conduit through area A-27. This conduit carries one other cable (14BBK30BA) which is a control cable for RCS head vent valve BBHV8001B and is normally de-energized. Therefore, a hot short that would cause valve BGHV8153B to open is not credible.

An intra-cable short in cable 14BGK48AB would not cause the valve to open because this failure mode would not energize the solenoid.

Based on this discussion, there is reasonable assurance that valve BGHV8153B will not spuriously open in the event of a fire in area A-27.

References: E-15000, XX-E-013, E-1F9301, E-13BG48, E-1R1423A, M-12BG01

5.2.3 Component Cooling Water Pumps and Room Coolers

DPEG01A, DPEG01B, DPEG01C and DPEG01D are motors for Component Cooling Water (CCW) Pumps A (PEG01A), B (PEG01B), C (PEG01C) and D (PEG01D). PEG01A and PEG01C circulate cooling water to essential components through the Train A Component Cooling Water (CCW) heat exchanger (EEG01A). PEG01B and PEG01D circulate cooling water to essential components through the Train B Component Cooling Water (CCW) heat exchanger (EEG01B). Each CCW Pump can supply 100 percent of the required cooling water to selected Engineered Safety Features (ESF) components.

Cables 11EGB01AA and 11EGB01CA are power cables for the Train A CCW pump motors and run in cable tray through fire area A-27. A fire in area A-27 could damage these cables and prevent operation of both pump motors.

Power and control cables associated with both Train B CCW pumps are unaffected by a fire in this area.

Power and control cables for Train B CCW pump room coolers are run in tray in the far South portion of area A-27. Damage to these cables will result in the loss of room cooling for the Train B CCW pump motors. Since Train B CCW is relied on for a fire in area A-27, the Train B CCW pumps need to be operable. PIR 2000-2646 was written to document and evaluate this condition. Calculation GL-M-006 was prepared to evaluate the area temperature on the 2026'-0" elevation of the Auxiliary Building in the event of a loss of the Trains A and B CCW pump room coolers. The calculation also assumes a loss of non-safety related ventilation in the area.

Based on Calculation GL-M-006, the maximum temperature on the 2026'-0" elevation of the auxiliary building, under the conditions stated above, is 123.7°F. Each CCW pump motor is designed to operate continuously at 122°F. The PIR evaluation states that a room temperature less than 2°F higher than the operating temperature of the motor will not have a significant impact on the operation of the motor. Consequently, based on Calculation GL-M-006 and PIR 2000-2646, a loss of CCW pump room cooling will not result in a loss of CCW.

Based on the above discussion, Train A CCW may be affected but Train B CCW is available.

References: E-15000, XX-E-013, E-1F9401A, E-0R1422, E-1R1421, E-1R1423B, E-13GL06, E-13EG01C, E-13EG01D, E-13NB02, E-13NB05, M-12EG01, GL-M-006, PIR 2000-2646, E-012.2-015-04

5.2.4 Steam Generator Feedwater Pumps

Main feedwater pump steam supply valves FCFV0005 and FCFV0105 are credited in the PFSSD analysis to trip the main feedwater pumps if the main steam isolation valves (MSIVs) are affected by a fire. Closing the MSIVs stops steam flow to the feedwater pumps' turbines and stops the feedwater pumps. The steam generator feedwater pumps are tripped in the event of a fire to prevent overfilling the steam generators.

Cable 16FCY35AA provides the primary source of 120 VAC power from distribution panel PN010A to panel FC170A. The alternate source of power to panel FC170A is not credited for

PFSSD and is assumed lost. Damage to cable 16FCY35AA could cause a loss of power to FC170A and prevent energizing trip relays associated with valve FCFV0105. This would prevent closing valve FCFV0105 to stop steam flow to the B feedwater pump.

A fire in area A-27 will not affect the ability to close the MSIVs from the control room. As discussed in Section 5.2.19, MSIV all-close hand switch ABHS0079 could be affected by a fire in this area. However, all-close hand switch ABHS0080 is unaffected and can be used to close the MSIVs from the control room.

Based on the above discussion, valve FCFV0105 may not close if a fire occurs in this area. However, the MSIVs can be closed using hand switch ABHS0080 in the main control room. Therefore, the configuration is acceptable.

References: E-15000, XX-E-013, E-13FC35, E-1F9103, E-1F9421

5.2.5 CCW to RHR Heat Exchanger Control Valves

PFSSD requires one train of residual heat removal (RHR) to be available for shutdown cooling. The RHR system is not used for hot standby.

Valve EGHV0101 is the Train A CCW to RHR Heat Exchanger control valve. Valve EGHV0102 is the Train B CCW to RHR Heat Exchanger control valve. The valves are normally closed during power operation. PFSSD requires that the valve on the operating train of CCW be closed until shutdown cooling mode is entered, at which time the valve on the operating train of RHR needs to be open.

Cable 14EGG07BA is the power cable for valve EGHV0102. Damage to this cable could prevent operation of the valve from the control room. Cable 14EGG07BB is a control cable for valve EGHV0102. Damage to this cable could either prevent operation of the valve from the control room or bypass the limit switch, possibly causing damage to the valve motor.

Damage to either cable will not cause valve EGHV0102 to spuriously open. This valve is not a Hi/Low pressure interface valve, so consideration of a 3-phase hot short is not required. Damage to the control cable in any manner is not sufficient to spuriously open the valve.

During cold shutdown, it may be necessary to either perform a cold shutdown repair or manually open valve EGHV0102 in fire area A-16 when transitioning to RHR Train B.

References: E-15000, XX-E-013, E-1F9401A, E-13EG07, E-13EG07A, E-1R1421, M-12EG02

5.2.6 Thermal Barrier Cooling Isolation Valves

PFSSD requires isolation of the CCW system from each RCP thermal barrier whenever a fire-induced loss of all seal cooling occurs. However, as long as at least one seal cooling method (seal injection or thermal barrier cooling) is available and is unaffected by the fire, the CCW system can remain lined-up to the RCP thermal barriers with no adverse impact on PFSSD.

A fire in area A-27 may cause a loss of Train A CCW due to damage to power cables associated with the CCW pumps. Both trains of CCPs remain available. If Train A CCW is operating at the time of the fire, the Train B CCW system can be lined up from the control room.

Cables associated with EGHV0062, EGHV0127 and EGHV0133 are run in this area. Damage to cables associated with EGHV0127 and EGHV0133 will have no adverse impact because these valves are located in the bypass lines for valves EGHV0058 and EGHV0061,

respectively. Valves EGHV0058 and EGHV0061 are unaffected by a fire in this area and will remain open.

Cables 14EGG10AC and 14EGG10AD associated with EGHV0062 are run in this area. Damage to cables 14EGG10AC or 14EGG10AD could cause the valve to spuriously close, preventing CCW flow to the thermal barrier heat exchangers. Bypass valve EGHV0132 is unaffected and can be opened from the control room to restore thermal barrier cooling. Loss of thermal barrier cooling would be indicated in the control room as a reduction in flow on flow indicators EGFI0128 and EGFI0129. Therefore, operators can diagnose a loss of thermal barrier cooling.

Based on the above discussion, isolation of thermal barrier cooling is not required for a fire in area A-27. The position of the thermal barrier isolation valves has no impact on PFSSD for a fire in area A-27.

References: E-15000, XX-E-013, E-1F9303, E-13EG10, E-13EG18, E-1R1421, M-12EG03

5.2.7 Train B Component Cooling Water Pumps Pressure Transmitter

EGPT0078 is a pressure transmitter that monitors the discharge pressure on the Train B CCW pumps discharge header. A low discharge pressure will automatically start the standby pump on the associated train. PFSSD requires that the pressure transmitter on the unaffected train be available.

Cable 14EGI13BA is an instrument cable for EGPT0078 and is run in the South portion of area A-27. Damage to this cable could cause a spurious low discharge pressure signal and cause the standby pump to automatically start. The running pump will remain operating until manually stopped by an operator in the control room.

Although a spurious low discharge pressure signal could complicate PFSSD, it will not prevent PFSSD from being achieved. An operator in the control room could allow both pumps to operate or place one of the pumps in pull-to-lock while ensuring the other pump is operating using the associated hand switch in the control room. It may also be necessary to locally monitor the discharge pressure on the operating pump using the discharge pressure indicator.

A fire in area A-27 will not prevent the operation of Train B CCW pumps in the event of damage to the discharge pressure transmitter circuit. A recovery action is available to ensure operation of either Train B CCW pump. With the availability of Train B CCW assured, no E-1F9900 OMA is required to achieve and maintain hot standby.

References: E-15000, XX-E-013, E-1R1421, E-13EG01C, E-13EG01D, E-13EG13, E-13RP08, M-12EG01.

5.2.8 Component Cooling Water Train B Heat Exchanger Bypass Isolation Valve

EGTV0030 is the bypass isolation valve for the Train B CCW heat exchanger. This valve is air operated using solenoid valve EGTY0030A. With solenoid valve EGTY0030A energized (normal state), valve EGTV0030 is automatically modulated to maintain required CCW heat exchanger outlet temperature. Loss of power to the solenoid will fail valve EGTV0030 closed, which is the desired PFSSD position.

Cable 14EGK16BA is associated with valve EGTV0030 and is run in tray the South portion of fire area A-27. An external (inter-cable) +125VDC hot short across conductor 11 will cause the solenoid to energize and permit modulation, regardless of the position of the hand switch. An open in this cable will de-energize the solenoid and close the valve, which is the desired PFSSD position.

Valve modulation is controlled mechanically by temperature detector EGTIC0030. The temperature detector is located adjacent to the CCW heat exchanger. The temperature detector monitors outlet temperature of the CCW heat exchanger and adjusts air pressure to the temperature control valve (EGTV0030) accordingly. This controls the amount of water that bypasses the CCW heat exchanger to maintain outlet temperature at the desired level. Therefore, valve modulation will not affect PFSSD.

A fire in area A-27 will not adversely affect the ability of valve EGTV0030 to perform its intended function. The valve will either modulate, as designed, or close in response to a control room signal.

References: E-15000, XX-E-013, E-13EG16, E-1R1421, M-12EG02

5.2.9 Steam Generator Atmospheric Relief Valves

Cables associated with Steam Generator Atmospheric Relief Valves ABPV0002 and ABPV0003 are run in area A-27. Cables associated with Steam Generator Atmospheric Relief Valves ABPV0001 and ABPV0004 are not run in area A-27.

PFSSD requires at least two steam generator atmospheric relief valves (ARV) be controlled and the other two closed. The ARVs are normally closed and require air pressure to open. Each valve is controlled by a pressure transmitter input signal from a pressure transmitter installed on the outlet side of the steam generator. The relief valve opens when the pressure reaches a designated set point.

Because of the fail-close design of the valve, it is unlikely that spurious signals due to cable damage will cause the valves to open. In the unlikely event the valves open, air pressure can be removed by closing appropriate air and nitrogen supply valves to fail close the valves. These valves are not located in area A-27 and access to the valves can be gained without having to traverse area A-27.

Damage to the associated cables could prevent controlling two of the four ARVs from the control room. The PFSSD methodology in area A-27 uses steam generators A and D to cool down. Local controllers ABFHC0002 and ABFHC0003, located in fire area A-23, can be used to close ARVs ABPV0002 and ABPV0003, respectively. ARVs ABPV0001 and ABPV0004 would be available to control cooldown using steam generators A and D, respectively.

Based on the above discussion, manual actions are available to ensure a fire in area A-27 will not prevent the control of two Steam Generator Atmospheric Relief Valves and the closure of the remaining two.

Up to three ARVs can fail closed or open without impacting ability to achieve and maintain hot standby according to thermal hydraulic analysis WCNOC-CP-002. With at least one ARV unaffected, no E-1F9900 OMA is required to address ARV closure or control. Reference Attachment 4, MSO Evaluation Scenario ID PWROG 23.

5.2.10 Safety Injection and Containment Spray

Calculation XX-E-013, Appendix 1 (PFSSD Support Section) provides a detailed discussion about the potential PFSSD impact of a spurious safety injection signal (SIS) and spurious containment spray actuation signal (CSAS). This section discusses the specific PFSSD impact if a fire occurs in this area.

Cables associated with GNPT0935 and GNPT0936 are run in area A-27. Cables associated with GNPT0934 and GNPT0937 are not run in area A-27. A fire in area A-27 could cause a spurious SIS and CSAS due to damage to cables associated with at least two pressure transmitters causing a spurious high containment pressure signal.

Cables associated with Train B containment spray isolation valve ENHV0012 are run in area A-27. Damage to these cables could cause the valve to spuriously open. However, as described below, a spurious CSAS can be mitigated from the control room. Therefore, spurious opening of this valve will not adversely impact PFSSD.

Cables associated with BBPT0456, BBPT0457 and BBPT0458 are run in area A-27. Cables associated with BBPT0455 are not run in area A-27. A fire in this area could cause a spurious SIS due to damage to cables associated with two of the four pressurizer pressure transmitters causing a spurious low pressurizer pressure signal.

Cables associated with steam line pressure transmitters ABPT0515, ABPT0525, ABPT0526, ABPT0535, ABPT0536 and ABPT0545 are run in area A-27. Consequently, a fire in area A-27 could cause a spurious SIS due to damage to cables associated with two out of three steam line pressure transmitters on loops 2 and 3.

A spurious SIS starts the charging sequence which starts the CCPs and opens the BIT flowpath valves. For a fire in this area, Train B CCP is credited for PFSSD since a number of Train A PFSSD components could be lost. Train B BIT flowpath valves EMHV8801B and EMHV8803B are unaffected and would open on a SIS. The Train B RWST to CCP suction header valve BNLCV0112B is unaffected and would open on a SIS. Also, Train B CCP mini flow valve BGHV8111 is unaffected and Train B CCW flow to the seal water heat exchanger is unaffected to ensure cooling of the recirc flow and RCP seal return. Train B CCW flow is also available to the Train B CCP oil cooler. Therefore, the Train B charging pump will not be affected by a spurious SIS caused by a fire in this area.

A start of the credited CCW system (Train B) will not adversely impact the system. The Train B ESW system is unaffected and will start on a spurious SIS, providing necessary cooling water to the CCW heat exchanger.

A start of the AFW pumps will not adversely impact PFSSD. The Train B AFW pump is credited for a fire in this area. Suction from the CST to the Train B AFW pump is unaffected. Discharge flow will either return to the CST or flow to the steam generators through the discharge control valves. Therefore, the Train B AFW pump is unaffected by a spurious SIS caused by a fire in this area.

A spurious SIS will start both RHR pumps. Train A RHR from RWST supply valve BNHV8812A is unaffected and will open. Train A RHR miniflow switch EJFIS0610 and miniflow valve EJFCV0610 are unaffected and EJFCV0610 will open on low flow in the RHR system. Train A CCW system could be affected per Section 5.2.3, which would prevent CCW flow to the Train A RHR heat exchanger. However, this will not cause damage to the RHR pump because CCW only flows to the RHR heat exchanger on a SIS coincident with low level in the RWST. The recirc flow combined with the supply from the RWST will ensure that the Train A RHR pump will not be damaged and gives operators time to stop the pump after the spurious SIS is terminated. Calculation EJ-M-018 shows there is 2 ½ hours available to stop the RHR pumps when flowing on recirculation only with no CCW flow to the RHR heat exchanger.

A spurious Containment Spray Actuation Signal (CSAS) due to spurious high containment pressure can be mitigated by placing CS pump control hand switches ENHIS0003 and

ENHIS0009 in pull-to-lock. These switches are located on control room panel RL017. Indication in the Control Room for SI and CS pump operation is unaffected by a fire in A-27.

Based on the above discussion, a fire in area A-27 could cause a spurious SIS due to low steamline pressure, low pressurizer pressure and high containment pressure. A fire in A-27 could also cause a spurious CSAS due to high containment pressure. The spurious SIS and CSAS will not cause damage to credited hot standby or cold shutdown equipment.

5.2.11 Turbine Driven Auxiliary Feedwater Pump (TDAFP)

A number of cables associated with the TDAFP are run through area A-27. These cables are listed in Table A-27-4. Damage to these cables could cause the TDAFP to be inoperable. Loss of the TDAFP is acceptable since the Train B Motor Driven Auxiliary Feedwater Pump (MDAFP) is available and is unaffected by a fire in area A-27. Therefore, the auxiliary feedwater requirement for decay heat removal is satisfied if a fire occurs in area A-27.

To prevent uncontrolled blowdown through the TDAFP flow path, either valves ABHV0005 and ABHV0006 or valve FCHV0312 needs to be closed. All three of these valves are normally closed and open upon receipt of an auxiliary feedwater actuation signal (AFAS). Based on Calculation XX-E-013, Appendix 1, the bypass valves (ABHV0048 and ABHV0049) on the ABHV0005 and ABHV0006 bypass lines are not included in the PFSSD design because blowdown through the 1-inch steam trap can be mitigated by adjusting the blowdown rate through the steam generator atmospheric relief valves.

Control cables associated with ABHV0005 (12ABK01AE and 12ABK01AF) and ABHV0006 (12ABK01BE and 12ABK01BF) are run through area A-27. Status indication cables associated with ABHV0005 (12SAZ23AA) and ABHV0006 (12SAZ23BA) are run through area A-27. It is unlikely that loss of status indication will cause a loss of control of these valves. However, damage to control cables could cause a loss of power to the control solenoid which would open the associated valve. Consequently, blowdown through the TDAFP is not controlled using valves ABHV0005 and ABHV0006.

Valve FCHV0312 is the turbine trip and throttle valve and is located downstream of valves ABHV0005 and ABHV0006 in the 4-inch steam line to KFC02. This valve is normally closed and, if maintained closed, will prevent uncontrolled steam blowdown through the AFP turbine. Cables associated with this valve (12FCK23AR, 12FCK23AS and 12FCK23AU) are run through area A-27. The possibility exists to spuriously open the valve due to a single intra-cable (conductor-to-conductor) or inter-cable (cable-to-cable) hot short between various combinations of conductors in these cables. Consequently, blowdown through the TDAFP is not controlled by valve FCHV0312.

Valve FCFV0313 is the TDAFP speed governing valve. Instrument cables associated with this valve (12FCK24AK and 12FCK24AQ) are run through area A-27. In addition, cable 12RPK09AA supplies power to relay panel RP266, which in turn powers panel FC219. Panel FC219 is the control panel for the TDAFP. Damage to cables 12FCK24AK and 12FCK24AQ could prevent operation of FCFV0313. Damage to cable 12RPK09AA could cause a loss of power to panel FC219 which would fail FCFV0313 full open. If this occurs coincident with either ABHV0005 or ABHV0006 failed open and FCHV0312 failed open, the turbine would overspeed and actuate the mechanical trip mechanism and close valve FCHV0312. This will prevent uncontrolled blowdown through the AFP turbine.

Cables associated with ALPT0026 (12ALI07KD and 12ALI07KE), TDAFW pump suction pressure transmitter, are run through area A-27. Loss of ALPT0026 is acceptable since MDAFW pump B is used for PFSSD if a fire occurs in area A-27.

Based on the above discussion, the TDAFP may not be available if a fire occurs in this area. The Train B MDAFP is available to supply auxiliary feedwater to steam generators A and D.

References: E-15000, XX-E-013, E-1F9101, E-13AB01, E-13AB01A, E-13AL07B, E-13FC23, E-13FC24, E-13SA23, M-0021-00086, M-12FC02, M-12AB02

5.2.12 Steam Generator Level Indication

The decay heat removal function for PFSSD requires the use of two RCS loops and two Steam Generators. Steam generator (SG) level indication is required to support this function. A fire in A-27 uses MDAFW pump B, which is normally aligned to supply SGs A and D. Table A-27-5 summarizes the level transmitters that could be affected by a fire in area A-27.

Table A-27-5
Steam Generator Level Transmitter Circuits in Area A-27

Transmitter	Description
AELT0502	SG B Wide Range Level Transmitter
AELT0503	SG C Wide Range Level Transmitter
AELT0504	SG D Wide Range Level Transmitter
AELT0517	SG A Narrow Range Level Transmitter
AELT0518	SG A Narrow Range Level Transmitter
AELT0519	SG A Narrow Range Level Transmitter
AELT0527	SG B Narrow Range Level Transmitter
AELT0528	SG B Narrow Range Level Transmitter
AELT0537	SG C Narrow Range Level Transmitter
AELT0538	SG C Narrow Range Level Transmitter
AELT0547	SG D Narrow Range Level Transmitter
AELT0548	SG D Narrow Range Level Transmitter
AELT0549	SG D Narrow Range Level Transmitter
AELT0552	SG B Narrow Range Level Transmitter
AELT0553	SG C Narrow Range Level Transmitter

As stated previously, a fire in area A-27 uses steam generators A and D. Steam generator A wide range level transmitter AELT0501 and narrow range level transmitter AELT0551 are available if a fire occurs in area A-27. Steam generator D narrow range level transmitter AELT0554 is available if a fire occurs in area A-27. Based on the above discussion, level indication on steam generators A and D is available if a fire occurs in area A-27.

References: E-15000, XX-E-013, E-1F9203, E-13AE08, E-13AE12, M-12AE02

5.2.13 Condensate Storage Tank Suction Pressure

The preferred suction source for auxiliary feedwater (AFW) is the condensate storage tank (CST). This tank provides a clean source of water to the steam generators. Upon low CST pressure, the suction source transfers to essential service water (ESW).

Three pressure transmitters are installed on the suction piping from the CST to the AFW pumps. These transmitters indicate CST pressure in the control room and automatically transfer the AFW suction to ESW upon low pressure on two out of three pressure transmitters.

Circuits for one of the three pressure transmitters (ALPT0038) run through fire area A-27. Damage to these circuits could prevent the pressure transmitter from functioning and could indicate a false low CST suction pressure. Circuits for the remaining two pressure transmitters (ALPT0027 and ALPT0029) are not run through area A-27. Therefore, CST level indication is available in the control room and spurious transfer to the ESW system is avoided.

A fire in area A-27 will not affect CST level indication in the control room and will not actuate a spurious ESFAS signal.

References: E-15000, XX-E-013, E-1F9202, E-13AL08, M-12AL01

5.2.14 RCS Hot and Cold Leg Temperature Elements

PFSSD requires RCS hot and cold leg temperature indication on at least one loop to verify flow through the steam generators. The temperature elements used for this purpose are listed in Table A-27-6.

The four cables associated with RCS temperature indication listed in Table A-27-4 run in the same raceway through area A-27 (2J1B1F). A fire could damage the cables and cause temperature indication on these four temperature elements (BBTE0413B, BBTE0423B, BBTE0433A and BBTE0443A) to be unavailable. Consequently, temperature indication on at least one leg on each loop could be lost, which is not in accordance with the PFSSD methodology at Wolf Creek.

Also, as discussed in Section 5.1.3, power to PN08 could be lost, resulting in a loss of power to temperature recorders BBTR0433 (loop 3) and BBTR0443 (loop 4). Based on drawing E-1F9201, this would result in a loss of temperature indication on loop 3 (hot and cold leg) and loop 4 (cold leg). The only available temperature indication is on loops 1 and 2 hot leg.

Table A-27-6
RCS Hot and Cold Leg Temperature Elements Used for PFSSD

COMPONENT	FUNCTION
BBTE0413A	RCS Hot Leg Temperature Element (WR) Loop 1
BBTE0413B	RCS Cold Leg Temperature Element (WR) Loop 1
BBTE0423A	RCS Hot Leg Temperature Element (WR) Loop 2
BBTE0423B	RCS Cold Leg Temperature Element (WR) Loop 2
BBTE0433A	RCS Hot Leg Temperature Element (WR) Loop 3
BBTE0433B	RCS Cold Leg Temperature Element (WR) Loop 3
BBTE0443A	RCS Hot Leg Temperature Element (WR) Loop 4
BBTE0443B	RCS Cold Leg Temperature Element (WR) Loop 4

EMG ES-04 provides alternate indication that may be used. One of these methods verifies that steam generator pressure is stable or decreasing. At least one pressure transmitter is available on each loop and can be used per EMG ES-04 to verify steam generator pressure in loops 1, 2, 3 and 4.

The configuration is acceptable because, in the event of fire in fire area A-27, cooldown will be performed using RCS loops 1 and 4. RCS wide range hot leg temperature indicator BBTI413A will provide temperature indication on loop 1 and and main steam line pressure transmitters ABPT514, ABPT0516, ABPT0544 and ABPT0546 will provide indication of RCS pressure on loops 1 and 4.

References: E-15000, XX-E-013, E-1F9201, E-13BB15, M-12AB01, M-12BB01

5.2.15 Residual Heat Removal (RHR)

PFSSD requires one train of residual heat removal (RHR) to be available for shutdown cooling. The RHR system is not used for hot standby. The PFSSD impact on the RHR system due to a spurious SIS is discussed in Section 5.2.10. This Section discusses fire damage to RHR system cables and components absent a spurious SIS. For a discussion of CCW to the RHR heat exchangers see Section 5.2.5.

Hot shutdown mode of PFSSD requires isolation of the RCS to RHR flow path by maintaining either BBPV8702A or EJHV8701A closed and either BBPV8702B or EJHV8701B closed. Cold shutdown mode of PFSSD requires RHR taking suction from the RCS. RHR pump suction from the RCS is controlled by valves BBPV8702A and EJHV8701A (Train A) and BBPV8702B and EJHV8701B (Train B).

A fire in area A-27 credits Train B RHR to achieve cold shutdown because Train A CCW could be lost as discussed in Section 5.2.3. Components and cables associated with Train A RHR system are unaffected by a fire in this area. However, loss of Train A CCW would prevent cooling of the Train A RHR heat exchanger. A number of Train B RHR components are affected by a fire in this area but, as described below, the damage will not prevent PFSSD because manual actions or repairs can be made within 72 hours. If Train A CCW is available, or if Train A CCW can be repaired within 72 hours, then operators can use Train A RHR for shutdown cooling.

Damage to cable 12BBI15NB, associated with pressure transmitter BBPT0403, could initiate a false High-1 RCS pressure signal and open the contacts on relay K734. This false High-1 pressure signal would prevent remote opening of valves BBPV8702A and BBPV8702B. Since cable 12BBI15NB runs through area A-27, a cold shutdown repair or a containment entry may be required to open valve BBPV8702B.

Cable 14BBG12AC is an interlock that prevents valve BBPV8702A from opening if valve EJHV8804A is open. Damage to this cable will have no impact on PFSSD since Train A RHR is not used for PFSSD if a fire occurs in area A-27.

Cables 14BBG12AF and 14BBG12AG are control cables associated with BBPV8702A. An inter-cable (cable-to-cable) hot short between conductors 2 in cable 14BBG12AF and 52 in cable 14BBG12AG will bypass the control room hand switch and open interlocks and cause valve BBPV8702A to open. Valve EJHV8701A will remain closed since cables associated with this valve are not run through area A-27. Therefore, the spurious opening of valve BBPV8702A is acceptable.

Cables 14BBG12BF and 14BBG12BG are control cables associated with BBPV8702B. An inter-cable (cable-to-cable) hot short between conductors 2 in cable 14BBG12BF and 52 in cable 14BBG12BG will bypass the control room hand switch and open interlocks and cause

valve BBPV8702B to open. Valve EJHV8701B will remain closed since cables associated with this valve are not run through area A-27. Therefore, the spurious opening of valve BBPV8702B is acceptable.

An open circuit in cable 14BBG12BF could prevent the remote opening of valve BBPV8702B when transitioning to RHR. If this occurs, a cold shutdown repair or a containment entry will be necessary to open the valve. Valve EJHV8701B can be controlled from the control room.

The RHR heat exchanger discharge control valve on the operating train (EJHCV0606 (Train A) or EJHCV0607 (Train B)) needs to be available. Cable 16EJI12BA, which is associated with EJHCV0607, runs through area A-27. Damage to cable 16EJI12BA could result in the loss of control of valve EJHCV0607. Valve EJHCV0607 is a fail open valve. Consequently, damage to this cable will most likely result in the valve remaining in its normally open position. If the valve closes, a cold shutdown repair or manual action will be necessary to open the valve.

The RHR pump discharge to RCS cold leg isolation valve (EJHV8809A or EJHV8809B) needs to be open on the operating train. Damage to cables 14EJG09BC and 14EJG09BD would likely result in valve EJHV8809B remaining in its as-is normally open position, which is the preferred PFSSD position. However, two proper intra-cable hot shorts in cable 14EJG09BD or one intra-cable hot short in cable 14EJG09BD combined with a short to ground on conductor U1 would spuriously close the valve. Cables for valve EJHV8809A are run in a separate fire area and are unaffected by a fire in area A-27. Therefore, Train A RHR pump discharge to RCS cold leg flow path is available for a fire anywhere in area A-27.

The cold shutdown mode of PFSSD requires isolation of hot leg recirculation. Valve EJHV8840 is used to isolate RHR flow to the RCS hot leg loops 2 and 3. This valve is normally closed and is required to be closed for cold shutdown. During hot standby, the valve can be in any position. Cables associated with valve EJHV8840 run through area A-27. Damage to cables 14EJG09AC and 14EJG09AD would likely result in valve EJHV8840 remaining in its as-is normally closed position, which is the preferred PFSSD position. However, two proper intra-cable hot shorts in cable 14EJG09AD or one intra-cable hot short in cable 14EJG09AD combined with a short to ground on conductor U1 would spuriously open the valve.

As stated above, the position valve EJHV8840 (open or closed) will not affect hot standby. The valve needs to be closed for cold shutdown. The valve has been modified to address NRC IN 92-18 and can be closed manually prior to entering shutdown cooling mode. The torque and limit switches are not bypassed by postulated damage to these cables.

Based on the above discussion, manual actions or cold shutdown repairs may be required to ensure the proper valve lineup when transferring to RHR. This is allowed per Wolf Creek's commitments to 10CFR50, Appendix R Section III.G.1.b. Therefore, the configuration is acceptable.

References: E-15000, XX-E-013, E-1F9205, E-13BB12A, E-13BB12B, E-13EJ05A, E-13EJ05B, E-13EJ08, E-13EJ09C, E-13EJ12, E-13PN01, E-13RL04, E-1R1421, J-200-00049, J-200-00051, M-12BB01, M-12EJ01, M-761-00104, CR 25002

5.2.16 Pressurizer Level Transmitters

PFSSD requires pressurizer level indication to be available. Pressurizer level indication is provided by level transmitters BBLT0459 and BBLT0460. Either level transmitter is required to be available for PFSSD.

Cable 12BBI16QB is run through area A-27 and is associated with BBLT0460. Damage to this cable will result in BBLT0460 being unavailable.

Circuits for BBLT0459 do not run through fire area A-27 and are unaffected by a fire in A-27. Therefore, pressurizer level indication is available for a fire in area A-27 using BBLT0459 and level indicator BBLI0459A.

References: E-15000, E-1F9301, E-13BB16

5.2.17 Control Room Lockout Relays

Lockout relay control panel RP334 houses relays used to isolate certain PFSSD components from the control room in the event of a control room fire. This panel is located in room 3302 (South ESF Switchgear Room).

Cable 12RPK15AA is associated with lockout relay 86XRP1, which is the lockout circuit for the TDAFP trip and throttle valve (FCHV0312). An open in this circuit will prevent isolating the control circuit for valve FCHV0312 from the control room. This is acceptable since the fire is not in the control room and damage to this circuit will not prevent the valve from performing its intended function. A conductor-to-conductor (intra-cable) short in this cable could bypass the hand switch and spuriously actuate the lock out relay signal. This will transfer control power for FCHV0312 to panel RP334, which is acceptable since the TDAFP is not required for PFSSD in the event of a fire in area A-27.

Cable 12RPK15BA is associated with lockout relay 86XRP2, which is the lockout circuit for the main steam supply valve to TDAFP (ABHV0006). An open in this circuit will prevent isolating the control circuit for valve ABHV0006 from the control room. This is acceptable since the fire is not in the control room and damage to this circuit will not prevent the valve from performing its intended function. A conductor-to-conductor (intra-cable) short in this cable could bypass the hand switch and spuriously actuate the lock out relay signal. This will transfer control power for ABHV0006 to panel RP334, which is acceptable since the TDAFP is not required for PFSSD in the event of a fire in area A-27.

Cable 12RPK15CA is associated with lockout relay 86XRP3, which is the lockout circuit for the main steam supply valve to TDAFP (ABHV0005). An open in this circuit will prevent isolating the control circuit for valve ABHV0005 from the control room. This is acceptable since the fire is not in the control room and damage to this circuit will not prevent the valve from performing its intended function. A conductor-to-conductor (intra-cable) short in this cable could bypass the hand switch and spuriously actuate the lock out relay signal. This will transfer control power for ABHV0005 to panel RP334, which is acceptable since the TDAFP is not required for PFSSD in the event of a fire in area A-27.

A fire in area A-27 involving the lockout relay circuits described above will not impact the ability to achieve and maintain PFSSD.

5.2.18 Refueling Water Storage Tank (RWST) and Containment Sump Isolation Valves

To prevent draindown of the RWST into the containment sump, PFSSD requires that either valve BNHV8812A or valve EJHV8811A and valve BNHV8812B or valve EJHV8811B be closed during hot standby. For cold shutdown, the operating train containment sump valve (EJHV8811A or EJHV8811B) must be closed to prevent flow diversion from the RCS to the containment sump. Valves BNHV8812A and BNHV8812B are normally open, and valves EJHV8811A and EJHV8811B are normally closed.

PFSSD cables for valves BNHV8812A and BNHV8812B do not run through fire area A-27. If valves EJHV8811A or EJHV8811B were to spuriously open, valves BNHV8812A and BNHV8812B can be closed from the control room.

Cables for valve EJHV8811A do not run through fire area A-27. Cable 14EJG06BC associated with EJHV8811B, runs in area A-27. Damage to cable 14EJG06BC will have no adverse impact since valve BNHV8812B is normally open, thereby preventing the permissive for valve EJHV8811B to open. If valve BNHV8812B is closed at the time of the fire and EJHV8811B spuriously opens, draindown will not occur because valve BNHV8812B is closed and will not spuriously open in the event of a fire in area A-27.

Cable 14BNI07FA, associated with RWST level transmitter BNLT0933, is run in area A-27. Cables for the remaining three RWST level transmitters do not run in area A-27. Consequently, a spurious low RWST level signal is not credible for a fire in area A-27.

Based on the above discussion, a fire in area A-27 will not cause the RWST to lose inventory into the containment sump.

References: E-15000, XX-E-013, E-1F9205, E-13BN03A, E-13BN07, E-13EJ06A, E-13EJ06B, M-12BN01, M-12EJ01, E-1R1423A, E-1R1423B

5.2.19 Main Steam Isolation Valve (MSIV) Bypass Valves

PFSSD requires that the MSIV bypass valves be closed to control cooldown. Several cables associated with the MSIV bypass valves (ABHV0012, ABHV0015, ABHV0018 and ABHV0021) are run in area A-27. These cables are associated with all close hand switch ABHS0079. Damage to these cables could result in the inability to maintain the MSIV bypass valves closed using ABHS0079.

Redundant means of ensuring the bypass valves remain closed are available and are unaffected by a fire in area A-27. This redundant means uses all close hand switch ABHS0080 to remove power to Separation Group 1 (Train A) solenoid valves ABHY0012A, ABHY0015A, ABHY0018A and ABHY0021A to close the valves. Therefore, a fire in A-27 will not prevent the closure of the MSIV bypass valves if they spuriously open.

Based on the above discussion, the MSIV bypass valves could spuriously open but can be re-closed using hand switch ABHS0080.

References: E-15000, XX-E-013, E-1F9101, E-13AB23A, E-13AB23B, E-13AB26, E-13AB27, E-13AB28, E-13AB29, M-12AB02

5.2.20 Reactor Coolant Pump (RCP) Seal Injection

PFSSD requires RCP seal injection to provide a boron injection path, provide makeup to the RCS and prevent damage to the RCP seals. Seal injection valves BBHV8351A, BBHV8351B, BBHV8351C and BBHV8351D are required to remain in their normally open position. Cables associated with these valves are listed in Table A-27-4.

Valves BBHV8351A, BBHV8351B, BBHV8351C and BBHV8351D are normally open and de-energized with the circuit breaker in the OFF position. Therefore, a fire affecting the control cables will not cause the valves to spuriously close. The seal injection valves are not high-low pressure interfaces, so consideration of a 3-phase hot short is not required. Therefore, damage to the power cables will not cause the valves to spuriously close.

Cable 14BGI51BA is associated with RCP seal total flow indicator BGFT0215B. Damage to this cable could prevent operation of the flow transmitter and could prevent operators from determining total RCP seal flow using flow indicator BGFI0215B. Flow indicator BGFI0215A is unaffected by a fire in area A-27 and can be used by operators to determine if seal flow is functioning.

Based on the above discussion, the seal injection valves will remain open in the event of a fire in area A-27. Therefore, RCP seal injection is available to provide hot standby inventory control and seal cooling. Loss of the operating charging pump would be indicated by loss of flow to the RCP seals using flow indicator BGFI0215A.

5.2.21 Reactor Coolant System (RCS) Pressure Indication

PFSSD requires RCS pressure indication to be available. RCS pressure indication is provided in the control room using BBPI0405 or BBPI0406.

Cable 14BBI16BA, associated with BBPT0406, runs through fire area A-27. Damage to this cable could prevent operation of the pressure transmitter and prevent pressure indication in the control room on BBPI0406.

Cables for BBPT0405 are run in a separate fire area and are unaffected by a fire in area A-27. Therefore, RCS pressure indication will be available using BBPI0405 if a fire occurs in area A-27.

References: E-15000, XX-E-013, E-1F9201, E-13BB15, E-13BB16, M-12BB04

5.2.22 Loss of Offsite Power

Cables associated with both trains of offsite power are run in area A-27. These cables are separation group 5 and 6 associated with XNB01 and XNB02. Damage to these cables will cause a loss of offsite power on both trains. Both trains of emergency diesel generators are available and can be lined up to the associated bus to provide power to PFSSD loads.

Loss of offsite power on both trains will not impact the ability to achieve and maintain PFSSD. For a more detailed evaluation of offsite power availability, refer to Calculation XX-E-013.

References: E-15000, XX-E-013, E-1F9425, E-1F9426, E-13NB03, E-13NB05, E-13NB10, E-13NB11

5.2.23 Steam Generator Blowdown to Blowdown Flash Tank Isolation Valves

The reactivity control function requires the steam generator blowdown to blowdown flash tank valves (BMHV0001, BMHV0002, BMHV0003, and BMHV0004) be closed to prevent reactivity addition from uncontrolled cooldown. Cables associated with these valves are run through area A-27 and are listed in Table A-27-4.

Damage to cable 14RPK09AA could cause a loss of power to auxiliary relays 3XBM9, 3XBM10, 3XBM11 and 3XBM12, located in panel RP210, which will fail close valves BMHV0001, BMHV0002, BMHV0003 and BMHV0004, respectively.

An open circuit on cables 14BMK06AC, 14BMK06BC, 14BMK06CC or 14BMK06DC will fail the associated valve closed, which is the desired PFSSD position. A hot short on these cables could prevent the associated valve from being closed using hand switches BMHIS0001A, BMHIS0002A, BMHIS0003A and BMHIS0004A.

Redundant means for closing valves BMHV0001, BMHV0002, BMHV0003 and BMHV0004 are available and are unaffected by a fire in area A-27. This redundant means uses BMHIS0001C, BMHIS0002C, BMHIS0003C and BMHIS0004C, located on the BM157 panel in the radwaste control room. Access to the radwaste control room can be gained from outside fire area A-27. As stated in Section 5.1.4, the possibility exists for a fire to cause loss of power to BM157. Loss of power will fail the valves closed, which is the desired PFSSD position.

A fire in area A-27 will not prevent closing steam generator blowdown valves BMHV0001, BMHV0002, BMHV0003 and BMHV0004.

Thermal hydraulic analysis WCNOC-CP-002 shows insignificant impact on SG inventory even with all four blowdown valves open. Therefore, no E-1F9900 OMA is required to close blowdown valves to achieve and maintain hot standby. Reference Attachment 4, MSO Evaluation Scenario ID PWROG 34.

References: E-15000, XX-E-013, E-1F9101, E-13BM06A, E-13BM06D, M-12BM01

5.2.24 Containment Coolers

PFSSD requires containment cooling to maintain the containment environment within EQ limits. Cables associated with both Train B containment coolers and all four Train B essential service water (ESW) supply valves are run in area A-27. These cables are listed in Table A-27-4.

Damage to these cables could prevent operation of the Train B containment coolers if a fire occurs in this area. Circuits for the Train A containment coolers are run in a separate fire area and are unaffected by a fire in area A-27. Train A ESW is available to supply water to the Train A containment coolers.

Based on the above discussion, the Train A containment coolers are available if a fire occurs in area A-27.

References: E-15000, XX-E-013, E-1F9403, E-1F9441, E-13EF07, E-13EF08, E-13EF09, E-13GN02, E-13GN02A, E-03NG01, M-12EF02, M-12GN01, SYS GK-200

5.2.25 Boron Injection Tank Flow Diversion

If charging flow through the BIT is used, flow diversion through the SIS test line should be avoided. Therefore, valves EMHV8843 and EMHV8882 need to be maintained closed. If either or both of these valves cannot be closed, then either valve EMHV8871 or EMHV8964 need to be closed. Cables associated with EMHV8882 are not run in area A-27. Therefore, valve EMHV8882 is unaffected by a fire in A-27 and will not spuriously open.

Cable 14EMK04CA is a control cable for EMHV8843. A +125 VDC external cable hot short in contact with conductor 2 in cable 14EMK04CA will energize the solenoid and open valve EMHV8843. The cable is run in raceways with cables carrying the proper voltage and polarity. The hot short would bypass the control room hand switch (EMHIS8843) on RL018 and control of this valve from the control room would be lost. Hand switch EMHS8843, located in room 1409, is unaffected by a fire in area A-27 and can be used to close valve EMHV8843 if this valve is unresponsive from the control room.

Cable 14EMK04EA is a control cable for EMHV8871. Damage to this cable could cause the valve to open due to an external +125VDC hot short.

Cables for normally closed valve EMHV8964 are unaffected by a fire in area A-27. Consequently, valve EMHV8964 will remain closed and flow diversion through the SIS test line will be averted.

References: E-15000, XX-E-013, E-1F9302, E-13EM04, E-13EM04A, E-13EM05A, M-12EM02

5.2.26 Safety Injection Accumulator Isolation Valves

PFSSD requires isolation of the SI accumulators prior to reducing RCS pressure below the injection pressure to avoid unnecessary accumulator discharge. This is accomplished by closing valves EPHV8808A, EPHV8808B, EPHV8808C and EPHV8808D. These valves are normally open with the MCC breaker locked in the open position. Cables 14EPG02CE and 14EPG02DE associated with valves EPHV8808B and EPHV8808D, respectively, are run in area A-27.

Since the breakers for these valves are normally open, damage to these cables will not cause the valve to spuriously change position. However, damage to the cables will prevent closing the associated valve from the control room, when necessary, after power is restored.

The SI accumulators need to be isolated during cold shutdown, prior to the RCS reaching 1000 psig. If necessary, a containment entry can be made to manually close the valves.

A fire in area A-27 may require a containment entry to close valves EPHV8808B and EPHV8808D if these valves are unresponsive from the control room.

References: E-15000, XX-E-013, E-13EP02A, M-12EP01

5.2.27 PFSSD Equipment Power Availability

PFSSD requires that one train of electrical systems required to power PFSSD components be available and be unaffected by a fire. Cable 14NBB14AD is a control cable for relay 62TDENB03. Damage to this cable could cause a spurious degraded voltage signal which could result in a loss of off-site power to bus NB02. If this occurs, the Train B Emergency Diesel Generator is available to power NB02.

A fire in area A-27 could result in a loss of off-site power. The Train B diesel generator is available to supply power to Train B safety-related and non-safety related PFSSD equipment.

References: E-15000, XX-E-013, E-1F9426, E-13NB14

5.2.28 Load Center Feeder Breakers PA0105 and PA0206

Load center feeder breakers PA0105 and PA0206 are credited for PFSSD because they supply power to credited non-safety related loads. Cables associated with these breakers run in this area. PFSSD impact due to damage to these cables is discussed below.

Cable 15PGA10AA is a control cable associated with breaker PA0105 and runs in fire area A-27. An intra-cable hot short in this cable will trip PA0105. Breaker PA0105 supplies power to the following PFSSD components:

- PG11JFR2 – Main Steam Supply to 2nd Stage Reheat Valve ABHV0031
- PG11KBR3 – Auxiliary Steam System Control Valve FBHV0081

PG11JFR2 and PG11KBR3 supply power to components downstream of the MSIVs. The MSIVs are unaffected by a fire in this area and can be closed from the control room using hand

switch ABHS0079. Therefore, the MSIV downstream components are not required if a fire occurs in this area.

Cable 16PGA10CA is a control cable associated with breaker PA0206 and runs in fire area A-27. An intra-cable hot short in this cable will trip PA0206. Breaker PA0206 supplies power to the following PFSSD components:

- PG12KAF4 – Main Steam Supply to 2nd Stage Reheat Valve ABHV0032
- PG12KAF5 – Main Steam Supply to Steam Seals Valve ABHV0046
- PG12KEF3 – Auxiliary Steam System Control Valve FBHV0080

PG12KAF4, PG12KAF5 and PG12KEF3 supply power to components downstream of the MSIVs. The MSIVs are unaffected by a fire in this area and can be closed from the control room using hand switch ABHS0079. Therefore, the MSIV downstream components are not required if a fire occurs in this area.

Based on the above discussion, loss of breakers PA0105 and PA0206 will have no adverse impact on PFSSD.

References: XX-E-013, E-15000, E-13PG10, E-1F9424E

5.2.29 Reactor Coolant Pumps

The reactor coolant pumps are not credited in the PFSSD analysis. However, the capability to stop the pumps from the control room in the event of a loss of all seal cooling is credited. Westinghouse Technical Bulletin TB-04-22, Rev. 1 recommends that if all seal cooling is lost (RCP seal injection and thermal barrier heat exchanger flow), operators need to stop the pumps before a seal LOCA occurs.

One control cable associated with each reactor coolant pump is run in fire area A-27. Damage to these cables in the event of a fire could prevent operators from stopping the RCPs from the control room. However, a fire in A-27 will not cause a loss of all seal cooling. Train B CCW is available to providing cooling to the RCP thermal barriers and the Train B CCP is available for seal injection.

Based on the above discussion, the inability to trip the RCPs from the control room will have no adverse impact on PFSSD. The pumps can continue to operate, providing forced flow circulation. If the pumps spuriously stop, natural circulation cooldown can be used.

References: E-15000, XX-E-013, E-13BB01, Westinghouse TB-04-22 Rev. 1

5.2.30 Normal Pressurizer Spray

The normal pressurizer spray valves are included in the PFSSD design because spurious operation of pressurizer sprays can cause a decrease in pressure which can lead to boiling in the core. The pressurizer spray valves are part of the pressurizer pressure control system.

The pressurizer normal spray valves (BBPCV0455B and BBPCV0455C) operate off a signal from the Ovation pressurizer pressure control system. The operation of the pressure control system is discussed in Calculation XX-E-013.

Instrument cables 12BBI16LB, 13BBI16MB and 14BBI16NB associated with pressurizer pressure transmitters BBPT0456, BBPT0457and BBPT0458, respectively, are run in fire area A-27. As discussed in Calculation XX-E-013, Appendix 1, damage to one or more pressure input channels will not cause the spurious operation of the pressurizer spray valves due to the

Ovation 4-channel validation logic. Therefore, a fire in area A-27 will not cause the spuriousoperation of pressurizer spray.

1.0 GENERAL AREA DESCRIPTION

Fire area A-28 is located on the 2026 elevation of the Auxiliary Building and includes the rooms listed in Table A-28-1.

Table A-28-1
Rooms Located in Fire Area A-28

ROOM #	DESCRIPTION
1413N	Train A Auxiliary Shutdown Panel (ASP) RP118A Room (North)
1413S	Train B Auxiliary Shutdown Panel (ASP) RP118B Room (South)

Fire area A-28 has automatic detection installed throughout. There is no automatic suppression in area A-28.

The area is divided into two distinct rooms divided by a 3-hour rated wall. The wall is credited as a qualified 3-hour fire barrier per drawing A-1803 but the two rooms are not considered separate fire areas. The 3-hour fire barrier meets the separation requirements of 10CFR50, Appendix R Section III.G.2.a.

2.0 PRIMARY EQUIPMENT USED FOR PFSSD

Table A-28-2 lists each system credited for post-fire safe shutdown and provides a discussion regarding the availability of the system to perform its Post Fire Safe Shutdown (PFSSD) function if a severe fire occurs in this area. For a summary of the area analysis results, see Section 8.0 of the Fire Area Analysis Narrative section.

Table A-28-2 Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-28			
System	**System Name**	**PFSSD Function***	**Comments**
AB	Main Steam	R, M, H, P, S	Room 1413N Control of steam generator ARVs ABPV0001 and ABPV0003 may not be achievable. Valve ABPV0001 can be failed closed by locally isolating air and nitrogen. Valve ABPV0003 can be controlled or closed using local controller ABFHC0003. Steam generator ARVs ABPV0002 and ABPV0004 are unaffected. Room 1413S Main steam to TDAFP valves ABHV0005 and ABHV0006 are affected and may not open. Control of steam generator ARVs ABPV0002 and ABPV0004 may not be achievable. Valve ABPV0002 can be controlled or closed using local controller ABFHC0002. Valve ABPV0004 can be closed by isolating air and nitrogen. Steam generator ARVs ABPV0001 and ABPV0003 are unaffected.
AC	Main Turbine	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-28.
AE	Main Feedwater	H, P	A fire in room 1413S could affect steam generator A, B, C and D level indication at RP118B. Steam generator level indication in the main control room is unaffected.
AL	Aux. Feedwater System	H, P	Room 1413N The TDAFP and the Train B MDAFP are available. The Train A MDAFP is affected. Use the TDAFP to supply SG B and the Train B MDAFP to supply SG D, since SGs B and D ARVs are unaffected. Room 1413S Train A MDAFP is available to supply SGs B and C. Steam generator B ARV may need to be locally controlled using ABFHC0002. The TDAFP and the Train B MDAFP are affected.
AP	Condensate Storage System	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-28.
BB	Reactor Coolant System	R, M, H, P, S	RCS level, pressure and temperature indication in room 1413S is affected. However, indication of these parameters in the control room is unaffected. Pressurizer backup group B heaters could be affected by a fire in room 1413S. The heaters are not credited for a fire in this area.

Table A-28-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-28

System	System Name	PFSSD Function*	Comments
BG	Chemical and Volume Control System	R, M, S	Room 1413N Letdown isolation valves BGLCV0459 and BGLCV0460 and letdown orifice isolation valves BGHV8149A, BGHV8149B, and BGHV8149C may not close using hand switches in the control room. These valves will automatically close when pressurizer level reaches 17%. Alternatively, the valves can be closed by isolating air to the valves. This can be accomplished by depressing the CLOSE push button on KAHIS0029 to close KAFV0029. KAHIS0029 is located on RL024. Pressurizer level indication is available using BBLI0459A and BBLI0460A. Room 1413S Valves BGLCV0459, BGLCV0460, BGHV8149A, BGHV8149B and BGHV8149C are unaffected by a fire in room 1413S.
BM	Steam Generator Blowdown System	R, M, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-28.
BN	Borated Refueling Water Storage System	R, M, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-28.
EF	Essential Service Water System	H, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-28.
EG	Component Cooling Water System	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-28.
EJ	Residual Heat Removal System	M, H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-28.
EM	High Pressure Coolant Injection	R, M	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-28.
EN	Containment Spray	R, M	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-28.
EP	Safety Injection Accumulators	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-28.
FB	Auxiliary Steam	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-28.

Table A-28-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-28

System	System Name	PFSSD Function*	Comments
FC	Auxiliary Turbines	R, H, P	Valves FCHV0312 and FCFV0313 are affected if a fire occurs in room 1413S. Use the Train A MDAFP to supply steam generators B and C.

Table A-28-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-28

System	System Name	PFSSD Function*	Comments
RP	Miscellaneous Control Panels	R, M, H, P, S	Room 1413N Panel RP118A and associated controls could be affected. Specific PFSSD components affected, and impact on the ability to achieve safe shutdown, is discussed in other sections. Room 1413S Panel RP118B and associated controls could be affected. Specific PFSSD components affected, and impact on the ability to achieve safe shutdown, is discussed in other sections. Control room lockout hand switches RPHIS0001 and RPHIS0002 could be damaged, causing a spurious lockout signal for associated Train B components. Redundant Train A components are unaffected. RPHIS0003 could also be damaged but this switch isolates PG2201 which supplies power to the pressurizer backup group B heaters. The heaters are only required for a control room fire.
SA	ESFAS	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-28.
SB	Reactor Protection System	R, S	Signals from process protection racks SB041, SB148A and SB148B to a number of process monitoring instruments located on RP118B could be affected. Redundant process monitoring instruments in the main control room are unaffected.
SC	Reactor Instrumentation	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-28.
SE	Ex-Core Neutron Monitoring	R, P	Source range indicator SENI0061B at RP118B is affected. Source range monitoring in the control room is unaffected.
SY	Switchyard	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-28.
UU	Supervisory System	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-28.

* R - Reactivity Control; M - Reactor Coolant Makeup; H - Decay Heat Removal; P - Process Monitoring; S - Support Function

3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD

This section describes operator actions that may need to be performed inside or outside the control room to achieve and maintain hot standby if a fire occurs in area A-28. This section also describes cold shutdown repairs that may need to be made to achieve and maintain cold shutdown conditions. Operator actions are proceduralized in OFN KC-016.

3.1 ACTIONS OUTSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

Operator Manual Actions (OMAs) are those actions outside the main control room required to achieve and maintain hot standby. OMAs are identified in E-1F9900 and were determined from thermal hydraulic analysis WCNOC-CP-002. Applicable E-1F9900 OMAs are annotated herein. All other actions outside the control room are desirable for plant control in support of hot standby but not required to achieve and maintain hot standby.

3.1.1 Steam Generator ARVs

Room 1413N

For a fire in this room, the available success path includes the TDAFP supplying AFW to SG B and the Train B MDAFP supplying AFW to SG D. Steam generator A ARV ABPV0001 may need to be failed closed by isolating air (KAV1435) and nitrogen (KAV1364) and bleeding air from the regulator. Steam generator C ARV ABPV0003 may need to be closed using local controller ABFHC0003. Both actions are completed in fire area A-23.

Room 1413S

For a fire in this room, the available success path includes the Train A MDAFP supplying AFW to SGs B and C. Steam generator B ARV ABPV0002 may need to be controlled locally using ABFHC0002. Steam generator D ARV ABPV0004 may need to be failed closed by isolating air (KAV1429) and nitrogen (KAV1365) and bleeding air from the regulator.

3.2 ACTIONS INSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

3.2.1 Isolation of Letdown

A fire in area A-28 North could prevent valves BGLCV0459, BGLCV0460, BGHV8149A, BGHV8149B, and BGHV8149C from being closed using their associated control room hand switches. The valves will automatically close on low pressurizer pressure. In the unlikely event the low pressurizer pressure signal does not work the valves can be closed by isolating air to the valves. This can be accomplished by depressing the CLOSE push button on KAHIS0029 to close KAFV0029. KAHIS0029 is located on RL024. Pressurizer level indication is available using BBLI0459A and BBLI0460A.

3.3 ACTIONS TO ACHIEVE AND MAINTAIN COLD SHUTDOWN

None specific to PFSSD

4.0 CONCLUSION

With some exceptions, redundant Post Fire Safe Shutdown capability exists if a severe fire occurs in area A-28. For those exceptions, feasible manual actions are available and are unaffected by the fire. Manual actions are documented in Section 3.0.

5.0 DETAILED ANALYSIS

This section describes the detailed component-by-component and cable-by-cable analysis for a fire in area A-28.

5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA A-28

PFSSD components (S. in E-15000) located in fire area A-28 are shown in Table A-28-3. An evaluation of each component and associated cables is provided in the sections that follow. The applicable evaluation section is listed in Table A-28-3.

5.1.1 Main Steam System

Several PFSSD cables and components associated with the main steam system are located in fire area A-28. These components are used for alternate shutdown if the control room needs to be evacuated. Each component, and associated cables, is discussed in the following paragraphs, as well as the impact of fire damage on the ability to safely shut down the plant.

Main Steam Supply to the TDAFP

ABHIS0005B is used in OFN RP-017 to open the steam supply from Loop 2 to the turbine driven auxiliary feedwater pump (TDAFP) (ABHV0005). ABHIS0006B is used in OFN RP-017 to open the steam supply from Loop 3 to the turbine driven auxiliary feedwater pump (TDAFP) (ABHV0006). Both hand switches are located in room 1413S and could be damaged if a fire occurs in this room. Either valve ABHV0005 or ABHV0006 is required to be open when using the TDAFP for PFSSD.

Cables 12ABK01AE, associated with ABHIS0005B, and 12ABK01BE, associated with ABHIS0006B, are run in room 1413S. Damage to the hand switches or associated cables could prevent opening at least one of the valves. Therefore, the TDAFP cannot be relied on if a fire occurs in room 1413S. A fire in room 1413N will not affect these valves, and therefore the steam supply to the TDAFP will be available for a fire in 1413N.

Main Steam Atmospheric Relief Valves

ABHS0001, ABHS0002, ABHS0003 and ABHS0004 are used to transfer control of atmospheric relief valves (ARV) ABPV0001, ABPV0002, ABPV0003 and ABPV0004 to the respective pressure indicating controller (PIC) at the auxiliary shutdown panel (ASP). Each hand switch has a normally open contact which, when closed, transfers control of the ARV to the respective Train ASP (RP118A or RP118B).

Room 1413N contains hand switches ABHS0001 and ABHS0003, and associated cables 11ABI20EC and 13ABI20GC. A fire in this room could cause a short in these cables and spuriously transfer control of ABPV0001 and ABPV0003 to panel RP118A. Pressure indicating controllers (PICs) ABPIC0001B and ABPIC0003B, and associated cables 11ABI20ED and 13ABI20GD, are also located in room 1413N. If these cables and/or PICs are also damaged, then the possibility exists for a loss of control of ABPV0001 and ABPV0003. Steam generator B and D ARVs ABPV0002 and ABPV0004 are unaffected by a fire in room 1413N. Steam generator A ARV ABPV0001 can be failed closed by isolating air and nitrogen to the valve and bleeding air off the regulator. Steam generator C ARV ABPV0003 can be controlled or closed using local controller ABFHC0003.

Room 1413S contains hand switches ABHS0002 and ABHS0004, and associated cables 12ABI20FK and 14ABI20HK. A fire in this room could cause a short in these cables and spuriously transfer control of ABPV0002 and ABPV0004 to panel RP118B. Pressure indicating controllers (PICs) ABPIC0002B and ABPIC0004B, and associated cables 12ABI20FG and 14ABI20HG, are also located in room 1413S. If these cables and/or PICs are also damaged, then the possibility exists for a loss of control of ABPV0002 and ABPV0004. Steam generator A and C ARVs ABPV0001 and ABPV0003 are unaffected by a fire in room 1413S. Steam generator D ARV ABPV0004 can be failed closed by isolating air and nitrogen to the valve and bleeding air off the regulator. Steam generator B ARV ABPV0002 can be controlled or closed using local controller ABFHC0002.

Based on the above discussion, at least two steam generator ARVs will be available if a fire occurs in either room 1413N or 1413S. For a discussion of Auxiliary Feedwater availability, see Section 5.1.3.

Up to three ARVs can fail closed or open without impacting ability to achieve and maintain hot standby according to thermal hydraulic analysis WCNOC-CP-002. With at least one ARV unaffected, no E-1F9900 OMA is required to address ARV closure or control. Reference Attachment 4, MSO Evaluation Scenario ID PWROG 23.

5.1.2 Steam Generator Level Indication

Each steam generator is provided with five level transmitters; four narrow range and one wide range. The main control room (MCR) is provided with level indicators for all five level transmitters. The PFSSD design requires at least one level transmitter/indicator on each steam generator to be available.

Both Auxiliary Shutdown Panels (ASP) RP118A and RP118B contain a redundant level indicator for one of the five level transmitters on each steam generator. The level indicators on panel RP118A are not considered PFSSD components since they are not credited in a control room fire. The level indicators on panel RP118B are considered PFSSD components.

A fire in room 1413N (RP118A) or room 1413S (RP118B) could prevent operation of the level indicators within the room, but the redundant level indicators in the control room remain available. In addition, the remaining level transmitters that do not have indication at either RP118A or RP118B are available to provide steam generator level indication in the control room.

Steam generator level indication in the MCR is unaffected by a fire in area A-28.

References: E-15000, XX-E-013, E-13AE08, E-13SB16, E-1F9203, M-12AE02

5.1.3 Auxiliary Feedwater

The auxiliary feedwater (AFW) system is required to feed at least two steam generators to ensure PFSSD. The Train A motor driven auxiliary feedwater pump (MDAFP) supplies AFW to steam generators B and C. The Train B MDAFP supplies AFW to steam generators A and D. The turbine driven auxiliary feedwater pump (TDAFP) supplies AFW to all four steam generators.

<u>Turbine Driven Auxiliary Feedwater Pump</u>

As stated in Section 5.1.1, the TDAFP may not be available if a fire occurs in room 1413S due to the possible loss of steam supply to the pump turbine. In addition, room 1413S contains controls for TDAFP speed governing valve FCFV0313 and trip and throttle valve FCHV0312. Therefore, the TDAFP cannot be relied on if a fire occurs in room 1413S.

Other cables and components associated with the TDAFP are located in room 1413S that could prevent the ability of this pump to supply AFW to steam generators A, B, C and D. Therefore, the TDAFP cannot be relied on if a fire occurs in room 1413S.

Room 1413N does not contain any cables or controls associated with the TDAFP. The room does, however, contain cables and controls associated with certain AFW to steam generator supply valves and Train A ESW to TDAFP suction valve ALHV0032

Hand switch ALHS0006, associated with TDAFP to SG D valve ALHV0006, is located in room 1413N. This switch is used to transfer control of ALHV0006 from the control room to the ASP

(RP118A). Hand switch ALHS0008, associated with TDAFP to SG A valve ALHV0008, is located in room 1413N. This switch is used to transfer control of ALHV0008 from the control room to the ASP (RP118A).

Damage to these hand switches and associated cables could prevent control of these valves from the control room. Therefore, if a fire occurs in room 1413N, the TDAFP may not be available to supply AFW to steam generators A and D. The TDAFP would be available to supply AFW to steam generators B and C. However, as discussed in Section 5.1.1, atmospheric relief valve control on steam generator C could be lost. Local controller ABFHC0003, in fire area A-23, can be used to control ARV ABPV0003 on steam generator C.

Pressure indicator ALPI0026B and associated cable is located in room 1413S. Damage to this indicator will have no adverse impact on PFSSD since control room indication is available.

Based on the above discussion, a fire in room 1413S could prevent operation of the TDAFP but a fire in room 1413N can use the TDAFP to supply AFW to steam generators B and C, however, steam generator C ARV ABPV0003 may need to be controlled locally.

Motor Driven Auxiliary Feedwater Pump A

Hand switch ALHS0009, associated with MDAFP A to SG B valve ALHV0009, is located in room 1413N. This switch is used to transfer control of ALHV0009 from the control room to the ASP (RP118A). Hand switch ALHS0011, associated with MDAFP A to SG C valve ALHV0011, is located in room 1413N. This switch is used to transfer control of ALHV0011 from the control room to the ASP (RP118A).

Damage to these hand switches or associated cables could prevent MDAFP A from supplying AFW to steam generators B and C. In addition, other cables and components associated with MDAFP A are located in room 1413N. Therefore, the Train A MDAFP cannot be relied on if a fire occurs in room 1413N.

A fire in room 1413S does not affect MDAFP A and associated components. Therefore, MDAFP A is available to supply AFW to steam generators B and C if a fire occurs in room 1413S. However, as discussed in Section 5.1.1, atmospheric relief valve control on steam generators B and D could be lost. Local controller ABFHC0002, in fire area A-23, could be used to control ARV ABPV0002 on steam generator B.

Based on the above discussion, a fire in room 1413N could prevent operation of the Train A MDAFP, but a fire in room 1413S can use the Train A MDAFP to supply AFW to steam generators B and C, however steam generator B ARV ABPV0002 may need to be controlled locally.

Motor Driven Auxiliary Feedwater Pump B

Hand indicating switch ALHIS0022B is used to start the Train B MDAFP from the ASP (RP118B) in room 1413S. Cable 14ALB01BM is associated with hand switch ALHIS0022B. A short within the cable could cause the pump to either spuriously start or stop. If the pump starts, it is acceptable for PFSSD since this is the desired mode. If the pump stops, it can be re-started from the control room using ALHIS0022A. However, a persistent short in the stop circuit will cause the pump to re-stop. Therefore, the Train B MDAFP cannot be relied on to perform its function if a fire occurs in room 1413S. If the pump spuriously starts, it can be shut down by placing ALHIS0022A in pull-to-lock.

Hand indicating switch ALHIS0030B is located in room 1413S and is used to control ESW flow to MDAFP B. Cable 14ALG04AD is associated with this hand switch. A short in the cable could cause valve ALHV0030 to spuriously open or close.

Hand indicating switch ALHIS0034B is located in room 1413S and is used to control CST flow to MDAFP B. Cable 14ALG02AD is associated with this hand switch. A short in the cable could cause valve ALHV0034 to spuriously open or close.

Other cables and components associated with Train B MDAFP are located in room 1413S that could prevent the ability of this pump to supply AFW to steam generators A and D. Therefore, the Train B MDAFP cannot be relied on if a fire occurs in room 1413S.

A fire in room 1413N does not affect MDAFP B and associated components. Therefore, MDAFP B is available to supply AFW to steam generators A and D if a fire occurs in room 1413N. However, as discussed in Section 5.1.1, atmospheric relief valve control on steam generators A and C could be lost, which would require ARV ABPV0001 to be failed closed.

Based on the above discussion, a fire in room 1413S could prevent operation of the Train B MDAFP, but a fire in room 1413N can use the Train B MDAFP to supply AFW to steam generators A and D, however steam generator A ARV ABPV0001 may need to be failed closed.

Summary

If a fire occurs in room 1413N, use the TDAFP to supply AFW to SG B with the CST or Train B ESW as the suction source and use ARV ABPV0002 to control steam release. Also, use MDAFP B to supply AFW to SG D and use ARV ABPV0004 to control steam release. Fail close ARV ABPV0001 by isolating air and nitrogen and bleeding air from the regulator. Fail close ARV ABPV0003 using local controller ABFHC0003. If MDAFP A spuriously starts, it can be stopped by placing ALHIS0023A in pull-to-lock.

If a fire occurs in room 1413S, use the Train A MDAFP to supply AFW to SGs B and C with ESW or the CST as the suction source. Steam generator B ARV ABPV0002 may need to be controlled locally using ABFHC0002 while SG C ARV ABPV0003 can be controlled from the control room. Fail close ARV ABPV0004 by isolating air and nitrogen and bleeding air from the regulator. Fail close ARV ABPV0002 using local controller ABFHC0002 in fire area A-23. If MDAFP B spuriously starts, it can be stopped by placing ALHIS0022A in pull-to-lock. If the TDAFP spuriously starts, it may be necessary to locally trip FCHV0312 using local push button FCHS0332A.

5.1.4 Primary System Instrumentation

Redundant indication associated with the RCS primary system is located on panels RP118A and RP118B. Indication located on RP118A is not considered in the PFSSD design since they are not credited in a control room fire.

Pressurizer Level Indication

Level transmitter BBLT0459 provides pressurizer level signals to level indicators BBLI0459A and BBLI0459B. Level indicator BBLI0459A is located in the main control room while BBLI0459B is located on panel RP118A.

Level transmitter BBLT0460 provides pressurizer level signals to level indicators BBLI0460A and BBLI0460B. Level indicator BBLI0460A is located in the main control room while

BBLI0460B is located on panel RP118B. Cable 14SBS16ZA runs in room 1413S to level indicator BBLI0460B.

A fire in either room 1413N (RP118A) or 1413S (RP118B) will not affect pressurizer level indicators in the control room. Cables providing level indication in the control room do not run through area A-28. Damage to the local indication circuits will not affect the redundant indicator in the control room. Therefore, pressurizer level indication will be available if a fire occurs in area A-28.

RCS Pressure Indication

RCS pressure transmitter BBPT0405 provides pressure signals to pressure indicators BBPI0405 and BBPI0405X. Pressure indicator BBPI0405 is located in the main control room while BBPI0405X is located on panel RP118A in room 1413N.

RCS pressure transmitter BBPT0406 provides pressure signals to pressure indicators BBPI0406 and BBPI0406X. Pressure indicator BBPI0406 is located in the main control room while BBPI0406X is located on panel RP118B in room 1413S. Cable 14SBS16NA runs in room 1413S to pressure indicator BBPI0406X.

A fire in either room 1413N (RP118A) or 1413S (RP118B) will not affect RCS pressure indicators in the control room. Cables providing RCS pressure indication in the control room do not run through area A-28. Damage to the local indication circuits will not affect the redundant indicator in the control room. Therefore, RCS pressure indication will be available if a fire occurs in area A-28.

RCS Temperature Indication

PFSSD requires RCS hot and cold leg temperature indication on at least one loop to verify flow through the steam generators.

RCS temperature element BBTE0423B provides loop 2 cold leg temperature signals to temperature indicators BBTI0423B in the control room and BBTI0423X at RP118B. Cable 14SBS16AA runs in room 1413S to BBTI0423X on panel RP118B.

RCS temperature element BBTE0443A provides loop 4 hot leg temperature signals to temperature indicator BBTI0443A at panel RP118B and temperature recorder BBTR0443 in the control room. Cable 14SBS16EA runs in room 1413S to BBTI0443A on panel RP118B.

A fire in either room 1413N (RP118A) or 1413S (RP118B) will not affect RCS temperature indication in the control room. Cables providing RCS temperature indication in the control room do not run through area A-28. Damage to the local indication circuits will not affect the redundant indicator in the control room. Therefore, RCS temperature indication will be available if a fire occurs in area A-28.

Summary

A fire in area A-28 will not adversely impact primary system instrumentation in the control room.

References: E-15000, XX-E-013, E-13BB15, E-13BB16, E-13SB09, E-13SB16, E-1F9201, E-1F9301, M-12BB01, M-12BB02, M-12BB04, M-761-02019, M-761-02029, M-761-02301, M-761-02302, M-761-02304, M-761-02311

5.1.5 Letdown Isolation Valves and Letdown Orifice Isolation Valves

During normal operation, letdown isolation valves BGLCV0459 and BGLCV0460 are open and at least one letdown orifice valve (BGHV8149A, BGHV8149B and BGHV8149C) is open. For PFSSD, the letdown flowpath is required to be isolated to prevent loss of inventory in the RCS. Letdown is isolated by closing either BGLCV0459 or BGLCV0460.

Hand switches BGHIS0459A and BGHIS0460A, and associated cables, are located in room 1413N. Placing either of these handswitches in the close position will open a maintained contact and de-energize the solenoid, causing the associated isolation valve (BGLCV0459 or BGLCV0460) to close. However, if any of the orifice valves (BGHV8149A, BGHV8149B and BGHV8149C) are open, the isolation valves (BGLCV0459 or BGLCV0460) will remain open until the orifice valves (BGHV8149A, BGHV8149B and BGHV8149C) are all closed or until the pressurizer reaches low level. A cable associated with all three letdown orifice isolation valves is located in fire area A-28 North. Damage to any of these cables could prevent closure of the associated orifice valve from the control room. In addition, a hot short within cables 15BGK10AD and 15BGK10BD could bypass the open contact on the handswitch, causing the isolation valves (BGLCV0459 or BGLCV0460) to open or remain open.

A hot short across the open contacts in hand switches BGHIS0459A and BGHIS0460A could provide a signal to open the valves. However, if any of the letdown orifice isolation valves are open, the letdown isolation valves (0459 and 0460) will not open. If the orifice valves are all closed, the flow path is isolated.

Based on the above discussion, a fire in room 1413N could prevent closing valves BGLCV0459 and BGLCV0460. However, the valves will automatically close when the pressurizer reaches low level. Alternatively, operators can fail air to the valves by closing valve KAFV0029 using KAHIS0029 in the main control room.

References: E-15000, XX-E-013, E-13BG10, E-13BG35, M-12BG01, E-1F9301

5.1.6 Auxiliary Shutdown Panel (Train A and B)

This fire area contains the auxiliary shutdown panels (RP118A and RP118B) for Train A and Train B. The effects of fire damage to these panels is discussed throughout this evaluation. Therefore, no further discussion will be made in this section.

5.1.7 Control Room Isolation Switches and Lock-Out Relays

Room 1413S contains control room lockout handswitches RPHIS0001, RPHIS0002 and RPHIS0003, and associated cables.

RPHIS0001 performs the following functions:

- Isolates valve FCHV0312 (TDAFP Turbine Trip and Throttle Valve) from the control room.
- Isolates main steam to TDAFP supply valves ABHV0005 and ABHV0006 from the control room.
- Isolates ABPV0002 indication from the control room.
- Isolates FCFV0313 (TDAFP Speed Governing Valve) position indication from the control room. (Note: This function is not required for PFSSD)

RPHIS0002 performs the following functions:

- Isolates BGHV8152 (Letdown Isolation Valve) from the control room. Note: This valve is no longer used for PFSSD.

- Isolates NB0208 trip hand switch from the control room. NB0208 supplies PG22, which supplies power to pressurizer heater backup group B. (This function is no longer required for PFSSD)
- Isolates valves ALHV0030, ALHV0033 and ALHV0034 from the control room and adds a redundant fuse in the circuit.
- Isolates ABPV0004 indication from the control room.
- Isolates MDAFP B from the control room and adds redundant fuses in the circuit.

RPHIS0003 performs the following functions:

- Isolates PG2201 control circuit from the control room. PG2201 supplies power to pressurizer heater backup group B. Isolation of the PG2201 control circuit using RPHIS0003 allows operation of the heater group using BBHIS0052B. The heaters are credited for a fire in the control room only (OFN RP-017).

A hot short across these hand switches or associated cables could initiate a false isolation signal and cause loss of control of these components from the control room. A loss of valves FCHV0312 and FCFV0313 is discussed in Section 5.1.3. Section 5.1.1 discusses valves ABHV0005 and ABHV0006. Position indication for valves ABPV0002 and ABPV0004 is discussed in Section 5.2.1. Valve BGHV8152 and breaker NB0208 are not PFSSD components, so a loss of these components will not affect PFSSD. Valves ALHV0030, ALHV0033 and ALHV0034 are discussed in Section 5.1.3. AFW pump DPAL01B is discussed in Section 5.1.3. Hand switch BBHIS0052B is discussed in Section 5.1.9.

Based on the above discussion and the discussions in Sections 5.1.1, 5.1.3 and 5.1.9, damage to control room lockout hand switches RPHIS0001, RPHIS0002 and RPHIS0003, and associated cables, will not prevent safe shutdown due to the availability of redundant capability in a separate fire area.

5.1.8 Source Range Indication

Source range indicator SENI0061X is located on panel RP118B. Damage to this indicator and associated cable will not affect source range indication in the control room. Therefore, source range monitoring is available if a fire occurs in area A-28.

References: E-15000, XX-E-013, E-13SE07, E-1F9101

5.1.9 Pressurizer Backup Heater Group B

The pressurizer backup group B heaters are credited for a control room fire per procedure OFN RP-017. The heaters are not required for post-fire safe shutdown following a fire in other areas of the plant.

Hand switch BBHIS0052B, associated with pressurizer backup group B heaters, is located in fire area A-28S. This hand switch is credited in the event of a control room fire to control the heater bank and maintain pressurizer pressure.

Damage to this hand switch could cause the spurious operation or mal-operation of the backup group B heaters. Calculation WCNOC-CP-002 shows that spurious operation or mal-operation of the heaters for a fire outside the control room will not adversely impact the ability to achieve

safe shutdown. Therefore, damage to this switch in the event of a fire in area A-28S will not affect safe shutdown.

5.2 PFSSD CABLE EVALUATION

Table A-28-4 lists all the PFSSD cables (S. in E-15000) located in fire area A-28. The applicable evaluation section is also listed in Table A-28-4.

1.0 GENERAL AREA DESCRIPTION

Fire area A-29 is located on the 2000 and 2013 elevations of the Auxiliary Building and includes the rooms listed in Table A-29-1.

Table A-29-1
Rooms Located in Fire Area A-29

ROOM #	DESCRIPTION
1304	Auxiliary Feedwater Pipe Chase El. 2013-6
1324	Feedwater Pump Valve Compartment No. 1 El. 2000-0
1327	Feedwater Pump Valve Compartment No. 2 El. 2000-0

There is no automatic fire suppression or detection in fire area A-29. The area is separated from adjacent areas by minimum 3-hour fire rated construction.

2.0 PRIMARY EQUIPMENT USED FOR PFSSD

Table A-29-2 lists each system credited for post-fire safe shutdown and provides a discussion regarding the availability of the system to perform its Post Fire Safe Shutdown (PFSSD) function if a severe fire occurs in this area. For a summary of the area analysis results, see Section 8.0 of the Fire Area Analysis Narrative section.

Table A-29-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-29

System	System Name	PFSSD Function*	Comments
AB	Main Steam	R, M, H, P, S	Steam Generator C ARV ABPV0003 may need to be controlled or closed using local controller ABFHC0003 in area A-23. The main control room pressure controller for Steam Generators A, B and D ARVs (ABPV0001, ABPV0002 and ABPV0004) may need to be placed in manual and the ARV controlled or closed from the control room.
AC	Main Turbine	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-29.
AE	Main Feedwater	H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-29.
AL	Aux. Feedwater System	H, P	All three auxiliary feedwater pumps are available. However, auxiliary feedwater flow from the Train B motor driven auxiliary feedwater pump (MDAFP) and the turbine driven auxiliary feedwater pump (TDAFP) to steam generators (SGs) A and D may be affected. In addition auxiliary feedwater flow from the TDAFP to SG B may be affected. The Train A MDAFP is available to supply auxiliary feedwater to SGs B and C and the TDAFP is available to supply auxiliary feedwater to SG C.
AP	Condensate Storage System	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-29.
BB	Reactor Coolant System	R, M, H, P, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-29.
BG	Chemical and Volume Control System	R, M, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-29.
BM	Steam Generator Blowdown System	R, M, H	The ability to isolate blowdown from the Radwaste Control Room may be affected. All four blowdown valves can be isolated from the main control room using BMHIS0001A, BMHIS0002A, BMHIS0003A and BMHIS0004A.
BN	Borated Refueling Water Storage System	R, M, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-29.
EF	Essential Service Water System	H, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-29.
EG	Component Cooling Water System	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-29.
EJ	Residual Heat Removal System	M, H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-29.

Table A-29-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-29

System	System Name	PFSSD Function*	Comments
EM	High Pressure Coolant Injection	R, M	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-29.
EN	Containment Spray	R, M	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-29.
EP	Safety Injection Accumulators	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-29.
FB	Auxiliary Steam	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-29.
FC	Auxiliary Turbines	R, H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-29.
GD	ESW Pump House HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-29.
GF	AFW Pump Room Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-29.
GK	Control Room and Class 1E Switchgear Room Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-29.
GL	Auxiliary Building HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-29.
GM	Emergency Diesel Generator Room HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-29.
GN	Containment Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-29.
JE	Diesel Fuel Oil	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-29.
KA	Instrument Air	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-29.
KC	Fire Protection	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-29.
KH	Service Gas	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-29.
KJ	Standby Diesel Engine	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-29.

Table A-29-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-29

System	System Name	PFSSD Function*	Comments
MA	Main Generation	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-29.
MR	Startup Transformer	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-29.
NB	4.16 kV System	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-29.
NE	Standby Diesel Generator	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-29.
NF	Load Shed and Emergency Load Sequencing	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-29.
NG	480V Load Centers and MCCs	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-29.
NK	125VDC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-29.
NN	120VAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-29.
PA	13.8kV	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-29.
PB	4.16kV	H, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-29.
PG	480V Load Centers and MCCs	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-29.
PK	125VDC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-29.
PL	Local Instrument Panels	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-29.
PN	120VAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-29.
QB	Standby AC Lighting	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-29.
QD	Emergency Lighting	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-29.

Table A-29-2 Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-29			
System	**System Name**	**PFSSD Function***	**Comments**
RL	Control Room MCB	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-29.
RP	Miscellaneous Control Panels	R, M, H, P, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-29.
SA	ESFAS	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-29.
SB	Reactor Protection System	R, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-29.
SC	Reactor Instrumentation	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-29.
SE	Ex-Core Neutron Monitoring	R, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-29.
SY	Switchyard	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-29.
UU	Supervisory System	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-29.

3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD

This section describes operator actions that may need to be performed inside or outside the control room to achieve and maintain hot standby if a fire occurs in area A-29. This section also describes cold shutdown repairs that may need to be made to achieve and maintain cold shutdown conditions. Operator actions are proceduralized in OFN KC-016.

3.1 ACTIONS OUTSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

Operator Manual Actions (OMAs) are those actions outside the main control room required to achieve and maintain hot standby. OMAs are identified in E-1F9900 and were determined from thermal hydraulic analysis WCNOC-CP-002. Applicable E-1F9900 OMAs are annotated herein. All other actions outside the control room are desirable for plant control in support of hot standby but not required to achieve and maintain hot standby.

3.1.1 Steam Generator ARVs

It may be necessary to control or close ARV ABPV0003 using local control station ABFHC0003. This action can be performed by an operator in fire area A-23. Emergency lighting and communication are available.

3.2 ACTIONS INSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

3.2.1 Steam Generator ARVs

ARVs ABPV0001, ABPV0002 and ABPV0004 may spuriously open. If this occurs, place ABPIC0001A, ABPIC0002A and ABPIC0004A in manual and control the ARVs from the main control room.

3.3 ACTIONS TO ACHIEVE AND MAINTAIN COLD SHUTDOWN

None

4.0 CONCLUSION

Redundant Post Fire Safe Shutdown capability that is unaffected by a severe design basis fire does not exist in area A-29. However, feasible manual actions are available and are unaffected by the fire. Manual actions are documented in Section 3.0.

5.0 DETAILED ANALYSIS

This section describes the detailed component-by-component and cable-by-cable analysis for a fire in area A-29.

5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA A-29

PFSSD components (S. in E-15000) located in fire area A-29 are shown in Table A-29-3. An evaluation of each component and associated cables is provided in the sections that follow. The applicable evaluation section is listed in Table A-29-3.

Table A-29-3
PFSSD Equipment Located in Fire Area A-29

Room #	PFSSD Equipment	Description	Evaluation Section	Comments
1304	ABPT0001	SG A Steamline Pressure Transmitter	5.1.1	
1304	ABPT0004	SG D Steamline Pressure Transmitter	5.1.1	
1304	ALFT0001	Auxiliary Feedwater to Steam Generator D Flow	5.1.2	
1304	ALFT0007	Auxiliary Feedwater to Steam Generator A Flow	5.1.2	
1324	ALHV0005	MDAFP B Discharge to SG D Isolation Valve	5.1.2	
1324	ALHV0007	MDAFP B Discharge to SG A Isolation Valve	5.1.2	
1327	ALHV0006	TDAFP Discharge to SG D Isolation Valve	5.1.2	
1327	ALHV0008	TDAFP Discharge to SG A Isolation Valve	5.1.2	
1327	ALHY0006	ALHV0006 I/P Converter	5.1.2	
1327	ALHY0008	ALHV0008 I/P Converter	5.1.2	

5.1.1 Steam Generator Atmospheric Relief Valves

Pressure transmitters ABPT0001 and ABPT0004 and associated cables are located in area A-29. In addition, cables associated with ABPT0002 and ABPT0003 are run in area A-29. The effects of damage to these cables and components are described in the following paragraphs.

Cable 11ABI20EA provides a signal from pressure transmitter ABPT0001 to ARV ABPV0001 controller and opens the valve when steamline pressure reaches a designated setpoint. Damage to the pressure transmitter or cable due to a fire could cause a spurious high pressure signal which would open the ARV. If this occurs, operators can place ABPIC0001A in manual and control the ARV from the control room. Position indication for ABPV0001 on RL006 remains available, so operators would quickly recognize if the ARV is open. Cables associated with the ARV controller I/P device (ABPY0001) do not run in area A-29.

Cable 12ABI20FH provides a signal from pressure transmitter ABPT0002 to ARV ABPV0002 controller and opens the valve when steamline pressure reaches a designated setpoint. Damage to the cable due to a fire could cause a spurious high pressure signal which would open the ARV. If this occurs, operators can place ABPIC0002A in manual and control the ARV from the control room. Position indication for ABPV0002 on RL006 remains available, so operators would quickly recognize if the ARV is open. Cables associated with the ARV controller I/P device (ABPY0002) do not run in area A-29.

Cable 13ABI20GE provides a signal from ARV ABPV0003 controller to pressure transducer ABPY0003. Cable 13ABI20GA provides a signal from ABPT0003 to ARV ABPV0003 controller. The transducer signals the position controller (ABZC0003) on ABPV0003 to open whenever steamline pressure reaches a designated setpoint. Damage to the cables due to a fire could cause a spurious signal which could open the ARV. Damage to cable 13ABI20GE could prevent manual operation of the valve from the control room. If the ARV spuriously opens, operators would have to close it using local controller ABFHC0003 in area A-23.

Cable 14ABI20HH provides a signal from pressure transmitter ABPT0004 to ARV ABPV0004 controller and opens the valve when steamline pressure reaches a designated setpoint. Damage to the pressure transmitter or cable due to a fire could cause a spurious high pressure signal which would open the ARV. If this occurs, operators can place ABPIC0004A in manual and control the ARV from the control room. Cables associated with the ARV controller I/P device (ABPY0004) do not run in area A-29.

Based on the above discussion, steam generator ARVs ABPV0001, ABPV0002 and ABPV0004 can be controlled or closed from the control room. Steam generator ARV ABPV0003 may need to be controlled or closed using local controller ABFHC0003 in fire area A-23. Based on Section 5.1.2, the Train B MDAFP may not be available to supply steam generators A and D but the Train A MDAFP is available to supply steam generators B and C. In addition, the TDAFP is available to supply steam generator C only.

Up to three ARVs can fail closed or open without impacting ability to achieve and maintain hot standby according to thermal hydraulic analysis WCNOC-CP-002. With at least one ARV unaffected, no E-1F9900 OMA is required to address ARV closure or control. Reference Attachment 4, MSO Evaluation Scenario ID PWROG 23.

5.1.2 Auxiliary Feedwater

Several components and cables associated with Auxiliary Feedwater are located in this area. The following paragraphs discuss the impact on PFSSD of damage to these cables and components.

Flow transmitters ALFT0001 and ALFT0007 and associated cables are located in this area. Damage to these components and cables could cause a spurious flow indication which could cause valves ALHV0005 and ALHV0007 to modulate or close, preventing adequate auxiliary feedwater flow from Train B motor driven auxiliary feedwater pump (PAL01B) to steam generators A and D.

All four auxiliary feedwater to steam generators A and D supply valves (ALHV0005, ALHV0006, ALHV0007 and ALHV0008) are located in this area. In addition, power and control cables associated with these valves are run in this area. Damage to these cables and valves could prevent auxiliary feedwater flow from PAL01B and the turbine driven auxiliary feedwater pump (PAL02) to steam generators A and D.

Cables associated with ALHV0010 are run in this area. Damage to these cables could affect the operability of the valve and could prevent auxiliary feedwater flow from PAL02 to steam generator B.

The Train A motor driven auxiliary feedwater pump (PAL01A) is available to supply auxiliary feedwater to steam generators B and C via valves ALHV0009 and ALHV0011. The TDAFP is also available but may be limited to supplying only steam generator C. Therefore, if a fire occurs in area A-29, the credited auxiliary feedwater flowpath is PAL01A supplying auxiliary feedwater to steam generators B and C. Based on the discussion in Section 5.1.1, steam generator C ARV ABPV0003 may need to be controlled locally in fire area A-23.

5.2.1 Safety Injection

A spurious safety injection signal (SIS) could cause the safety injection pumps to operate. This condition is not desirable for PFSSD at Wolf Creek.

Safety injection (SI) is initiated automatically by any of the following conditions:

1. Two out of three high containment pressures monitored by pressure transmitters GNPT0934, GNPT0935 and GNPT0936.
2. Two out of four low pressurizer pressures monitored by pressure transmitters BBPT0455, BBPT0456, BBPT0457 and BBPT0458.
3. Two out of three low steam line pressures on any steam generator monitored by ABPT0514, ABPT0515 and ABPT0516 on SG A; ABPT0524, ABPT0525 and ABPT0526 on SG B; ABPT0534, ABPT0535 and ABPT0536 on SG C; and, ABPT0544, ABPT0545 and ABPT0546 on SG D. Two out of three logic must be satisfied on a single steam generator line. Low pressure on a single pressure transmitter co-incident with low pressure on another pressure transmitter on a different steam generator line will not initiate SIS.

Cables associated with steam line pressure transmitters ABPT0514, ABPT0526, ABPT0536 and ABPT0544 are run in area A-29. Consequently, the two out of three logic for low steam line pressure initiation of SIS cannot be satisfied if a fire occurs in area A-29.

5.2.2 Steam Generator Blowdown to Blowdown Flash Tank Isolation Valves

The reactivity control function requires the steam generator blowdown to blowdown flash tank valves (BMHV0001, BMHV0002, BMHV0003, and BMHV0004) be closed to prevent reactivity addition from uncontrolled cooldown. The valves are air operated and each valve is controlled by three solenoid valves. All three solenoid valves are required to be energized to open the valve. If any one solenoid is de-energized, the associated valve will close or remain closed. Only two of the three solenoids for each valve are considered in the PFSSD analysis, so the third solenoid is assumed energized throughout the event.

Cables 15BMK06AA and 15BMK06DA, associated with blowdown valves BMHV0001 and BMHV0004, are run in area A-29. These cables are associated with blowdown handswitches located on the BM157 panel in the radwaste control room. Damage to these cables will have no adverse impact on the ability to close the blowdown valves using applicable handswitches in the main control room.

1.0 GENERAL AREA DESCRIPTION

Fire area A-30 is located on the 2000 elevation of the Auxiliary Building and includes the rooms listed in Table A-30-1.

Table A-30-1
Rooms Located in Fire Area A-30

ROOM #	DESCRIPTION
1305	Auxiliary Feedwater Pipe Chase El. 2013-6
1328	Feedwater Pump Valve Compartment No. 3 El. 2000-0
1330	Feedwater Pump Valve Compartment No. 4 El. 2000-0

There is no automatic fire suppression or detection in fire area A-30. The area is separated from adjacent areas by minimum 3-hour fire rated construction.

2.0 PRIMARY EQUIPMENT USED FOR PFSSD

Table A-30-2 lists each system credited for post-fire safe shutdown and provides a discussion regarding the availability of the system to perform its Post Fire Safe Shutdown (PFSSD) function if a severe fire occurs in this area. For a summary of the area analysis results, see Section 8.0 of the Fire Area Analysis Narrative section.

Table A-30-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-30

System	System Name	PFSSD Function*	Comments
AB	Main Steam	R, M, H, P, S	Steam Generator C ARV ABPV0003 may need to be controlled or closed using local controller ABFHC0003 in area A-23. The controller (ABPIC0002A) for Steam Generator B ARV may need to be placed in manual and the ARV controlled or closed from the control room. Steam generators A and D ARVs ABPV0001 and ABPV0004 are unaffected by a fire in this area.
AC	Main Turbine	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-30.
AE	Main Feedwater	H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-30.
AL	Aux. Feedwater System	H, P	All three auxiliary feedwater pumps are available. However, auxiliary feedwater flow from the Train A motor driven auxiliary feedwater pump (MDAFP) and the turbine driven auxiliary feedwater pump (TDAFP) to steam generators (SGs) B and C may be affected. In addition auxiliary feedwater flow from the TDAFP to SGs A and D may be affected. The Train B MDAFP is available to supply auxiliary feedwater to SGs A and D.
AP	Condensate Storage System	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-30.
BB	Reactor Coolant System	R, M, H, P, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-30.
BG	Chemical and Volume Control System	R, M, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-30.
BM	Steam Generator Blowdown System	R, M, H	The ability to isolate blowdown from the Radwaste Control Room may be affected. All four blowdown valves can be isolated from the main control room using BMHIS0001A, BMHIS0002A, BMHIS0003A and BMHIS0004A.
BN	Borated Refueling Water Storage System	R, M, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-30.
EF	Essential Service Water System	H, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-30.
EG	Component Cooling Water System	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-30.
EJ	Residual Heat Removal System	M, H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-30.

Table A-30-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-30

System	System Name	PFSSD Function*	Comments
EM	High Pressure Coolant Injection	R, M	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-30.
EN	Containment Spray	R, M	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-30.
EP	Safety Injection Accumulators	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-30.
FB	Auxiliary Steam	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-30.
FC	Auxiliary Turbines	R, H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-30.
GD	ESW Pump House HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-30.
GF	AFW Pump Room Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-30.
GK	Control Room and Class 1E Switchgear Room Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-30.
GL	Auxiliary Building HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-30.
GM	Emergency Diesel Generator Room HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-30.
GN	Containment Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-30.
JE	Diesel Fuel Oil	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-30.
KA	Instrument Air	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-30.
KC	Fire Protection	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-30.
KH	Service Gas	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-30.
KJ	Standby Diesel Engine	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-30.

Table A-30-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-30

System	System Name	PFSSD Function*	Comments
MA	Main Generation	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-30.
MR	Startup Transformer	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-30.

3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD

This section describes operator actions that may need to be performed inside or outside the control room to achieve and maintain hot standby if a fire occurs in area A-30. This section also describes cold shutdown repairs that may need to be made to achieve and maintain cold shutdown conditions. Operator actions are proceduralized in OFN KC-016.

3.1 ACTIONS OUTSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

Operator Manual Actions (OMAs) are those actions outside the main control room required to achieve and maintain hot standby. OMAs are identified in E-1F9900 and were determined from thermal hydraulic analysis WCNOC-CP-002. Applicable E-1F9900 OMAs are annotated herein. All other actions outside the control room are desirable for plant control in support of hot standby but not required to achieve and maintain hot standby.

3.1.1 Steam Generator ARVs

It may be necessary to control or close ABPV0003 using local control station ABFHC0003. This action can be performed by an operator in fire area A-23. Emergency lighting and communication are available.

3.2 ACTIONS INSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

3.2.1 Steam Generator ARVs

ARV ABPV0002 may spuriously open. If this occurs, place ABPIC0002A in manual and control or close the ARV from the main control room.

3.3 ACTIONS TO ACHIEVE AND MAINTAIN COLD SHUTDOWN

None

4.0 CONCLUSION

Redundant Post Fire Safe Shutdown capability that is unaffected by a severe design basis fire does not exist in area A-30. However, feasible manual actions are available and are unaffected by the fire. Manual actions are documented in Section 3.0.

5.0 DETAILED ANALYSIS

This section describes the detailed component-by-component and cable-by-cable analysis for a fire in area A-30.

5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA A-30

PFSSD components (S. in E-15000) located in fire area A-30 are shown in Table A-30-3. An evaluation of each component and associated cables is provided in the sections that follow. The applicable evaluation section is listed in Table A-30-3.

Table A-30-3
PFSSD Equipment Located in Fire Area A-30

Room #	PFSSD Equipment	Description	Evaluation Section	Comments
1305	ABPT0002	SG B Steamline Pressure Transmitter	5.1.1	
1305	ABPT0003	SG C Steamline Pressure Transmitter	5.1.1	
1305	ALFT0011	Auxiliary Feedwater Flow To SG C	5.1.2	
1305	ALFT0009	Auxiliary Feedwater Flow To SG B	5.1.2

1330	ALHY0012	ALHV0012 I/P Converter	5.1.2	

5.1.1 Steam Generator Atmospheric Relief Valves

Pressure transmitters ABPT0002 and ABPT0003 and associated cables are located in fire area A-30. The effects of damage to these cables and components are described in the following paragraphs.

Cable 12ABI20FH provides a signal from pressure transmitter ABPT0002 to ARV ABPV0002 controller and opens the valve when steamline pressure reaches a designated setpoint. Damage to the pressure transmitter or cable due to a fire could cause a spurious high pressure signal which would open the ARV. If this occurs, operators can place ABPIC0002A in manual and control the ARV from the control room. Cables associated with the ARV controller I/P device (ABPY0002) do not run in area A-30.

Cable 13ABI20GE provides a signal from ARV ABPV0003 controller to pressure transducer ABPY0003. Cable 13ABI20GA provides a signal from ABPT0003 to ARV ABPV0003 controller. The transducer signals the position controller (ABZC0003) on ABPV0003 to open whenever steamline pressure reaches a designated setpoint. Damage to the cables due to a fire could cause a spurious signal which could open the ARV. Damage to cable 13ABI20GE could prevent manual operation of the valve from the control room. If the ARV spuriously opens, operators would have to close it using local controller ABFHC0003 in fire area A-23.

Based on the above discussion, steam generator ARVs ABPV0001, ABPV0002 and ABPV0004 can be controlled or closed from the control room. Steam generator ARV ABPV0003 may need to be controlled or closed using local controller ABFHC0003 in fire area A-23. Based on Section 5.1.2, the Train A MDAFP may not be available to supply steam generators B and C but the Train B MDAFP is available to supply steam generators A and D.

Up to three ARVs can fail closed or open without impacting ability to achieve and maintain hot standby according to thermal hydraulic analysis WCNOC-CP-002. With at least one ARV unaffected, no E-1F9900 OMA is required to address ARV closure or control. Reference Attachment 4, MSO Evaluation Scenario ID PWROG 23.

References: E-15000, XX-E-013, E-13AB20A, E-13AB20B, E-1F9101, M-12AB01

5.1.2 Auxiliary Feedwater

Several components and cables associated with Auxiliary Feedwater (AFW) are located in this area. The following paragraphs discuss the impact of damage to these cables and components on PFSSD.

Flow transmitters ALFT0009 and ALFT0011 and associated cables are located in this area. Damage to these components and cables could cause a spurious flow indication which could cause valves ALHV0009 and ALHV0011 to modulate or close, preventing adequate auxiliary feedwater flow from the Train A motor driven auxiliary feedwater pump (PAL01A) to steam generators B and C.

All four auxiliary feedwater to steam generators B and C supply valves (ALHV0009, ALHV0010, ALHV0011 and ALHV0012) are located in this area. In addition, power and control cables associated with these valves are run in this area. Damage to these cables and valves could prevent auxiliary feedwater flow from PAL01A and turbine driven auxiliary feedwater pump PAL02 to steam generators B and C.

Cables associated with ALHV0006 and ALHV0008 are run in this area. Damage to these cables could affect the operability of the valve and could prevent auxiliary feedwater flow from PAL02 to steam generators A and D.

The Train B motor driven auxiliary feedwater pump (PAL01B) is available to supply auxiliary feedwater to steam generators A and D via valves ALHV0005 and ALHV0007.

Cables associated with pressure transmitters ALPT0037, ALPT0038 and ALPT0039 are run in area A-30. Damage to these cables could cause a spurious low suction pressure (LSP) signal (2/3 logic) and initiate auxiliary feedwater suction swapover to the ESW system. This is acceptable for PFSSD since the ESW system is the safety related water source for AFW.

Based on the above discussion, the Train B motor driven auxiliary feedwater pump (PAL01B) is available to supply water to steam generators A and D. The suction source for AFW could swap to ESW due to a spurious LSP signal, but this will not adversely impact PFSSD. Based on Section 5.1.1, steam generator ARV ABPV0003 may need to be isolated using local controller ABFHC0003 but the remaining ARVs can be controlled or closed from the main control room.

5.2.1 Safety Injection

A spurious safety injection signal (SIS) could cause the safety injection pumps to operate. This condition is not desirable for PFSSD at Wolf Creek.

Safety injection (SI) is initiated automatically by any of the following conditions:

1. Two out of three high containment pressures monitored by pressure transmitters GNPT0934, GNPT0935 and GNPT0936.
2. Two out of four low pressurizer pressures monitored by pressure transmitters BBPT0455, BBPT0456, BBPT0457 and BBPT0458.
3. Two out of three low steam line pressures on any steam generator monitored by ABPT0514, ABPT0515 and ABPT0516 on SG A; ABPT0524, ABPT0525 and ABPT0526 on SG B; ABPT0534, ABPT0535 and ABPT0536 on SG C; and, ABPT0544, ABPT0545 and ABPT0546 on SG D. Two out of three logic must be satisfied on a single steam generator line. Low pressure on a single pressure transmitter co-incident with low pressure on another pressure transmitter on a different steam generator line will not initiate SIS.

Cables associated with steam line pressure transmitters ABPT0526 and ABPT0536 are run in area A-30. Cables for the remaining components identified above are unaffected by a fire in area A-30. Consequently, a spurious SIS will not occur in the event of a fire in area A-30.

5.2.2 Steam Generator Blowdown to Blowdown Flash Tank Isolation Valves

The reactivity control function requires the steam generator blowdown to blowdown flash tank valves (BMHV0001, BMHV0002, BMHV0003, and BMHV0004) be closed to prevent reactivity addition from uncontrolled cooldown. The valves are air operated and each valve is controlled by three solenoid valves. All three solenoid valves are required to be energized to open the valve. If any one solenoid is de-energized, the associated valve will close or remain closed. Only two of the three solenoids for each valve are considered in the PFSSD analysis, so the third solenoid is assumed energized throughout the event.

Cables 15BMK06AA, 15BMK06BA, 15BMK06CA and 15BMK06DA, associated with blowdown valves BMHV0001, BMHV0002, BMHV0003 and BMHV0004, are run in area A-30. These cables are associated with the solenoid valve for the handswitches located on the BM157 panel in the radwaste control room. Damage to these cables will have no adverse impact on the ability to close the blowdown valves using the handswitches in the main control room.

Based on the above discussion, steam generator blowdown to blowdown flash tank valves BMHV0001, BMHV0002, BMHV0003, and BMHV0004 can be closed using hand switches BMHIS0001A, BMHIS0002A, BMHIS0003A and BMHIS0004A, respectively, in the main control room.

1.0 GENERAL AREA DESCRIPTION

Fire area A-33 is located on the 1989 elevation of the Auxiliary Building and includes the rooms listed in Table A-33-1.

Table A-33-1
Rooms Located in Fire Area A-33

ROOM #	DESCRIPTION
1206	Auxiliary Feedwater Pipe Chase West
1207	Auxiliary Feedwater Pipe Chase East

Fire area A-33 is protected with an automatic wet-pipe sprinkler system. In addition, automatic fire detection is installed throughout. The automatic suppression and detection system meets the requirements of 10CFR50, Appendix R, Section III.G.2.c.

Circuits associated with redundant success paths are run through this area. In some cases, one success path is protected with a raceway fire barrier material meeting the requirements for a 1-hour fire rating. The 1-hour electrical raceway fire wrap in addition to automatic fire suppression and detection, meets Wolf Creek's commitments to 10CFR50, Appendix R Section III.G.2(c) and provides reasonable assurance that a fire in area A-33 will not impact safe shutdown.

2.0 PRIMARY EQUIPMENT USED FOR PFSSD

Table A-33-2 lists each system credited for post-fire safe shutdown and provides a discussion regarding the availability of the system to perform its Post Fire Safe Shutdown (PFSSD) function if a severe fire occurs in this area. For a summary of the area analysis results, see Section 8.0 of the Fire Area Analysis Narrative section.

Table A-33-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-33

System	System Name	PFSSD Function*	Comments
AB	Main Steam	R, M, H, P, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-33.
AC	Main Turbine	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-33.
AE	Main Feedwater	H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-33.
AL	Aux. Feedwater System	H, P	The TDAFP is available taking suction from the CST or ESW, depending on the location of the postulated fire. Valves ALHV0010 and ALHV0012 may be affected, preventing flow from the TDAFP to SGs B and C. Flow from the TDAFP to SGs A and D is available through valves ALHV0006 and ALHV0008. Valves ALHV0009 and ALHV0011 may lose power, causing loss of control of AFW from Train A MDAFP to SGs B and C. The TDAFP is available to supply all four steam generators.
AP	Condensate Storage System	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-33.
BB	Reactor Coolant System	R, M, H, P, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-33.
BG	Chemical and Volume Control System	R, M, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-33.
BM	Steam Generator Blowdown System	R, M, H	All PFSSD functions associated with the steam generator blowdown system are satisfied. Steam generator blowdown is isolated by closing valves BMHV0001, BMHV0002, BMHV0003 and BMHV0004 using BMHIS0001A, BMHIS0002A, BMHIS0003A and BMHIS0004A, located on the RL024 panel in the main control room.
BN	Borated Refueling Water Storage System	R, M, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-33.
EF	Essential Service Water System	H, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-33.
EG	Component Cooling Water System	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-33.
EJ	Residual Heat Removal System	M, H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-33.

Table A-33-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-33

System	System Name	PFSSD Function*	Comments
EM	High Pressure Coolant Injection	R, M	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-33.
EN	Containment Spray	R, M	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-33.
EP	Safety Injection Accumulators	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-33.
FB	Auxiliary Steam	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-33.
FC	Auxiliary Turbines	R, H, P	The TDAFP is available.
GD	ESW Pump House HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-33.
GF	AFW Pump Room Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-33.
GK	Control Room and Class 1E Switchgear Room Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-33.
GL	Auxiliary Building HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-33.
GM	Emergency Diesel Generator Room HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-33.
GN	Containment Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-33.
JE	Diesel Fuel Oil	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-33.
KA	Instrument Air	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-33.
KC	Fire Protection	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-33.
KH	Service Gas	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-33.
KJ	Standby Diesel Engine	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-33.
MA	Main Generation	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-33.

3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD

This section describes operator actions that may need to be performed inside or outside the control room to achieve and maintain hot standby if a fire occurs in area A-33. This section also describes cold shutdown repairs that may need to be made to achieve and maintain cold shutdown conditions. Operator actions are proceduralized in OFN KC-016.

3.1 ACTIONS OUTSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

None

3.2 ACTIONS INSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

3.2.1 Auxiliary Feedwater Lineup

Both motor driven auxiliary feedwater pumps may be unavailable. Turbine driven auxiliary feedwater to steam generators B and C may be affected. Align the Turbine Driven Auxiliary Feedwater Pump (TDAFP) to steam generators A and D using either train of ESW or the CST as the suction source.

3.3 ACTIONS TO ACHIEVE AND MAINTAIN COLD SHUTDOWN

None

4.0 CONCLUSION

Post Fire Safe Shutdown is assured for a fire in area A-33. Redundant capability exists and is unaffected by a fire in area A-33.

5.0 DETAILED ANALYSIS

This section describes the detailed component-by-component and cable-by-cable analysis for a fire in area A-33.

5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA A-33

PFSSD components (S. in E-15000) located in fire area A-33 are shown in Table A-33-3. An evaluation of each component and associated cables is provided in the sections that follow. The applicable evaluation section is listed in Table A-33-3.

Table A-33-3
PFSSD Equipment Located in Fire Area A-33

Room #	PFSSD Equipment	Description	Evaluation Section	Comments
1206	ALHV0030	ESW To Mtr Driven Aux Feedwater Pump B	5.2.1	
1206	ALHV0031	ESW To Mtr Driven Aux Feedwater Pump A	5.2.1	
1206	ALHV0034	CST To Mtr Driven Aux Feedwater Pump B	5.2.1	
1206	ALHV0035	CST To Mtr Driven Aux Feedwater Pump A	5.2.1	
1207	ALHV0032	TDAFW Pump Suction From ESW A	5.2.1	
1207	ALHV0033	TDAFW Pump Suction From ESW B	5.2.1	
1207	ALHV0036	TDAFW Pump Suction From CST	5.2.1	
1207	ALPT0037	ESFAS Low Suction Pressure	5.1.1	
1207	ALPT0038	ESFAS Low Suction Pressure	5.1.1	
1207	ALPT0039	ESFAS Low Suction Pressure	5.1.1	
1207	FCFV0310	AFWP Turbine Drain Trap To Condenser Iso Vlv	5.1.2	
1207	FCFY0310	FCFV310 Solenoid Valve	5.1.2	

5.1.1 Condensate Storage Tank Pressure Transmitters

Condensate storage tank (CST) pressure transmitters ALPT0037, ALPT0038 and ALPT0039 are included in the PFSSD design because they initiate swapover to ESW upon 2/3 low CST pressure indications. A spurious low CST pressure due to fire damage to cables associated with two of these pressure transmitters will swap the water source to ESW.

All three CST pressure transmitters, and associated cables, are located in fire area A-33 within approximately 10 feet of one another. Damage to these transmitters could initiate a spurious swapover from CST to ESW, or prevent an automatic swapover from occurring. A spurious swapover will not impact PFSSD because at least one ESW to TDAFP suction valve is available, as discussed in Section 5.2.1. Damage to the transmitters and associated cables in a manner that prevents automatic swapover is mitigated by manually aligning the ESW source after indication that the CST level or TDAFP suction pressure is low. Level transmitter APLT0004, although not a PFSSD component, is available to provide CST level indication in the control room. Circuits associated with this level transmitter do not run through area A-33. Pressure transmitter ALPT0026, located on the TDAFP suction line, is available if a fire occurs in area A-33 and can be used by operators to establish suction pressure on the TDAFP and initiate manual swapover to ESW if necessary.

Based on the above discussion, damage to all three CST pressure transmitters will have no adverse impact on PFSSD.

References: E-15000, XX-E-013, E-1F9202

5.1.2 TDAFP Drain Trap Isolation Valve

Valve FCFV0310 is an isolation valve on the 1-inch steam trap line associated with the TDAFP. Solenoid valve FCFY0310 controls the position of valve FCFV0310. PFSSD requires this valve to be closed to prevent uncontrolled loss of steam through this flow path.

Cable 14FCK21AA is a control cable associated with valve FCFV0310. Inter or intra-cable hot shorts could cause the valve to spuriously open. There are no energized 125 VDC cables in the same conduit as cable 14FCK21AA, so inter-cable hot shorts causing the valve to open are not possible. An intra-cable hot short from conductor 2 to conductor 1 will energize the solenoid and open the valve. This can be mitigated by depressing the close pushbutton on hand switch FCHIS0310. However, since this is a momantary contact switch, the operator would have to maintain the the button in the depressed position.

Uncontrolled blowdown through this 1-inch line is bounded by the main steam line break analysis and loss of steam through this line will not result in uncontrolled cooldown. Therefore, if the valve remains open, PFSSD is assured.

5.2.1 Auxiliary Feedwater

The PFSSD design requires the use of one auxiliary feedwater pump supplying water to at least two steam generators. The turbine driven auxiliary feedwater pump (TDAFP) is normally aligned to supply all four steam generators. The Train A motor driven auxiliary feedwater pump (MDAFP) is aligned to supply steam generators B and C. The Train B MDAFP is aligned to supply steam generators A and D.

The normal source of water to the AFPs is the condensate storage tank (CST). The emergency supply is from the essential service water (ESW) system. For commercial concerns, the CST is the preferred source and contains sufficient volume to supply the entire AFW demand to achieve cold shutdown.

Motor operated valves (MOVs) in the system allow operators to line up the auxiliary feedwater system as required to achieve and maintain safe shutdown. Damage to the MOV circuits due to a fire could prevent operators from lining up the system from the control room.

Cable 11ALB01AA is a power cable for the Train A motor driven auxiliary feedwater pump. Damage to this cable will prevent operation of PAL01A. Cable 14ALB01BA is a power cable for the Train B motor driven auxiliary feedwater pump. Damage to this cable will prevent operation of PAL01B.

Cable 11ALY09CE is a power cable associated with the Modutronic controller on valve ALHV0009 (Train A MDAFP to Steam Generator B). Damage to this cable could disable power to the controller and prevent flow control from the Train A MDAFP to SG B. As stated above, the Train A MDAFP may not be available, therefore valve ALHV0009 is not required if a fire occurs in this area.

Cable 11ALY09DE is a power cable associated with the Modutronic controller on valve ALHV0011 (Train A MDAFP to Steam Generator C). Damage to this cable could disable power to the controller and prevent flow control from the Train A MDAFP to SG C. As stated above, the Train A MDAFP may not be available, therefore valve ALHV0011 is not required if a fire occurs in this area.

Fire area A-33 contains all 7 suction isolation valves and associated cables for all three auxiliary feedwater pumps. These valves control the suction source from either the essential service water system or the condensate storage tank (CST) to the auxiliary feedwater pumps. Each of these valves is discussed in the following paragraphs.

Valve ALHV0030 is a normally closed suction isolation valve from ESW to Train B motor driven auxiliary feedwater pump. Cables 14ALG04AA, 14ALG04AB and 14ALG04AJ are power, control and indication cables, respectively, associated with this valve and run through area A-33. Damage to cables 14ALG04AA and 14ALG04AB due to a fire may result in the failure of valve ALHV0030 to open in response to an automatic or manual open signal. Damage to cable 14ALG04AJ may result in a loss of valve position indication on RP118B, which has no impact on PFSSD. Loss of capability to control this valve has no impact on PFSSD due to the availability of the TDAFP and associated valves.

Valve ALHV0031 is a normally closed suction isolation valve from ESW to Train A motor driven auxiliary feedwater pump. Cables 11ALG04BA and 11ALG04BB are power and control cables, respectively, associated with this valve and run through area A-33. Damage to these cables due to a fire may result in the failure of valve ALHV0031 to open in response to an automatic or manual open signal and may result in loss of valve position indication in the control room. Loss of capability to control this valve has no impact on PFSSD due to the availability of the TDAFP and associated valves.

Valve ALHV0034 is a normally open suction isolation valve from CST to Train B motor driven auxiliary feedwater pump. Cables 14ALG02AA, 14ALG02AB and 14ALG02AJ are power, control and indication cables, respectively, associated with this valve. Damage to cable 14ALG02AA will most likely result in the valve failing in the as-is open position. A 3-phase hot short on this cable is not postulated since the valve is not at a high-low pressure interface. Damage to cable 14ALG02AB will most likely result in the valve failing in the as-is open position. However, a short between conductors X4 and 2 will bypass the open position switch (ZS/11) and torque switch (WS/18) resulting in high opening torque and possible damage to the valve operator. If this occurs, the protective fuses on the control power transformer will blow, protecting the operator from further damage. Damage to cable 14ALG02AJ may result in a loss of valve position indication on RP118B, which has no impact on PFSSD. Loss of capability to control this valve has no impact on PFSSD due to the availability of the TDAFP and associated valves.

Valve ALHV0035 is a normally open suction isolation valve from CST to Train A motor driven auxiliary feedwater pump. Cables 11ALG02BA and 11ALG02BB are power and control cables, respectively, associated with this valve. Damage to cable 11ALG02BA will most likely result in the valve failing in the as-is open position. A 3-phase hot short on this cable is not postulated since the valve is not at a high-low pressure interface. Damage to cable 11ALG02BB will most likely result in the valve failing in the as-is open position. However, a short between conductors X1 and 2 will bypass the open position switch (ZS/5) and torque switch (WS/18) resulting in high opening torque and possible damage to the valve operator. If this occurs, the protective fuses on the control power transformer will blow, protecting the operator from further damage. Loss of capability to control this valve has no impact on PFSSD due to the availability of the TDAFP and associated valves.

Valve ALHV0032 is a normally closed suction isolation valve from ESW to the TDAFP. Cables 11ALG04CA and 11ALG04CB are power and control cables, respectively, associated with this valve. Damage to these cables due to a fire may result in the failure of valve ALHV0032 to open in response to an automatic or manual open signal and may result in loss of valve position indication in the control room. The cables are enclosed in conduit which has been wrapped with a qualified 1-hour fire resistant material. The valve and operator are not enclosed in 1-hour material but are separated from redundant valve ALHV0033 by at least 20 feet with no intervening combustibles. In addition, the area is protected with automatic fire suppression and detection throughout. This configuration meets the Wolf Creek commitments to 10CFR50, Appendix R and is, therefore, acceptable.

Valve ALHV0033 is a normally closed suction isolation valve from ESW to the TDAFP. Cables 14ALG04DA, 14ALG04DB and 14ALG04DJ are power, control and indication cables, respectively, associated with this valve. Damage to cables 14ALG04DA and 14ALG04DB due to a fire may result in the failure of valve ALHV0033 to open in response to an automatic or manual open signal. Damage to cable 14ALG04DJ may result in a loss of valve position indication on RP118B, which has no impact on PFSSD. Redundant valve ALHV0032 and associated cables are separated by at least 20 feet with no intervening combustibles or else the cables are protected with a qualified 1-hour fire-resistant material. In addition, the area is protected with automatic fire suppression and detection throughout. This configuration meets the Wolf Creek commitments to 10CFR50, Appendix R and is, therefore, acceptable.

Valve ALHV0036 is a normally open suction isolation valve from CST to the TDAFP. The PFSSD design requires this valve to be closed when using ESW as a suction source. Cables 11ALG02CA and 11ALG02CB are power and control cables, respectively, associated with this valve. The cables are enclosed in conduit which has been wrapped with a qualified 1-hour fire resistant material. The valve and operator are not enclosed in 1-hour material and are separated from redundant valves ALHV0032 and ALHV0033 by approximately 13 feet and 7 ½ feet, respectively with no intervening combustibles. In addition, the area is protected with automatic fire suppression and detection throughout. Depending on the location of the fire,

valve ALHV0036 may be available to ensure CST suction to the TDAFP. However, PFSSD is assured using the ESW suction source via valve ALHV0032 or ALHV0033.

Cables associated with the turbine driven auxiliary feedwater pump (TDAFP) are located in a separate fire area and are unaffected by a fire in area A-33. The TDAFP is redundant to both motor driven auxiliary feedwater pumps and is unaffected by a fire in area A-33. Therefore, the TDAFWP is available to provide feedwater to the steam generators in the event of a fire in A-33.

Based on the above discussion, both motor driven auxiliary feedwater pumps may be unavailable if a fire occurs in this area but the turbine driven auxiliary feedwater pump is unaffected and is available to supply all four steam generators. Depending on the location of the postulated fire, either the CST or the ESW system is available to supply suction to the TDAFP.

5.2.2 TDAFP To Steam Generator Isolation Valves

PFSSD requires one auxiliary feedwater pump supplying water to at least two steam generators. The turbine driven auxiliary feedwater pump (TDAFP) is normally aligned to supply all four steam generators. The Train A motor driven auxiliary feedwater pump (MDAFP) is aligned to supply steam generators B and C. The Train B MDAFP is aligned to supply steam generators A and D.

Valve ALHV0010 is an isolation valve on the TDAFP discharge to Steam Generator B. Cables 14ALI05AG, 14ALI05AH and 14ALI05AJ are instrumentation cables associated with this valve. Damage to these cables could cause a loss of control of valve ALHV0010 and prevent auxiliary feedwater flow to SG B.

Valve ALHV0012 is an isolation valve on the TDAFP discharge to Steam Generator C. Cables 14ALI05BD, 14ALI05BE and 14ALI05BF are instrumentation cables associated with this valve. Damage to these cables could cause a loss of control of valve ALHV0012 and prevent auxiliary feedwater flow to SG C.

Valves ALHV0006 and ALHV0008 are unaffected by a fire in area A-33. These valves control water from the TDAFP to SGs D and A, respectively. Therefore, PFSSD is assured based on the ability to supply feedwater to SGs A and D using the TDAFP.

References: E-15000, XX-E-013, E-13AL05A, E-13AL05B, E-1F9203, M-12AL01

5.2.3 Steam Generator Blowdown to Blowdown Flash Tank Isolation Valves

The reactivity control function requires the steam generator blowdown to blowdown flash tank valves (BMHV0001, BMHV0002, BMHV0003, and BMHV0004) be closed to prevent reactivity addition from uncontrolled cooldown.

Cables 15BMK06AA, 15BMK06BA, 15BMK06CA and 15BMK06DA are control cables associated with the BM157 panel mounted hand switches for each of the BMHV valves. Damage to these cables could impact the ability to close the valves from BM157 in the Radwaste Control Room.

The normal means of closing the blowdown valves, using the RL024 mounted hand switches in the Main Control Room, remains available. Therefore, a fire in area A-33 will not prevent the closure of valves BMHV0001, BMHV0002, BMHV0003, and BMHV0004.

1.0 GENERAL AREA DESCRIPTION

Fire area A-34 is located on the 2000 elevation of the Auxiliary Building and includes the rooms listed in Table A-34-1.

Table A-34-1
Rooms Located in Fire Area A34

ROOM #	ROOM #
1316	Seal Water Heat Exchanger Valve Compartment
1317	Seal Water Heat Exchanger Room

There is no automatic fire suppression or detection installed. The area is separated from all adjacent areas by minimum 3-hour fire rated construction meeting the requirements of 10 CFR 50, Appendix R.

2.0 PRIMARY EQUIPMENT USED FOR PFSSD

Table A-34-2 lists each system credited for post-fire safe shutdown and provides a discussion regarding the availability of the system to perform its Post Fire Safe Shutdown (PFSSD) function if a severe fire occurs in this area. For a summary of the area analysis results, see Section 8.0 of the Fire Area Analysis Narrative section.

Table A-34-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area A-34

System	System Name	PFSSD Function*	Comments
AB	Main Steam	R, M, H, P, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-34.
AC	Main Turbine	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-34.
AE	Main Feedwater	H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area A-34.

3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD

There are no operator actions specific to PFSSD either inside or outside the control room to achieve and maintain safe shutdown in the event of a fire in this area.

4.0 CONCLUSION

Redundant Post-Fire Safe Shutdown capability exists if a severe fire occurs in this area.

5.0 DETAILED ANALYSIS

This section describes the detailed component-by-component and cable-by-cable analysis for a fire in area A-34.

5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA A-34

PFSSD components (S. in E-15000) located in fire area A-34 are shown in Table A-34-3. An evaluation of each component and associated cables is provided in the sections that follow. The applicable evaluation section is listed in Table A-34-3.

Table A-34-3
PFSSD Equipment Located in Fire Area A-34

Room #	PFSSD Equipment	Description	Evaluation Section	Comments
1316	BGLT0185	VCT Level Transmitter	5.1.1	
1317	TB13208	Terminal Box for BGLT0185	5.1.1	
1317	EBG03	Seal Water Heat Exchanger	5.1.2	

5.1.1 VCT Level Indication

Volume Control Tank (VCT) level transmitter BGLT0185 is included in the PFSSD design because it initiates refueling water sequence upon sensing low-low water level in the VCT. The transmitter also provides VCT level indication in the control room. BGLT0185 uses sealed capillary tubing as instrument lines. Sealed capillary tubing can be affected by the heat generated by a fire. Therefore, the instrument tubing for this instrument is also considered to be damaged by a fire.

Damage to the VCT level transmitter, the instrument tubing or associated circuits could cause one or more of the following to occur:

1. Loss of VCT level indication in the Control Room
2. False low-low level in the VCT, initiating swap-over to the RWST
3. Inability to sense low-low level in the VCT, resulting in a loss of suction to the CCPs.

Redundant VCT level transmitter BGLT0112, and associated cables, is located in a separated fire area and is unaffected by a fire in fire area A-34. Therefore, VCT level indication remains available in the event of a fire in this area.

A sporadic low-low VCT level signal caused by damage to BGLT0185 and/or associated cables will start the RWST sequence, which is the desired PFSSD lineup. Therefore, this will not prevent PFSSD in the event of a fire in this area.

If transmitter BGLT0185 and associated cables are damaged, redundant VCT level transmitter BGLT0112 remains available to initiate RWST sequence upon low-low level in the VCT.

Based on the above discussion, damage to BGLT0185 and/or associated circuits will not prevent safe shutdown in the event of a fire in area A-34.

5.1.2 Seal Water Heat Exchanger

The seal water heat exchanger is required for PFSSD to maintain charging pump suction temperatures below acceptable limits. The seal water heat exchanger cools the water returning from the reactor coolant pump seals prior to the seal return water entering the CCP suction header. In addition, the seal water heat exchanger cools the recirculating water from the CCP discharge when the CCPs are operating on minimum flow.

The seal water heat exchanger is located in fire area A-34. There are no components on the heat exchanger that will fail in the event of a fire. Therefore, the heat exchanger will remain operable if a fire occurs in area A-34.

5.2 PFSSD CABLE EVALUATION

Table A-34-4 lists all the PFSSD cables (S. in E-15000) located in fire area A-34. Since all PFSSD cables terminate at the associated PFSSD equipment in this fire area, the cable evaluation is included in Section 5.1.

Table A-34-4
PFSSD Cables Located in Fire Area A-34

Cable #	Location	Primary PFSSD Equipment	Cable Function (P) Power (C) Control (I) Instrumentation	Evaluation Section	Comments
14BGI51DA	1317	BGLT0185	I	5.1.1	VCT Level Transmitter
14BGI51DB	1316, 1317	BGLT0185	I	5.1.1	VCT Level Transmitter

1.0 GENERAL AREA DESCRIPTION

Fire area AB-1 includes the Auxiliary Boiler room located on the South side of the Turbine Building and includes the room listed in Table AB-1-1.

Table AB-1-1
Rooms Located in Fire Area AB-1

ROOM #	DESCRIPTION
4315	Auxiliary Boiler Room

Fire area AB-1 has no installed automatic fire suppression system. The area is provided with automatic flame detection.

2.0 PRIMARY EQUIPMENT USED FOR PFSSD

Fire area AB-1 contains no post-fire safe shutdown cables or equipment. Therefore, both trains of PFSSD equipment are available if a fire occurs in this area.

3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD

Not applicable to fire area AB-1.

4.0 CONCLUSION

Post-fire safe shutdown is assured if a fire occurs in this area.

5.0 DETAILED ANALYSIS

A detailed analysis is not required since this area contains no PFSSD cables or components.

1.0 GENERAL AREA DESCRIPTION

Fire area C-1 is located on the 1974 elevation of the Control Building and includes the rooms listed in Table C-1-1.

Table C-1-1
Rooms Located in Fire Area C-1

ROOM #	DESCRIPTION
3101	Essential Service Water Pipe Space
3104	Stairway from Access Control

Fire area C-1 is protected with an automatic wet-pipe sprinkler system. In addition, automatic fire detection is installed in the area of the motor-operated ESW valves. A minimum 20 foot combustible and fire hazard free zone separates the north and south portions of this area. Redundant PFSSD components and cables are located at least 20 feet apart, except where identified in this report, and are bounded by the minimum 20 foot combustible and fire hazard free zone. The automatic suppression and detection system and 20 foot combustible free zone meets the intent of 10CFR50, Appendix R, Section III.G.2.b.

2.0 PRIMARY EQUIPMENT USED FOR PFSSD

Table C-1-2 lists each system credited for post-fire safe shutdown and provides a discussion regarding the availability of the system to perform its Post Fire Safe Shutdown (PFSSD) function if a severe fire occurs in this area. For a summary of the area analysis results, see Section 8.0 of the Fire Area Analysis Narrative section.

Table C-1-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-1

System	System Name	PFSSD Function*	Comments
AB	Main Steam	R, M, H, P, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-1.
AC	Main Turbine	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-1.
AE	Main Feedwater	H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-1.
AL	Aux. Feedwater System	H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-1.
AP	Condensate Storage System	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-1.
BB	Reactor Coolant System	R, M, H, P, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-1.
BG	Chemical and Volume Control System	R, M, S	A fire in the South end, including room 3104, will affect Train B CCP. Train A CCP remains available. Use the appropriate train of CCP depending on the location of the fire and the available train of ESW.
BM	Steam Generator Blowdown System	R, M, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-1.
BN	Borated Refueling Water Storage System	R, M, H	Valve BNLCV0112E may not respond if a fire occurs on the South end of this area. Valve BNHV8812B may not respond if a fire occurs on the South end of this area.
EF	Essential Service Water System	H, S	Both trains of ESW Flow Transmitters (EFFT0053 and EFFT0054) may be lost. Use alternate diagnostic instrumentation on operating Train components. A fire in the North end will affect Train A ESW but Train B will be available. A fire in the South end will affect Train B ESW but Train A will be available.
EG	Component Cooling Water System	S	CCW is not directly impacted by a fire in area C-1. Use the appropriate train of CCW depending on the location of the fire and the available train of ESW.
EJ	Residual Heat Removal System	M, H, P	If a fire occurs on the South end, RHR Train B may be unavailable. Use RHR Train A.
EM	High Pressure Coolant Injection	R, M	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-1.

Table C-1-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-1

System	System Name	PFSSD Function*	Comments
EN	Containment Spray	R, M	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-1.
EP	Safety Injection Accumulators	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-1.
FB	Auxiliary Steam	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-1.
FC	Auxiliary Turbines	R, H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-1.
GD	ESW Pump House HVAC	S	A fire on the South end may affect Train B ESW pump room ventilation. Train A ESW pump room ventilation is available. A fire on the North end does not affect Train A or Train B ESW pump room ventilation.
GF	AFW Pump Room Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-1.
GK	Control Room and Class 1E Switchgear Room Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-1.
GL	Auxiliary Building HVAC	S	If a fire occurs on the South end, Train B CCP and RHR pump room coolers may not be available. Train A CCP and RHR pump room coolers remain available.
GM	Emergency Diesel Generator Room HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-1.
GN	Containment Coolers	S	Use the appropriate train of containment coolers depending on the location of the fire and the available train of ESW.
JE	Diesel Fuel Oil	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-1.
KA	Instrument Air	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-1.
KC	Fire Protection	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-1.
KH	Service Gas	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-1.
KJ	Standby Diesel Engine	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-1.
MA	Main Generation	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-1.
MR	Startup Transformer	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-1.

Table C-1-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-1

System	System Name	PFSSD Function*	Comments
NB	4.16 kV System	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-1.
NE	Standby Diesel Generator	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-1.
NF	Load Shed and Emergency Load Sequencing	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-1.
NG	480V Load Centers and MCCs	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-1.
NK	125VDC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-1.
NN	120VAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-1.
PA	13.8kV	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-1.
PB	4.16kV	H, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-1.
PG	480V Load Centers and MCCs	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-1.
PK	125VDC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-1.
PL	Local Instrument Panels	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-1.
PN	120VAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-1.
QB	Standby AC Lighting	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-1.
QD	Emergency Lighting	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-1.
RL	Control Room MCB	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-1.
RP	Miscellaneous Control Panels	R, M, H, P, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-1.
SA	ESFAS	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-1.

Table C-1-2 Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-1			
System	**System Name**	**PFSSD Function***	**Comments**
SB	Reactor Protection System	R, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-1.
SC	Reactor Instrumentation	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-1.
SE	Ex-Core Neutron Monitoring	R, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-1.
SY	Switchyard	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-1.
UU	Supervisory System	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-1.

3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD

This section describes operator actions that may need to be performed inside or outside the control room to achieve and maintain hot standby if a fire occurs in area C-1. This section also describes cold shutdown repairs that may need to be made to achieve and maintain cold shutdown conditions. Operator actions are proceduralized in OFN KC-016.

3.1 ACTIONS OUTSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

None

3.2 ACTIONS INSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

3.2.1 ESW System Lineup

If the fire is on the South end, Train B ESW may be affected. If this occurs, line up Train A ESW using normal operating procedures. If the fire is on the North end, Train A ESW may be affected. If this occurs, line up Train B ESW using normal operating procedures.

3.2.2 Component Cooling Water

Depending on the location of the fire and the operating CCW train at the time of the fire, it may be necessary to swap to the opposite CCW Train if ESW is lost.

3.2.3 Refueling Water Storage Tank

If the fire is on the South end, valve BNLCV0112E may not respond. Line up the RWST to the charging header by opening BNHV0112D using BNHIS0112D.

3.2.4 Charging Pump Mini-Flow Valves

If the fire is on the South end, Valve BGHV8111 may be affected. Train A CCP mini-flow valve BGHV8110 is unaffected and can be lined up using BGHIS8110.

3.3 ACTIONS TO ACHIEVE AND MAINTAIN COLD SHUTDOWN

3.3.1 RHR System Lineup

Train A RHR is assured if the fire is on the South end of this area. Train B RHR is assured if the fire is on the North end of this area. A fire on the South end could affect BNHV8812B but BNHV8812A is unaffected.

4.0 CONCLUSION

Redundant Post-Fire Safe Shutdown capability exists if a severe fire occurs in this area.

5.0 DETAILED ANALYSIS

This section describes the detailed component-by-component and cable-by-cable analysis for a fire in area C-1.

5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA C-1

PFSSD components (S. in E-15000) located in fire area C-1 are shown in Table C-1-3. An evaluation of each component and associated cables is provided in the sections that follow. The applicable evaluation section is listed in Table C-1-3.

Table C-1-3
PFSSD Equipment Located in Fire Area C-1

Room #	PFSSD Equipment	Description	Evaluation Section	Comments
3101	EFFT0053	ESW Train A To Power Block Flow Transmitter	5.1.1	
3101	EFFT0054	ESW Train B To Power Block Flow Transmitter	5.1.1	
3101	EFHV0023	ESW A/Service Water Cross Connect Valve	5.1.2	
3101	EFHV0024	ESW B/Service Water Cross Connect Valve	5.1.2	
3101	EFHV0025	ESW A/Service Water Cross Connect Valve	5.1.2	
3101	EFHV0026	ESW B/Service Water Cross Connect Valve	5.1.2	
3101	EFHV0037	ESW A To Ultimate Heat Sink Isolation Valve	5.1.2	
3101	EFHV0038	ESW B To Ultimate Heat Sink Isolation Valve	5.1.2	
3101	EFHV0039	ESW A To Service Water Isolation Valve	5.1.2	
3101	EFHV0040	ESW B To Service Water Isolation Valve	5.1.2	
3101	EFHV0041	ESW A To Service Water Isolation Valve	5.1.2	
3101	EFHV0042	ESW B To Service Water Isolation Valve	5.1.2	
3101	EFV0470	ESW to Service Water Train A Cross Connect Check Valve	5.1.2	
3101	EFV0471	ESW to Service Water Train B Cross Connect Check Valve	5.1.2	
3102	TB32103	Terminal Box	5.1.3	

5.1.1 Essential Service Water (ESW) Flow Transmitters

Flow transmitters EFFT0053 (Train A) and EFFT0054 (Train B) are included in the PFSSD design to provide diagnostic instrumentation of ESW system operation. The associated flow indicators are located on panel RL019 in the main control room and allow operators to ensure adequate ESW flow on the operating train. The transmitters have no interlocks that would prevent operation of other PFSSD components if damaged by the fire.

The flow transmitters are physically separated by a distance of 17'-0". Cables 11EFI11EA and 14EFI11FA, associated with these transmitters, are separated by no less than 17'-0". The horizontal separation provided does not meet the requirements of 10CFR50, Appendix R, Section III.G.2, which requires more than 20 feet of separation between redundant PFSSD components.

Loss of both flow transmitters due to a fire will have no impact on the operation of the required ESW train. The only purpose of the transmitters is to provide flow indication to the operators in the control room when the ESW system is operating. In the event a fire renders both transmitters inoperable, alternate indication is available to ensure ESW flow. Alternate indication includes any available instrumentation on individual PFSSD components served by the ESW system.

5.1.2 ESW/Service Water Valves

The PFSSD methodology credits ESW as the source of service water to essential components. In order to ensure successful operation of the system, the control valves need to be aligned properly. A number of valves associated with the service water and ESW systems are located in area C-1. Depending on the location of the fire, either Train A ESW or Train B ESW will need to be aligned.

Valves EFHV0023 and EFHV0025 are normally open series valves from the service water system to the Train A ESW header. When operating Train A ESW system, one of these valves is required to be closed or check valve EFV0470 is required to be closed to prevent flow diversion to the service water piping. Per Assumption 3-A-24 in calculation XX-E-013 check valves are assumed to close in the direction of potential flow diversion. Therefore, there is reasonable assurance that the check valve will prevent flow diversion. Furthermore, motor operated valves EFHV0023 and EFHV0025 are separated by more than 20 feet of horizontal separation with no intervening combustibles or fire hazards. Cables 11EFG02AA and 11EFG02AB are power and control cables, respectively, associated with valve EFHV0023. Cables 14EFG02CA and 14EFG02CB are power and control cables, respectively, associated with valve EFHV0025. Cables associated with each valve are separated by more than 20 feet of horizontal separation with no intervening combustibles or fire hazards. The physical separation, along with automatic fire suppression and detection in the area, meets the requirements of 10CFR50, Appendix R, Section III.G.2 and is therefore acceptable. In the event that the check valve fails, one of the two MOVs will be available to isolate ESW from service water.

Valves EFHV0024 and EFHV0026 are normally open series valves from the service water system to the Train B ESW header. When operating Train B ESW system, one of these valves is required to be closed or check valve EFV0471 is required to be closed to prevent flow diversion to the service water piping. Per Assumption 3-A-24 in calculation XX-E-013 check valves are assumed to close in the direction of potential flow diversion. Therefore, there is reasonable assurance that the check valve will prevent flow diversion. Furthermore, motor operated valves EFHV0024 and EFHV0026 are separated by more than 20 feet of horizontal separation with no intervening combustibles or fire hazards. Cables 11EFG02BA and

11EFG02BB are power and control cables, respectively, associated with valve EFHV0024. Cables 14EFG02DA and 14EFG02DB are power and control cables, respectively, associated with valve EFHV0026. Cables associated with each valve are separated by more than 20 feet of horizontal separation with no intervening combustibles or fire hazards. The separation, along with automatic fire suppression and detection in the area meets the requirements of 10CFR50, Appendix R, Section III.G.2 and is therefore acceptable. In the event that the check valve fails, one of the two MOVs will be available to isolate ESW from service water.

Valve EFHV0037 is a normally throttled valve installed on the Train A ESW to Ultimate Heat Sink (UHS) line. When shutting down after a fire using the A Train ESW, this valve is required to be open to ensure adequate return flow to the UHS. Cables 11EFG06AA and 11EFG06AB are power and control cables, respectively, associated with valve EFHV0037. Damage to the power cable will likely result in the valve failing as-is, which is acceptable for PFSSD. Damage to the control cable could result in the valve spuriously closing, which is not desired.

Valve EFHV0038 is a normally throttled valve installed on the Train B ESW to Ultimate Heat Sink (UHS) line. When shutting down after a fire using the B Train ESW, this valve is required to be open to ensure adequate return flow to the UHS. Cables 14EFG06BA and 14EFG06BB are power and control cables, respectively, associated with valve EFHV0038. Damage to the power cable will likely result in the valve failing as-is, which is acceptable for PFSSD. Damage to the control cable could result in the valve spuriously closing, which is not desired.

Valves EFHV0037 and EFHV0038 are separated by more than 20 feet of horizontal separation with no intervening combustibles or fire hazards. With one exception, cables associated with these valves are separated by more than 20 feet of horizontal separation with no intervening combustibles or fire hazards. The exception occurs in one location where the distance between conduit 131U3019 and 134U3003 is only 19’ - 11”, which does not meet the literal requirements of 10CFR50, Appendix R. The length of conduit within the 20 foot Appendix R separation zone is approximately one foot. Based on the absence of significant quantities of combustible materials and the presence of automatic suppression and detection in the area, there is reasonable assurance that PFSSD can be achieved.

Valves EFHV0039 and EFHV0041 are normally throttled series valves located on the return line from Train A ESW system to service water system. When operating Train A ESW system, one of these valves is required to be closed to prevent flow diversion to the service water piping. The valves and associated cables are located in area C-1 with more than 20 feet of horizontal separation and no intervening combustibles or fire hazards. Cables 14EFG03AA and 14EFG03AB are power and control cables, respectively, associated with valve EFHV0039. Cables 11EFG03CA and 11EFG03CB are power and control cables, respectively, associated with valve EFHV0041. Cables associated with each valve are separated by more than 20 feet of horizontal separation with no intervening combustibles or fire hazards. The separation, along with automatic fire suppression and detection in the area, meets the requirements of 10CFR50, Appendix R, Section III.G.2 and is therefore acceptable.

Valves EFHV0040 and EFHV0042 are normally throttled series valves located on the return line from Train B ESW system to service water system. When operating Train B ESW system, one of these valves is required to be closed to prevent flow diversion to the service water piping. The valves and associated cables are located in area C-1 with more than 20 feet of horizontal separation and no intervening combustibles or fire hazards. Cables 14EFG03BA and 14EFG03BB are power and control cables, respectively, associated with valve EFHV0040. Cables 11EFG03DA and 11EFG03DB are power and control cables, respectively, associated with valve EFHV0042. Cables associated with each valve are separated by more than 20 feet of horizontal separation with no intervening combustibles or fire hazards. The separation, along with automatic fire suppression and detection in the area, meets the requirements of 10CFR50, Appendix R, Section III.G.2 and is therefore acceptable.

Based on the above discussion, adequate separation exists between redundant valves and associated circuits such that there is reasonable assurance that a single fire in this area will not impair both trains of ESW. The horizontal separation and presence of automatic suppression and detection meets the intent of 10CFR50, Appendix R and is therefore acceptable.

References: E-15000, XX-E-013, E-13EF02, E-13EF02A, E-13EF03, E-13EF06, E-13EF06A, E-1F9402A, E-1F9402B, E-1R3112

5.1.3 ESW Pump Room Ventilation

Terminal box TB32103 is located in room 3104, which is the stairway from access control to the 1974 elevation of the Auxiliary Building. The terminal box contains cables (14EFG11SA, 14EFG11TA, 14GDG01BE and 14GDG01BH) associated with Train B ESW pump room supply fan CGD01B. Damage to these cables could prevent operating the supply fan using local control hand switch GDHS11 in room 3302. Cables associated with Train A ESW pump room supply fan CGD01A do not run through fire area C-1.

Cable 14GDY01BA is a control cable associated with Train B ESW pump room supply fan. Cable 14GDI04BA is an instrument cable associated with Train B ESW pump room temperature element GDTE0011. Damage to these cables could prevent automatic and manual operation of the Train B ESW pump room fan.

Cable 14GDI04BB is an instrument cable associated with Train B ESW pump room inlet damper actuator GDTZ0011A. Damage to this cable could prevent operation of the damper. Train A ESW pump room inlet damper actuator GDTZ0001A is unaffected by a fire in this area.

Cable 14GDI04BC is an instrument cable associated with Train B ESW pump room recirculation damper actuator GDTZ0011B. Damage to this cable could prevent operation of the damper. Train A ESW pump room recirculation damper actuator GDTZ0001B is unaffected by a fire in this area.

If a fire occurs on the North end of this fire area, cables 14EFG11SA, 14EFG11TA, 14GDG01BE, 14GDG01BH, 14GDI04BA, 14GDI04BB, 14GDI04BC and 14GDY01BA are unaffected due to 20 feet of horizontal separation with no intervening combustibles, suppression and detection. As discussed in Section 5.1.2, Train A components may be lost if a fire occurs in the North end. If this occurs, Train B ESW is available to ensure PFSSD.

If a fire occurs in the South end of this fire area, cables 14EFG11SA, 14EFG11TA, 14GDG01BE, 14GDG01BH, 14GDI04BA, 14GDI04BB, 14GDI04BC and 14GDY01BA and other Train B circuits may be affected. If this occurs, Train A ESW is available to ensure PFSSD.

Based on the above discussion, a fire in area C-1 will not prevent safe shutdown.

5.2.1 CCP Mini-Flow Valves

Valve BGHV8111 is a mini-flow valve on the CCP B discharge. This valve is required to be open during low flow operation of the B Train CCP to provide recirculation flow and prevent damage to the pump. Cables 14BGG11DA and 14BGG11DB are power and control cables, respectively, associated with valve BGHV8111 and are run in the south end of area C-1 in room 3104. Damage to these cables may prevent opening valve BGHV8111 or may cause the valve to spuriously close.

Valve BGHV8110 is the mini-flow valve associated with Train A CCP and is unaffected by a fire in area C-1. A fire in the south end of area C-1, including room 3104, may affect a number of components associated with Train B. Redundant Train A components are either located outside this fire area or are separated by more than 20 feet of horizontal separation with no intervening combustibles and suppression and detection installed in the area.

Based on the above discussion, redundant capability exists to ensure either Train A or Train B CCP mini-flow valves are available if a fire occurs in area C-1.

References: E-15000, XX-E-013, E-13BG11B, E-1F9102, E-1F9302, E-1R3212, M-12BG03

5.2.2 VCT and RWST Outlet to Charging Pump Suction Valves

Valves BGLCV0112B and BGLCV0112C are normally open series valves on the outlet of the VCT. The PFSSD methodology requires either valve BGLCV0112B or BGLCV0112C be closed and that suction to the CCPs be taken from the RWST by opening either valve BNLCV0112D (Train A) or BNLCV0112E (Train B).

Cable 14BGG12BD is the close permissive interlock circuit that isolates the Volume Control Tank (VCT) to Charging Pump suction valve (BGLCV0112C) when the RWST to CCP B valve (BNLCV0112E) is fully open. An intra-cable short in this cable due to a fire will provide a false close permissive signal, possibly causing the valve to close prior to establishing suction from the RWST. However, if a SIS or low-low VCT level signal is not present, then the valve will not close. A spurious SIS or low-low VCT level is not credible for a fire in area C-1.

Based on a review of drawing E-13BG12A a short to ground involving cable 14BGG12BD could blow the control power fuse and prevent closing valve BGLCV0112C. However, ZS/10, K602 and K647 contacts are normally open and will prevent a short to ground from blowing the fuse. The K602 contact closes on a SIS. A fire in area C-1 will not cause a spurious SIS. Therefore, the K602 contact will remain open during the event. The K647 contact closes on VCT low-low level. A fire in C-1 will not cause a spurious low-low VCT level. However, if makeup to the VCT is affected (assumed to occur because the components are not analyzed) and swapover to the RWST is not completed in a timely manner, an actual low-low level in the VCT could occur. Contact ZS/16 is closed with the valve in the open position. Therefore, a short to ground could blow the control power fuse.

A short to ground on conductor 11 in cable 14BGG12BD would have no impact as long as the close switch for valve BGLCV0112C stays in the normal position. However, as soon as operators place the switch in the close position, the fuse would blow, causing the valve to stall in the open position.

Cables 14BNG01BA and 14BNG01BB are power and control cables, respectively, associated with RWST to CCP B suction valve BNLCV0112E and are run in room 3104. Damage to these cables could prevent manual opening of valve BNLCV0112E from the control room or prevent automatic opening upon receipt of a SIS or low-low VCT level signal.

If a fire occurs on the south end of area C-1, including room 3104, Train A CCP is available, taking suction from the RWST via valve BNLCV0112D. When a low-low level signal in the VCT is received, valve BGLCV0112B will automatically close when BNLCV0112D is fully open, as designed, to isolate the VCT. Alternatively, operators can manually close valve BGLCV0112B from the control room using BGHIS0112B.

If a fire occurs on the north end of area C-1, cables 14BGG12BD, 14BNG01BA and 14BNG01BB are unaffected due to physical separation along with suppression and detection installed in the area.

Based on the above discussion, redundant capability exists to ensure the VCT is isolated and a suction source to the CCPs is available if a fire occurs in area C-1.

References: E-15000, XX-E-013, E-13BG12, E-13BG12A, E-13BN01, E-1F9102, E-1F9302, E-1R3212, M-12BG03, M-12BN01

5.2.3 CCP Discharge to RCP Seals Isolation Valves

Valve BGHV8357B is a normally closed valve on the discharge side of Train B CCP to RCP seals. The valve is required to be open when using Train B CCP to charge through the RCP seals. Hand indicating switch BGHIS8357B is used to open this valve from the control room.

Cables 14BGG52BA and 14BGG52BB are power and control cables, respectively, associated with BGHV8357B. These cables are run in the south end of area C-1 in room 3104. Damage to these cables may prevent opening valve BGHV8357B from the control room.

Cables associated with Train A CCP to RCP seals isolation valve BGHV8357A are not run in area C-1 and are unaffected by a fire in this area. Therefore, a fire in the south end of area C-1 will use Train A CCP and valve BGHV8357A to provide charging flow through the RCP seals. If the fire occurs in the north end, Train B CCP is available due to physical separation along with suppression and detection installed in the area.

Based on the above discussion, redundant capability exists to ensure one CCP train is available to charge through the RCP seals if a fire occurs in area C-1.

References: E-15000, XX-E-013, E-13BG52, E-1F9102, E-1F9302, E-1R3212, M-12BG03

5.2.4 RWST to RHR Pump B Suction Valve

Valve BNHV8812B is the isolation valve from RWST to Train B RHR pump. This valve, or valve EJHV8811B, is required to be closed to prevent draindown of the RWST into the containment sump. Cables associated with EJHV8811B are not run in area C-1.

Damage to cables 14BNG03BA or 14BNG03BB could prevent automatic or manual closing of valve BNHV8812B. However, since valve EJHV8811B is unaffected by a fire in area C-1, RWST draindown to the containment sump is averted.

Based on the above discussion, a fire in area C-1 will not cause the draindown of the RWST into the containment sump.

References: E-15000, XX-E-013, E-13BN03A, E-1F9102, E-1F9205, E-1R3212, M-12BN01, M-12EJ01

5.2.5 ESW Pumps

The traveling water screen on the operating ESW train is required to be operable. The traveling water screen motor starts either manually using a local hand switch in the ESW pump house or automatically when the ESW pump starts, provided the associated screen wash valve is open.

Cable 14EFG02SD is a control cable associated with ESW B pump running contact. This cable is run in the South end of area C-1 in room 3104. A short on this cable could provide a false permissive signal and start the traveling water screen motor DFEF01B, which has no adverse impact on PFSSD. An open in this cable will prevent an automatic start of DFEF01B. However, the traveling water screen can be manually started using local hand switch EFHIS0004.

Cable 14EFG03SD is a control cable associated with Train B ESW screen wash valve EFHV0092. This cable is run in the South end of area C-1 in room 3104. Damage to this cable could prevent the valve from automatically opening when the ESW pump starts or cause the valve to spuriously close when the pump is running. In either case, hand switch EFHS0092 is available to override the spurious signal.

Cable 14EFG06SD is a control cable associated with ESW B air release valve EFHV0098. This cable is run in the South end of area C-1 in room 3104. This valve relieves air from the ESW pump discharge line for a period of 15 seconds after the pump starts, at which time the valve automatically closes. Damage to this cable could prevent the valve from closing after a 15 second delay or could cause the valve to spuriously close prior to the 15 second delay.

Cable 14EFI08RB is an instrument cable associated with ESW B discharge pressure transmitter EFPT0002. This cable is run in the South end of area C-1 in room 3104. Damage to this cable could cause a loss of pressure indication in the control room.

Cable 14EFK01SA is a control cable associated with ESW pump PEF01B local hand indicating switch EFHIS0056B. This cable is run in the South end of area C-1 in room 3104. Damage to this cable could prevent operating the B Train ESW pump due to a short across conductors P1 and 21 which will energize AR-C and provide a false stop signal.

Cable 14EFB01SB is a control cable associated with Train B ESW pump motor DPEF01B. This cable is run in the South end of area C-1 in room 3104. Damage to this cable could prevent operation of the B Train ESW pump.

If a fire occurs in the South end of area C-1, Train B ESW may be unavailable due to damage to the cables discussed above. However, Train A ESW is unaffected due to physical separation along with suppression and detection installed in the area. If a fire occurs in the North end, Train B ESW is available. Cables for Train A ESW traveling water screen, screen wash valve and air release valve are not run in area C-1.

Based on the above discussion, a fire in area C-1 will not prevent operation of one train of ESW.

References: E-15000, XX-E-013, E-K3EF01A, E-K3EF02, E-K3EF03, E-K3EF06, E-K3EF08, E-1F9402A, E-1F9402B, E-1R3212

5.2.6 RHR Pump B to Safety Injection Pump Isolation Valve

Valve EJHV8804B is the RHR pump B to Safety Injection pump isolation valve. The PFSSD position of this valve is closed during RHR Train B operation. A fire in area C-1 South uses RHR Train A.

Cable 14EJG04BA is the power cable for valve EJHV8804B. Cable 14EJG04BB is a control cable for valve EJHV8804B. These cables run in the South end of area C-1 in room 3104. Valve EJHV8804B is normally closed.

The only possible failure mode that would cause valve EJHV8804B to spuriously open would be a three-phase external (inter-cable) cable-to-cable hot short across the conductors in cable 14EJG04BA. However, the assumptions section in Calculation XX-E-013 states that the probability of a three-phase hot short in the proper sequence is extremely low and does not require evaluation, except in cases of high-low pressure interfaces. Valve EJHV8804B is not a high-low pressure interface.

There is reasonable assurance that a fire in area C-1 will not cause the spurious opening of valve EJHV8804B. In the unlikely event valve EJHV8804B spuriously opens, PFSSD is assured since RHR pump A is available for a fire in area C-1 South.

References: E-15000, XX-E-013, E-13EJ04B

5.2.7 RHR Pump Mini Flow Valves

Valve EJFCV0611 is installed on the recirculation line of the ‘B’ RHR pump and controls recirc flow to protect the pump during low flow conditions. The valve is required to be open during RHR pump B operation (cold shutdown). The valve is not required during hot standby.

Cable 14EJG08BB is the control cable for RHR pump B mini-flow valve EJFCV0611. Cable 14EJG08BE is the power cable for valve EJFCV0611. Cable 14EJG08BF is the control cable for RHR pump B mini-flow switch EJFIS0611. These cables run in the South end of area C-1 in room 3104. Damage to these cables could prevent the mini-flow valve from operating as designed. Therefore, RHR pump B may not be available if a fire occurs on the South end of area C-1.

Cables associated with Train A RHR mini-flow valve EJFCV0610 are unaffected by a fire in area C-1. If a fire occurs in South end of area C-1, Train A RHR is available for cold shutdown. If the fire is on the North end, Train B RHR is unaffected due to physical separation along with suppression and detection installed in the area.

References: E-15000, XX-E-013, E-13EJ08, E-13EJ08A

5.2.8 Centrifugal Charging Pump (CCP) and Residual Heat Removal (RHR) Pump Room Coolers

Cable 14GLG05BA is the power cable to the ‘B’ RHR pump room cooler (DSGL10B). Cable 14GLG05HA is the power cable to the ‘B’ CCP pump room cooler (DSGL12B). These cables run in the South end of area C-1 in room 3104.

Damage to either of these cables will prevent operation of the associated Train B room cooler. Cables associated with Train A RHR and CCP room coolers are unaffected by a fire in area C-1. If a fire occurs in the South end of area C-1, Train A RHR and CCP room coolers are available to ensure PFSSD. If a fire occurs in the North end, Train B RHR and CCP room coolers are unaffected due to physical separation along with suppression and detection installed in the area.

Based on the above discussion, a fire in area C-1 will not prevent operation of one train of RHR and CCP room coolers.

References: E-15000, XX-E-013, E-13GL05

5.2.9 4160 V Distribution to ESW Pump House

Cable 14NGB10SB is a control cable associated with the 4160V transformer feeder breaker 152NB0216 overcurrent protective circuit. Feeder breaker NB0216 feeds ESW Train B pump house 480V loads. Damage to this cable due to a fire could cause a loss of feeder breaker 152NB0216 control and loss of power to Train B ESW pumphouse loads.

Cables associated with Train A ESW pumphouse feeder breaker NB0116 do not run in area C-1. If a fire occurs in the South end of area C-1, Train A ESW equipment is available to ensure PFSSD. If a fire occurs in the North end, Train B ESW equipment is available to ensure PFSSD due to physical separation along with suppression and detection installed in the area.

Based on the above discussion, a fire in area C-1 will not prevent operation of at least one train of ESW.

References: E-15000, XX-E-013, E-K3NG10A

5.2.10 CVCS Heat Tracing

Heat tracing has been installed to maintain the emergency borate line and other fluid lines above the solidification temperature in the Train A SI pump room. Both safety trains can power the heat tracing; an automatic transfer switch (QJS0001) switches from Train A (primary source) to Train B (alternate source) on loss of A Train.

Fire area C-1 contains a cable (14NGY13BA) associated with the CVCS heat tracing system. This cable provides a secondary source of power to the heat tracing system. The primary source of power from cable 11NGY13AA (Not a PFSSD cable) is unaffected.

Per Calculation XX-E-013, the emergency borate line and heat tracing is credited for long term boration after a control room fire. The heat tracing system is not credited for PFSSD where the fire is outside the control room. Although a fire in area C-1 could affect the secondary source of power to the heat tracing system, the system is not required for a fire in area C-1. Loss of this cable will not adversely impact PFSSD. Therefore, the configuration is acceptable.

1.0 GENERAL AREA DESCRIPTION

Fire area C-2 is located on the 1974 elevation of the Control Building and includes the room listed in Table C-2-1.

Table C-2-1
Rooms Located in Fire Area C-2

ROOM #	DESCRIPTION
3106	North small electrical chase.

Fire area C-2 is protected with an automatic wet-pipe sprinkler system and automatic smoke detection. The area is separated on all sides by minimum 3-hour fire resistance rated barriers.

2.0 PRIMARY EQUIPMENT USED FOR PFSSD

Fire area C-2 contains no post-fire safe shutdown cables or equipment. Therefore, both trains of PFSSD equipment are available if a fire occurs in this area.

3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD

Not applicable to fire area C-2.

4.0 CONCLUSION

Post-fire safe shutdown is assured if a fire occurs in this area.

5.0 DETAILED ANALYSIS

A detailed analysis is not required since this area contains no PFSSD cables or components.

NAC	Area Above Suspended Ceiling

Fire area C-5 is protected with an automatic wet-pipe sprinkler system above and below the suspended ceiling. In addition, partial automatic fire detection is installed. The fire area is separated from adjacent fire areas by minimum 3-hour fire resistant construction.

2.0 PRIMARY EQUIPMENT USED FOR PFSSD

Table C-5-2 lists each system credited for post-fire safe shutdown and provides a discussion regarding the availability of the system to perform its Post Fire Safe Shutdown (PFSSD) function if a severe fire occurs in this area. For a summary of the area analysis results, see Section 8.0 of the Fire Area Analysis Narrative section.

Table C-5-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-5

System	System Name	PFSSD Function*	Comments
AB	Main Steam	R, M, H, P, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-5.
AC	Main Turbine	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-5.
AE	Main Feedwater	H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-5.
AL	Aux. Feedwater System	H, P	Train A motor driven auxiliary feedwater pump may not be available. Train B motor driven auxiliary feedwater pump and the turbine driven auxiliary feedwater pump are unaffected by a fire in area C-5.
AP	Condensate Storage System	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-5.
BB	Reactor Coolant System	R, M, H, P, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-5.
BG	Chemical and Volume Control System	R, M, S	Train A centrifugal charging pump may not be available. Train B centrifugal charging pump is unaffected.
BM	Steam Generator Blowdown System	R, M, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-5.
BN	Borated Refueling Water Storage System	R, M, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-5.
EF	Essential Service Water System	H, S	Several Train A ESW components could be affected. Train B ESW is unaffected.
EG	Component Cooling Water System	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-5.
EJ	Residual Heat Removal System	M, H, P	Train A residual heat removal pump may not be available. Train B residual heat removal pump is unaffected.
EM	High Pressure Coolant Injection	R, M	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-5.
EN	Containment Spray	R, M	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-5.

Table C-5-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-5

System	System Name	PFSSD Function*	Comments
EP	Safety Injection Accumulators	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-5.
FB	Auxiliary Steam	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-5.
FC	Auxiliary Turbines	R, H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-5.
GD	ESW Pump House HVAC	S	Train A ESW pump room ventilation may be affected. Train B ESW pump room ventilation is unaffected.
GF	AFW Pump Room Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-5.
GK	Control Room and Class 1E Switchgear Room Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-5.
GL	Auxiliary Building HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-5.
GM	Emergency Diesel Generator Room HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-5.
GN	Containment Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-5.
JE	Diesel Fuel Oil	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-5.
KA	Instrument Air	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-5.
KC	Fire Protection	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-5.
KH	Service Gas	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-5.
KJ	Standby Diesel Engine	S	Since Train A ESW could be lost, the Train A diesel engine may not be available. The Train B diesel engine is available.
MA	Main Generation	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-5.
MR	Startup Transformer	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-5.

Table C-5-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-5

System	System Name	PFSSD Function*	Comments
NB	4.16 kV System	S	Off-site power to buses NB01 and NB02 could be affected. The Train B emergency diesel generator is available to energize NB02. The train A emergency diesel generator may not be available due to potential loss of Train A ESW.
NE	Standby Diesel Generator	S	Since Train A ESW could be lost, the Train A diesel generator may not be available. The Train B diesel generator is available.
NF	Load Shed and Emergency Load Sequencing	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-5.
NG	480V Load Centers and MCCs	S	Train A 480 VAC load centers NG01 and NG03 and motor control center (MCC) NG05E could lose power. Redundant PFSSD components are available using Train B load centers NG02 and NG04 and MCC NG06E.
NK	125VDC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-5.
NN	120VAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-5.
PA	13.8kV	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-5.
PB	4.16kV	H, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-5.

3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD

This section describes operator actions that may need to be performed inside or outside the control room to achieve and maintain hot standby if a fire occurs in fire area C-5. This section also describes cold shutdown repairs that may need to be made to achieve and maintain cold shutdown conditions. Operator actions are proceduralized in OFN KC-016.

3.1 ACTIONS OUTSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

None

3.2 ACTIONS INSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

None

3.3 ACTIONS TO ACHIEVE AND MAINTAIN COLD SHUTDOWN

None

4.0 CONCLUSION

Post Fire Safe Shutdown is assured if a fire occurs in fire area C-5.

5.0 DETAILED ANALYSIS

This section describes the detailed component-by-component and cable-by-cable analysis for a fire in area C-5.

5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA C-5

PFSSD components (S. in E-15000) located in fire area C-5 are shown in Table C-5-3. An evaluation of each component and associated cables is provided in the sections that follow. The applicable evaluation section is listed in Table C-5-3.

5.2 PFSSD CABLE EVALUATION

Table C-5-4 lists all the PFSSD cables (S. in E-15000) located in fire area C-5. The applicable evaluation section is also listed in Table C-5-4.

5.2.1 Auxiliary Feedwater

For decay heat removal, the PFSSD design requires the use of one auxiliary feedwater pump (AFP) supplying water to at least two steam generators. The turbine driven auxiliary feedwater pump (TDAFP) is normally aligned to supply all four steam generators. The Train A motor driven auxiliary feedwater pump (MDAFP) is aligned to supply steam generators B and C. The Train B MDAFP is aligned to supply steam generators A and D.

Power cable 11ALB01AA, associated with Train A MDAFP motor DPAL01A, is run in fire area C-5. Damage to this cable could prevent operation of the pump. Redundant Train B MDAFP cables are run in a separate fire area and are unaffected by a fire in area C-5. In addition, the TDAFP is unaffected by a fire in area C-5.

Based on the above discussion, auxiliary feedwater is assured using the Train B MDAFP to supply steam generators A and D or the TDAFP to supply steam generators A, B, C and D.

References: XX-E-013, E-15000, E-13NB01, E-1F9202, E-1F9204, M-12AL01

5.2.2 Centrifugal Charging

At least one centrifugal charging pump (CCP) is required for PFSSD to supply a source of borated water to the RCS and to provide makeup due to inventory loss in the RCS. For PFSSD, the safety related CCPs are credited. The normal charging pump may continue to operate, but it is not credited for PFSSD so it is assumed lost.

A power cable (11BGB01AA) associated with the Train A CCP runs through fire area C-5. Damage to this cable could prevent operation of the pump. Redundant Train B CCP cables are run in a separate fire area and are unaffected by a fire in area C-5. Therefore, PFSSD is assured using Train B CCP if a fire occurs in area C-5.

References: XX-E-013, E-15000, E-13NB01, E-1F9102, E-1F9302, M-12BG03

5.2.3 Essential Service Water System

One train of Essential Service Water (ESW) is required to be operable to ensure adequate cooling for credited PFSSD equipment. The available ESW train needs to be capable of supplying its respective PFSSD loads during the event.

Terminal box TB32114 includes PFSSD cables 11GDG01AC, 11GDG01AD, 11GDY01AA and 11GDY01AD, which are the only PFSSD cables in TB32114. Cables 11GDG01AC and 11GDG01AD are associated with the indicator lights on Train A ESW pump room supply fan CGD01A hand switch GDHIS0001B. Cables 11GDY01AA and 11GDY01AD are associated with Train A ESW pump room supply fan CGD01A control circuit and allow control of the fan from the control room using hand switch GDHIS0001A. Damage to these cables could prevent operation or cause maloperation of the supply fan. If this occurs, the Train A ESW pump room may not have sufficient ventilation when the Train A ESW pump is operating.

Terminal box TB32105 includes PFSSD cables 11EFG11SA, 11EFG11TA and 11EFK01SB. Cables 11EFG11SA and 11EFG11TA were originally spare cables but the conductors are now used for various functions at the ESW pumphouse. Cable 11EFK01SB is a control cable for Train B ESW pump local hand switch EFHIS0055B. The function supported by these cables is to provide local control of the Train A ESW pump. Damage to the cables could prevent operation of the Train A ESW pump.

Cables 11EFB01SE and 11EFB01SF are power cables for the Train A ESW pump motor DPEF01A. Cable 11EFB01SB is a control cable associated with Train A ESW pump breaker NB00115. Damage to these cables will prevent operation of the Train A ESW pump.

Cable 11EFG02SD is a control cable that provides an automatic start signal to the Train A ESW traveling water screen when the Train A ESW pump runs. Damage to the cable could prevent automatic operation of the screen. Circuits for Train B traveling water screen do not run through area C-5.

Cable 11EFG03SD is a control cable associated with ESW Train A screen wash water valve EFHV0091. Damage to this cable could prevent automatic operation of the valve. Circuits for Train B screen wash water valve EFHV0092 do not run through area C-5.

Cable 11EFG06SD is associated with Train A ESW pump air release valve EFHV0097. The air release valve purges air from the pump casing upon pump start to ensure pump operability. Damage to the cable could prevent automatic operation of the air release valve. Circuits for Train B ESW pump air release valve EFHV0098 do not run through area C-5.

Pressure transmitter EFPT0001 and flow transmitter EFFT0053 are included in the PFSSD design to provide diagnostic instrumentation of ESW system operation. Cables 11EFI08RB and 11EFI11EA associated with these transmitters are run in fire area C-5. Damage to the cables could prevent proper diagnostic instrumentation of Train A ESW operation. Pressure and flow transmitters associated with the Train B ESW system are unaffected by a fire in area C-5.

Cable 11GDI04AA provides ESW A room temperature from temperature element GDTE0001 to temperature controller GDTC0001. Cables 11GDI04AB and 11GDI04AC provide signals from GDTC0001 to outside air intake damper GDTZ0001A and recirculation damper GDTZ0001B, respectively, to change position based on room temperature. Damage to these cables could prevent operation of the dampers. Temperature controls for Train B ESW pump room are unaffected by a fire in area C-5.

Power and control cables associated with a number of valves in the Train A ESW system are run in fire area C-5. Damage to the cables due to a fire could cause the spurious operation or prevent operation of the valves from the control room. If this occurs, redundant valves are available to ensure operability of the Train B ESW system.

Cable 11NGB10SB is associated with Train A ESW pump room load center NG05E feeder breaker NB0116. Cable 11NGG01SA is a power cable from NB0116 to XNG05. Damage to 11NGB10SB could cause the breaker to spuriously trip or spuriously close. Damage to 11NGG01SA could prevent operation of the breaker. Train B ESW pump room load center NG06E is unaffected by a fire in area C-5.

Based on the above discussion, Train A ESW may not be available if a fire occurs in fire area C-5. PFSSD is assured for a fire in area C-5 using Train B ESW pump PEF01B and associated components.

References: E-15000, XX-E-013, E-13EF02, E-13EF03, E-13EF06, E-13EF11, E-K3EF01, E-K3EF02, E-K3EF03, E-K3EF06, E-K3EF08, E-K3EF11, E-K3GD01, E-K3GD04, E-K3NG01, E-K3NG10, E-1F9402A, E-1F9402B, E-1F9403, E-1F9443, M-12EF01, M-12EF02, M-K2EF01, M-K2GD01

5.2.4 Class 1E 4.16 kV ESF Switchgear Buses NB01 and NB02

One Class 1E 4.16 kV bus is required to power PFSSD equipment in the event of a fire. Bus NB01 normally powers Train A safety related equipment while Bus NB02 normally powers Train B safety related equipment. The normal source of power is from off-site sources while the safety-related source of power is from the emergency diesel generators. Each bus can be cross-trained to the opposite transformer.

Cables 15NBB03AA, 15NBB03AC and 15NBB03AE are power cables that provide the normal off-site source of power from transformer XNB01 to bus NB01. Cables 16NBB05AA,

16NBB05AB and 16NBB05AC are power cables that provide the normal off-site source of power from transformer XNB02 to bus NB02. Damage to these cables will cause a loss of off-site power on NB01 and NB02. As discussed in Section 5.2.3, Train A ESW may not be available. Therefore, the Train A emergency diesel generator may not be available. The train B emergency diesel generator remains available.

Based on the above discussion, off-site power to NB01 and NB02 could be lost if a fire occurs in this area and the Train A emergency diesel generator may not be available. The Train B emergency diesel generator remains available to energize NB02.

References: E-15000, XX-E-013, E-13NB03, E-13NB05, E-13NB06, E-1F9423

5.2.5 Residual Heat Removal System

The residual heat removal (RHR) system is required to remove decay heat from the RCS during transition from hot shutdown to cold shutdown. At least one RHR train is required to be operable for PFSSD.

A power cable (11EJB01AA) associated with Train A RHR pump motor DPEJ01A is run in fire area C-5. Damage to this cable will prevent operation of the Train A RHR pump. Redundant Train B RHR cables are run in a separate fire area and are unaffected by a fire in area C-5. Therefore, PFSSD is assured using Train B RHR if a fire occurs in area C-5.

References: XX-E-013, E-15000, E-13NB01, E-1F9205

5.2.6 Train A 480 Volt Class 1E Power

One train of class 1E 480 Volt power is required to be operable to energize the credited PFSSD components.

A fire in area C-5 could disrupt power to Train A 480 Volt Class 1E Load Centers NG01 and NG03. Cable 11NGG01AA supplies power from NB0113 to transformer XNG01. Loss of power to XNG01 will interrupt power to load center NG01. Cables 11NGG01AB and 11NGG01AC are power cables that supply power to motor control center (MCC) NG01A. Cable 11NGG01BA supplies power from NB0110 to transformer XNG03. Therefore, all power to NG01 and NG03 could be lost in the event of a fire in area C-5.

Logic diagrams E-1F9424A and E-1F9424C identify all PFSSD components affected by a loss of power to NG01 and NG03. If this occurs, power to redundant Train B components is available using load centers NG02 and NG04, which are unaffected by a fire in area C-5. Therefore, loss of power to Train A components supplied by NG01 and NG03 will not impact the ability to achieve and maintain safe shutdown following a fire in this area.

1.0 GENERAL AREA DESCRIPTION

Fire area C-6 is located on the 1984 elevation of the Control Building and includes the rooms listed in Table C-6-1.

Table C-6-1
Rooms Located in Fire Area C-6

ROOM #	DESCRIPTION
3201	Stairway C-1
3202	Controlled H.P. Tool & Instrument Storage Room
3203	Hot Janitors Closet
3204	Corridor No. 1
3205	H.P. Area
3205A	Partial Height Electrical Chase
3207	RCA Ingress
3208	RP Calibration Lab #1
3209	Decon Area
3210	Decon Shower
3211	HP Conference Room (East)
SAC	Area Above Suspended Ceiling

Fire area C-6 is protected with an automatic wet-pipe sprinkler system above and below the suspended ceiling. In addition, partial automatic fire detection is installed. The fire area is separated from adjacent fire areas by minimum 3-hour fire resistant construction.

2.0 PRIMARY EQUIPMENT USED FOR PFSSD

Table C-6-2 lists each system credited for post-fire safe shutdown and provides a discussion regarding the availability of the system to perform its Post Fire Safe Shutdown (PFSSD) function if a severe fire occurs in this area. For a summary of the area analysis results, see Section 8.0 of the Fire Area Analysis Narrative section.

Table C-6-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-6

System	System Name	PFSSD Function*	Comments
AB	Main Steam	R, M, H, P, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-6.
AC	Main Turbine	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-6.
AE	Main Feedwater	H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-6.
AL	Aux. Feedwater System	H, P	Train B motor driven auxiliary feedwater pump may not be available. Train A motor driven auxiliary feedwater pump and the turbine driven auxiliary feedwater pump are unaffected by a fire in area C-6.
AP	Condensate Storage System	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-6.
BB	Reactor Coolant System	R, M, H, P, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-6.
BG	Chemical and Volume Control System	R, M, S	Train B centrifugal charging pump may not be available. Train A centrifugal charging pump is unaffected.
BM	Steam Generator Blowdown System	R, M, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-6.
BN	Borated Refueling Water Storage System	R, M, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-6.
EF	Essential Service Water System	H, S	Several Train B ESW components could be affected. Train A ESW is unaffected.
EG	Component Cooling Water System	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-6.
EJ	Residual Heat Removal System	M, H, P	Train B residual heat removal pump may not be available. Train A residual heat removal pump is unaffected.
EM	High Pressure Coolant Injection	R, M	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-6.
EN	Containment Spray	R, M	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-6.

Table C-6-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-6

System	System Name	PFSSD Function*	Comments
EP	Safety Injection Accumulators	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-6.
FB	Auxiliary Steam	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-6.
FC	Auxiliary Turbines	R, H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-6.
GD	ESW Pump House HVAC	S	Train B ESW pump room ventilation may be affected. Train A ESW pump room ventilation is unaffected.
GF	AFW Pump Room Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-6.
GK	Control Room and Class 1E Switchgear Room Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-6.
GL	Auxiliary Building HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-6.
GM	Emergency Diesel Generator Room HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-6.
GN	Containment Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-6.
JE	Diesel Fuel Oil	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-6.
KA	Instrument Air	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-6.
KC	Fire Protection	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-6.
KH	Service Gas	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-6.
KJ	Standby Diesel Engine	S	Since Train B ESW could be lost, the Train B diesel engine may not be available. The Train A diesel engine is available.
MA	Main Generation	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-6.
MR	Startup Transformer	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-6.

Table C-6-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-6

System	System Name	PFSSD Function*	Comments
NB	4.16 kV System	S	Off-site power to bus NB01 and NB02 could be affected. The Train A emergency diesel generator is available to energize NB01. The train B emergency diesel generator may not be available due to potential loss of Train B ESW.
NE	Standby Diesel Generator	S	Since Train B ESW could be lost, the Train B diesel generator may not be available. The Train A diesel generator is available.
NF	Load Shed and Emergency Load Sequencing	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-6.
NG	480V Load Centers and MCCs	S	Train B 480 VAC load centers NG02 and NG04 and motor control center (MCC) NG06E could lose power. Redundant PFSSD components are available using Train A load centers NG01 and NG03 and MCC NG05E.
NK	125VDC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-6.
NN	120VAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-6.

3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD

This section describes operator actions that may need to be performed inside or outside the control room to achieve and maintain hot standby if a fire occurs in fire area C-6. This section also describes cold shutdown repairs that may need to be made to achieve and maintain cold shutdown conditions. Operator actions are proceduralized in OFN KC-016.

3.1 ACTIONS OUTSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

None

3.2 ACTIONS INSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

None

3.3 ACTIONS TO ACHIEVE AND MAINTAIN COLD SHUTDOWN

None

4.0 CONCLUSION

Post Fire Safe Shutdown is assured if a fire occurs in fire area C-6.

5.0 DETAILED ANALYSIS

This section describes the detailed component-by-component and cable-by-cable analysis for a fire in area C-6.

5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA C-6

There are no PFSSD components located in fire area C-6.

5.2 PFSSD CABLE EVALUATION

Table C-6-3 lists all the PFSSD cables (S. in E-15000) located in fire area C-6. The applicable evaluation section is also listed in Table C-6-3.

Table C-6-3

16PKG13AA	3211	PK04	P	5.2.8	125 VDC Non-Class 1E Battery Charger

5.2.1 Auxiliary Feedwater

For decay heat removal, the PFSSD design requires the use of one auxiliary feedwater pump (AFP) supplying water to at least two steam generators. The turbine driven auxiliary feedwater pump (TDAFP) is normally aligned to supply all four steam generators. The Train A motor driven auxiliary feedwater pump (MDAFP) is aligned to supply steam generators B and C. The Train B MDAFP is aligned to supply steam generators A and D.

Power cable 14ALB01BA, associated with Train B MDAFP motor DPAL01B, is run in fire area C-6. Damage to this cable could prevent operation of the pump. Redundant Train A MDAFP cables are run in a separate fire area and are unaffected by a fire in area C-6. In addition, the TDAFP is unaffected by a fire in area C-6.

Based on the above discussion, auxiliary feedwater is assured using the Train A MDAFP to supply steam generators B and C or the TDAFP to supply steam generators A, B, C and D.

References: XX-E-013, E-15000, E-13NB04, E-1F9202, E-1F9204, M-12AL01

5.2.2 Centrifugal Charging

At least one centrifugal charging pump (CCP) is required for PFSSD to supply a source of borated water to the RCS and to provide makeup due to inventory loss in the RCS. For PFSSD, the safety related CCPs are credited. The normal charging pump may continue to operate, but it is not credited for PFSSD so it is assumed lost.

A power cable (14BGB01BA) associated with the Train B CCP runs through fire area C-6. Damage to this cable could prevent operation of the pump. Redundant Train A CCP cables are run in a separate fire area and are unaffected by a fire in area C-6. Therefore, PFSSD is assured using Train A CCP if a fire occurs in area C-6.

References: XX-E-013, E-15000, E-13NB04, E-1F9102, E-1F9302, M-12BG03

5.2.3 Essential Service Water System

One train of Essential Service Water (ESW) is required to be operable to ensure adequate cooling for credited PFSSD equipment. The available ESW train needs to be capable of supplying its respective PFSSD loads during the event.

Cables 14EFB01SE and 14EFB01SF are power cables for the Train B ESW pump motor DPEF01B. Cable 14EFB01SB is a control cable associated with Train B ESW pump motor DPEF01B. Cable 14EFK01SA is a control cable for Train B ESW pump local hand switch EFHIS0056B. Damage to these cables could prevent operation of the Train B ESW pump.

Cables 14EFG11SA and 14EFG11TA were originally spare cables but the conductors are now used for various functions at the ESW pumphouse. The PFSSD function supported by these two cables is to control the Train B ESW pump room supply fan. Damage to the cables could prevent operation of the Train B ESW pump room supply fan.

Cable 14EFG02SD is a control cable that provides an automatic start signal to the Train B ESW traveling water screen when the Train B ESW pump runs. Damage to the cable could prevent automatic operation of the screen. Circuits for Train A traveling water screen do not run through area C-6.

Cable 14EFG03SD is a control cable associated with ESW Train B screen wash water valve EFHV0092. Damage to this cable could prevent automatic operation of the valve. Circuits for Train A screen wash water valve EFHV0091 do not run through area C-6.

Cable 14EFG06SD is associated with Train A ESW pump air release valve EFHV0098. The air release valve purges air from the pump casing upon pump start to ensure pump operability.

Damage to the cable could prevent automatic operation of the air release valve. Circuits for Train A ESW pump air release valve EFHV0097 do not run through area C-6.

Pressure transmitter EFPT0002 and flow transmitter EFFT0054 are included in the PFSSD design to provide diagnostic instrumentation of ESW system operation. Cables 14EFI08RB and 14EFI11FA associated with these transmitters are run in fire area C-6. Damage to the cables could prevent proper diagnostic instrumentation of Train B ESW operation. Pressure and flow transmitters associated with the Train A ESW system are unaffected by a fire in area C-6.

Cables 14GDG01BE, 14GDG01BH and 14GDY01BA are associated with Train B ESW pump room supply fan CGD01B control circuit and allow control of the fan from the control room using hand switch GDHIS0011B. Damage to these cables could prevent operation or cause maloperation of the supply fan. If this occurs, the Train B ESW pump room may have insufficient ventilation when the Train B ESW pump is operating.

Cable 14GDI04BA provides ESW B room temperature from temperature element GDTE0011 to temperature controller GDTC0011. Cables 14GDI04BB and 14GDI04BC provide signals from GDTC0011 to outside air intake damper GDTZ0011A and recirculation damper GDTZ0011B, respectively, to change position based on room temperature. Damage to these cables could prevent operation of the dampers. Temperature controls for Train A ESW pump room are unaffected by a fire in area C-6.

Power and control cables associated with a number of valves in the Train B ESW system are run in fire area C-6. Damage to the cables due to a fire could cause the spurious operation or prevent operation of the valves from the control room. If this occurs, redundant valves are available to ensure operability of the Train A ESW system.

Cable 14NGB10SB is associated with Train B ESW pump room load center NG06E feeder breaker NB0216. Cable 14NGG01SA is a power cable from NB0216 to XNG06. Damage to 14NGB10SB could cause the breaker to spuriously trip or spuriously close. Damage to 14NGG01SA could prevent operation of the breaker. Train A ESW pump room load center NG05E is unaffected by a fire in area C-6.

Based on the above discussion, Train B ESW may not be available if a fire occurs in fire area C-6. PFSSD is assured for a fire in area C-6 using Train A ESW pump PEF01A and associated components.

References: E-15000, XX-E-013, E-13EF02, E-13EF02A, E-13EF03, E-13EF06A, E-13EF11, E-K3EF01A, E-K3EF02, E-K3EF03, E-K3EF06, E-K3EF08, E-K3EF11, E-K3GD01A, E-K3GD04A, E-K3NG01, E-K3NG10A, E-1F9402A, E-1F9402B, E-1F9403, E-1F9443, M-12EF01, M-12EF02, M-K2EF01, M-K2GD01

5.2.4 Class 1E 4.16 kV ESF Switchgear Buses NB01 and NB02

One Class 1E 4.16 kV bus is required to power PFSSD equipment in the event of a fire. Bus NB01 normally powers Train A safety related equipment while Bus NB02 normally powers Train B safety related equipment. The normal source of power is from off-site sources while the safety-related source of power is from the emergency diesel generators. Each bus can be cross-trained to the opposite transformer.

Cables 16NBB05AA, 16NBB05AB and 16NBB05AC are power cables that provide the normal off-site source of power from transformer XNB02 to bus NB02. Damage to these cables will cause a loss of off-site power to XNB02. Based on Calculation XX-E-013, Appendix 2, off-site power can be lost to both safety-related buses NB01 and NB02. Therefore, off-site power to NB01 and NB02 could be lost in the event of a fire in this area. As discussed in Section 5.2.3, Train B ESW may not be available. Therefore, the Train B emergency diesel generator may not be available. The Train A emergency diesel generator remains available.

Based on the above discussion, off-site power to NB01 and NB02 could be lost if a fire occurs in this area and the Train B emergency diesel generator may not be available. The Train A emergency diesel generator remains available to energize NB01.

References: E-15000, XX-E-013, E-13NB03, E-13NB05, E-13NB06, E-1F9423

5.2.5 Residual Heat Removal System

The residual heat removal (RHR) system is required to remove decay heat from the RCS during transition from hot shutdown to cold shutdown. At least one RHR train is required to be operable for PFSSD.

A power cable (14EJB01BA) associated with Train B RHR pump motor DPEJ01B is run in fire area C-6. Damage to this cable will prevent operation of the Train B RHR pump. Redundant Train A RHR cables are run in a separate fire area and are unaffected by a fire in area C-6. Therefore, PFSSD is assured using Train A RHR if a fire occurs in area C-6.

References: XX-E-013, E-15000, E-13NB04, E-1F9205

5.2.6 Train A 480 Volt Class 1E Power

One train of class 1E 480 Volt power is required to be operable to energize the credited PFSSD components.

A fire in area C-6 could disrupt power to Train B 480 Volt Class 1E Load Centers NG02 and NG04. Cable 14NGG01AA supplies power from NB0213 to transformer XNG02. Loss of power to XNG02 will interrupt power to load center NG02. Cables 14NGG01AB and 14NGG01AC are power cables that supply power to motor control center (MCC) NG02A. Cable 14NGG01BA supplies power from NB0210 to transformer XNG04. Therefore, all power to NG02 and NG04 could be lost in the event of a fire in area C-6.

Logic diagrams E-1F9424B and E-1F9424D identify all PFSSD components affected by a loss of power to NG02 and NG04. If this occurs, power to redundant Train A components is available using load centers NG01 and NG03, which are unaffected by a fire in area C-6. Therefore, loss of power to Train B components supplied by NG02 and NG04 will not impact the ability to achieve and maintain safe shutdown following a fire in this area.

References: XX-E-013, E-15000, E-13NG01A, E-1F9424A, E-1F9424B, E-1F9424C, E-1F9424D

5.2.7 Non-Class 1E 125 VDC Power

Non-class 1E 125 VDC power is required to energize non-safety related equipment credited for PFSSD. The primary source of 125 VDC power is from inverters that transform 480 VAC to 125 VDC. The backup source of 125 VDC power is from storage batteries.

Cable 16PKG11BA is a power cable that provides 480 VAC power from NG0409 to inverter PK22, which energizes non-class 1E 125 VDC bus PK02. Damage to this cable will disrupt the primary source of power to PK02. Non-class 1E battery rack PK12 is unaffected by a fire in area C-6 and is available to supply short-term power to PK02

Cables associated with non-class 1E 125 VDC bus PK01 are unaffected by a fire in this area. Therefore, long term power remains available to PK01. Components credited for a fire in this area rely on PK01, so loss of PK02 will have no adverse impact on PFSSD.

References: XX-E-013, E-15000, E-11PK01, E-11PK02, E-13PK11, E-1F9422C

5.2.8 Non-Class 1E 125 VDC Battery Charger PK24

Cable 16PKG13AA is the 480 VAC power cable from NG0410 to 125 VDC battery charger PK24. Damage to this cable could result in a loss of the PK24 power feed to 125 VDC bus PK04. PK04 supplies 125 VDC power to 10 kVA inverter PN04, which supplies backup 120 VAC power to RP043 and primary 120 VAC power to RP047.

Redundant power feed to the PK04 bus is unaffected by a fire in area C-6. This power feed originates from 125 VDC battery group PK14 and is normally aligned to feed power to PK04 in the event PK24 is lost.

Based on the above discussion, a fire in area C-6 could result in a loss of power to PK24 but redundant power source PK14 is available and is unaffected by the fire. In addition, redundant power to panels RP043 and RP047 is available from PN310. Therefore, 120 VAC power to panels RP043 and RP047 is available if a fire occurs in fire area C-6.

1.0 GENERAL AREA DESCRIPTION

Fire area C-7 is located on the 1984 elevation of the Control Building and includes the room listed in Table C-7-1.

Table C-7-1
Room Located in Fire Area C-7

ROOM #	DESCRIPTION
3230	Electrical Chase

Fire area C-7 is protected with an automatic wet-pipe sprinkler system and automatic smoke detection. The area is separated on all sides by minimum 3-hour fire resistance rated barriers.

2.0 PRIMARY EQUIPMENT USED FOR PFSSD

Table C-7-2 lists each system credited for post-fire safe shutdown and provides a discussion regarding the availability of the system to perform its Post Fire Safe Shutdown (PFSSD) function if a severe fire occurs in this area. For a summary of the area analysis results, see Section 8.0 of the Fire Area Analysis Narrative section.

Table C-7-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-7

System	System Name	PFSSD Function*	Comments
AB	Main Steam	R, M, H, P, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-7.
AC	Main Turbine	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-7.
AE	Main Feedwater	H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-7.
AL	Aux. Feedwater System	H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-7.
AP	Condensate Storage System	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-7.
BB	Reactor Coolant System	R, M, H, P, S	Reactor coolant pumps A and B may not stop using the control room hand switch. RCP seal injection and thermal barrier cooling remain available. Therefore, the inability to stop the RCPs will have no adverse impact on PFSSD. Pressurizer spray valves BBPCV0455B and BBPCV0455C could spuriously open. If this occurs, pressurizer spray can be stopped by closing KAFV0029 using KAHIS0029 in the main control room.
BG	Chemical and Volume Control System	R, M, S	Letdown isolation valves BGLCV0459 and BGLCV0460 and letdown orifice isolation valves BGHV8149A, BGHV8149B, and BGHV8149C may need to be failed closed by closing valve KAFV0029 using KAHIS0029 in the main control room.
BM	Steam Generator Blowdown System	R, M, H	Valves BMHV0001, BMHV0002, BMHV0003 and BMHV0004 can be isolated using respective handswitches in the main control room.
BN	Borated Refueling Water Storage System	R, M, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-7.
EF	Essential Service Water System	H, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-7.
EG	Component Cooling Water System	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-7.
EJ	Residual Heat Removal System	M, H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-7.

Table C-7-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-7

System	System Name	PFSSD Function*	Comments
EM	High Pressure Coolant Injection	R, M	It may be necessary to charge through the BIT if the letdown flowpath cannot be isolated. The BIT flowpath is available using either Train A or Train B charging pump. Flow diversion through the SIS test line, when charging through the BIT, is prevented by either isolating EMHV8871 or EMHV8964.
EN	Containment Spray	R, M	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-7.
EP	Safety Injection Accumulators	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-7.
FB	Auxiliary Steam	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-7.
FC	Auxiliary Turbines	R, H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-7.
GD	ESW Pump House HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-7.
GF	AFW Pump Room Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-7.
GK	Control Room and Class 1E Switchgear Room Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-7.
GL	Auxiliary Building HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-7.
GM	Emergency Diesel Generator Room HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-7.
GN	Containment Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-7.
JE	Diesel Fuel Oil	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-7.
KA	Instrument Air	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-7.
KC	Fire Protection	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-7.
KH	Service Gas	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-7.

Table C-7-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-7

System	System Name	PFSSD Function*	Comments
KJ	Standby Diesel Engine	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-7.

3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD

This section describes operator actions that may need to be performed inside or outside the control room to achieve and maintain hot standby if a fire occurs in area C-7. This section also describes cold shutdown repairs that may need to be made to achieve and maintain cold shutdown conditions. Operator actions are proceduralized in OFN KC-016.

3.1 ACTIONS OUTSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

None

3.2 ACTIONS INSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

3.2.1 Normal Pressurizer Spray

Pressurizer spray valves BBPCV0455B and BBPCV0455C could spuriously open. If this occurs, the spray can be stopped by isolating air to the valves. This can be accomplished by depressing the CLOSE push button on KAHIS0029 to close KAFV0029. KAHIS0029 is located on RL024. Pressurizer pressure indication is available using BBPI0455A, BBPI0456, BBPI0457 and BBPI0458.

3.2.2 Isolation of Letdown

A fire in area C-7 could prevent valves BGLCV0459, BGLCV0460, BGHV8149A, BGHV8149B, and BGHV8149C from being closed using their associated control room hand switches. If this occurs, the valves can be closed by isolating air to the valves. This can be accomplished by depressing the CLOSE push button on KAHIS0029 to close KAFV0029. KAHIS0029 is located on RL024. Pressurizer level indication is available using BBLI0459A and BBLI0460A.

3.3 ACTIONS TO ACHIEVE AND MAINTAIN COLD SHUTDOWN

None specific to PFSSD.

4.0 CONCLUSION

With some exceptions, redundant Post Fire Safe Shutdown capability exists if a severe fire occurs in area C-7. For those exceptions, feasible manual actions are available and are unaffected by the fire. Manual actions are documented in Section 3.0.

5.0 DETAILED ANALYSIS

This section describes the detailed component-by-component and cable-by-cable analysis for a fire in area C-7.

5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA C-7

There are no PFSSD components located in area C-7. This fire area only contains cables associated with PFSSD equipment located in other areas.

5.2 PFSSD CABLE EVALUATION

Table C-7-3 lists all the PFSSD cables (S. in E-15000) located in fire area C-7. The applicable evaluation section is also listed in Table C-7-3.

Cable #	Location	Primary PFSSD Equipment	Cable Function (P) Power (C) Control (I) Instrumentation	Evaluation Section	Comments
15BBA01AC	3230	DPBB01A	C	5.2.4	Reactor Coolant Pump A Motor

5.2.1 Letdown Isolation Valves

Valves BGLCV0459 and BGLCV0460 are isolation valves installed in series on the inlet side of the regenerative heat exchanger. PFSSD requires that either of these valves be closed.

Cables 15BGK10AA and 15BGK10AD are power/control cables for the BGLCV0459 solenoid valve (BGHY0459). Air supplied by an open (energized) solenoid valve will open valve BGLCV0459. A closed (de-energized) solenoid valve will cause loss of air pressure and closure of valve BGLCV0459.

Cables 15BGK10BA and 15BGK10BD are power/control cables for the BGLCV0460 solenoid valve (BGHY0460). Air supplied by an open (energized) solenoid valve will open valve BGLCV0460. A closed (de-energized) solenoid valve will cause loss of air pressure and closure of valve BGLCV0460.

Either BGLCV0459 or BGLCV0460 must be closed or letdown orifice isolation valves BGHV8149A, BGHV8149B, and BGHV8149C must be closed. The cables for BGLCV0459 or BGLCV0460 are routed in a common enclosure in cable trays. A hot short on the cables could cause the valves to open. A hot short on 15BGK10AA and 15BGK10BA prevents closing BGLCV0459 and BGLCV0460 from the control room. Other cables routed in the cable trays have the proper voltage for hot shorts. The hot shorts bypass MCB hand switches for BGLCV0459 and BGLCV0460. BGLCV0459 and BGLCV0460 constitute a high/low pressure interface. Therefore, multiple simultaneous hot shorts must be considered.

Letdown orifice isolation valves BGHV8149A, BGHV8149B, and BGHV8149C are listed as PFSSD components because of the interlock between these valves and BGLCV0459 and BGLCV0460. The interlock prevents closure of the letdown valves when any one or more orifice isolation valves are open. Cables associated with all three letdown orifice isolation valves are located in this fire area. Damage to these cables could prevent closure of the valves from the control room. Therefore, a fire in area C-7 will prevent closure of all three letdown orifice isolation valves (BGHV8149A, BGHV8149B, and BGHV8149C) as well as the two letdown isolation valves (BGLCV0459 and BGLCV0460).

Valves BGLCV0459, BGLCV0460, BGHV8149A, BGHV8149B, and BGHV8149C are air operated and fail in the closed position. The valves are located in containment. Instrument air to containment is controlled by valve KAFV0029, which is unaffected by a fire in area C-7. Hand switch KAHIS0029 can be used to close the valve from the control room and isolate instrument air to containment. Pressurizer level indication is available using BBLI0459A and BBLI0460A.

Based on the above discussion, letdown valves BGLCV0459 and BGLCV0460 and letdown orifice valves BGHV8149A, BGHV8149B, and BGHV8149C can be closed from the control room if a fire occurs in area C-7.

5.2.2 Steam Generator Blowdown to Blowdown Flash Tank Isolation Valve

The reactivity control function requires the steam generator blowdown to blowdown flash tank valves (BMHV0001, BMHV0002, BMHV0003, and BMHV0004) be closed to prevent reactivity addition from uncontrolled cooldown. Cables 15BMK06AB, 15BMK06BB, 15BMK06CB and 15BMK06DB are associated with the BM157 panel mounted hand switches for each of the BMHV valves. Damage to these cables could impact the ability to close the valves from BM157 in the Radwaste Control Room. However, the normal means of closing these valves using the RL024 mounted hand switches in the Main Control Room remains available. Therefore, a fire in area C-7 will not prevent the closure of valves BMHV0001, BMHV0002, BMHV0003, and BMHV0004.

Panel RP211 is an auxiliary relay rack located in room 1101. Power to this panel is supplied by PK5129 through cable 15RPK09EA. Loss of power to the relay panel will result in loss of power to relay 3XBM46. Calculation XX-E-013 identifies relay 3XBM46 as the only PFSSD related relay located in this enclosure. The function of this relay is to close valves BMHV0001, BMHV0002, BMHV0003, and BMHV0004 if a blowdown and sample process isolation signal is received. Under normal conditions the relay is de-energized, the auxiliary contacts are closed, and valves BMHV0001, BMHV0002, BMHV0003, and BMHV0004 are open.

Loss of power to relay 3XBM46 will result in a loss of automatic valve closure upon receipt of a blowdown and sample process isolation signal. However, the capability to isolate these valves from the control room is unaffected by the fire. In addition, valve position indication on the RL024 panel in the Main Control Room is unaffected by a fire in area C-7.

Based on the above discussion, a fire in area C-7 that damages cables 15BMK06AB, 15BMK06BB, 15BMK06CB, 15BMK06DB and 15RPK09EA will not prevent safe shutdown of the plant due to the availability of redundant capability located in a different fire area.

5.2.3 Boron Injection Tank Flowpath

The Boron Injection Tank (BIT) flowpath is credited for reactivity control and reactor coolant makeup. For reactivity control, the BIT flowpath is credited as an alternate source of boration in the event RCP seal injection is unavailable. Based on Calculation XX-E-013, RCP seal injection will provide sufficient boration to achieve and maintain cold shutdown reactivity conditions. Therefore, the BIT flowpath is not required for reactivity control if RCP seal injection is available. Since RCP seal injection is limited to 5 gpm per seal or 20 gpm total injection to the RCS, an additional RCS charging flowpath is required for adequate RCS makeup during plant transition from hot standby to cold shutdown. The BIT injection path was selected as the additional RCS charging flowpath.

A fire in area C-7 will not result in a loss of seal injection. However, based on the discussion in 5.2.1, a fire in area C-7 has the possibility to cause a momentary loss of inventory through the letdown flow path until the letdown isolation valves are failed closed. Therefore, charging through the BIT flow path may be required for hot standby. In addition, as discussed above, the BIT flowpath is required for transition to cold shutdown.

To prevent CCP flow diversion through the SIS test line when charging through the BIT, valves EMHV8843 and EMHV8882 need to be closed. If either or both of these valves cannot be closed, then closing or maintaining closed either valve EMHV8871 or EMHV8964 will accomplish the PFSSD objective.

Cable 15EMK05EA is a control cable for EMHV8882. A hot short in cable 15EMK05EA will energize the solenoid and open valve EMHV8882. The cable is run in raceways with cables carrying the proper voltage and polarity for a cable to cable hot short. The hot short would bypass the control room handswitch (EMHIS8882) on RL018 and control of this valve from the control room would be lost.

CCP flow diversion through the SIS test line is prevented by valves EMHV8871 or EMHV8964. Cables associated with EMHV8871 and EMHV8964 are run in a different fire area. Therefore, the flow path can be isolated using either EMHV8871 or EMHV8964.

References: E-15000, XX-E-013, E-13EM05A, E-1F9302, M-12EM01, M-12EM02

5.2.4 Reactor Coolant Pumps

The reactor coolant pumps are not credited in the PFSSD analysis. However, the capability to stop the pumps from the control room in the event of a loss of all seal cooling or spuriously open pressurizer spray is credited. Westinghouse Technical Bulletin TB-04-22, Rev. 1 recommends that if all seal cooling is lost (RCP seal injection and thermal barrier heat exchanger flow), operators need to stop the pumps before a seal LOCA occurs. Calculation WCNOC-CP-002 shows that if pressurizer spray spuriously actuates, the spray flow needs to be stopped within 50 minutes.

One control cable associated with reactor coolant pumps A and B is run in fire area C-7. Damage to these cables in the event of a fire could prevent operators from stopping the A and B RCPs from the control room. However, a fire in C-7 will not cause a loss of all seal cooling since RCP seal injection and thermal barrier cooling remain available. As discussed in Section 5.2.5, if pressurizer spray spuriously operates, operators can stop the spray by isolating air to the valve from the control room. Therefore, tripping the RCPs is not required to mitigate spurious pressurizer spray.

Based on the above discussion, the inability to trip RCPs A and B from the control room will have no adverse impact on PFSSD. If pressurizer spray spuriously actuates, the valves can be closed by isolating air to the valves from the control room. In addition, seal injection and thermal barrier cooling are unaffected by a fire in area C-7. Therefore, the RCPs do not have to be tripped in the event of a fire in area C-7.

5.2.5 Normal Pressurizer Spray

The normal pressurizer spray valves are included in the PFSSD design because spurious operation of pressurizer sprays can cause a decrease in pressure which can lead to boiling in the core. The pressurizer spray valves are part of the pressurizer pressure control system.

The pressurizer normal spray valves (BBPCV0455B and BBPCV0455C) operate off a signal from the Ovation pressurizer pressure control system. The operation of the pressure control system is discussed in Calculation XX-E-013.

Cable 15BBI19AA associated with pressurizer spray valve BBPCV0455B, and cable 15BBI19BA associated with pressurizer spray valve BBPCV0455C are run in this area. Damage to these cables could cause the spurious opening of the spray valves.

The pressurizer spray valves are electro/pneumatic operated and loss of air pressure will close the valves. The air supply comes from the compressed air system. Closing valve KAFV0029 using KAHIS0029 on RL024 will isolate compressed air to containment which will cause the pressurizer spray valves to close or prevent them from opening. Based on WCNOC-CP-002, spray flow needs to be stopped within 50 minutes. Since this is a control room action, this can be completed well within 50 minutes.

Based on the above discussion, the pressurizer spray valves could spuriously open if a fire occurs in this area. Pressurizer spray can be stopped by closing valve KAFV0029 from the main control room. Pressurizer pressure indication is available using BBPI0455A, BBPI0456, BBPI0457 and BBPI0458.

1.0 GENERAL AREA DESCRIPTION

Fire area C-8 is located on the 1984 elevation of the Control Building and includes the room listed in Table C-8-1.

Table C-8-1
Rooms Located in Fire Area C-8

ROOM #	DESCRIPTION
3229	South electrical chase.

Fire area C-8 is protected with an automatic wet-pipe sprinkler system and automatic smoke detection. The area is separated on all sides by minimum 3-hour fire resistance rated barriers.

2.0 PRIMARY EQUIPMENT USED FOR PFSSD

Table C-8-2 lists each system credited for post-fire safe shutdown and provides a discussion regarding the availability of the system to perform its Post Fire Safe Shutdown (PFSSD) function if a severe fire occurs in this area. For a summary of the area analysis results, see Section 8.0 of the Fire Area Analysis Narrative section.

Table C-8-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-8

System	System Name	PFSSD Function*	Comments
AB	Main Steam	R, M, H, P, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-8.

UU	Supervisory System	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-8.

* R - Reactivity Control; M - Reactor Coolant Makeup; H - Decay Heat Removal; P - Process Monitoring; S - Support Function

3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD

This section describes operator actions that may need to be performed inside or outside the control room to achieve and maintain hot standby if a fire occurs in area C-8. This section also describes cold shutdown repairs that may need to be made to achieve and maintain cold shutdown conditions. Operator actions are proceduralized in OFN KC-016.

3.1 ACTIONS OUTSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

None

3.2 ACTIONS INSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

None

3.3 ACTIONS TO ACHIEVE AND MAINTAIN COLD SHUTDOWN

None

4.0 CONCLUSION

Post-Fire Safe Shutdown capability is assured if a severe fire occurs in this area.

5.0 DETAILED ANALYSIS

This section describes the detailed component-by-component and cable-by-cable analysis for a fire in area C-8.

5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA C-8

There are no PFSSD components located in area C-8. This fire area only contains cables associated with PFSSD equipment located in other areas.

5.2 PFSSD CABLE EVALUATION

Table C-8-3 lists all the PFSSD cables (S. in E-15000) located in fire area C-8. The applicable evaluation section is also listed in Table C-8-3.

Table C-8-3
PFSSD Cables Located in Fire Area C-8

Cable #	Location	Primary PFSSD Equipment	Cable Function (P) Power (C) Control (I) Instrumentation	Evaluation Section	Comments
16BBA01CC	3229	DPBB01C	C	5.2.1	Reactor Coolant Pump C Motor
16BBA01DC	3229	DPBB01D	C	5.2.1	Reactor Coolant Pump D Motor
16PGA11AC	3229	PA0207	C	5.2.2	Load Centers PG14, PG18, PG20 and PG24 Fdr Bkr

5.2.1 Reactor Coolant Pumps

The reactor coolant pumps are not credited in the PFSSD analysis. However, the capability to stop the pumps from the control room in the event of a loss of all seal cooling is credited. Westinghouse Technical Bulletin TB-04-22, Rev. 1 recommends that if all seal cooling is lost (RCP seal injection and thermal barrier heat exchanger flow), operators need to stop the pumps before a seal LOCA occurs.

One control cable associated with reactor coolant pumps C and D is run in fire area C-8. Damage to these cables in the event of a fire could prevent operators from stopping the C and D RCPs from the control room. However, a fire in C-8 will not cause a loss of all seal cooling since RCP seal injection and thermal barrier cooling remain available.

Based on the above discussion, the inability to trip the C and D RCPs from the control room will have no adverse impact on PFSSD. The pumps can continue to operate, providing forced flow circulation. If the pumps spuriously stop, natural circulation cooldown can be used.

References: E-15000, XX-E-013, E-13BB01, Westinghouse TB-04-22 Rev. 1

5.2.2 Load Center Feeder Breaker PA0207

Load center feeder breaker PA0207 is credited for PFSSD because it supplies power to credited non-safety related loads. Cable 16PGA11AC, associated with PA0207, runs in this area. A fire induced short circuit in this cable will trip the associated breaker.

Breaker PA0207 supplies power to the following PFSSD components:

- PG20GBR217 – MCB Misc. Power Circuits RL023
- PG20GER5 – Instr. Bus Transformer Alt. Feed XPN08D

PFSSD components powered from PG20GBR217 are associated with MSIV downstream components. The MSIVs are unaffected by a fire in this area and can be closed from the control room. Therefore, the MSIV downstream components are not required if a fire occurs in this area.

PG20GER5 is credited as one source of power to PN08. The redundant source of power from NG02BBF1 is unaffected by a fire in this area.

Based on the above discussion, loss of breaker PA0207 will not adversely affect PFSSD if a fire occurs in this area.

1.0 GENERAL AREA DESCRIPTION

Fire area C-9 is located on the 2000'-0" elevation of the Control Building and includes the rooms listed in Table C-9-1.

Table C-9-1
Rooms Located in Fire Area C-9

ROOM #	DESCRIPTION
3301	Train A Engineered Safety Features Switchgear Room

Fire area C-9 is protected with an automatic Halon fire suppression system. In addition, automatic fire detection is installed throughout.

Fire Area C-9 primarily contains cables and equipment for Train A and non-safety related components. Redundant Train B cables and components are located in a separate fire area divided by 3-hour fire rated construction. The 3-hour fire rated barrier provides reasonable assurance that a fire in area C-9 will not affect Train B components and therefore the ability to achieve and maintain safe shutdown in the event of a fire in area C-9 is assured.

2.0 PRIMARY EQUIPMENT USED FOR PFSSD

Table C-9-2 lists each system credited for post-fire safe shutdown and provides a discussion regarding the availability of the system to perform its Post Fire Safe Shutdown (PFSSD) function if a severe fire occurs in this area. For a summary of the area analysis results, see Section 8.0 of the Fire Area Analysis Narrative section.

Table C-9-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-9

System	System Name	PFSSD Function*	Comments
AB	Main Steam	R, M, H, P, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-9.
AC	Main Turbine	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-9.
AE	Main Feedwater	H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-9.
AL	Aux. Feedwater System	H, P	Train A motor driven auxiliary feedwater pump and the turbine driven auxiliary feedwater pump may not be available. Train B motor driven auxiliary feedwater pump is available and is unaffected by the fire.
AP	Condensate Storage System	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-9.
BB	Reactor Coolant System	R, M, H, P, S	Pressurizer PORV Block Valve BBHV8000A may not close. However, PORV BBPCV0455A is unaffected by the fire.
BG	Chemical and Volume Control System	R, M, S	Train A CVCS components may not be available. Train B CVCS components are available and are unaffected by the fire. VCT isolation valve BGLCV0112B may not operate. VCT isolation valve BGLCV0112C is available. Seal injection using Train A flow throttling valve BGHV8357A may not be available. Train B flow throttling valve BGHV8357B is available.
BM	Steam Generator Blowdown System	R, M, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-9.
BN	Borated Refueling Water Storage System	R, M, H	The Train A CCP suction isolation valve from the RWST (BNLCV0112D) may not open. Train B CCP suction isolation valve BNLCV0112E is available. The Train A RHR suction isolation valve from the RWST (BNHV8812A) may not open. Train B RHR suction isolation valve BNHV8812B is available.
EF	Essential Service Water System	H, S	Several Train A ESW components may be affected by a fire in this area. Train B ESW remains available.
EG	Component Cooling Water System	S	Train A CCW pumps PEG01A and PEG01C may be affected. Train B CCW system is available.
EJ	Residual Heat Removal System	M, H, P	Train A RHR pump and miniflow valve EJFCV0610 may be affected. Train B RHR system remains available.
EM	High Pressure Coolant Injection	R, M	Safety Injection pump PEM01A could spuriously start. This can be mitigated by de-energizing the NB01 bus.

Table C-9-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-9

System	System Name	PFSSD Function*	Comments
EN	Containment Spray	R, M	Containment Spray pump PEN01A could spuriously start. This can be mitigated by de-energizing the NB01 bus.
EP	Safety Injection Accumulators	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-9.
FB	Auxiliary Steam	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-9.
FC	Auxiliary Turbines	R, H, P	Valves FCHV0312 and FCFV0313 may be affected by the fire, preventing steam flow to the turbine driven auxiliary feedwater pump. The Train B motor driven auxiliary feedwater pump is unaffected. Valve FCFV0005 may be affected. The MSIVs can be closed using all-close hand switches ABHS0079 or ABHS0080.
GD	ESW Pump House HVAC	S	Train A ESW pump room supply fan CGD01A may not be available. Train B ESW pump room supply fan CGD01B is unaffected.
GF	AFW Pump Room Coolers	S	Train A AFW pump room cooler SGF02A may not be available. Train B AFW pump room cooler SGF02B is unaffected.
GK	Control Room and Class 1E Switchgear Room Coolers	S	The Train A control room and Class 1E room coolers may be affected. The Train B room coolers remain available.
GL	Auxiliary Building HVAC	S	The Train A RHR pump room cooler SGL10A, CCP pump room cooler SGL12A and CCW pump room cooler SGL11A may be affected. Train B room coolers are available.
GM	Emergency Diesel Generator Room HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-9.
GN	Containment Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-9.
JE	Diesel Fuel Oil	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-9.
KA	Instrument Air	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-9.
KC	Fire Protection	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-9.
KH	Service Gas	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-9.

Table C-9-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-9

System	System Name	PFSSD Function*	Comments
KJ	Standby Diesel Engine	S	Power to Train A diesel engine control panel KJ121 could be lost. Train B diesel engine is available.
MA	Main Generation	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-9.
MR	Startup Transformer	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-9.
NB	4.16 kV System	S	Several components associated with Train A 4.16 kV system may be affected. Train B 4.16 kV system is unaffected.
NE	Standby Diesel Generator	S	The Train A diesel generator may be affected. The Train B diesel generator is available.
NF	Load Shed and Emergency Load Sequencing	S	Cables associated with all four undervoltage relays on Train A are run in area C-9. Cables associated with two of the four undervoltage relays on Train B are run in area C-9. Emergency load shed/sequencer operates when 2/4 UV relays sense undervoltage on the bus. Therefore, Train B Load Shed and Emergency Load Sequencing will be available.
NG	480V Load Centers and MCCs	S	Train A 480 V load centers may be affected. Train B 480 V load centers are available.
NK	125VDC	S	Train A 125 VDC Swing Battery Charger NK25 is affected. Redundant Train B Swing Battery Charger NK26 is unaffected. Train A Swing Inverter NN15 DC power source selector switch NK79 may be affected. Train B Swing Inverter NN16 DC power source selector switch NK80 is unaffected.
NN	120VAC	S	The Train A 120 VAC distribution system may be affected. The Train B 120 VAC system is unaffected.
PA	13.8kV	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-9.
PB	4.16kV	H, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-9.
PG	480V Load Centers and MCCs	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-9.
PK	125VDC	S	Battery charger PK21 may be affected. Redundant charger PK22 is unaffected.
PL	Local Instrument Panels	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-9.

Table C-9-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-9

System	System Name	PFSSD Function*	Comments
PN	120VAC	S	One of the two power feeds to non-class 1E 120 VAC panel PN07 may be affected. The redundant power feed to PN07 remains available. Both power feeds to panel PN08 are unaffected.
QB	Standby AC Lighting	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-9.
QD	Emergency Lighting	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-9.
RL	Control Room MCB	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-9.
RP	Miscellaneous Control Panels	R, M, H, P, S	Relay panel RP139 may be affected. Redundant relay panel RP140 is unaffected.
SA	ESFAS	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-9.
SB	Reactor Protection System	R, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-9.
SC	Reactor Instrumentation	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-9.
SE	Ex-Core Neutron Monitoring	R, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-9.
SY	Switchyard	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-9.
UU	Supervisory System	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-9.

* R - Reactivity Control; M - Reactor Coolant Makeup; H - Decay Heat Removal; P - Process Monitoring; S - Support Function

3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD

This section describes operator actions that may need to be performed inside or outside the control room to achieve and maintain hot standby if a fire occurs in area C-9. This section also describes cold shutdown repairs that may need to be made to achieve and maintain cold shutdown conditions. Operator actions are proceduralized in OFN KC-016.

3.1 ACTIONS OUTSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

None

3.2 ACTIONS INSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

3.2.1 De-Energize the NB01 Bus

To mitigate spurious operation of Train A equipment, de-energize the NB01 bus to disable power to the equipment. To ensure NB01 is completely de-energized, place 1HS-SY018 and 1HS-SY022 in pull-to-lock to open switchyard breakers 13-8 and 13-48, respectively. It may also be necessary to de-energize XNB02 if alternate feeder breaker NB0109 spuriously closes. This can be done by opening breaker PA0201 by placing NBHIS0001 in pull-to-lock. If the Train A diesel generator spuriously starts due to loss of power to the bus, then stop the diesel locally using any available means.

3.2.2 Component Cooling Water

Train A CCW could be affected by a fire in this area. If this occurs, swap to Train B CCW using normal operating procedures if Train B CCW is not already running.

3.2.3 Reactor Coolant Pump Seal Cooling

If Train A CCW is operating at the time of the fire, it could be lost causing a temporary loss of thermal barrier cooling. The normal charging pump is not analyzed and is assumed lost. Operators should swap to Train B CCW to restore thermal barrier cooling and line up the Train B CCP to restore RCP seal injection.

3.3 ACTIONS TO ACHIEVE AND MAINTAIN COLD SHUTDOWN

None

4.0 CONCLUSION

With some exceptions, redundant Post-Fire Safe Shutdown capability exists if a severe fire occurs in this area. For those exceptions, feasible manual actions are available and are unaffected by the fire. Manual actions are documented in Section 3.0.

5.0 DETAILED ANALYSIS

This section describes the detailed component-by-component and cable-by-cable analysis for a fire in area C-9.

5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA C-9

PFSSD components (S. in E-15000) located in fire area C-9 are shown in Table C-9-3. An evaluation of each component and associated cables is provided in the sections that follow. The applicable evaluation section is listed in Table C-9-3.

Table C-9-3
PFSSD Equipment Located in Fire Area C-9

Room #	PFSSD Equipment	Description	Evaluation Section	Comments
3301	BBHS8000C	Pressurizer PORV Isolation Valve BBHV8000A Hand Sw.	5.1.1

3301	XNG03	480V Class 1E Load Center Xfmr - Ctrl Bldg	5.1.6	
3301	PN09	Non-Class 1E 120 VAC Inverter	5.1.9	

Table C-9-3 PFSSD Equipment Located in Fire Area C-9				
Room #	**PFSSD Equipment**	**Description**	**Evaluation Section**	**Comments**
3301	PN09A	Non-Class 1E 120 VAC Distribution Panel	5.1.9	

5.1.1 Pressurizer PORV Block Valve BBHV8000A

Hand switch BBHS8000C is used to isolate the control room from the valve control circuit and allows manual closure of the valve at the Motor Control Center. Damage to this switch due to a fire could prevent operation of valve BBHV8000A from the control room. Valve BBHV8000A is required to be closed for PFSSD, or pressurizer PORV BBPCV0455A is required to be closed. Cables for pressurizer PORV BBPCV0455A do not run through area C-9 and are therefore unaffected by a fire in C-9.

Cables 11BBG39AF and 11BBG39AJ, associated with block valve BBHV8000A, are also run through area C-9 and may be damaged by a fire, preventing operation of the valve. This is acceptable for PFSSD as long as PORV BBPCV0455A is able to perform its intended function.

A fire in area C-9 could impact the ability to operate valve BBHV8000A. However, pressurizer PORV BBPCV0455A is unaffected by a fire in area C-9 and remains available to perform its intended function.

References: XX-E-013, E-15000, E-13BB39, E-13BB40, E-1F9301

5.1.2 Train A Class 1E 4.16 kV ESF Switchgear Bus NB01

Bus NB01 supplies power to Train A Engineered Safety Features (ESF) components. A fire in area C-9 could damage NB01 and associated feeder breakers and disrupt power to all Train A ESF components. The following table identifies the NB01 PFSSD feeder breakers that could be lost in the event of a fire in area C-9.

Class 1E 4.16 kV ESF Switchgear Bus NB01	
Feeder Breaker	**Description**
NB0101	RHR Pump A
NB0102	Containment Spray Pump A
NB0103	Safety Injection Pump A
NB0104	Centrifugal Charging Pump A
NB0105	Auxiliary Feedwater Pump A
NB0107	Component Cooling Water Pump A
NB0108	Component Cooling Water Pump C
NB0109	NB01 to XNB02 Transformer
NB0110	480 Volt Load Center NG03
NB0111	Diesel Generator A to NB01
NB0112	ESF XFMR XNB01 to NB01
NB0113	480 Volt Load Center NG01
NB0115	ESW Pump A
NB0116	480 Volt Load Center NG05
NB0117	125 VDC Control Power for NB0101 to NB0117

Control cables associated with these breakers are also run in area C-9. Damage to these cables could cause a loss of capability of the associated equipment. In addition, bus NB01 control room monitoring circuits are located in the area and damage could cause loss of control room monitoring capability.

The main power cables from XNB01 to bus NB01 are run in area C-9. In addition, cables associated with differential protective relay 287/T1 are run in area C-9. Damage to these cables could disrupt power to bus NB01.

Control cables associated with the bus NB01 Synchro-scope and associated switches are run in area C-9. Damage to these cables could prevent some of the monitoring functions for NB01 but would not cause a loss of the NB01 bus.

Redundant Train B ESF components, supplied by NB02, are unaffected by a fire in area C-9. Therefore, loss of power to Train A components identified in the above table due to a fire in area C-9 will not impact the ability to achieve and maintain safe shutdown.

References: XX-E-013, E-15000, E-13NB01, E-13NB02, E-13NB03, E-13NB05, E-13NB13, E-13NE01, E-13NG01A, E-13NG10, E-K3NG01, E-K3NG10

5.1.3 Local Switchgear Mounted Hand Switches

Several local switchgear mounted hand switches are located in area C-9 and could be damaged by a fire, causing the switch contacts to fail in an undesired position. The following table lists each hand switch as well as a description of what the switch serves.

Local Switchgear Mounted Hand Switches on NB01	
Hand Switch	**Description**
NB0102HIS	Containment Spray Pump A
NB0103HIS	Safety Injection Pump A
NB0107HIS	Component Cooling Water Pump A
NB0108HIS	Component Cooling Water Pump C
NB0109HIS	NB01 to XNB02 Transformer
NB0112HIS	ESF XFMR XNB01 to NB01
NB0115HIS	ESW Pump A

Damage to any of these hand switches could cause spurious actuation of the component, which may be undesirable for PFSSD. To prevent maloperation of Train A components, the NB01 bus can be completely de-energized as described in the following paragraphs. In addition, de-energizing the bus ensures the safety of the fire brigade fighting the fire.

If a fire occurs in area C-9, operators can de-energize the NB01 bus by placing hand switches NBHIS0002 (NB01 normal supply breaker NB0112), NBHIS0003 (NB01 alternate supply breaker NB0109), and NEHIS0025 (NB01 emergency supply breaker NB0111) in pull-to-lock. The hand switches are located in the control room but the breakers are located in the fire affected area. If the control room hand switches do not work due to damage to one or more of these breakers, operators can open switchyard breakers 13-8 (Alternate feeder to XNB01) or 13-48 (Normal feeder to XNB01) to de-energize transformer XNB01. This is done by placing control room hand switches 1HS-SY018 (13-8) or 1HS-SY022 (13-48) in pull-to-lock. Cables associated with these hand switches do not run through area C-9.

If the A Train diesel generator NE01 starts upon loss of power to the NB01 bus, and breaker NB0111 closes, then it may be necessary to stop the diesel to prevent energizing the NB01 bus. This can be done using control room hand switch KJHS0008A. If control power is lost due to the fire and KJHS0008A is ineffective in shutting down the diesel, then operators can stop the diesel locally using any method available. Access to the diesel generator room is available without having to traverse through area C-9.

A fire may also cause spurious closure of normally open breaker NB0109, which provides power to NB01 from XNB02. If this occurs, operators can de-energize XNB02 and use Train B diesel generator NE02 to supply power to NB02. To de-energize NB02, operators can open breaker NB0209 by placing control room hand switch NBHIS0004 in pull-to-lock and open breaker PA0201 by placing control room hand switch NBHIS0001 in pull-to-lock.

References: XX-E-013, E-15000, E-13EN01, E-13NB01, E-13NB02, E-13NB03, E-13NB05, E-13NB13, E-13NE01, E-03NG01, E-1000-SY00, E-1000-SY12, E-1000-UU00, E-1005-SY01, E-1005-SY07, KD-7496, SYS NB-320

5.1.4 Train A 480 Volt Class 1E Load Center NG01

A fire in area C-9 could disrupt power to 480 Volt Class 1E Load Center NG01 and associated components. The following table identifies the NG01 PFSSD feeder breakers that could be lost in the event of a fire in area C-9.

Train A Class 1E 480 Volt Load Center NG01	
Feeder Breaker	**Description**
NG0101	Transformer XNG01 to Bus NG01
NG0102	125 Volt Non-Vital Battery Charger PK21
NG0103	125 Volt Vital Battery Charger NK21
NG0105	Train A Control Room A/C Unit
NG0106	Control Building MCC NG01A
NG0107	Auxiliary Building MCC NG01B
NG0108	Train A Containment Cooler (DSGN01A)
NG0109	125 Volt Swing Battery Charger NK25

In addition, load center NG01 transformer XNG01 is located in area C-9 and could be damaged by the fire.

Power and control cables associated with the equipment shown in the above table are also run in area C-9. These cables are listed in Table C-9-4. Damage to these cables due to a fire could cause a loss of the associated equipment.

Cables supplying 125 VDC control power to NG01 breakers from NK51 are run in area C-9. Damage to these cables could prevent operation of the breakers listed in the above table.

Redundant Train B components, supplied by NG02, are unaffected by a fire in area C-9. Therefore, loss of power to Train A components identified in the above table due to a fire in area C-9 will not impact the ability to achieve and maintain safe shutdown.

5.1.5 Train A 480 Volt Class 1E Control Building MCC NG01A

A fire in area C-9 could disrupt power to 480 Volt Class 1E Control Building MCC NG01A and associated components. The following table identifies the NG01A PFSSD MCC breakers that could be lost in the event of a fire in area C-9.

Train A 480 Volt Load Class 1E Control Building MCC NG01A	
MCC Breaker	**Description**
NG01AAF4	Class 1E Electrical Equip A/C Unit (SGK05A)
NG01AAF7	Incoming Line From Load Center NG01
NG01ABF1	Instr Bus Xfmr - Fed By NG01BEF4 (XPN07)
NG01ACF3	RHR Pump Room Cooler Motor (DSGL10A)
NG01ACF5	CCP A Miniflow Isolation Valve (BGHV8110)
NG01ACF6	RHR Mini Flow Iso Valve Loop A (EJFCV610)
NG01ACR1	Train A Control Building 480 Volt Distribution Panel
NG01ACR2	RWST To RHR Pump A Suction Valve (BNHV8812A)
NG01ACR3	Bypass Voltage Regulating Transformer (NN11)
NG01ADF1	Relay Panel
NG01AEF1	Charging Pump A RWST Suction Vlv (BNLCV112D)
NG01AEF3	Terminal Board Section
NG01AER1	ESW A To Ultimate Heat Sink Iso Vlv (EFHV37)
NG01AFF2	VCT Outlet Isolation Valve (BGLCV112B)
NG01AFR3	ESW B To Service Wtr Isolation Vlv (EFHV42)
NG01AFR4	ESW A To Service Wtr Isolation Vlv (EFHV41)
NG01AGF1	ESW A To Service Wtr Cross Connect Vlv (EFHV23)
NG01AGF2	ESW B To Service Wtr Cross Connect Vlv (EFHV24)
NG01AGF3	Bypass Voltage Regulating Transformer (NN13)
NG01AGF4	Bypass Voltage Regulating Transformer (NN15)
NG01AGR1	Centrifugal Charging Pmp Rm Cooler (DSGL12A)
NG01AGR4	CCP A Discharge To RCP Seals Vlv (BGHV8357A)

Power and control cables associated with the equipment shown in the above table are also run in area C-9. These cables are listed in Table C-9-4. Damage to these cables due to a fire could cause a loss of the associated equipment.

Redundant Train B components, supplied by NG02A, are unaffected by a fire in area C-9. Therefore, loss of power to Train A components identified in the above table due to a fire in area C-9 will not impact the ability to achieve and maintain safe shutdown.

References: XX-E-013, E-15000, E-11NG01, E-13NG01A, E-13NN01

5.1.6 Train A 480 Volt Class 1E Load Center NG03

A fire in area C-9 could disrupt power to 480 Volt Class 1E Load Center NG03 and associated components. The following table identifies the NG03 PFSSD feeder breakers that could be lost in the event of a fire in area C-9.

Train A Class 1E 480 Volt Load Center NG03	
Feeder Breaker	**Description**
NG0301	Transformer XNG03 to Bus NG03
NG0303	125 Volt Vital Battery Charger NK23
NG0305	Train A Containment Cooler (DSGN01C)
NG0306	Auxiliary Building MCC NG03C
NG0307	Train A Diesel Generator Room MCC NG03D
NG0308	Train A Diesel Generator Room Supply Fan (DCGM01A)

In addition, load center NG03 transformer XNG03 is located in area C-9 and could be damaged by the fire.

Power and control cables associated with the equipment shown in the above table are also run in area C-9. These cables are listed in Table C-9-4. Damage to these cables due to a fire could cause a loss of the associated equipment.

Cables supplying 125 VDC control power to NG03 breakers from NK51 are run in area C-9. Damage to these cables could prevent operation of the breakers listed in the above table.

Redundant Train B components, supplied by NG04, are unaffected by a fire in area C-9. Therefore, loss of power to Train A components identified in the above table due to a fire in area C-9 will not impact the ability to achieve and maintain safe shutdown.

References: XX-E-013, E-15000, E-11NG01, E-13NG01A, E-13NG11

5.1.7 Swing Battery Charger NK25

Swing battery charger NK25 provides backup power and battery charging to Train A 125 VDC busses NK01 and NK03 and battery banks NK11 and NK13. Swing battery charger NK25 allows battery chargers NK21 or NK23 to be taken out of service without loss of power to NK01 or NK03. A fire in area C-9 could cause damage to battery charger NK25, or could cause a loss of 480 VAC power to the battery charger, which would render it inoperable. In addition, the fire could cause damage to the power cables between NK25 transfer switch NK75 and transfer switches NK71 and NK73.

Battery chargers NK21 and NK23, and battery banks NK11 and NK13 are located in a different fire area. However, cables supplying 480 VAC power to battery chargers NK21 and NK23 are run in area C-9. Power to these chargers is supplied by 480 VAC breakers NG0103 (NK21) and NG0303 (NK23). In the event a fire in C-9 damages battery charger NK25, and disrupts charging power to NK21 and NK23, power to Train A busses NK01 and NK03 will still be available through battery banks NK11 and NK13, since the batteries are unaffected by a fire in area C-9. In the event power to NK01 and NK03 is unavailable, redundant Train B 125 VDC system remains available.

Transfer switches NK75 and NK77 are also located in area C-9. Damage to these switches and associated cables due to a fire will have no adverse impact on safe shutdown due to the availability of redundant Train B components in a different fire area.

Hand switches NKHS0109 and NKHS0025 may also be damaged by the fire. However, due to the availability of Train B 125 VDC system, this will have no adverse impact on PFSSD.

Based on the above discussion, a loss of swing battery charger NK25 and associated transfer switches will not adversely impact the ability to achieve and maintain safe shutdown due to the availability of redundant Train B components.

5.1.8 Auxiliary Relay Rack RP139

Relay rack RP139 contains a number of PFSSD relays used for operation of Train A equipment. The following table identifies the PFSSD relays located in panel RP139.

RP139 Auxiliary Relays	
Relay #	**Description**
1XEF31	ESW Pump Motor A Interposing Relay
1XEF33	ESW Pump Motor A Interposing Relay
1XEF35	ESW Pump Motor A Interposing Relay
3XEG01	CCW Pump A Auxiliary Relay
3XEG03	CCW Pump C Auxiliary Relay
62XBB01	Pressurizer PORV Block Valve Auxiliary Relay
62XBB03	Pressurizer PORV Block Valve Auxiliary Relay
63TDEEG02	CCW Pump A Auxiliary Relay
63TDEEG04	CCW Pump C Auxiliary Relay
83XGK03	GKHZ0029A/29B Auxiliary Relay
K1119	Load Sequencer Relay

A fire in area C-9 could damage panel RP139 and associated PFSSD relays shown in the above table. In addition, cables supplying 125 VDC and 120 VAC power to the various relays within RP139 are run in area C-9. Damage to the power cables and/or relays could prevent operation of the associated component, or could cause the component to spuriously operate. If the components spuriously operate, PFSSD is assured since spurious operation of these components will not have an adverse impact on the ability to achieve and maintain PFSSD.

Redundant relay panel RP140, containing redundant PFSSD relays for Train B components, is located in fire area C-10 and is unaffected by a fire in area C-9. Cables associated with RP140 do not run through area C-9.

References: XX-E-013, E-15000, E-13RP09

5.1.9 Steam Generator Feedwater Pumps

Main feedwater pump steam supply valves FCFV0005 and FCFV0105 are credited in the PFSSD analysis to trip the main feedwater pumps if the main steam isolation valves (MSIVs) are affected by a fire. Closing the MSIVs stops steam flow to the feedwater pumps' turbines and stops the feedwater pumps. The steam generator feedwater pumps are tripped in the event of a fire to prevent overfilling the steam generators.

Non-Class 1E 120 VAC Inverter PN09 and distribution panel PN09A provide power to FCFV0005 trip relays in panel FC169C. Cable 15RPY10AA supplies power from PN0712 to

inverter PN09. Cable 15RPY10AB supplies power from inverter PN09 to distribution panel PN09A. Cable 15FCY35AA provides the primary source of 120 VAC power from distribution panel PN09A to panel FC169A, which distributes power to the trip relays in panel FC169C. The alternate source of power to panel FC169A is not credited for PFSSD and is assumed lost.

A fire in area C-9 could damage inverter PN09, distribution panel PN09A or cables 15FCY35AA, 15RPY10AA and 15RPY10AB. If this occurs, operators in the control room would not be able to close valve FCFV0005 to stop steam flow to steam generator feedwater pump PAE01A.

A fire in area C-9 will not affect the ability to close the MSIVs from the control room. All-close hand switches ABHS0079 and ABHS0080 are unaffected and can be used to close the MSIVs from the control room.

Based on the above discussion, valve FCFV0005 may not close if a fire occurs in this area. However, the MSIVs can be closed using either hand switch ABHS0079 or ABHS0080 in the main control room. Therefore, the configuration is acceptable.

5.2.1 Auxiliary Feedwater Pump A (PAL01A)

Power and control cables associated with Train A auxiliary feedwater pump are run through area C-9. Damage to these cables could prevent operation of the pump. Redundant Train B auxiliary feedwater pump cables are run in a separate fire area and are unaffected by a fire. Therefore, PFSSD is assured using Train B auxiliary feedwater pump if a fire occurs in area C-9.

References: XX-E-013, E-15000

5.2.2 Centrifugal Charging Pumps

At least one centrifugal charging pump (CCP) is required for PFSSD to provide RCP seal cooling, reactivity control and inventory control. These functions are accomplished using a CCP taking suction from the refuelling water storage tank (RWST) and injecting through the RCP seals. RCP seal injection provides approximately 20 gpm makeup to the RCS and provides adequate boron concentration to maintain sub-critical reactivity conditions. If RCP seal injection is unavailable, reactivity and inventory control is provided by lining up the CCPs to the boron injection tank (BIT). The normal charging pump (NCP) is not credited and is assumed lost.

Power and control cables associated with Train A Centrifugal Charging Pump (CCP) are run through area C-9. Damage to these cables could prevent operation of the pump. Redundant Train B CCP cables are run in a separate fire area and are unaffected by a fire. Therefore, PFSSD is assured using Train B CCP if a fire occurs in area C-9.

Power and control cables associated with Train A charging pump miniflow valve BGHV8110 are run through area C-9. Redundant Train B cables for miniflow valve BGHV8111 are run in a different area and are unaffected by a fire in area C-9. Therefore, PFSSD is assured using Train B CCP miniflow valve if a fire occurs in area C-9.

Power and control cables associated with Train A CCP room cooler SGL12A are run in area C-9. Damage to these cables will prevent operation of the room cooler. Train B CCP room cooler SGL12B circuits do not run in area C-9 and are unaffected by a fire. Therefore, Train B CCP room cooler will be available.

Based on the above discussion, the Train A CCP could be affected but the Train B CCP is available if a fire occurs in area C-9.

References: XX-E-013, E-15000, E-13BG01, E-13BG11B, E-13GL05, E-13NB01

5.2.3 Volume Control Tank (VCT) Isolation Valve (BGLCV0112B)

Power and control cables associated with VCT valve BGLCV0112B run through fire area C-9. Cables for redundant VCT valve BGLCV0112C are run in a separate fire area and are unaffected by a fire in area C-9. The PFSSD position of these valves is at least one closed. Therefore, PFSSD can be accomplished by isolation of BGLCV0112C.

Cable damage due to a fire could bypass the BNLCV0112D interlock and cause inadvernent closure of BGLCV0112B. If this occurs prior to establishing suction from the RWST, damage to the operating charging pump could occur due to loss of suction. Calculation XX-E-013, assumption 3-A-22, states that systems and components are in their normal operating position or status prior to the fire. The Normal Charging Pump (NCP) is the normally operated pump and is assumed to be operating at the time of the fire. Inadvertent closure of valve BGLCV0112B with no suction from the RWST would result in damage to the NCP but the

centrifugal charging pumps would remain unaffected. As stated in 5.2.2, the A Train CCP could be unavailable but the B Train CCP is unaffected by the fire.

Based on the above discussion, the ability to achieve and maintain PFSSD is unaffected by a fire in area C-9 which affects VCT valve BGLCV0112B. Therefore, the configuration is acceptable.

References: XX-E-013, E-15000, E-13BG12, E-13BN01

5.2.4 Reactor Coolant Pump Seal Injection

PFSSD requires RCP seal injection to provide a boron injection path, provide makeup to the RCS and provide cooling to the RCP seals. The redundant boron injection and makeup path is through the boron injection tank (BIT). The redundant seal cooling method uses thermal barrrier cooling.

Power and control cables associated with Train A RCP seal injection flow throttling valve BGHV8357A are run in area C-9. Damage to these cables will prevent operation of the valve from the control room. Cables associated with redundant Train B valve BGHV8357B are run in a separate fire area and are unaffected by a fire in area C-9.

Based on the above discussion, PFSSD is assured using Train B charging pump and aligning RCP seal injection flow through BGHV8357B.

References: XX-E-013, E-15000, E-13BG52, M-12BG03

5.2.5 RWST To Charging Pump A Isolation Valve (BNLCV0112D)

Power and control cables associated with normally closed valve BNLCV0112D are run in area C-9. Damage to these cables will prevent operation of the valve from the control room. PFSSD requires suction from the RWST to the operating charging pump. Cables associated with redundant Train B valve BNLCV0112E are run in a separate fire area and are unaffected by a fire in area C-9.

Based on the above, PFSSD is assured using Train B charging pump and aligning suction through BNLCV0112E. Therefore, the configuration is acceptable.

References: XX-E-013, E-15000, E-13BN01

5.2.6 RWST To RHR Pump A Isolation Valve (BNHV8812A)

Power and control cables associated with normally open valve BNHV8812A are run in area C-9. Damage to these cables will prevent operation of the valve from the control room. This by itself does not cause a concern for PFSSD. However, if this valve were to remain open while EJHV8811A spuriously opened, the RWST would drain to the containment sump. Cables associated with valve EJHV8811A do not run in area C-9, so the valve cannot spuriously open. Therefore, draindown of the RWST to the containment sump is prevented in the event of a fire in area C-9.

References: XX-E-013, E-15000, E-13BN03

5.2.7 Essential Service Water Pumps and Associated Components

Either the Train A or the Train B essential service water (ESW) system is required to be available to ensure PFSSD. The ESW system supplies water to the following PFSSD components on the associated train:

- CCP room cooler
- RHR pump room cooler
- Class 1E switchgear room A/C condenser
- diesel generator engine cooling
- control room A/C condenser
- auxiliary feedwater pump room cooler
- motor and turbine driven auxiliary feedwater pump suction (backup to CST)
- containment air coolers
- electrical penetration room cooler
- component cooling water pump room cooler
- component cooling water heat exchanger
- component cooling water system makeup

Power and control cables associated with ESW pump A are run in area C-9. Damage to these cables will prevent the pump from operating. Cables associated with redundant Train B ESW pump PEF01B are run in a separate fire area and are unaffected by a fire in area C-9.

Cable 11EFG02SD is a control cable that provides an automatic start signal to the Train A ESW traveling water screen when the Train A ESW pump runs. An intra-cable short between the two conductors in this cable will start the screen in the absence of a running pump. If this occurs, operators can stop the screen using EFHIS0003 in the control room. An open in this cable will prevent the automatic start of the screen but operators can start it using EFHIS0003 in the control room. A short to ground would blow the CPT secondary side fuse and drop power to the control circuit, preventing the screen from operating. As stated in the previous paragraph, Train A ESW pump may not be available due to a fire in area C-9 but Train B ESW pump is available. Circuits for Train B traveling water screen do not run through area C-9.

Cable 11EFG03SD is a control cable associated with ESW Train A screen wash water valve EFHV0091. Damage to this cable could prevent operation of the valve. As stated above, Train A ESW pump may not be available due to a fire in area C-9 but Train B ESW pump is available. Circuits for Train B screen wash water valve EFHV0092 do not run through area C-9.

Cables 11EFG06SD and 11EFG06SE are associated with Train A ESW pump air release valve EFHV0097. Cable 11EFY10CA is a control cable associated with the air release valve time delay relay. The air release valve purges air from the pump casing upon pump start to encure pump operability. The time delay relay closes the air release valve after 15 seconds of ESW pump operation. Circuits for Train B ESW pump air release valve EFHV0098 do not run through area C-9 and are unaffected by the fire.

Cable 11EFK01SB is a control cable associated with the local start and stop switch for Train A ESW pump motor DPEF01A. Cable damage due to a fire could bypass local hand switch EFHIS0055B, located on control panel EF155, and spuriously start the Train A ESW pump. This would not adversely impact PFSSD due to the continued availability of the Train B ESW pump.

Cable 11GDY01AB is associated with the automatic start on the Train A ESW pump room supply fan control circuit. Upon start of the Train A ESW pump, the contacts on this circuit close and energize the ARC relay, which closes a contact to start the supply fan. A bistable

element will prevent the fan from starting if the room temperature is below a pre-determined set point. Cable damage due to a fire could spuriously start the fan or prevent it from starting. In either case, PFSSD is assured using the Train B ESW pump room supply fan, which is unaffected by a fire in area C-9.

Cable 11RPY10BA supplies 120 VAC control power to the automatic and manual start circuits for the Train A ESW pump room supply fan CGD01A. The control power is supplied via this cable to control room panel RP068 and is distributed to a number of fuse blocks including 1FU3, which provides circuit protection for CGD01A control power. If power is lost to the control circuit due to damage to this cable, then the Train A ESW pump room supply fan will not start either automatically, when the ESW pump starts, or manually from the control room. If this occurs, the Train B ESW pump room supply fan remains unaffected by the fire.

Based on the above discussion, Train A ESW may be affected by a fire in area C-9. PFSSD is assured for a fire in area C-9 using Train B ESW pump PEF01B and associated components.

References: XX-E-013, E-15000, E-13RP10, E-K3EF01, E-K3EF02, E-K3EF03, E-K3GD01, J-201-00137, J-201-00139

5.2.8 Essential Service Water To Service Water and UHS Isolation Valves

The Essential Service Water (ESW) system supplies water to various PFSSD components on the associated train. In order to ensure proper flow of ESW to the supplied loads, valves in the system need to be in the proper lineup.

Valve EFHV0023 is a normally open isolation valve on the service water system feed to the Train A Essential Service Water System. Either this valve or valve EFHV0025 is required to be closed when operating the Train A ESW system for PFSSD. Power and control cables associated with EFHV0023 are run in this area. Damage to these cables could prevent closing EFHV0023 from the control room. Redundant valve EFHV0025 is unaffected by a fire in area C-9 and can be closed from the control room to isolate this flowpath. In addition, check valve EFV0470 is installed in this line and will prevent flow diversion in the unlikely event valve EFHV0025 cannot be closed.

Valve EFHV0024 is a normally open isolation valve on the service water system feed to the Train B Essential Service Water System. Either this valve or valve EFHV0026 is required to be closed when operating the Train B ESW system for PFSSD. Power and control cables associated with EFHV0024 are run in this area. Damage to these cables could prevent closing EFHV0024 from the control room. Redundant valve EFHV0026 is unaffected by a fire in area C-9 and can be closed from the control room to isolate this flowpath. In addition, check valve EFV0471 is installed in this line and will prevent flow diversion in the unlikely event valve EFHV0026 cannot be closed.

Valve EFHV0041 is a normally open isolation valve on the return line from the Train A Essential Service Water System to the service water system. Either this valve or valve EFHV0039 is required to be closed when operating the Train A ESW system for PFSSD. Power and control cables associated with EFHV0041 are run in this area. Damage to these cables could prevent closing EFHV0041 from the control room. Redundant valve EFHV0039 is unaffected by a fire in area C-9 and can be closed from the control room to isolate this flowpath.

Valve EFHV0042 is a normally open isolation valve on the return line from the Train B Essential Service Water System to the service water system. Either this valve or valve EFHV0040 is required to be closed when operating the Train B ESW system for PFSSD. Power and control cables associated with EFHV0042 are run in this area. Damage to these cables could prevent closing EFHV0042 from the control room. Redundant valve EFHV0040 is

unaffected by a fire in area C-9 and can be closed from the control room to isolate this flowpath.

Valve EFHV0037 is the Train A return isolation valve from ESW to the Ultimate Heat Sink. This valve is required to be open when operating the Train A ESW system for PFSSD. Power and control cables associated with this valve is run in this area and damage could cause the valve to spuriously close. Circuits for redundant Train B valve EFHV0038 are not run in area C-21 and will be unaffected by the fire.

Based on the above discussion, several Train A valves associated with the ESW system could be affected by a fire in this area but redundant Train B valves are unaffected.

References: XX-E-013, E-15000, E-13EF02, E-13EF02A, E-13EF03, E-1F9402A, E-1F9402B, E-1F9403

5.2.9 Component Cooling Water (CCW)

For PFSSD, the component cooling water (CCW) system is used to provide cooling to the centrifugal charging pump (CCP) oil cooler, seal water heat exchanger, RHR heat exchangers and RHR pump seal coolers. In addition, the CCW system provides cooling to the RCP thermal barriers and is credited as a backup to RCP seal injection for maintaining seal cooling.

Power and control cables associated with Train A CCW pump motors DPEG01A and DPEG01C are run through area C-9. Damage to these cables could prevent operation of either pump or could cause the spurious operation of either or both pumps. Power to these pumps are supplied by 4.16 kV bus NB01. As stated earlier, bus NB01 can be completely de-energized if a fire occurs in area C-9. Therefore, spurious operation of the pumps can be mitigated.

Cable 11GLG06AD is associated with the automatic start circuit for the Train A CCW pump room cooler SGL11A. With hand switch GLHIS0002 in AUTO position, operation of either Train A CCW pump will close a contact in this circuit and start the room cooler. Damage to this cable due to a fire will either spuriously start the room cooler, prevent it from starting or blow the CPT secondary side fuse and drop power to the control circuit. In either case, Train B CCW room cooler SGL11B is unaffected by a fire in area C-9.

Power and control cables associated with Train A CCW Pump Room cooler exhaust dampers GLHZ0080 and GLHZ0081 are run in area C-9. Damage to these cables could prevent operation of the dampers. There are no exhaust dampers associated with Train B CCW pump room cooler.

Cable 11EGG05CD, associated with Train A CCW valve EGHV0053, is run in this area. This cable supplies power to auxiliary relay 3XEG9 which provides permissives to open or close valves in the CCW supply to and from the Radwaste building. If Train A CCW is operating at the time of the fire, valve EGHV0053 will be open. Damage to cable 11EGG05CD could cause the control power fuse to blow and prevent closure of EGHV0053 when lining up Train B CCW. A loss of power to NB01, which is possible if a fire occurs in this area, could also prevent closure of valves EGHV0015 and EGHV0053. Operation of Train B CCW with valves EGHV0015 and EGHV0053 open could cause Train B CCW flow to divert to Train A CCW system. Per calculation M-EG-24, the system will continue to operate with no damage to the pumps if the valves in the opposite train are open.

Train B CCW pumps PEG01B and PEG01D are unaffected by a fire in area C-9 and will be used to provide essential cooling to supplied Train B PFSSD components. Therefore, PFSSD is assured using Train B CCW system if a fire occurs in area C-9.

References: XX-E-013, E-15000, E-13EG01A, E-13EG01B, E-13EG05B, E-13NB02, Calculation M-EG-24

5.2.10 Residual Heat Removal System

Power and control cables associated with Train A RHR pump motor DPEJ01A are run through area C-9. Damage to these cables could prevent operation or cause spurious operation of the pump. Power to this pump is supplied by 4.16 kV bus NB01. As stated earlier, bus NB01 can be completely de-energized if a fire occurs in area C-9. Therefore, spurious operation of the pump can be mitigated. Power and control cables associated with Train B RHR pump motor DPEJ01B are not run through area C-9 and will be unaffected by the fire.

Power and control cables associated with Train A RHR pump miniflow valve EJFCV0610 are run in area C-9. Damage to these cables could prevent operation of the valve and cause damage to the Train A RHR pump, if it is operating. Train B RHR miniflow valve EJFCV0611 is unaffected by a fire in area C-9.

Power and control cables associated with Train A RHR pump room cooler SGL10A are run in area C-9. Damage to these cables will prevent operation of the room cooler. Train B RHR room cooler SGL10B circuits do not run in area C-9 and are unaffected by a fire. Therefore, Train B RHR room cooler will be available.

Train B RHR pump PEJ01B and associated components are unaffected by a fire in area C-9 and will be used to provide decay heat removal during cold shutdown. Therefore, PFSSD is assured using Train B RHR system if a fire occurs in area C-9.

References: XX-E-013, E-15000, E-13EJ01, E-13GL05, E-13NB01

5.2.11 Safety Injection (SI) Pumps

Spurious start of the SI pumps may complicate PFSSD due to the depletion of inventory in the RWST. Therefore, a spurious start of the SI pumps should be avoided or mitigated. A control cable associated with the Train A SI pump PEM01A runs through area C-9 and could cause the spurious start of the pump. The damage could prevent stopping the pump from the control room. The pump is powered from the 4.16 kV bus NB01. As stated earlier, the NB01 bus can be completely de-energized if a fire occurs in area C-9. Therefore, spurious operation of the pump can be mitigated.

References: XX-E-013, E-15000, E-13EM01, E-13NB01

5.2.12 Containment Spray (CS) Pumps

Spurious start of the CS pumps may complicate PFSSD due to the depletion of inventory in the RWST. Therefore, a spurious start of the CS pumps should be avoided or mitigated. A control cable associated with the Train A CS pump PEN01A runs through area C-9 and could cause the spurious start of the pump. The damage could prevent stopping the pump from the control room. The pump is powered from the 4.16 kV bus NB01. As stated earlier, the NB01 bus can be completely de-energized if a fire occurs in area C-9. Therefore, spurious operation of the pump can be mitigated.

References: XX-E-013, E-15000, E-13EN01, E-13NB01

5.2.13 Auxiliary Feedwater Pump (AFWP) Room Cooler

Cable 11GFG01AC is associated with the automatic start circuit on the Train A AFWP room cooler SGF02A. Upon start of the Train A AFWP, the contact associated with this circuit will close and the room cooler will start, as long as the hand switch is in the auto position. Damage to the cable due to a fire will either spuriously start the cooler or prevent it from automatically starting. In either case, the local hand switch (GFHIS0015) can be used to control the room cooler, provided a short to ground has not caused a loss of power to the control circuit.

Circuits associated with Train B AFWP room cooler SGF02B do not run through area C-9 and are unaffected by the fire. Therefore, PFSSD is assured using Train B Motor Driven AFWP to provide auxiliary feedwater to steam generators A and D if a fire occurs in area C-9.

References: XX-E-013, E-15000, E-13GF01

5.2.14 Control Room A/C Units

Cable 11GKG02AA is the SGK04A 480 VAC power cable from Load Center NG0105 to power and control panel GK198C. Damage to this cable due to a fire could prevent operation of Train A Control Room A/C unit SGK04A. Circuits for Train B Control Room A/C unit SGK04B do not run through area C-9 and are unaffected by a fire.

Power and control cables associated with Train A Control Room A/C unit supply and return dampers GKHZ0029A and GKHZ0029B are run in area C-9. Damage to these cables could prevent operation of the associated dampers. Circuits for Train B Control Room A/C unit dampers do not run in area C-9.

Based on the above discussion, Control Room environmental conditions will be unaffected by a fire in area C-9.

References: XX-E-013, E-15000, E-13GK02B, E-13GK02C

5.2.15 Class 1E Electrical Equipment Room A/C Unit

Power and control cables associated with Train A Class 1E Electrical Equipment room A/C unit SGK05A are run in area C-9. A fire could damage these circuits and prevent operation of the unit. Circuits for Train B Class 1E Electrical Equipment A/C unit SGK05B do not run in area C-9. Train B equipment is primarily used if a fire occurs in area C-9.

Based on the above discussion, Train B class 1E equipment room cooling is available and is unaffected by a fire in area C-9.

References: XX-E-013, E-15000, E-13GK13

5.2.16 Standby Diesel Generator Power Availability

Several cables associated with Train A diesel generator power and control are run in area C-9. Damage to these cables could prevent the Train A diesel generator from automatically or manually lining up to supply power to NB01. Train B diesel generator power and control circuits do not run in area C-9 and are unaffected by the fire.

Cable 11KJK01AA provides 125 VDC power to panel KJ121. Damage to this cable could prevent operation of the Train A diesel generator due to the loss of control power to the stop and control circuits. Cables associated with Train B diesel generator control panel KJ122 do not run in area C-9.

Based on the above discussion, the Train B diesel generator is unaffected by the fire and can be lined up to supply essential PFSSD equipment if a fire occurs in area C-9.

References: XX-E-013, E-15000, E-13KJ01A, E-13NE01, E-13NE10, E-13NE12

5.2.17 Load Shedder / Emergency Load Sequencer

The load shedder and emergency load sequencers are included in the PFSSD design to evaluate the impact of spurious operation or mal-operation. The load shedder/emergency load sequencer operates upon presence of the following conditions:

1. An undervoltage (UV) on a safeguards bus,
2. A safety injection signal (SIS) or a containment spray actuation signal (CSAS), or
3. An undervoltage on a safeguards bus with a SIS or CSAS.

Eight inputs (four undervoltage (UV) inputs and four degraded voltage inputs) on each safeguards bus (NB01 and NB02) monitor voltage conditions on that bus. An undervoltage condition on two of four UV relays on each bus will actuate the load shedder/sequencer and send a signal to start the associated diesel generator. In addition, degraded voltage sensed by two of four degraded voltage potential transformers (PTs) will, after a time delay, provide a signal to open the offsite feeder breakers on the associated bus. This will, in turn, initiate an undervoltage condition and actuate the load shedder/sequencer and send a signal to start the associated diesel generator.

Cables associated with all four UV relays on NB01 and two of four UV relays on NB02 are run in area C-9. In addition, cables associated with all four PTs on NB01 and two of four PTs on NB02 are run in area C-9. Damage to these cables could provide a false undervoltage/degraded voltage condition on both safegaurds buses.

If both trains of diesel generators start and the load shedder/sequencer actuates, there will be no adverse impact on PFSSD. Therefore, a fire in area C-9 involving cables associated with the under voltage/degraded voltage signals will not adversely impact the ability to achieve and maintain safe shutdown.

References: XX-E-013, E-15000, E-11NB01, E-11NB02, E-12NF01, E-13NF01, E-10NF, E-1F9411A, E-1F9411B, E-1F9412A, E-1F9412B, E-1F9402A, E-1F9402B, E-1F9403, E-1F9425, E-1F9426

5.2.18 Class 1E 120 VAC Electrical Distribution System

The Class 1E 120 VAC electrical distribution system provides power to vital instrumentation and control loads for shutdown and normal operation. Under normal conditions, the system is supplied by inverters connected to the 125 VDC NK battery system. Swing inverters allow the primary inverters to be taken out of service for maintainance or repair without disrupting power to the associated vital AC bus. In the event of a loss of power to the inverters, a backup source of power is automatically lined up. The backup power source originates from the 480 VAC electrical distribution system (NG).

Cable 11NNG01AA supplies 480 VAC power from NG0~~0~~1ACR3 to inverter NN11. Cable 11NNG01BA supplies 480 VAC power from NG01AGF4 to swing inverter NN15. Cable 11NNG01CA supplies 480 VAC power from NG01AGF3 to inverter NN13. Damage to these cables will disrupt the 480 VAC power source to Inverters NN11, NN13 and NN15.

Cables 11NNK01JA and 11NNK01JB supply 125 VDC power from NK0103 to manual transfer switch NK79. Cables 13NNK01KA and 13NNK01KB supply 125 VDC power from NK0303 to manual transfer switch NK79. Cables 11NNK01JC and 11NNK01JD supply 125 VDC power

from manual transfer switch NK79 to swing inverter NN15. Damage to these cables will disrupt the 125 VDC power supply to swing inverter NN15.

Cables 11NNY01EA and 11NNY01EB supply 120 VAC power from swing inverter NN15 to bus NN01 through a manual transfer switch in inverter NN11. Cables 13NNY01FA and 13NNY01FB supply 120 VAC power from swing inverter NN15 to bus NN03 through a manual transfer switch in inverter NN13. Damage to these cables will disrupt the 120 VAC power supply from swing inverter NN15 to the associated 120 VAC distribution panel.

Inverters NN11 and NN13 and 120 VAC vital distribution buses NN01 and NN03 are located in a separate fire area and are unaffected by a fire in area C-9. The 125 VDC power supply to inverters NN11 and NN13 is unaffected by a fire in area C-9. However, as stated in other sections of this evaluation (5.1.4, 5.1.6, 5.1.7), a fire in area C-9 could cause a loss of 480 VAC power to the Train A NK battery chargers (NK21, NK23 and NK25) which will cause a loss of normal power to the NK01 and NK03 125 VDC busses. Batteries NK11 and NK13 are unaffected and can supply 125 VDC to busses NK01 and NK03 to provide power to inverters NN11 and NN13 for a limited time.

Train B vital 120 VAC distribution panels NN02 and NN04 are unaffected by a fire in area C-9. Therefore, in the event of a loss of Train A Class 1E 120 VAC electrical distribution system, the Train B Class 1E electrical distribution switchboards are available to supply redundant PFSSD loads.

Based on the above discussion, damage to cables and components associated with Train A vital 120 VAC distribution panels NN01 and NN03 will not adversely impact the ability to achieve and maintain safe shutdown in the event of a fire in area C-9.

References: XX-E-013, E-15000, E-13NN01

5.2.19 Non-Class 1E 120 VAC Electrical Distribution System

The PFSSD function of the non-Class 1E 120 VAC electrical distribution system is to supply 120 VAC power to Main Control Boards RL017/RL018 and RL021/RL022. The power is split at each MCB to supply specific PFSSD components.

Cables 11PNG01AD and 11PNG01AE supply 480 VAC power from NG001BEF4 to 480/120V transformer XPN07A. Damage to either of these cables due to a fire in area C-9 will result in a loss of power to the transformer and loss of 120 VAC feed to PN07 from this power source. A redundant source of power to PN07 exists. The redundant power feed originates from PG19GFR3 (480 VAC) and supplies 480/120V transformer XPN07D. Transformer XPN07D supplies 120 VAC power to voltage regulator PN07A which then supplies the alternate source of power to PN07.

Cables associated with the alternate power feed to PN07, through transformer XPN07D, do not run in area C-9 and are unaffected by the fire. Therefore, panel PN07 remains available to supply its respective PFSSD loads. Both power feeds to non-class 1E 120 VAC panel PN08 are unaffected.

References: XX-E-013, E-15000, E-13PN01, E-13PN01A, E-1F9421

5.2.20 Turbine Driven Auxiliary Feedwater Pump Trip and Throttle Valve (FCHV0312)

The PFSSD design requires the use of one auxiliary feedwater pump supplying water to at least two steam generators. The turbine driven auxiliary feedwater pump (TDAFP) is normally aligned to supply all four steam generators. The Train A motor driven auxiliary feedwater pump (MDAFP) is aligned to supply steam generators B and C. The Train B MDAFP is aligned to supply steam generators A and D.

Cable 12FCK23AX is a control cable associated with valves FCHV0312 and FCHV0313. One conductor within this five conductor cable is used in the close circuit of valve FCHV0312 and the remaining four cables are used in the control circuit of valve FCFV0313. Damage to this cable could prevent operation of valves FCHV0312 and FCFV0313.

In the event valves FCHV0312 and FCFV0313 fail due to damage to this cable, the Train B Motor Driven Auxiliary Feedwater Pump is available to provide auxiliary feedwater to steam generators A and D.

References: XX-E-013, E-15000, E-13FC23, E-13FC24, E-1F9202, M-12FC02

5.2.21 Engineered Safety Features (ESF) Transformer XNB01

Cables 15NBA10AA and 15NBA10AD are associated with the automatic fault protection circuit for ESF transformer XNB01. Damage to these cables due to a fire in area C-9 could cause a spurious trip of switchyard breakers 13-8 and 13-48, which provide power to XNB01. Damage could also prevent automatic trip of the breakers in the event of a fault.

As discussed in Section 5.1.3, transformer XNB01 can be isolated using available hand switches in the control room. Loss of power to XNB01 will not adversely impact PFSSD since Train B diesel generator is available to supply bus NB02 and associated Train B PFSSD loads. Therefore, damage to these cables will not impact the ability to achieve and maintain safe shutdown in the event of a fire in area C-9.

References: XX-E-013, E-15000, E-13NB10

5.2.22 Train B Class 1E Equipment Bus NB02

Cable 16NBA11AE is associated with the fault protective circuit on XNB02 feeder breaker PA0201. Damage to this cable due to a fire could cause a loss of power to the fault and indication portions of the PA0201 control circuit, which would prevent tripping on fault conditions but would not prevent operation of the breaker from the control room. Damage could also cause a spurious fault condition which will trip breaker PA0201 and prevent operation of the breaker from the control room.

Cable 16NBB05AL is associated with the differential protective relay for XNB02. Damage to this cable due to a fire could cause a spurious differential current signal and trip XNB02 feeder breaker PA0201.

Loss of power to XNB02 due to damage to the cables listed above will not adversely impact PFSSD due to the availability of the Train B diesel generator to supply power to NB02. Therefore, PFSSD can be achieved using Train B Class 1E equipment powered by the Train B emergency diesel generator.

5.2 PFSSD CABLE EVALUATION 25

1.0 GENERAL AREA DESCRIPTION

Fire area C-10 is located on the 2000-0 elevation of the Control Building and includes the rooms listed in Table C-10-1.

Table C-10-1
Rooms Located in Fire Area C-10

ROOM #	DESCRIPTION
3302	Train B Engineered Safety Features Switchgear Room

Fire area C-10 is protected with an automatic Halon fire suppression system. In addition, automatic fire detection is installed throughout.

Fire Area C-10 primarily contains cables and equipment for Train B and non-safety related components. Redundant Train A cables and components are located in a separate fire area divided by 3-hour fire rated construction. The 3-hour fire rated barrier provides reasonable assurance that a fire in area C-10 will not affect Train A components and therefore the ability to achieve and maintain safe shutdown in the event of a fire in area C-10 is assured.

2.0 PRIMARY EQUIPMENT USED FOR PFSSD

Table C-10-2 lists each system credited for post-fire safe shutdown and provides a discussion regarding the availability of the system to perform its Post Fire Safe Shutdown (PFSSD) function if a severe fire occurs in this area. For a summary of the area analysis results, see Section 8.0 of the Fire Area Analysis Narrative section.

Table C-10-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-10

System	System Name	PFSSD Function*	Comments
AB	Main Steam	R, M, H, P, S	All PFSSD functions associated with the main steam system are satisfied. Steam generator A ARV can be isolated from the control room. Steam generator C ARV can be controlled from the control room. Steam generator B ARV may need to be controlled using local controller ABFHC0002. Steam generator D ARV may need to be isolated by closing the air and nitrogen lines to the ARV.
AC	Main Turbine	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-10.
AE	Main Feedwater	H, P	All PFSSD functions associated with the main feadwater system are satisfied. Steam generator B wide range level transmitter AELT0502 and steam generator D wide range level transmitter AELT0504 may be affected. Wide range level transmitters on steam generators A and C are unaffected. Narrow range level transmitters on all four steam generators are unaffected.
AL	Aux. Feedwater System	H, P	All PFSSD functions associated with the auxiliary feedwater system are satisfied. Train B motor driven auxiliary feedwater pump and the turbine driven auxiliary feedwater pump may not be available. Train A motor driven auxiliary feedwater pump is available to supply water to steam generators B and C.
AP	Condensate Storage System	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-10.
BB	Reactor Coolant System	R, M, H, P, S	All PFSSD functions associated with the reactor coolant system are satisfied. Pressurizer PORV Block Valve BBHV8000B may not close. However, PORV BBPCV0456A is unaffected by the fire and will prevent a loss of RCS inventory. RCS process monitoring instruments BBLT0460 (narrow range pressurizer level); BBPT0406 (RCS pressure); BBTE0423B (RCS loop 2 cold leg temperature); and BBTE0443A (RCS loop 4 hot leg temperature) may be affected. Redundant RCS process monitoring instruments are unaffected.
BG	Chemical and Volume Control System	R, M, S	All PFSSD functions associated with the chemical and volume control system are satisfied. Components associated with Train B CVCS may be affected. Redundant Train A CVCS components are available. VCT isolation valve BGLCV0112C may not operate. VCT isolation valve BGLCV0112B is available. Seal injection using Train B flow throttling valve BGHV8357B may not be available. Train A flow throttling valve BGHV8357A is available.
BM	Steam Generator Blowdown System	R, M, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-10.

Table C-10-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-10

System	System Name	PFSSD Function*	Comments
BN	Borated Refueling Water Storage System	R, M, H	All PFSSD functions associated with the Borated Refueling Water Storage system are satisfied. The Train B CCP suction isolation valve from the RWST (BNLCV0112E) may not open. Train A CCP suction isolation valve BNLCV0112D is available. The Train B RHR suction isolation valve from the RWST (BNHV8812B) may not open. Train A RHR suction isolation valve BNHV8812A is available.
EF	Essential Service Water System	H, S	All PFSSD functions associated with the Essential Service Water System are satisfied. Several Train B ESW components may be affected by a fire in this area. Train A ESW remains available.
EG	Component Cooling Water System	S	The PFSSD function associated with the Component Cooling Water System is satisfied. Train B CCW pumps PEG01B and PEG01D may be affected. Train A CCW system is available.
EJ	Residual Heat Removal System	M, H, P	All PFSSD functions associated with the Residual Heat Removal System are satisfied. Train B RHR pump and miniflow valve EJFCV0611 may be affected. Train A RHR system remains available.
EM	High Pressure Coolant Injection	R, M	Train B safety injection pump PEM01B could spuriously start. Injection will not occur with the reactor at normal pressure and SI flow would divert back to the RWST through valve EMHV8814B.
EN	Containment Spray	R, M	Train B containment spray pump PEN01B could spuriously start. A spurious containment spray actuation signal will not occur and valve ENHV0012 will remain closed to prevent flow. Damage to the CS pump could occur but PFSSD is still assured.
EP	Safety Injection Accumulators	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-10.
FB	Auxiliary Steam	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-10.
FC	Auxiliary Turbines	R, H, P	The TDAFP trip and throttle valve (FCHV0312) and the speed governing valve (FCFV0313) may be affected. The Train A MDAFP is available. Valve FCFV0105 may be affected. The MSIVs can be closed using all-close hand switches ABHS0079 or ABHS0080.
GD	ESW Pump House HVAC	S	Train B ESW pump room ventilation may be affected. Train A ESW pump room ventilation is unaffected.
GF	AFW Pump Room Coolers	S	Train B Motor Driven AFW pump room cooler SGF02B may be affected. Train A MDAFP room cooler is unaffected.

Table C-10-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-10

System	System Name	PFSSD Function*	Comments
GK	Control Room and Class 1E Switchgear Room Coolers	S	Train B control room and Class 1E switchgear room coolers may be affected. Train A room coolers are unaffected.
GL	Auxiliary Building HVAC	S	The PFSSD function associated with the Auxiliary Building HVAC System is satisfied. The Train B RHR pump room cooler SGL10B, CCP pump room cooler SGL12B and CCW pump room cooler SGL11B may be affected. Train A room coolers are available.
GM	Emergency Diesel Generator Room HVAC	S	The PFSSD function associated with the Emergency Diesel Generator Room HVAC System is satisfied. Diesel generator room B exhaust damper GMHZ0019 may be affected. Train A diesel generator room exhaust damper GMHZ0009 is unaffected. Train B EDG room ventilation could be affected. Train A EDG room ventilation is unaffected.
GN	Containment Coolers	S	The PFSSD function associated with the Containment Cooling System is satisfied. Train B containment coolers may not operate due to loss of Train B ESW. Train A containment coolers remain available.
JE	Diesel Fuel Oil	S	The PFSSD function associated with the Diesel Fuel Oil System is satisfied. The Train B emergency fuel oil transfer pump PJE01B may be affected. The Train A emergency fuel oil transfer pump PJE01A is unaffected.
KA	Instrument Air	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-10.
KC	Fire Protection	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-10.
KH	Service Gas	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-10.
KJ	Standby Diesel Engine	S	The PFSSD function associated with the Standby Diesel Engine System is satisfied. The Train B diesel engine may be affected. The Train A diesel engine is unaffected.
MA	Main Generation	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-10.
MR	Startup Transformer	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-10.
NB	4.16 kV System	S	Off-site power to NB01 and NB02 could be lost. The Train A EDG is available to energize the NB01 bus.
NE	Standby Diesel Generator	S	The Train B diesel generator may be affected. The Train A diesel generator is unaffected.

Table C-10-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-10

System	System Name	PFSSD Function*	Comments
NF	Load Shed and Emergency Load Sequencing	S	All four undervoltage (UV) relays on Train B may be affected. Two of the four UV relays on Train A may be affected. Emergency load shed/sequencer operates when 2/4 UV relays sense undervoltage on the bus. Therefore, Train A Load Shed and Emergency Load Sequencing will be available.
NG	480V Load Centers and MCCs	S	Train B 480 V load centers may be affected. Train A 480 V load centers are available.
NK	125VDC	S	Train B 125 VDC Swing Battery Charger NK26 is affected. Redundant Train A Swing Battery Charger NK25 is unaffected. Train B Swing Inverter NN16 DC power source selector switch NK80 may be affected. Train A Swing Inverter NN15 DC power source selector switch NK79 is unaffected.
NN	120VAC	S	The Train B 120 VAC distribution system may be affected. The Train A 120 VAC system is unaffected.
PA	13.8kV	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-10.
PB	4.16kV	H, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-10.
PG	480V Load Centers and MCCs	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-10.
PK	125VDC	S	Battery charger PK22 may be affected. Redundant charger PK21 is unaffected.
PL	Local Instrument Panels	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-10.
PN	120VAC	S	One of the two redundant power feeds to PN08 could be affected. The remaining power feed is unaffected. Therefore, PN08 is available to perform its intended function.
QB	Standby AC Lighting	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-10.
QD	Emergency Lighting	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-10.
RL	Control Room MCB	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-10.
RP	Miscellaneous Control Panels	R, M, H, P, S	Relay rack RP140, BOP instrument rack RP147A/B and lockout relay racks RP334 and RP335 may be affected. Relay rack RP139 is unaffected. Damage to RP147A/B and RP334/335 will not affect PFSSD.

Table C-10-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-10

System	System Name	PFSSD Function*	Comments
SA	ESFAS	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-10.
SB	Reactor Protection System	R, S	Process monitoring fire isolation cabinets SB148A and SB148B may be affected. Damage to these cabinets will not affect PFSSD.
SC	Reactor Instrumentation	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-10.
SE	Ex-Core Neutron Monitoring	R, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-10.
SY	Switchyard	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-10.
UU	Supervisory System	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-10.

3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD

This section describes operator actions that may need to be performed inside or outside the control room to achieve and maintain hot standby if a fire occurs in area C-10. This section also describes cold shutdown repairs that may need to be made to achieve and maintain cold shutdown conditions. Operator actions are proceduralized in OFN KC-016.

3.1 ACTIONS OUTSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

Operator Manual Actions (OMAs) are those actions outside the main control room required to achieve and maintain hot standby. OMAs are identified in E-1F9900 and were determined from thermal hydraulic analysis WCNOC-CP-002. Applicable E-1F9900 OMAs are annotated herein. All other actions outside the control room are desirable for plant control in support of hot standby but not required to achieve and maintain hot standby.

3.1.1 Steam Generator Atmospheric Relief Valves

It may be necessary to control steam flow through ARV ABPV0002 by using local controller ABFHC0002. In addition, it may be necessary to fail close ARV ABPV0004 by isolating the air and nitrogen supplies using KAV1429 and KAV1365, respectively. Local controller ABFHC0002 as well as the air and nitrogen supply valves for ABPV0004 are located in fire area A-23 and access is available without having to traverse area C-10.

3.1.2 De-energize Bus NB02

If control power to breaker PA0201 is lost, operators may not be able to open the breaker from the control room. If this occurs, breaker PA0201 can be tripped using the manual trip push button located at the breaker. The operator performing this action will have to wear protective clothing per the Wolf Creek electrical safety manual.

Bus NB02 could remain energized if the emergency diesel generator NE02 starts and breaker NB0211 spuriously closes. If the fire is in C-10, access to the emergency diesel generator to locally stop it is unavailable. As discussed in Section 5.1.9, an energized NB02 bus will not adversely impact PFSSD.

3.2 ACTIONS INSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

3.2.1 De-Energize Bus NB02

It may be necessary to de-energize XNB02 if alternate feeder breaker NB0212 spuriously closes. This can be done by placing 1HS-SY018 and 1HS-SY022 in pull-to-lock to open switchyard breakers 13-8 and 13-48, respectively. However, as stated in 3.1.2, the diesel generator could operate and maintain power on NB02.

3.2.2 Component Cooling Water

Train B CCW could be affected by a fire in this area. If this occurs, swap to Train A CCW using normal operating procedures if Train A CCW is not already running.

3.2.3 Reactor Coolant Pump Seal Cooling

If Train B CCW is operating at the time of the fire, it could be lost causing a temporary loss of thermal barrier cooling. The normal charging pump is not analyzed and is assumed lost. Operators should swap to Train A CCW to restore thermal barrier cooling and line up the Train A CCP to restore RCP seal injection.

3.3 ACTIONS TO ACHIEVE AND MAINTAIN COLD SHUTDOWN

None

4.0 CONCLUSION

With some exceptions, redundant Post-Fire Safe Shutdown capability exists if a severe fire occurs in this area. For those exceptions, feasible manual actions are available and are unaffected by the fire. Manual actions are documented in Section 3.0.

5.0 DETAILED ANALYSIS

This section describes the detailed component-by-component and cable-by-cable analysis for a fire in area C-10.

5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA C-10

PFSSD components (S. in E-15000) located in fire area C-10 are shown in Table C-10-3. An evaluation of each component and associated cables is provided in the sections that follow. The applicable evaluation section is listed in Table C-10-3.

Table C-10-3 PFSSD Equipment Located in Fire Area C-10

5.1.1 MDAFP B to S/G D Control Valve (ALHV0005)

Valve ALHV0005 is a control valve installed on the discharge side of Motor Driven Auxiliary Feedwater Pump B and controls auxiliary feedwater flow to Steam Generator D. The valve is capable of throttling whenever the combined flow from the B MDAFP and the TDAFP exceeds 300 gpm. Control panel RP147B, which is located in fire area C-10, houses the controls for this feature. Instrumentation and control cables associated with the valve control logic are also run in area C-10. Controller ALFY0005B, located within RP147B, provides the signal to throttle ALHV0005, as required, to ensure flow to S/G D does not exceed 300 gpm.

A fire in area C-10 will damage a number of Train B components, including power and control cables for Train B MDAFP. The Train A MDAFP is unaffected by a fire in area C-10 and will be available to supply auxiliary feedwater to steam generators B and C. Valves ALHV0009 (MDAFP A to SG B) and ALHV0011 (MDAFP A to SG C) are unaffected by a fire in area C-10. Therefore, damage to components associated with ALHV0005 will not adversely impact post-fire safe shutdown.

References: XX-E-013, E-15000, E-13AL09, E-1F9204, J-110-00939

5.1.2 Pressurizer PORV Block Valve BBHV8000B

Hand switch BBHS8000D is an isolation switch used to isolate the control room circuits from the remaining valve control circuits. The switch allows manual closure of the valve at the Motor Control Center if the normal means of closing the valve from the control room are unavailable. The isolation switch is used in OFN RP-017 for a fire in the control room. Damage to this switch due to a fire could prevent operation of valve BBHV8000B from the control room. Valve BBHV8000B is required to be closed for PFSSD, or pressurizer PORV BBPCV0456A is required to be closed. Cables for pressurizer PORV BBPCV0456A do not run through area C-10 and are therefore unaffected by a fire in C-10.

Cables 14BBG39BF and 14BBG39BJ, associated with block valve BBHV8000B, are also run through area C-10 and may be damaged by a fire, preventing operation of the valve. This is acceptable for PFSSD as long as PORV BBPCV0456A is able to perform its intended function.

A fire in area C-10 could impact the ability to operate valve BBHV8000B. However, pressurizer PORV BBPCV0456A is unaffected by a fire in area C-10 and remains available to perform its intended function.

References: XX-E-013, E-15000, E-13BB39, E-13BB40, E-1F9301

5.1.3 VCT Isolation Valve BGLCV0112C

Hand switch BGHS0112C is used to isolate BGLCV0112C from the control room and allows manual closure of the valve at the MCC. The isolation switch is used in OFN RP-017 for a fire in the control room.

Cables 14BGG12BA, 14BGG12BB, 14BGG12BC, 14BGG12BD and 14BGG12BE are associated with BGLCV0112C and are run in area C-10.

Damage to BGHS0112C or the cables listed above could cause the spurious closure of BGLCV0112C or could prevent closing the valve from the control room. PFSSD requires either this valve or valve BGLCV0112B be closed after the RWST is lined up to provide a suction source to the operating charging pump.

Failure of the valve to close is mitigated by closing valve BGLCV0112B, which is unaffected by a fire in area C-10. If the valve spuriously closes prior to lining up the RWST, then damage to

the operating charging pump could occur due to loss of a suction source. Calculation XX-E-013, assumption 3-A-22, states that systems and components are in their normal operating position or status prior to the fire. The Normal Charging Pump (NCP) is the normally operated pump and is assumed to be operating at the time of the fire. Inadvertent closure of valve BGLCV0112C with no suction from the RWST would result in damage to the NCP but the centrifugal charging pumps would remain unaffected. The Train A CCP is unaffected by a fire in area C-10.

Based on the above discussion, the ability to achieve and maintain PFSSD is unaffected by a fire in area C-10 which affects VCT valve BGLCV0112C. Therefore, the configuration is acceptable.

References: XX-E-013, E-15000, E-13BG12A, E-13BN01

5.1.4 RWST to RHR Pump B Iso Valve (BNHV8812B)

Valve BNHV8812B is a normally open isolation valve from the RWST and supplies a suction source to the Train B RHR pump. Either this valve or valve EJHV8811B is required to be closed for PFSSD to prevent draindown of the RWST into the containment sump. Hand switch BNHS8812B is an isolation switch used to isolate this valve from the control room in the event of a control room fire. The hand switch is used in OFN RP-017 to manually close BNHV8812B from the MCC.

Cables 14BNG03BA, 14BNG03BB, 14BNG03BC and 14BNG03BJ are associated with BNHV8812B. Damage to these cables or the isolation switch due to a fire in area C-10 could prevent closure of valve BNHV8812B. Cables associated with EJHV8811B are not run in area C-10 and, therefore, valve EJHV8811B will remain closed to prevent draindown of the RWST into the containment sump. In addition, cables associated with all four RWST level transmitters are run outside of area C-10, so a spurious RWST low level signal initiating the automatic opening of EJHV8811B is not credible for a fire in area C-10.

Based on the above discussion, draindown of the RWST into the containment sump is prevented if a fire occurs in area C-10.

References: XX-E-013, E-15000, E-13BN03A, E-13BN07, E-13EJ06B

5.1.5 Process Monitoring Fire Isolation Cabinets SB148A and SB148B

The PFSSD function of cabinets SB148A and SB148B is to provide reliable process monitoring instrumentation at the remote shutdown panel in the event of a fire in the control room. This allows operators the ability to monitor critical process variables during shutdown from outside the control room. Those variables monitored at the remote shutdown panel, and whose instrumentation cables run to SB148A or SB148B, are as follows:

- Steam Generator B Water Level using AELI0502A (SB148A)
- Steam Generator D Water Level using AELI0504A (SB148B)
- Pressurizer Level using BBLI0460B (SB148A)
- RCS Cold Leg Loop 2 Temperature using BBTI0423X (SB148A)
- RCS Hot Leg Loop 4 Temperature using BBTI0443A (SB148A)
- RCS Pressure using BBPI0406X (SB148B)

A fire in area C-10 could cause a loss of control room process monitoring capability from the transmitters associated with the above listed indicators. Instrumentation cables associated with the transmitters run to cabinets SB148A or SB148B before the signals split and run to both the control room and the auxiliary shutdown panel. Therefore, a fire in area C-10 that

damages the cabinets or associated cables could prevent the control room from receiving signals from the following transmitters:

- AELT0502 – Steam Generator B Wide Range Water Level
- AELT0504 – Steam Generator D Wide Range Water Level
- BBLT0460 – Pressurizer Level Transmitter Narrow Range
- BBTE0423B – RCS Loop 2 Cold Leg Temperature Element
- BBTE0443A – RCS Loop 4 Hot Leg Temperature Element
- BBPT0406 – RCS Pressure Transmitter

In addition, power cables that provide 120 vac to cabinets SB148A and SB148B run through area C-10. Damage to these cables could disrupt power to the cabinets and prevent operation of the instruments.

Redundant means of monitoring the process variables listed above are available and are unaffected by a fire in area C-10. These redundant means are described below:

- AELT0527, AELT0528, AELT0529 and AELT0552 are available to provide level indication (narrow range) for steam generator B to associated indicators in the control room.
- AELT0547, AELT0548, AELT0549 and AELT0554 are available to provide level indication (narrow range) for steam generator D to associated indicators in the control room.
- BBLT0459 is available to provide pressurizer level (wide range) to level indicator BBLI0459A in the control room.
- BBTE0413B, BBTE0433B, and BBTE0443B are available to provide RCS Cold Leg temperature to associated indicators in the control room.
- BBTE0413A, BBTE0423A, and BBTE0433A are available to provide RCS Hot Leg temperature to associated indicators in the control room.
- BBPT0405 is available to provide RCS pressure to pressure indicator BBPI0405.

Based on the above discussion, a fire in area C-10 that affects the process monitoring instrumentation associated with cabinets SB148A and SB148B will not impact the ability to achieve and maintain PFSSD due to the availability of redundant process monitoring instrumentation in the control room.

References: XX-E-013, E-15000, E-13AE08, E-13BB15, E-13BB16, E-13SB09, E-13SB16, E-13NN01

5.1.6 Lockout Relay Panels RP334 and RP335

Relay panels RP334 and RP335 house the PFSSD relays identified in the following table.

Relay #	Description
Panel RP334 PFSSD Relays	
86XRP1	Turbine Driven AFWP Trip and Throttle Valve (FCHV0312)
86XRP2	Main Steam Supply Valve to TDAFP (ABHV0006)
86XRP3	Main Steam Supply Valve to TDAFP (ABHV0005)
86XRP9	Pressurizer Backup Group B Heaters
Panel RP335 PFSSD Relays	
86XRP5	Train B MDAFP from CST and ESW Supply Valves (ALHV0034 and ALHV0030)
86XRP6	ESW to TDAFP Supply Valve (ALHV0033)

Relay #	Description
86XRP7	Train B MDAFP (PAL01B)

The relays identified in the above table are used in OFN RP-017 to isolate the control room from the listed components in the event of a fire in the control room. The lockout relays (LOR) are actuated by operators placing hand switches RPHIS0001, RPHIS0002 and RPHIS0003 in isolate position.

Damage to the relays and/or associated cables due to a fire in area C-10 could prevent operation of the listed equipment. If this occurs, Train A equipment, located in a separate fire area, is available and is unaffected by the fire.

Cable 12RPK09BA provides Class 1E 125 VDC power from NK4201 to panel RP334. Damage to this cable could disrupt power to the TDAFP loads served by panel RP334, which could prevent operation of the TDAFP. Cable 14RPK09NA provides Class 1E 125 VDC power from NK4419 to panel RP335. Damage to this cable could disrupt power to the loads served by panel RP335, which could prevent operation of the associated equipment. The Train A MDAFP is available and is unaffected by the fire.

Based on the above discussion, a fire involving lockout relay panels RP334 and RP335 will not adversely impact PFSSD.

References: XX-E-013, E-15000, E-13AB01, E-13AB01A, E-13AL02B, E-13AL04B, E-13BB24, E-13FC23, E-13RP09, E-13RP11, E-13RP12, E-13RP14, E-13RP15, OFN RP-017

5.1.7 ESW Pump Room Ventilation

Hand switch GDHS0011 is an isolation switch used to isolate Train B ESW pump room supply fan control circuit from the control room and manually start the fan. The switch is used in OFN RP-017 when aligning Train B ESW in response to a fire in the control room.

Cables 14GDG01BE, 14GDG01BF, 14GDG01BH and 14GDY01BB, associated with the Train B ESW pump room supply fan, is run in area C-10. Damage to these cables, or the associated hand switches, could prevent operation of the supply fan.

Cable 14GDI04BF provides ESW B room temperature from temperature element GDTE0011 to temperature controller GDTC0011. Cable 14GDI04BG provides signals from GDTC0011 to outside air intake damper GDTZ0011A. Cable 14GDI04BH provides signals from GDTC0011 to recirculation damper GDTZ0011B. Damage to these cables could prevent operation of the dampers. Temperature controls for Train A ESW pump room are unaffected by a fire in area C-10.

Cable 14GDY01BB is associated with the automatic start on the Train B ESW pump room supply fan control circuit. Upon start of the Train B ESW pump, the contacts on this circuit close and energize the ARC relay, which closes a contact to start the supply fan. Cable 14GDY01BD is associated with low temperature switch GDTSL0011 that prevents the fan from starting if the room temperature is below a pre-determined set point. Damage to these cables due to a fire could spuriously start the fan or prevent it from starting. In either case, the Train A ESW pump room ventilation system is unaffected by a fire in area C-10.

Cable 14RPY10BA supplies 120 VAC control power to the automatic and manual start circuits for the Train B ESW pump room supply fan CGD01B. The control power is supplied via this cable to control room panel RP068 and is distributed to a number of fuse blocks including 4FU1, which provides circuit protection for CGD01B control power. If power is lost to the

control circuit due to damage to this cable, then the Train B ESW pump room supply fan will not start either automatically, when the ESW pump starts, or manually from the control room. If this occurs, the Train A ESW pump room supply fan remains unaffected by the fire.

Cables and components associated with Train A ESW pump room supply fan and dampers are not run in area C-10 and are therefore unaffected by the fire. Therefore, Train A ESW pump room supply fan is available to maintain the required environmental conditions while the Train A ESW pump is operating.

References: XX-E-013, E-15000, E-K3GD01A, E-K3GD04A

5.1.8 Train B Class 1E 4.16 kV ESF Switchgear Bus NB02

Bus NB02 supplies power to Train B Engineered Safety Features (ESF) components. A fire in area C-10 could damage NB02 and associated feeder breakers and disrupt power to all Train B ESF components. The following table identifies the NB02 PFSSD feeder breakers that could be lost in the event of a fire in area C-10.

Class 1E 4.16 kV ESF Switchgear Bus NB02	
Feeder Breaker	**Description**
NB0201	Centrifugal Charging Pump B
NB0202	Safety Injection Pump B
NB0203	Containment Spray Pump B
NB0204	RHR Pump B
NB0205	Auxiliary Feedwater Pump B
NB0206	Component Cooling Water Pump B
NB0207	Component Cooling Water Pump D
NB0208	Pressurizer Backup Group B Heaters
NB0209	ESF XFMR XNB02 to NB02
NB0210	480 Volt Load Center NG04
NB0211	Diesel Generator B to NB02
NB0212	ESF Transformer XNB01 to NB02
NB0213	480 Volt Load Center NG02
NB0215	ESW Pump B
NB0216	480 Volt Load Center NG06
NB0217	125 VDC Control Power for NB0201 to NB0217

Power and control cables associated with the components fed by the above listed breakers are also run in area C-10. Damage to the cables could cause a loss of the associated equipment. In addition, bus NB02 control room monitoring circuits are located in the area, and damage could cause loss of control room monitoring capability.

Control cables associated with bus NB02 Synchro-scope and associated switches are run in area C-10. Damage to these cables could prevent some of the monitoring functions for NB02, but would not cause a loss of the NB02 bus.

The main power cables from XNB02 to bus NB02 are run in area C-10. In addition, cables associated with differential protective relay 287/T2 are run in area C-10. Damage to these cables could disrupt power to bus NB02. Based on Calculation XX-E-013, Appendix 2, off-site power to NB01 and NB02 can be lost if a fire occurs in area C-10.

Based on the above discussion, a loss of off-site power can occur on NB01 and NB02 if a fire occurs in this area. Also, based on the discussion later in this evaluation the Train B emergency diesel generator may not be available to supply NB02. Redundant Train A 4.16 kV switchgear bus NB01 is available, powered from the Train A emergency diesel generator. Therefore, loss of power to Train B components identified in the above table will not impact the ability to achieve and maintain safe shutdown.

References: XX-E-013, E-15000, E-13NB04, E-13NB05, E-13NB06, E-13NB11, E-13NB14, E-13NB15, E-13NE02, E-13NG01A, E-13NG10A, E-K3NG01, E-K3NG10A

5.1.9 Local Switchgear Mounted Hand Switches

Several local switchgear mounted hand switches are located in area C-10 and could be damaged by a fire, causing the switch contacts to fail in an undesired position. The following table lists each hand switch as well as a description of what the switch serves.

Local Switchgear Mounted Hand Switches on NB02	
Hand Switch	**Description**
NB0202HIS	Safety Injection Pump B
NB0203HIS	Containment Spray Pump B
NB0204HIS	RHR Pump B
NB0206HIS	Component Cooling Water Pump B
NB0207HIS	Component Cooling Water Pump D
NB0209HIS	ESF XFMR XNB02 to NB02
NB0215HIS	ESW Pump B

Damage to any of these hand switches could cause spurious actuation of the component, which may be undesirable for PFSSD. To prevent maloperation of Train B components, the NB02 bus can be de-energized as described in the following paragraphs. In addition, de-energizing the bus ensures the safety of the fire brigade fighting the fire.

If a fire occurs in area C-10, operators can de-energize the NB02 bus by placing hand switches NBHIS0004 (NB02 normal supply breaker NB0209), NBHIS0005 (NB02 alternate supply breaker NB0212), and NEHIS0026 (NB02 emergency supply breaker NB0211) in pull-to-lock. The hand switches are located in the control room but the breakers are located in the fire affected area. If the control room hand switches do not work due to damage to one or more of these breakers, operators can open breaker PA0201 to de-energize transformer XNB02 by placing NBHIS0001 in pull-to-lock. However, if breaker PA0201 control power is lost due to a short within cables 16NBA11AC or 16NBA11AE, operators can manually trip the breaker using the manual trip push button.

If the Train B diesel generator NE02 starts upon loss of power to the NB02 bus, and breaker NB0211 spuriously closes, then it may be necessary to stop the diesel to prevent re-energizing the NB02 bus. This can be done using control room hand switch KJHS0108A. If control power is lost due to the fire and KJHS0108A is ineffective in shutting down the diesel, then bus NB02 will remain energized, since access to the diesel generator room to manually shut down the diesel generator is not available without traversing fire area C-10. This is acceptable for PFSSD as described below. No E-1F9900 OMA is required for de-energizing NB02 to achieve and maintain hot standby.

Spurious operation of the Containment Spray and Safety Injection pumps could complicate PFSSD. However, spurious operation of the remaining components listed in the above table

will have no adverse impact on PFSSD. For a discussion of the safety injection and containment spray pumps, see Sections 5.2.11 and 5.2.12.

A fire may also cause spurious closure of normally open breaker NB0212, which provides alternate power to NB02 from XNB01. If this occurs, operators can de-energize XNB01 and use Train A diesel generator NE01 to supply power to NB01. To de-energize XNB01, operators can open switchyard breakers 13-8 (Alternate feeder to XNB01) or 13-48 (Normal feeder to XNB01) by placing control room hand switches 1HS-SY018 (13-8) or 1HS-SY022 (13-48) in pull-to-lock.

5.1.10 Isolation Handswitch NBHS0014

Hand switch NBHS0014 is an isolation switch that was used in OFN RP-017 to isolate the trip and indication circuits for CCP B, CCW Pump B and ESW Pump B. Revision 18 of OFN RP-017 removed the hand switch from the procedure and added a step for operators to de-energize 125 VDC control power to bus NB02 by opening breaker NK4401. This step ensures the ability to operate Train B components when performing OFN RP-017 in response to a control room fire.

Damage to the hand switch due to a fire in area C-10 could prevent operation of the pumps listed above. Redundant Train A pumps are unaffected by a fire in area C-10 and will be used to achieve safe shutdown.

References: XX-E-013, E-15000, E-13BG01A, E-13EG01C, E-13NE11, E-13NG10A, E-13PG12A E-K3EF01A, E-K3NG10A,

5.1.11 Train B 480 Volt Class 1E Load Center NG02

A fire in area C-10 could disrupt power to 480 Volt Class 1E Load Center NG02 and associated components. The following table identifies the NG02 PFSSD feeder breakers that could be lost in the event of a fire in area C-10.

Train B Class 1E 480 Volt Load Center NG02	
Feeder Breaker	**Description**
NG0201	Transformer XNG02 to Bus NG02
NG0203	125 Volt Vital Battery Charger NK24
NG0205	Control Room Air Conditioning Unit (SGK04B)
NG0206	Control Building MCC NG02A
NG0207	Auxiliary Building MCC NG02B
NG0208	Train B Containment Cooler DSGN01B (NG02T)

In addition, load center NG02 transformer XNG02 is located in area C-10 and could be damaged by the fire.

Power and control cables associated with the equipment shown in the above table are also run in area C-10. These cables are listed in Table C-10-4. Damage to these cables due to a fire could cause a loss of the associated equipment.

Cables supplying 125 VDC control power to NG02 breakers from NK54 are run in area C-10. Damage to these cables could prevent operation of the breakers listed in the above table.

Isolation Switch NGHIS0015 is used in OFN RP-017 to isolate the trip and indication circuits on the NG0201 control circuit. This is done in response to a control room fire to ensure cable damage does not cause the breaker to spuriously trip, which would cause a loss of power to the NG02 bus. Damage to this switch due to a fire could spuriously trip NG0201 and de-energize the NG02 bus.

Redundant Train A components, supplied by NG01 and NG03, are unaffected by a fire in area C-10. Therefore, loss of power to Train B components identified in the above table due to a fire in area C-10 will not impact the ability to achieve and maintain safe shutdown.

5.1.12 Train B 480 Volt Class 1E Control Building MCC NG02A

A fire in area C-10 could disrupt power to 480 Volt Class 1E Control Building MCC NG02A and associated components. The following table identifies the NG02A PFSSD MCC breakers that could be lost in the event of a fire in area C-10.

Train B 480 Volt Load Class 1E Control Building MCC NG02A	
MCC Breaker	**Description**
NG02ABF4	Class 1E Electrical Equip A/C Unit (SGK05B)
NG02ABF5	Incoming Line From Load Center NG02
NG02ABR1	Bypass Voltage Regulating Transformer (NN12)
NG02ACR1	480 vac Distribution Panel
NG02ADF1	Instr Bus Xfmr - Fed By NG02BBF1 (XPN08)
NG02ADF3	RHR Pump Room Cooler Motor (DSGL10B)
NG02ADR1	Centrifugal Charging Pmp Rm Cooler (DSGL12B)
NG02ADR5	CCP B Discharge To RCP Seals Vlv (BGHV8357B)
NG02AEF1	Relay Panel Section
NG02AER4	ESW B To Service Wtr Isolation Vlv (EFHV40)
NG02AFF1	Bypass Voltage Regulating Transformer (NN16)
NG02AFF3	Bypass Voltage Regulating Transformer (NN14)
NG02AFF4	RWST To RHR Pump B Suction Valve (BNHV8812B)
NG02AFR1	ESW A To Service Wtr Isolation Vlv (EFHV39)
NG02AFR2	VCT Outlet Isolation Valve (BGLCV112C)
NG02AFR3	RHR B To SI Pump B Isolation Vlv (EJHV8804B)
NG02AGR3	RHR Mini Flow Iso Valve Loop B (EJFCV611)
NG02AHF1	ESW A/Service Wtr Cross Connect Vlv (EFHV25)
NG02AHF2	ESW B/Service Wtr Cross Connect Vlv (EFHV26)
NG02AHF3	ESW B To Ultimate Heat Sink Iso Vlv (EFHV38)
NG02AHR1	CCP B Miniflow Isolation Valve (BGHV8111)
NG02AHR3	Charging Pump B RWST Suction Vlv (BNLCV112E)

Power and control cables associated with the equipment shown in the above table are also run in area C-10. These cables are listed in Table C-10-4. Damage to these cables due to a fire could cause a loss of the associated equipment.

Redundant Train A components, supplied by NG01A, are unaffected by a fire in area C-10. Therefore, loss of power to Train B components identified in the above table due to a fire in area C-10 will not impact the ability to achieve and maintain safe shutdown.

References: XX-E-013, E-15000, E-11NG02, E-11NG20, E-13NG01A, E-13NN01

5.1.13 Train B 480 Volt Class 1E Load Center NG04

A fire in area C-10 could disrupt power to 480 Volt Class 1E Load Center NG04 and associated components. The following table identifies the NG04 PFSSD feeder breakers that could be lost in the event of a fire in area C-10.

Train B Class 1E 480 Volt Load Center NG04	
Feeder Breaker	**Description**
NG0401	Transformer XNG04 to Bus NG04
NG0403	125 Volt Vital Battery Charger NK22
NG0405	Train B Containment Cooler DSGN01D
NG0406	Auxiliary Building MCC NG04C
NG0407	Control Building MCC NG04D
NG0408	Train B Diesel Generator Room Supply Fan (DCGM01B)
NG0409	125 Volt Non-Vital Battery Charger PK22
NG0410	125VDC Non-Class 1E Battery Charger (PK24)
NG0411	125 Volt Swing Battery Charger NK26

In addition, load center NG04 transformer XNG04 is located in area C-10 and could be damaged by the fire.

Power and control cables associated with the equipment shown in the above table are also run in area C-10. These cables are listed in Table C-10-4. Damage to these cables due to a fire could cause a loss of the associated equipment.

Cables supplying 125 VDC control power to NG04 breakers from NK44 are run in area C-10. Damage to these cables could prevent operation of the breakers listed in the above table.

Isolation Switch NGHIS0016 is used in OFN RP-017 to isolate the trip and indication circuits on the NG0401 control circuit. This is done in response to a control room fire to ensure cable damage does not cause the breaker to spuriously trip, which would cause a loss of power to the NG04 bus. Damage to this switch due to a fire could spuriously trip NG0401 and de-energize the NG04 bus.

Redundant Train A components, supplied by NG01 and NG03, are unaffected by a fire in area C-10. Therefore, loss of power to Train B components identified in the above table due to a fire in area C-10 will not impact the ability to achieve and maintain safe shutdown.

References: XX-E-013, E-15000, E-11NG02, E-11PK02, E-13NG01A, E-13NG11A, E-13PK11, DCP 13324

5.1.14 Swing Battery Charger NK26

Swing battery charger NK26 provides backup power and battery charging to Train B 125 VDC busses NK02 and NK04 and battery banks NK12 and NK14. Swing battery charger NK26 allows battery chargers NK22 or NK24 to be taken out of service without loss of power to NK02 or NK04. A fire in area C-10 could cause damage to battery charger NK26, or could cause a loss of 480 VAC power to the battery charger, which would render it inoperable. In addition, the fire could cause damage to the power cables between NK26 transfer switch NK76 and transfer switches NK72 and NK74.

Battery chargers NK22 and NK24, and battery banks NK12 and NK14 are located in a different fire area. However, cables supplying 480 VAC power to battery chargers NK22 and NK24 are run in area C-10. Power to these chargers is supplied by 480 VAC breakers NG0203 (NK24) and NG0403 (NK22). In the event a fire in C-10 damages battery charger NK26, and disrupts charging power to NK22 and NK24, power to Train B busses NK02 and NK04 will still be available through battery banks NK12 and NK14, since the batteries are unaffected by a fire in area C-10. In the event power to NK02 and NK04 is unavailable, redundant Train A 125 VDC system remains available.

Transfer switches NK76 and NK78 are also located in area C-10. Damage to these switches and associated cables due to a fire will have no adverse impact on safe shutdown due to the availability of redundant Train A components in a different fire area.

Hand switches NKHS0026 and NKHS0411 may also be damaged by the fire. However, due to the availability of Train A 125 VDC system, this will have no adverse impact on PFSSD.

Based on the above discussion, a loss of swing battery charger NK26 and associated transfer switches will not adversely impact the ability to achieve and maintain safe shutdown due to the availability of redundant Train A components.

References: XX-E-013, E-15000, E-11NK01, E-11NK02, E-11NG02, E-13NK10, E-13NK12A

5.1.15 Auxiliary Relay Rack RP140

Relay rack RP140 contains a number of PFSSD relays used for operation of Train B equipment. The following table identifies the PFSSD relays located in panel RP140.

RP140 Auxiliary Relays	
Relay #	**Description**
1XEF32	ESW Pump Motor B Interposing Relay
1XEF34	ESW Pump Motor B Interposing Relay
1XEF36	ESW Pump Motor B Interposing Relay
3XEG05	CCW Pump B Auxiliary Relay
3XEG07	CCW Pump D Auxiliary Relay
62XBB02	Pressurizer PORV Block Valve Auxiliary Relay
62XBB04	Pressurizer PORV Block Valve Auxiliary Relay
63TDEEG06	CCW Pump B Auxiliary Relay
63TDEEG08	CCW Pump D Auxiliary Relay
83XGK02	GKHZ0040A/40B Auxiliary Relay
K4119	Load Sequencer Relay

A fire in area C-10 could damage panel RP140 and associated PFSSD relays shown in the above table. In addition, cables supplying 125 VDC and 120 VAC power to the various relays within RP140 are run in area C-10. Damage to the power cables and/or relays could prevent operation of the associated component, or could cause the component to spuriously operate. If the components spuriously operate, PFSSD is assured since spurious operation of these components will not have an adverse impact on the ability to achieve and maintain PFSSD.

Redundant relay panel RP139, containing redundant PFSSD relays for Train A components, is located in fire area C-9 and is unaffected by a fire in area C-10. Cables associated with RP139 do not run through area C-10.

References: XX-E-013, E-15000, E-13RP09

5.1.16 BOP Instrument Racks RP147A and RP147B

Instrument racks RP147A and RP147B house logic and instrumentation controls for various PFSSD functions associated with alternative and dedicated safe shutdown (fire in the control room). These functions are associated with steam generator and auxiliary feedwater control for steam generators B and D. The control room evacuation procedure (OFN RP-017) uses steam generators B and D, as well as the Turbine Driven Auxiliary Feedwater Pump (TDAFP) and the Train B Motor Driven Auxiliary Feedwater Pump to achieve safe shutdown if a fire occurs in the control room.

One PFSSD function supported by instrument racks RP147A and RP147B is atmospheric control of steam generator atmospheric relief valves (ARV) ABPV0002 and ABPV0004, respectively. The PFSSD methodology requires steam generator atmospheric control on all four steam generators.

Cables and components associated with steam generator atmospheric relief valves ABPV0001 and ABPV0003 are not located in area C-10 and are therefore unaffected by the fire. Steam generator atmospheric control on steam generators A and C can therefore be achieved.

A fire in area C-10 uses primarilly Train A equipment, including Train A motor driven auxiliary feedwater pump (MDAFP). The Train A MDAFP is aligned to supply auxiliary feedwater to steam generators B and C. Steam generator ARV ABPV0002 is located on the steam generator B loop (loop 2) whereas steam generator ARV ABPV0004 is located on the steam generator D loop (loop 4).

A fire in area C-10 could cause a loss of control of steam generator ARVs ABPV0002 and ABPV0004. Since Train A MDAFP is used to supply auxiliary feedwater to SGs B and C, it is desired that atmospheric control on SGs B and C be achieved and that the ARVs on SGs A and D be closed. As stated above, atmospheric control on SG C is unaffected by a fire in area C-10. However, atmospheric control on SG B could be affected. If SG B ARV ABPV0002 fails to open, operators can manually control it using local controller ABFHC0002 located in fire area A-23. If ARV ABPV0002 spuriously opens, then that is the desired position. However, to re-gain control of the ARV, operators can use local controller ABFHC0002.

Steam generator D ARV ABPV0004 control could be lost if a fire occurs in area C-10. If the ARV remains closed, that is the desired PFSSD position. If the ARV spuriously opens, operators can isolate the air and nitrogen supply to fail the ARV closed. Air is isolated by closing valve KAV1429 and nitrogen is isolated by closing valve KAV1365. The air and nitrogen supply valves are located in fire area A-23 and access is available without having to traverse area C-10.

Up to three ARVs can fail closed or open without impacting ability to achieve and maintain hot standby according to thermal hydraulic analysis WCNOC-CP-002. With at least one ARV unaffected, no E-1F9900 OMA is required to address ARV closure or control. Reference Attachment 4, MSO Evaluation Scenario ID PWROG 23.

Instrument racks RP147A and RP147B also house instrumentation for the TDAFP and the Train B motor driven auxiliary feedwater pump. Pressure transmitter ALPT0026, located on the TDAFP suction, sends a signal to panel RP147A which then sends the signal to pressure indicators in the control room and auxiliary shutdown panel. Pressure transmitter ALPT0024, located on the Train B MDAFP suction, sends a signal to panel RP147B where it is then sent to pressure indicators in the control room and auxiliary shutdown panel. These signals allow operators to monitor suction pressure on the TDAFP and the Train B MDAFP during normal conditions and emergency shutdown due to a fire in the control room.

Instrument rack RP147A also contains circuits for the TDAFP speed governing valve FCFV0313. Damage to these circuits could prevent operation of the valve. If this valve fails full open at the same time valve FCHV0312 fails open, the TDAFP would likely trip on high speed. If the valve fails closed, the TDAFP will not be operable but the Train A MDAFP remains available to ensure safe shutdown.

Loss of pressure transmitters or a spurious pressure signal on the TDAFP and Train B MDAFP suction headers will not adversely impact PFSSD since the Train A MDAFP pressure transmitter ALPT0025 is unaffected by a fire in area C-10.

Flow transmitter ALFT0001, located on the auxiliary feedwater supply header to steam generator D, sends a signal to panel RP147B where it is then sent to flow indicators in the control room and auxiliary shutdown panel. This allows operators to monitor auxiliary feedwater flow to steam generator D during normal conditions and emergency shutdown due to a fire in the control room.

Loss of flow transmitter ALFT0001 will not adversely impact PFSSD since a fire in area C-10 uses Train A MDAFP supplying steam generators B and C.

Based on the above discussion, PFSSD can be achieved if a fire in area C-10 affects instrument racks RP147A and RP147B.

References: XX-E-013, E-15000, E-13AB20A, E-13AB20B, E-13AL07B, E-13FC24, E-13RP09, E-1F9101, J-110-00933, J-110-00934

5.1.17 Steam Generator Feedwater Pumps

Main feedwater pump steam supply valves FCFV0005 and FCFV0105 are credited in the PFSSD analysis to trip the main feedwater pumps if the main steam isolation valves (MSIVs) are affected by a fire. Closing the MSIVs stops steam flow to the feedwater pumps' turbines and stops the feedwater pumps. The steam generator feedwater pumps are tripped in the event of a fire to prevent overfilling the steam generators.

Non-Class 1E 120 VAC Inverter PN10 and distribution panel PN10A provide power to FCFV0105 trip relays in panel FC170C. Cable 16RPY10AA supplies power from PN0806 to inverter PN10. Cable 16RPY10AB supplies power from inverter PN10 to distribution panel PN10A. Cable 16FCY35AA provides the primary source of 120 VAC power from distribution panel PN010A to panel FC170A, which distributes power to the trip relays in panel FC170C. The alternate source of power to panel FC170A is not credited for PFSSD and is assumed lost.

A fire in area C-10 could damage inverter PN10, distribution panel PN10A or cables 16FCY35AA, 16RPY10AA or 16RPY10AB. If this occurs, operators in the control room would

not be able to close valve FCFV0105 to stop steam flow to steam generator feedwater pump PAE01B.

A fire in area C-10 will not affect the ability to close the MSIVs from the control room. All-close hand switches ABHS0079 and ABHS0080 are unaffected and can be used to close the MSIVs from the control room.

Based on the above discussion, valve FCFV0105 may not close if a fire occurs in this area. However, the MSIVs can be closed using either hand switch ABHS0079 or ABHS0080 in the main control room. Therefore, the configuration is acceptable.

5.2.1 Load Shedder / Emergency Load Sequencer

The load shedder and emergency load sequencers are included in the PFSSD design to evaluate the impact of spurious operation or mal-operation. The load shedder/emergency load sequencer operates upon presence of the following conditions:

1. An undervoltage (UV) on a safeguards bus,
2. A safety injection signal (SIS) or a containment spray actuation signal (CSAS), or
3. An undervoltage on a safeguards bus with a SIS or CSAS.

Eight inputs (four undervoltage (UV) inputs and four degraded voltage inputs) on each safeguards bus (NB01 and NB02) monitor voltage conditions on that bus. An undervoltage condition on two of four UV relays on each bus will actuate the load shedder/sequencer and send a signal to start the associated diesel generator. In addition, degraded voltage sensed by two of four degraded voltage potential transformers (PTs) will, after a time delay, provide a signal to open the offsite feeder breakers on the associated bus. This will, in turn, initiate an undervoltage condition and actuate the load shedder/sequencer and send a signal to start the associated diesel generator.

Cables associated with all four UV relays on NB02 and two of four UV relays on NB01 are run in area C-10. In addition, cables associated with all four PTs on NB02 and two of four PTs on NB01 are run in area C-10. Damage to these cables could provide a false undervoltage/degraded voltage condition on both safegaurds buses and actuate the signals described in the previous paragraph. A spurious start of the Train A diesel generator will not adversely impact PFSSD since an operating Train A diesel generator is the desired condition for a fire in area C-10.

A fire in area C-10 involving cables associated with the under voltage/degraded voltage signals will have no adverse impact on PFSSD.

References: XX-E-013, E-15000, E-11NB01, E-11NB02, E-12NF01, E-13NF01, E-10NF, E-1F9411A, E-1F9411B, E-1F9412A, E-1F9412B, E-1F9402A, E-1F9402B, E-1F9403, E-1F9425, E-1F9426

5.2.2 Auxiliary Feedwater

Power and control cables associated with Train B Motor Driven Auxiliary Feedwater Pump (MDAFP) are run through area C-10. Damage to these cables could prevent operation of the pump. As stated earlier, the Turbine Driven Auxiliary Feedwater Pump (TDAFP) may also be unavailable if a fire occurs in area C-10.

Power and control cables for redundant Train A MDAFP are run in a separate fire area and are unaffected by a fire in area C-10. Therefore, PFSSD is assured using Train A MDAFP if a fire occurs in area C-10.

Cable 14GFG01BC is associated with the automatic start circuit on the Train B AFWP room cooler SGF02B. Upon start of the Train B AFWP, the contact associated with this circuit will close and the room cooler will start, as long as the hand switch is in the auto position. Damage to the cable due to a fire will either spuriously start the cooler or prevent it from automatically starting.

Circuits associated with Train A AFWP room cooler SGF02A do not run through area C-10 and are unaffected by the fire. Therefore, PFSSD is assured using Train A Motor Driven AFWP to provide auxiliary feedwater to steam generators B and C if a fire occurs in area C-10.

References: XX-E-013, E-15000, E-13AL01B, E-13GF01, E-13NB04

5.2.3 TDAFP to Steam Generator B Supply Valve ALHV0010

Valve ALHV0010 provides isolation and control of auxiliary feedwater flow from the Turbine Driven Auxiliary Feedwater Pump (TDAFP) to steam generator B. Instrument cables associated with this valve are run to panel RP147B in area C-10. Damage to these cables due to a fire could prevent operation of the valve which would prevent auxiliary feedwater flow from the TDAFP to the B steam generator.

A fire in area C-10 has the potential to cause a loss of the TDAFP and the Train B Motor Driven Auxiliary Feedwater Pump (MDAFP). The Train A MDAFP is available to supply auxiliary feedwater to steam generators B and C. Therefore, damage to the cables associated with valve ALHV0010 will not adversely impact the ability to achieve and maintain safe shutdown.

References: XX-E-013, E-15000, E-13AL05B

5.2.4 Centrifugal Charging Pumps

At least one centrifugal charging pump (CCP) is required for PFSSD to provide RCP seal cooling, reactivity control and inventory control. These functions are accomplished using a CCP taking suction from the refuelling water storage tank (RWST) and injecting through the RCP seals. RCP seal injection provides approximately 20 gpm makeup to the RCS and provides adequate boron concentration to maintain sub-critical reactivity conditions. If RCP seal injection is unavailable, reactivity and inventory control is provided by lining up the CCPs to the boron injection tank (BIT). The normal charging pump (NCP) is not credited and is assumed lost.

Power and control cables associated with Train B Centrifugal Charging Pump (CCP) are run through area C-10. Damage to these cables could prevent operation of the pump. Redundant Train A CCP cables are run in a separate fire area and are unaffected by a fire. Therefore, PFSSD is assured using Train A CCP if a fire occurs in area C-10.

Power and control cables associated with Train B charging pump miniflow valve BGHV8111 are run through area C-10. Redundant Train A cables for miniflow valve BGHV8110 are run in a different area and are unaffected by a fire in area C-10. Therefore, PFSSD is assured using Train A CCP miniflow valve if a fire occurs in area C-10.

Power and control cables associated with Train B CCP room cooler SGL12B are run in area C-10. Damage to these cables will prevent operation of the room cooler. Train A CCP room cooler SGL12A circuits do not run in area C-10 and are unaffected by a fire. Therefore, Train A CCP room cooler will be available.

Based on the above discussion, the Train B CCP could be affected but the Train A CCP is available if a fire occurs in area C-10.

References: XX-E-013, E-15000, E-13BG01A, E-13BG11B, E-13GL05, E-13NB04

5.2.5 Reactor Coolant Pump Seal Injection

PFSSD requires RCP seal injection to provide a boron injection path, provide makeup to the RCS and provide cooling to the RCP seals. The redundant boron injection and makeup path is through the boron injection tank (BIT). The redundant seal cooling method uses thermal barrrier cooling.

Power and control cables associated with RCP seal injection flow throttling valve BGHV8357B are run in area C-10. Damage to these cables will prevent operation of the valve from the control room. Cables associated with redundant Train A valve BGHV8357A are run in a separate fire area and are unaffected by a fire in area C-10.

Based on the above discussion, PFSSD is assured using Train A charging pump and aligning RCP seal injection flow through BGHV8357A.

References: XX-E-013, E-15000, E-13BG52, M-12BG03

5.2.6 RWST To Charging Pump A Isolation Valve (BNLCV0112E)

Power and control cables associated with normally closed valve BNLCV0112E are run in area C-10. Damage to these cables will prevent operation of the valve from the control room. PFSSD requires suction from the RWST to the operating charging pump. Cables associated with redundant Train A valve BNLCV0112D are run in a separate fire area and are unaffected by a fire in area C-10.

Based on the above, PFSSD is assured using Train A charging pump and aligning suction through BNLCV0112D. Therefore, the configuration is acceptable.

References: XX-E-013, E-15000, E-13BN01

5.2.7 Essential Service Water Pumps and Associated Components

Either the Train A or the Train B essential service water (ESW) system is required to be available to ensure PFSSD. The ESW system supplies water to the following PFSSD components on the associated train:

- CCP room cooler
- RHR pump room cooler
- Class 1E switchgear room A/C condenser
- diesel generator engine cooling
- control room A/C condenser
- auxiliary feedwater pump room cooler
- motor and turbine driven auxiliary feedwater pump suction (backup to CST)
- containment air coolers
- electrical penetration room cooler
- component cooling water pump room cooler
- component cooling water heat exchanger
- component cooling water system makeup

Power and control cables associated with ESW pump B are run in area C-10. Damage to these cables will prevent the pump from operating. Cables associated with redundant Train A ESW pump PEF01A are run in a separate fire area and are unaffected by a fire in area C-10.

Cable 14EFG02SD is a control cable that provides an automatic start signal to the Train B ESW traveling water screen when the Train B ESW pump runs. An intra-cable short between the two conductors in this cable will start the screen in the absence of a running pump. If this

occurs, operators can stop the screen using EFHIS0004 in the control room. An open in this cable will prevent the automatic start of the screen but operators can start it using EFHIS0004 in the control room. A short to ground would blow the CPT secondary side fuse and drop power to the control circuit, preventing the screen from operating. As stated in the previous paragraph, Train B ESW pump may not be available due to a fire in area C-10 but Train A ESW pump is available. Circuits for Train A traveling water screen do not run through area C-10.

Cable 14EFG03SD is a control cable associated with ESW Train B screen wash water valve EFHV0092. Damage to this cable could prevent operation of the valve. As stated above, Train B ESW pump may not be available due to a fire in area C-10 but Train A ESW pump is available. Circuits for Train A screen wash water valve EFHV0091 do not run through area C-10.

Cables 14EFG06SD and 14EFG06SE are associated with Train B ESW pump air release valve EFHV0098. Cable 14EFY10DA is a control cable associated with the air release valve time delay relay. The air release valve purges air from the pump casing upon pump start to ensure pump operability. The time delay relay closes the air release valve after 15 seconds of ESW pump operation. Circuits for Train A ESW pump air release valve EFHV0097 do not run through area C-10 and are unaffected by the fire.

Cable 14EFK01SA is a control cable associated with the local start and stop switch for Train B ESW pump motor DPEF01B. Cable damage due to a fire could bypass local hand switch EFHIS0056B, located on control panel EF156, and spuriously start the Train B ESW pump. This would not adversely impact PFSSD due to the continued availability of the Train A ESW pump.

Based on the above discussion, Train B ESW may be affected by a fire in area C-10. PFSSD is assured for a fire in area C-10 using Train A ESW pump PEF01A and associated components.

References: XX-E-013, E-15000, E-K3EF01A, E-K3EF02, E-K3EF03, E-K3EF06, E-K3EF10, E-K3GD01A, J-201-00133

5.2.8 ESW To Service Water and UHS Isolation Valves

The Essential Service Water (ESW) system supplies water to various PFSSD components on the associated train. In order to ensure proper flow of ESW to the supplied loads, valves in the system need to be in the proper lineup.

Valve EFHV0025 is a normally open isolation valve on the service water system feed to the Train A Essential Service Water System. Either this valve or valve EFHV0023 is required to be closed when operating the Train A ESW system for PFSSD. Power and control cables associated with EFHV0025 are run in this area. Damage to these cables could prevent closing EFHV0025 from the control room. Redundant valve EFHV0023 is unaffected by a fire in area C-10 and can be closed from the control room to isolate this flowpath. In addition, check valve EFV0470 is installed in this line and will prevent flow diversion in the unlikely event valve EFHV0023 cannot be closed.

Valve EFHV0026 is a normally open isolation valve on the service water system feed to the Train B Essential Service Water System. Either this valve or valve EFHV0024 is required to be closed when operating the Train B ESW system for PFSSD. Hand switch EFHS0026A is used to close the valve and isolate the circuit if a fire occurs in the control room. Power and control cables associated with EFHV0026 are run in this area. Damage to these cables could prevent closing EFHV0026 from the control room. Redundant valve EFHV0024 is unaffected by a fire in area C-10 and can be closed from the control room to isolate this flowpath. In addition,

check valve EFV0471 is installed in this line and will prevent flow diversion in the unlikely event valve EFHV0024 cannot be closed.

Valve EFHV0038 is an isolation valve on the return line from Train B ESW to the UHS. Hand switch EFHS0038A provides a means of isolating valve EFHV0038 from the control room and allows manual closure of the valve from the MCC. The switch is used in OFN RP-017 in response to a fire in the control room. Valve EFHV0038 is required to be open when operating the Train B ESW system. Cables associated with valve EFHV0038 are run in this fire area. Damage to these cables or the hand switch could cause spurious closure of the valve. If this occurs, Train A ESW is available to ensure safe shutdown.

Valve EFHV0039 is a normally open isolation valve on the return line from the Train A Essential Service Water System to the service water system. Either this valve or valve EFHV0041 is required to be closed when operating the Train A ESW system for PFSSD. Power and control cables associated with EFHV0039 are run in this area. Damage to these cables could prevent closing EFHV0039 from the control room. Redundant valve EFHV0041 is unaffected by a fire in area C-10 and can be closed from the control room to isolate this flowpath.

Valve EFHV0040 is a normally open isolation valve on the return line from the Train B Essential Service Water System to the service water system. Either this valve or valve EFHV0042 is required to be closed when operating the Train B ESW system for PFSSD. Power and control cables associated with EFHV0040 are run in this area. Damage to these cables could prevent closing EFHV0040 from the control room. Redundant valve EFHV0042 is unaffected by a fire in area C-10 and can be closed from the control room to isolate this flowpath.

References: XX-E-013, E-15000, E-13EF02, E-13EF02A, E-13EF03, E-13EF06A, E-1F9402A, E-1F9402B, E-1F9403

5.2.9 Component Cooling Water

For PFSSD, the component cooling water (CCW) system is used to provide cooling to the centrifugal charging pump (CCP) oil cooler, seal water heat exchanger, RHR heat exchangers and RHR pump seal coolers. In addition, the CCW system provides cooling to the RCP thermal barriers and is credited as a backup to RCP seal injection for maintaining seal cooling.

Power and control cables associated with Train B CCW pump motors DPEG01B and DPEG01D are run through area C-10. Damage to these cables could prevent operation of either pump or could cause the spurious operation of either or both pumps. Power to these pumps are supplied by 4.16 kV bus NB02. Spurious operation or maloperation of the Train B CCW pumps will not impact the ability to achieve and maintain PFSSD

Cable 14GLG06BD is associated with the automatic start circuit for the Train B CCW pump room cooler SGL11B. With hand switch GLHIS0023 in AUTO position, operation of either Train B CCW pump will close a contact in this circuit and start the room cooler. Damage to this cable due to a fire will either spuriously start the room cooler, prevent it from starting or blow the CPT secondary side fuse and drop power to the control circuit. In either case, Train A CCW room cooler SGL11A is unaffected by a fire in area C-10.

Cable 14EGG05DD, associated with Train B CCW valve EGHV0054, is run in this area. This cable supplies power to auxiliary relay 3XEG10 which provides permissives to open or close valves in the CCW supply to and from the Radwaste building. If Train B CCW is operating at the time of the fire, valve EGHV0054 will be open. Damage to cable 14EGG05DD could cause the control power fuse to blow and prevent closure of EGHV0054 when lining up Train A CCW. A loss of power to NB02, which is possible if a fire occurs in this area, could also prevent

closure of valves EGHV0016 and EGHV0054. Operation of Train A CCW with valves EGHV0016 and EGHV0054 open could cause Train A CCW flow to divert to Train B CCW system. Per calculation M-EG-24, the system will continue to operate with no damage to the pumps if the valves in the opposite train are open.

Based on the above discussion, Train B CCW could be affected by a fire in this area but Train A CCW is available.

References: XX-E-013, E-15000, E-13EG01C, E-13EG01D, E-13EG05D, E-13GL06, E-13NB05, Calculation M-EG-24

5.2.10 Residual Heat Removal System

Power and control cables associated with Train B RHR pump motor DPEJ01B are run through area C-10. Damage to these cables could prevent operation or cause spurious operation of the pump. Power to this pump is supplied by 4.16 kV bus NB02. As stated earlier, bus NB02 can be de-energized if a fire occurs in area C-10, however the Train B diesel generator may start and re-energize NB02. If the Train B RHR pump operates, PFSSD is assured since power and control cables associated with Train A RHR pump motor DPEJ01A are not run through area C-10 and will be unaffected by the fire.

Power and control cables for Train B RHR pump discharge valve EJHV8804B to the safety injection pumps runs through area C-10. This valve is required to be closed when operating the Train B RHR system for PFSSD to prevent inventory loss from the RCS. Since the B Train RHR pump could be unavailable, the position of this valve (open or closed) will have no adverse impact on PFSSD because the Train A RHR system is available if a fire occurs in area C-10.

Power and control cables associated with Train B RHR pump miniflow valve EJFCV0611 are run in area C-10. Damage to these cables could prevent operation of the valve and cause damage to the Train B RHR pump, if it is operating. Train A RHR miniflow valve EJFCV0610 is unaffected by a fire in area C-10.

Power and control cables associated with Train B RHR pump room cooler SGL10B are run in area C-10. Damage to these cables will prevent operation of the room cooler. Train A RHR room cooler SGL10A circuits do not run in area C-10 and are unaffected by a fire. Therefore, Train A RHR room cooler will be available.

Train A RHR pump PEJ01A and associated components are unaffected by a fire in area C-10 and will be used to provide decay heat removal during cold shutdown. Therefore, PFSSD is assured using Train A RHR system if a fire occurs in area C-10.

References: XX-E-013, E-15000, E-13EJ01, E-13EJ04B, E-13EJ08, E-13EJ08A, E-13GL05, E-13NB04

5.2.11 Safety Injection (SI) Pumps

The preferred PFSSD condition of the SI pumps is off. Therefore, a spurious start of the SI pumps should be avoided or mitigated. A control cable (14EMB01BB) associated with the Train B SI pump PEM01B runs through area C-10 and could cause the spurious start of the pump. The cable damage could prevent stopping the pump from the control room.

The pump is powered from the 4.16 kV bus NB02. As stated earlier, the NB02 bus can be de-energized, except that a spurious start of the Train B diesel generator may occur. In addition, breaker NB0211 could spuriously close due to damage to control cables associated with

breaker NB0211, which would re-energize the bus and provide power to the Train B SI pump motor.

If the Train B SI pump spuriously starts with the reactor at normal pressure, PFSSD will be assured. The pump will not discharge into the RCS due to the pressure differential between the RCS (2,235 psig) and the SI pump shutoff pressure (1,565 psig). In addition, the setpoint of the discharge relief valve (EM8853B) to the Recycle Holdup Tank is 1,825 psig. Therefore, no inventory is lost from the RWST. With the SI pump operating with no flow, damage to the pump could occur which is a commercial concern since the SI pump is not credited in the PFSSD analysis. Based on a review of the cable routing in E-15000, valve EMHV8814B is unaffected by the fire and would likely remain open to ensure an operable return flow path to the RWST. Maintaining this valve open ensures minimum flow across the pump to prevent damage due to cavitation. Since the position of EMHV8814B does not affect PFSSD, it is not credited as a PFSSD component.

Based on the above discussion, spurious operation of the Train B SI pump will not adversely impact PFSSD.

References: XX-E-013, E-15000, E-13EM01, E-13NB04

5.2.12 Containment Spray (CS) Pumps

Spurious start of the CS pumps may complicate PFSSD due to the possible depletion of inventory in the RWST. Therefore, a spurious start of the CS pumps should be avoided or mitigated. A control cable (14ENB01BB) associated with the Train B CS pump PEN01B runs through area C-10 and could cause the spurious start of the pump. The cable damage could prevent stopping the pump from the control room.

The pump is powered from the 4.16 kV bus NB02. As stated earlier, the NB02 bus can be de-energized, except that a spurious start of the Train B diesel generator may occur. In addition, breaker NB0211 could spuriously close due to damage to control cables associated with breaker NB0211, which would re-energize the bus and provide power to the Train B CS pump motor.

If the Train B CS pump spuriously starts, normally closed valve ENHV0012 will remain closed, since a spurious containment spray actuation signal (CSAS) is not credible for a fire in area C-10. In addition, cables associated with valve ENHV0012 do not run in area C-10. Therefore, if the CS pump operates, inventory will not be lost from the RWST.

References: XX-E-013, E-15000, E-13EN01, E-13NB04

5.2.13 Control Room A/C Units

Cable 14GKG02BA is the SGK04B 480 VAC power cable from Load Center NG0205 to power and control panel GK199C. Damage to this cable due to a fire could prevent operation of Train B Control Room A/C unit SGK04B. Circuits for Train A Control Room A/C unit SGK04A do not run through area C-10 and are unaffected by a fire.

Power and control cables associated with Train B Control Room A/C unit supply and return dampers GKHZ0040A and GKHZ0040B are run in area C-10. Damage to these cables could prevent operation of the associated dampers. Circuits for Train A Control Room A/C unit dampers do not run in area C-10.

Based on the above discussion, Control Room environmental conditions will be unaffected by a fire in area C-10.

References: XX-E-013, E-15000, E-13GK02C, E-13GK02D

5.2.14 Class 1E Electrical Equipment Room A/C Unit

Power and control cables associated with Train B Class 1E Electrical Equipment room A/C unit SGK05B are run in area C-10. A fire could damage these circuits and prevent operation of the unit. Circuits for Train A Class 1E Electrical Equipment A/C unit SGK05A do not run in area C-10. Train A equipment is primarily used if a fire occurs in area C-10.

Based on the above discussion, Train B class 1E equipment room cooling is available and is unaffected by a fire in area C-9.

References: XX-E-013, E-15000, E-13GK13A

5.2.15 Train B Diesel Generator Room Ventilation

Diesel generator room ventilation is required to ensure a suitable environment for operation of the diesel engine and associated equipment. In addition, diesel generator room ventilation is required to provide combustion air to the diesel engine.

Control cables associated with Train B diesel generator room exhaust damper GMHZ0019 are run in area C-10. The damper is maintained closed by an energized 125 VDC solenoid, and opens upon loss of power to the solenoid. Loss of power to the circuit due to cable damage will cause the damper to fail open, which is the desired PFSSD position when operating the Train B diesel generator. A hot short could maintain power to the solenoid and prevent automatic opening of the damper when the diesel runs or the supply fan operates.

Cable 14GMI02CA is associated with Train B diesel generator room temperature element GMTE0011. Cable 14GMI02CB is associated with Train B diesel generator room inlet damper GMTZ0011A. Cable 14GMI02CC is associated with Train B diesel generator room recirculation damper GMTZ0011B. Damage to these cables could prevent proper operation of the ventilation system. The Train A diesel generator room ventilation system is unaffected by a fire in this area.

Cable 14GMG01BH is associated with control room isolation switch GMHS0011B for ventilation supply fan DCGM01B. Damage to the cable could prevent operation of the fan.

Temperature switch GMTSL0011 is located in panel RP147B. The temperature switch contact opens on low room temperature and prevents operation of supply fan DCGM01B. Damage to cable 14GMG01BK or this temperature switch could prevent operation of the supply fan. Train A diesel generator room supply fan DCGM01A is unaffected by a fire in area C-10.

Based on the above discussion, the Train B emergency diesel generator room ventilation system could be affected by a fire in area C-10. The Train A emergency diesel generator room ventilation system is unaffected.

References: XX-E-013, E-15000, E-13GM01A, E-13GM02, E-13GM04, E-13GM04A

5.2.16 Train B Emergency Fuel Oil Transfer Pump PJE01B

Control cables associated with the Train B emergency fuel oil transfer pump are run in area C-10. Damage to these cables due to a fire could cause a hot short that would spuriously start the transfer pump. The hot short could bypass the high day tank level contact, which would prevent automatic shutdown of the transfer pump. If this occurs, diesel fuel could continuously be pumped from the underground storage tank into the day tank. The day tank overflow will direct the fuel back to the underground storage tank and is capable of handling full flow from the transfer pump, even with the diesel generator not operating.

Based on the piping configuration of the day tank vent and overflow, it is unlikely that fuel oil will be pumped through the outside vent opening. However, if this does occur, PFSSD is assured due to the 100% capacity Train A diesel generator storage tank. Splling diesel fuel on the ground only poses an environmental concern, not a PFSSD concern.

Damage to the cables could also prevent operation of the transfer pump. The EDG can only operate for approximately 1 hour fully loaded on the contents of the day tank. Loss of the transfer pump would prevent continuous operation of the Train B EDG.

A fire in area C-10 credits Train A components using the Train A EDG. Off-site power to NB01 could be lost. Loss of the Train B EDG due to a fire in this area will not affect PFSSD.

References: XX-E-013, E-15000, E-13JE01, E-13JE01A, E-13JE02, E-13JE04, M-10JE, M-12JE01

5.2.17 Train B Emergency Diesel Generator

Power and control cables associated with Train B diesel generator control panel KJ122 are run in area C-10. Damage to these cables could prevent operation of the diesel generator. As stated throughout this evaluation, several Train B components are affected by a fire in area C-10, however redundant Train A components, including the Train A diesel generator, are available. Cables associated with Train A diesel generator control panel KJ121 do not run in area C-10.

Cable 14KJK07AE is associated with the Train B emergency diesel generator governor control. Damage to this cable could prevent operation or cause maloperation of the Train B diesel generator. The Train A diesel generator governor controls are located in a separate fire area and are unaffected by the fire.

References: XX-E-013, E-15000, E-13KJ03A

5.2.18 Standby Diesel Generator Power Availability

Several cables associated with Train B diesel generator power and control are run in area C-10. Damage to these cables could prevent the Train B diesel generator from automatically or manually lining up to supply power to NB02. Train A diesel generator power and control circuits do not run in area C-10 and are unaffected by the fire.

References: XX-E-013, E-15000, E-13NE02, E-13NE11, E-13NE13

5.2.19 Class 1E 120 VAC Electrical Distribution System

The Class 1E 120 VAC electrical distribution system provides power to vital instrumentation and control loads for shutdown and normal operation. Under normal conditions, the system is supplied by inverters connected to the 125 VDC NK battery system. Swing inverters allow the primary inverters to be taken out of service for maintainance or repair without disrupting power to the associated vital AC bus. In the event of a loss of power to the inverters, a backup source of power is automatically lined up. The backup power source originates from the 480 VAC electrical distribution system (NG).

Cable 14NNG01AA supplies 480 VAC power from NG0~~0~~2AFF3 to inverter NN14. Cable 14NNG01BA supplies 480 VAC power from NG02ABR1 to inverter NN12. Cable 14NNG01CA supplies 480 VAC power from NG02AFF1 to swing inverter NN16. Damage to these cables will disrupt the 480 VAC power source to Inverters NN12, NN14 and NN16.

Cables 14NNK01MA and 14NNK01MB supply 125 VDC power from NK0403 to manual transfer switch NK80. Cables 12NNK01LA and 12NNK01LB supply 125 VDC power from NK0203 to manual transfer switch NK80. Cables 14NNK01MC and 14NNK01MD supply 125 VDC power from manual transfer switch NK80 to swing inverter NN16. Damage to these cables will disrupt the 125 VDC power supply to swing inverter NN16.

Cables 12NNY01GA and 12NNY01GB supply 120 VAC power from swing inverter NN16 to bus NN02 through a manual transfer switch in inverter NN12. Cables 14NNY01HA and 14NNY01HB supply 120 VAC power from swing inverter NN16 to bus NN04 through a manual transfer switch in inverter NN14. Damage to these cables will disrupt the 120 VAC power supply from swing inverter NN16 to the associated 120 VAC distribution panel.

Inverters NN12 and NN14 and 120 VAC vital distribution buses NN02 and NN04 are located in a separate fire area and are unaffected by a fire in area C-10. The 125 VDC power supply to inverters NN12 and NN14 is unaffected by a fire in area C-10. However, as stated in other sections (5.1.11, 5.1.13, 5.1.14), a fire in area C-10 could cause a loss of 480 VAC power to the Train B NK battery chargers (NK22, NK24 and NK26) which will cause a loss of normal power to the NK02 and NK04 125 VDC busses. Batteries NK12 and NK14 are unaffected and can supply 125 VDC to busses NK02 and NK04 to provide power to inverters NN12 and NN14 for a limited time.

Train A vital 120 VAC distribution panels NN01 and NN03 are unaffected by a fire in area C-10. Therefore, in the event of a loss of Train B Class 1E 120 VAC electrical distribution system, the Train A Class 1E electrical distribution switchboards are available to supply redundant PFSSD loads.

Based on the above discussion, damage to cables and components associated with Train B vital 120 VAC distribution panels NN02 and NN04 will not adversely impact the ability to achieve and maintain safe shutdown in the event of a fire in area C-10.

References: XX-E-013, E-15000, E-13NN01

5.2.20 Non-Class 1E 120 VAC Electrical Distribution System

The PFSSD function of the non-Class 1E 120 VAC electrical distribution system is to supply 120 VAC power to Main Control Boards RL017/RL018 and RL021/RL022. The power is split at each MCB to supply specific PFSSD components.

The PFSSD components that depend on 120 VAC power from RL017/RL018 are Residual Heat Removal (RHR) discharge valves EJHCV0606 (Train A) and EJHCV0607 (Train B). Non-class 1E switchboard panel PN07 supplies power from switch PN0736 to valve positioner EJHY0606. Valve positioner EJHY0606 controls the position of EJHCV0606 using hand controller EJHIC0606. Non-class 1E switchboard panel PN08 supplies power from switch PN0833 to valve positioner EJHY0607. Valve positioner EJHY0607 controls the position of EJHCV0607 using hand controller EJHIC0607.

The PFSSD components that depend on 120 VAC power from RL021/RL022 are temperature recorders BBTR0423, BBTR0433 and BBTR0443. Non-class 1E switchboard panel PN07 supplies power from switch PN0738 to temperature recorder BBTR0423. Non-class 1E switchboard panel PN08 supplies power from switch PN0835 to temperature recorders BBTR0433 and BBTR0443.

Cables 14PNG01AD and 14PNG01AE supply 480 VAC power from NG002BBF1 to 480/120V transformer XPN08A. Damage to either of these cables due to a fire in area C-10 will result in a loss of power to the transformer and loss of 120 VAC feed to PN08 from this power source.

A redundant source of power to PN08 exists. The redundant power feed originates from PG20GER5 (480 VAC) and supplies 480/120V transformer XPN08D. Transformer XPN08D supplies 120 VAC power to voltage regulator PN08A which then supplies the alternate source of power to PN08.

Cables associated with the alternate power feed to PN08, through transformer XPN08D, do not run in area C-10 and are unaffected by the fire. Therefore, PN08 remains available to energize its respective PFSSD loads.

Non-class 1E 120 VAC power to panel PN07 is unaffected by a fire in this area.

References: XX-E-013, E-15000, E-13PN01, E-13PN01A, E-1F9421

5.2.21 Engineered Safety Features (ESF) Transformer XNB01

Cable 16NBA10AB is associated with the automatic fault protection circuit for ESF transformer XNB01. Damage to this cable due to a fire in area C-10 could cause a spurious trip of switchyard breakers 13-8 and 13-48, which provide power to XNB01. Damage could also prevent automatic trip of the breakers in the event of a fault.

As discussed in Section 5.1.9, transformer XNB01 can be isolated using available hand switches in the control room. Loss of power to XNB01 will not adversely impact PFSSD since Train A diesel generator is available to supply bus NB01 and associated Train A PFSSD loads. Therefore, damage to this cable will not impact the ability to achieve and maintain safe shutdown in the event of a fire in area C-10.

References: XX-E-013, E-15000, E-13NB10

5.2.22 Train B Class 1E Equipment Bus NB02

Cable 16NBB03AB is associated with the differential protective relay 287/T1 that monitors the potential differential between the primary side of XNB01 and the secondary side at alternate feeder breaker NB0212. Damage to this cable due to a fire could cause a spurious differential signal. If XNB01 is being used to supply NB02 at the time of the fire, the feeder breaker to XNB01 may trip, causing a loss of power to NB01 and NB02.

Cables 16NBB05AD and 16NBB05AL are associated with the differential protective relay for XNB02. Damage to this cable due to a fire could cause a spurious differential current signal and trip the feeder breaker to XNB02.

Loss of power to XNB01 and XNB02 due to damage to the cables listed above will not adversely impact PFSSD due to the availability of the Train A diesel generator to supply power to NB01. Therefore, PFSSD can be achieved using Train A Class 1E equipment powered by the Train A emergency diesel generator.

References: XX-E-013, E-15000, E-13NB03, E-13NB05, E-13NB06, E-13NB11

5.2.23 CVCS Heat Tracing

Heat tracing has been installed to maintain the emergency borate line and other fluid lines above the solidification temperature in the Train A SI pump room. Both safety trains can power the heat tracing; an automatic transfer switch (QJS0001) switches from Train A (primary source) to Train B (alternate source) on loss of A Train.

Fire area C-10 contains one cable (14NGY13BA) associated with the CVCS heat tracing system. Damage to this cable will affect the secondary power feed to the heat tracing system but the primary power feed is unaffected. Therefore, CVCS heat tracing is not affected by a fire in this area.

5.2 PFSSD CABLE EVALUATION 10

1.0 GENERAL AREA DESCRIPTION

Fire area C-11 is located on the 2000 elevation of the Control Building and includes the room listed in Table C-11-1.

Table C-11-1
Rooms Located in Fire Area C-11

ROOM #	DESCRIPTION
3305	South Electrical Chase - 2000 Elevation

Fire area C-11 is protected with an automatic wet-pipe sprinkler system and automatic fire detection. The area is separated from adjacent areas by minimum 3-hour fire resistant construction.

2.0 PRIMARY EQUIPMENT USED FOR PFSSD

Table C-11-2 lists each system credited for post-fire safe shutdown and provides a discussion regarding the availability of the system to perform its Post Fire Safe Shutdown (PFSSD) function if a severe fire occurs in this area. For a summary of the area analysis results, see Section 8.0 of the Fire Area Analysis Narrative section.

Table C-11-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-11

System	System Name	PFSSD Function*	Comments
AB	Main Steam	R, M, H, P, S	Cables associated with S/G ARV ABPV0004 may be damaged, preventing control of this valve from the control room. The ARV can be isolated by closing air supply valve KAV1429 and nitrogen supply valve KAV1365, then bleeding air from the regulator but this action is not required for PFSSD.
AC	Main Turbine	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-11.
AE	Main Feedwater	H, P	Steam generator D wide range level indicator AELI0504 in the main control room (MCR) may be affected. Steam generators B and D wide range level indication at the auxiliary shutdown panel (ASP) may be affected. All four narrow range level indicators in the (MCR) are unaffected.
AL	Aux. Feedwater System	H, P	Train B motor driven auxiliary feedwater pump (MDAFP) may be affected. Train A MDAFP is available to supply auxiliary feedwater to SGs B and C. The turbine driven auxiliary feedwater pump will operate, but it may be limited to supplying only steam generators A, C and D. Steam generator D flow transmitter ALFT0001 may be affected. Steam generators A, B and C flow transmitters are unaffected. Valves ALHV0005 (MDAFP B to SG D) and ALHV0010 (TDAFP to SG B) may be affected. Valves from MDAFP A to SGs B and C and from the TDAFP to SGs A, C and D are unaffected. MDAFP B suction pressure transmitter ALPT0024 may be affected. MDAFP A suction pressure transmitter ALPT0025 is unaffected. TDAFP suction pressure transmitter ALPT0026 is unaffected.
AP	Condensate Storage System	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-11.
BB	Reactor Coolant System	R, M, H, P, S	Block valve BBHV8000B may fail to respond to a close signal. PORV BBPCV0456A is unaffected and will remain closed. RCS pressure transmitter BBPT0406 may be affected and pressure indicator BBPI0406 may not function. Pressure transmitter/indicator BBPT0405/BBPI0405 is unaffected. Pressurizer level indicator BBLI0460B located at the ASP may be affected. Pressurizer level indication in the MCR using BBLI0459A or BBLI0460A is unaffected. Reactor coolant pumps C and D may not stop using the control room hand switch. RCP seal injection and thermal barrier cooling remain available. Therefore, the inability to stop the RCPs will have no adverse impact on PFSSD.
BG	Chemical and Volume Control System	R, M, S	VCT outlet valve BGLCV0112C may not close in response to a control room signal or could spuriously close. Redundant valve BGLCV0112B is unaffected. Train B centrifugal charging pump (CCP) to RCP seal injection isolation valve BGHV8357B could be affected. The Train A RCP seal injection valve BGHV8357A is unaffected.

Table C-11-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-11

System	System Name	PFSSD Function*	Comments
BM	Steam Generator Blowdown System	R, M, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-11.
BN	Borated Refueling Water Storage System	R, M, H	The Train B RWST to CCP suction valve BNLCV0112E may be affected. The Train A RWST to CCP suction valve BNLCV0112D is unaffected. RWST to Train B RHR pump valve BNHV8812B may be affected. RWST to Train A RHR pump valve BNHV8812A is unaffected.
EF	Essential Service Water System	H, S	Several Train B ESW valves and the Train B ESW pump may be affected. Train A ESW system is unaffected.
EG	Component Cooling Water System	S	Train B CCW pumps PEG01B and PEG01D may be affected. Train A CCW pumps PEG01A and PEG01C are unaffected.
EJ	Residual Heat Removal System	M, H, P	Several components in the Train B RHR system, including the Train B RHR pump, may be affected. The Train A RHR system is unaffected.
EM	High Pressure Coolant Injection	R, M	The Train B SI pump may spuriously start and may not be able to be stopped from the control room. Actual safety injection will not occur until the RCS pressure decreases below that of the pump shutoff pressure. The pump can be stopped, if necessary, by opening breaker NB0202, but this action is not required for PFSSD.
EN	Containment Spray	R, M	The Train B CS pump may spuriously start. Valve ENHV0012 will remain closed, preventing flow from the CS nozzles. The pump can be stopped, if necessary, by opening breaker NB0203, but this action is not required for PFSSD.
EP	Safety Injection Accumulators	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-11.
FB	Auxiliary Steam	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-11.
FC	Auxiliary Turbines	R, H, P	Valve FCFV0105 may be affected. The MSIVs can be closed using all-close hand switches ABHS0079 or ABHS0080.
GD	ESW Pump House HVAC	S	Train B ESW pump room ventilation may be affected. Train A ESW pump room ventilation is unaffected.
GF	AFW Pump Room Coolers	S	Train B motor driven auxiliary feedwater pump room cooler SGF02B may be affected. Train A motor driven auxiliary feedwater pump room cooler SGF02A is unaffected.

Table C-11-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-11

System	System Name	PFSSD Function*	Comments
GK	Control Room and Class 1E Switchgear Room Coolers	S	Train B control room A/C unit SGK04B may be affected. Train A control room A/C unit SGK04A is unaffected. Train B Class 1E electrical equipment A/C unit SGK05B may be affected. Train A Class 1E electrical equipment A/C unit SGK05A is unaffected.
GL	Auxiliary Building HVAC	S	Train B RHR pump room cooler SGL10B may be affected. Train A RHR pump room cooler SGL10A is unaffected. Train B CCW pump room cooler SGL11B may be affected. Train A CCW pump room cooler SGL11A is unaffected. Train B CCP pump room cooler SGL12B may be affected. Train A CCP pump room cooler SGL12A is unaffected.
GM	Emergency Diesel Generator Room HVAC	S	Cables associated with Train B diesel generator room exhaust damper GMHZ0019 are run in this area. Train A diesel generator room ventilation is unaffected.
GN	Containment Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-11.
JE	Diesel Fuel Oil	S	Train B emergency diesel fuel oil transfer pump DPJE01B may be affected. Level indication for the Train B fuel oil storage tank may be lost. Train A emergency diesel fuel oil transfer pump DPJE01A and Train A fuel oil storage tank level transmitter are unaffected.
KA	Instrument Air	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-11.
KC	Fire Protection	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-11.
KH	Service Gas	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-11.
KJ	Standby Diesel Engine	S	Train B emergency diesel engine may not be available. The Train A emergency diesel engine is unaffected.
MA	Main Generation	S	A cable associated with phase differential relay 287/T1 in transformer protection relay panel MA104F could be affected. This could cause a loss of offsite power to NB01. Cables associated with MA104E are unaffected.
MR	Startup Transformer	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-11.
NB	4.16 kV System	S	A loss of off-site power to NB01 and NB02 may occur. The Train A diesel generator is available to energize the NB01 bus if this occurs.

Table C-11-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-11

System	System Name	PFSSD Function*	Comments
NE	Standby Diesel Generator	S	Train B emergency diesel generator may not be available. The Train A emergency diesel generator is unaffected.
NF	Load Shed and Emergency Load Sequencing	S	Some cables associated with the load shedder/sequencer on both trains could be affected. However, damage to these cables will not prevent the equipment from performing its intended function.
NG	480V Load Centers and MCCs	S	A loss of offsite power to the Train A and B 480 Volt load centers may occur. The Train A diesel generator is available to energize the Train A load centers if this occurs.
NK	125VDC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-11.
NN	120VAC	S	Train B Class 1E 120 VAC electrical distribution system may be affected. The Train A Class 1E 120 VAC electrical distribution switchboards are unaffected.
PA	13.8kV	S	Cables associated with PA0201 phase differential relay 287/T2 could be affected, causing a loss of off-site power to NB02. In addition, the Train B EDG may not be available. The Train A EDG is available to supply power to Train A PFSSD loads.
PB	4.16kV	H, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-11.
PG	480V Load Centers and MCCs	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-11.
PK	125VDC	S	Battery charger PK22 may be affected. Battery set PK12 will provide short-term 125 VDC power to PK02. Train A non-class 1E 125 VDC system is unaffected.
PL	Local Instrument Panels	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-11.
PN	120VAC	S	The primary source of power to non-class 1E 120 VAC switchboard PN08 may be affected but the alternate source of power is unaffected. Both sources of power to non-class 1E 120 VAC switchboard PN07 are unaffected.
QB	Standby AC Lighting	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-11.
QD	Emergency Lighting	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-11.

Table C-11-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-11

System	System Name	PFSSD Function*	Comments
RL	Control Room MCB	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-11.
RP	Miscellaneous Control Panels	R, M, H, P, S	Panel RP140 could lose Class 1E 125 VDC power from NK4415. This affects three relays associated with Train B ESW system. Train A ESW remains available. Panel RP335 could lose Class 1E 125 VDC power from NK4419. This affects control room lockout relays associated with Train B motor driven and turbine driven auxiliary feedwater. Train A motor driven auxiliary feedwater remains available. Train B 120 VAC power to control room panels RP147B and RP068 could be lost. Train A 120 VAC power remains available to supply redundant PFSSD loads.
SA	ESFAS	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-11.
SB	Reactor Protection System	R, S	120 VAC power to cabinet SB148B could be lost. Loss of power to SB148B will result in a loss of capability to monitor AELT0504 and BBPT0406 from the ASP and the MCR. 120 VAC Power to SB148A is unaffected. A number of cables from SB148A and SB148B to the auxiliary shutdown panel (ASP) could be affected, causing a loss of process monitoring at the ASP. Process monitoring in the main control room remains available.
SC	Reactor Instrumentation	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-11.
SE	Ex-Core Neutron Monitoring	R, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-11.
SY	Switchyard	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-11.
UU	Supervisory System	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-11.

* R - Reactivity Control; M - Reactor Coolant Makeup; H - Decay Heat Removal; P - Process Monitoring; S - Support Function

3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD

This section describes operator actions that may need to be performed inside or outside the control room to achieve and maintain hot standby if a fire occurs in area C-11. This section also describes cold shutdown repairs that may need to be made to achieve and maintain cold shutdown conditions. Operator actions are proceduralized in OFN KC-016.

3.1 ACTIONS OUTSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

Operator Manual Actions (OMAs) are those actions outside the main control room required to achieve and maintain hot standby. OMAs are identified in E-1F9900 and were determined from thermal hydraulic analysis WCNOC-CP-002. Applicable E-1F9900 OMAs are annotated herein. All other actions outside the control room are desirable for plant control in support of hot standby but not required to achieve and maintain hot standby.

3.1.1 Steam Generator ARVs

Cables associated with S/G ARV ABPV0004 may be damaged, preventing control of this valve from the control room. The ARV can be isolated by closing air supply valve KAV1429 and nitrogen supply valve KAV1365, then bleeding air from the regulator. Per calculation WCNOC-CP-002, this action is not required to ensure safe shutdown.

3.2 ACTIONS INSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

3.2.1 Component Cooling Water

Train B CCW could be affected by a fire in this area. If this occurs, swap to Train A CCW using normal operating procedures if Train A CCW is not already running.

3.2.2 Reactor Coolant Pump Seal Cooling

If Train B CCW is operating at the time of the fire, it could be lost causing a temporary loss of thermal barrier cooling. The normal charging pump is not analyzed and is assumed lost. Operators should swap to Train A CCW to restore thermal barrier cooling and line up the Train A CCP to restore RCP seal injection.

3.3 ACTIONS TO ACHIEVE AND MAINTAIN COLD SHUTDOWN

None

4.0 CONCLUSION

Post Fire Safe Shutdown is assured if a fire occurs in fire area C-11.

5.0 DETAILED ANALYSIS

This section describes the detailed component-by-component and cable-by-cable analysis for a fire in area C-11.

5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA C-11

Table C-11-3 lists all the PFSSD equipment (S. in E-15000) located in fire area C-11. The applicable evaluation section is also listed in Table C-11-3.

Table C-11-3 PFSSD Equipment Located in Fire Area C-13				
Room #	**PFSSD Equipment**	**Description**	**Evaluation Section**	**Comments**
3305	TB33106	Terminal Box Train B ESW Damper Control Circuit	5.2.9	
3305	TB33107	Terminal Box Valve BNHV8812B Control Circuit	5.2.8	

5.2 PFSSD CABLE EVALUATION

Table C-11-4 lists all the PFSSD cables (S. in E-15000) located in fire area C-11. The applicable evaluation section is also listed in Table C-11-4.

Table C-11-4
PFSSD Cables Located in Fire Area C-11

Cable #	Location	Primary PFSSD Equipment	Cable Function (P) Power (C) Control (I) Instrumentation	Evaluation Section	Comments

5.2.1 Steam Generator Atmospheric Relief Valves

PFSSD requires at least two steam generator atmospheric relief valves (ARV) be controlled and the other two closed. The ARVs are pneumatically operated using air from the compressed air system (KA) or nitrogen from the nitrogen accumulators. The valves open by pneumatic pressure and close by spring action. A pressure transmitter installed on the outlet side of the steam generator sends a signal to a controller and automatically controls the associated ARV position. Alternatively, each ARV can be controlled manually from the control room or the auxiliary shutdown panel by placing the pressure indicating controller (PIC) in manual.

Cables associated with steam generator D ARV ABPV0004 are run in area C-11. Damage to these cables could cause the ARV to spuriously open or prevent control or closure of the ARV. Cables associated with the remaining ARVs are run in a different fire area.

Up to three ARVs can fail closed or open without impacting ability to achieve and maintain hot standby according to thermal hydraulic analysis WCNOC-CP-002. With at least one ARV unaffected, no E-1F9900 OMA is required to address ARV closure or control. Reference Attachment 4, MSO Evaluation Scenario ID PWROG 23.

If ABPV0004 remains open and does not self-mitigate, operators can close the ARV by isolating air and nitrogen to fail the ARV closed. Air is isolated by closing valve KAV1429 and nitrogen is isolated by closing valve KAV1365. The air and nitrogen supply valves are located in fire area A-23 and access is available without having to traverse area C-11.

Based on the above discussion, ARV ABPV0004 could fail in the open or closed position but no action is necessary to mitigate the failed ARV. PFSSD is assured using the remaining three ARVs.

References: E-15000, XX-E-013, E-13AB20B, E-1F9101, M-12AB01, M-12KA04, M-12KA05, WCNOC-CP-002

5.2.2 Process Monitoring Fire Isolation Cabinets SB148A and SB148B

The PFSSD function of cabinets SB148A and SB148B is to provide reliable process monitoring instrumentation at the auxiliary shutdown panel (ASP) in the event of a fire in the control room. This allows operators the ability to monitor critical process variables during shutdown from outside the control room. Process variables that can be monitored at the ASP as well as in the main control room (MCR) are as follows:

- AELT0502 – Steam Generator B Wide Range Water Level (SB148A)
- AELT0504 – Steam Generator D Wide Range Water Level (SB148B)
- BBLT0460 – Pressurizer Level Transmitter Narrow Range (SB148A)
- BBTE0423B – RCS Loop 2 Cold Leg Temperature Element (SB148A)
- BBTE0443A – RCS Loop 4 Hot Leg Temperature Element (SB148A)
- BBPT0406 – RCS Wide Range Hot Leg Pressure Transmitter (SB148B)

The instrument cable from each transmitter or temperature element runs to the SB148 cabinet indicated above. The signal is split and runs to the ASP and MCR via independent instrument cables. Cable 14SBY09HA is a power cable that provides 120 VAC to cabinet SB148B. A loss of power to SB148B could result in a loss of capability to monitor AELT0504 and BBPT0406 from the ASP and the MCR.

A loss of capability to monitor AELT0504 and BBPT0406 from the MCR will not adversely impact PFSSD. Redundant capability exists to monitor these variables as described below:

- AELT0547, AELT0548, AELT0549 and AELT0554 are available to provide level indication (narrow range) for steam generator D to associated indicators in the control room.
- BBPT0405 is available to provide RCS pressure to pressure indicator BBPI0405.

Based on the above discussion, a fire in area C-11 that affects the process monitoring instrumentation associated with cabinet SB148B will not impact the ability to achieve and maintain PFSSD due to the availability of redundant process monitoring instrumentation in the control room.

References: XX-E-013, E-15000, E-13AE08, E-13BB15, E-13BB16, E-13SB09, E-13SB16, E-13NN01, E-1F9201, E-1F9203, E-1F9205, E-1F9301, E-1F9421, M-12AE02, M-12BB01, M-12BB04

5.2.3 Steam Generator Level Indication

The decay heat removal function for PFSSD requires the use of two RCS loops and two Steam Generators. Steam generator (SG) level indication is required to support this function.

An instrument cable associated with steam generator D wide range level transmitter AELT0504 is run in this area. Damage to this cable could prevent wide range indication of steam generator D level in the control room. Cables associated with all four steam generator D narrow range level transmitters are run in a different fire area and are unaffected by a fire in C-11. Therefore, level indication on steam generator D is available.

Based on the above discussion, steam generator level indication is available on all four steam generators.

References: E-15000, XX-E-013, E-13AE08, E-1F9203, M-12AE02

5.2.4 Auxiliary Feedwater

The PFSSD design requires the use of one auxiliary feedwater pump (AFP) supplying water to at least two steam generators. The turbine driven auxiliary feedwater pump (TDAFP) is aligned to supply all four steam generators. The Train A motor driven auxiliary feedwater pump (MDAFP) is aligned to supply steam generators B and C. The Train B MDAFP is aligned to supply steam generators A and D.

Cables associated with Train B MDAFP are run in area C-11. Damage to these cables could prevent operation of the pump. The Train A MDAFP and the TDAFP remain available to ensure auxiliary feedwater.

Cables associated with valves ALHV0030 and ALHV0034 could be damaged by a fire and cause the valves to spuriously close, or prevent operation from the control room. These valves control the Train B MDAFP suction from the essential service water (ESW) and condensate storage tank (CST) sources, respectively. Suction supply valves from ESW and CST to the Train A MDAFP are unaffected by a fire in this area.

Cables associated with valve ALHV0033 could be damaged by a fire and prevent operation from the control room. This valve provides a suction source from Train B ESW to the TDAFP and is normally closed. The CST and Train A ESW suction sources to the TDAFP are unaffected.

The Train B MDAFP to steam generator (SG) D control valve (ALHV0005) may spuriously close or may not operate. The TDAFP is available to supply SG D through valve ALHV0006, which is unaffected by a fire in area C-11.

Valve ALHV0010 could be affected such that the valve cannot be controlled from the control room or the valve may spuriously close. This valve controls auxiliary feedwater flow from the TDAFP to SG B. Valve ALHV0009 is unaffected by a fire in area C-11 and is available to ensure an adequate auxiliary feedwater supply from the Train A MDAFP to SG B.

Auxiliary feedwater to SG D flow transmitter ALFT0001 may be affected. Flow transmitters on SGs A, B and C supply lines are unaffected.

Train B MDAFP suction pressure transmitter (ALPT0024) may be affected. Suction pressure transmitters on Train A MDAFP and TDAFP suction lines are unaffected.

A cable (14GFG01BC) associated with the Train B MDAFP room cooler motor (DSGF02B) is run in this area. Damage to this cable could prevent operation of the cooler. The Train A MDAFP room cooler (SGF02A) is unaffected.

In summary, the Train A MDAFP is available to supply auxiliary feedwater to SGs B and C using either the CST or the ESW as the supply. In addition, the TDAFP is available to supply auxiliary feedwater to steam generators A, C and D using either the CST or the ESW as the supply, however the flow transmitter for SG D may not be available.

References: E-15000, XX-E-013, E-13AL01B, E-13AL02B, E-13AL03B, E-13AL04B, E-13AL05B, E-13AL07B, E-13AL09, E-13GF01, E-1F9202, E-1F9203, E-1F9204, E-1F9444, M-12AL01, M-12GF01

5.2.5 Pressurizer Power Operated Relief Valves and Associated Block Valves

PFSSD requires that either the pressurizer power operated relief valve (PORV) or its associated block valve be closed.

A fire in area C-11 could damage cables for block valve BBHV8000B such that the block valve fails to respond to a close signal. Cables associated with redundant pressurizer PORV BBPCV0456A do not run in area C-11. Therefore, the pressurizer PORV will function normally throughout the event. Cables associated with BBHV8000A and BBPCV0455A do not run in fire area C-11.

Based on the above discussion, both pressurizer relief flow paths will remain isolated in the event of a fire in area C-11.

References: E-15000, XX-E-013, E-13BB39, E-1F9301, M-12BB02

5.2.6 Reactor Coolant System (RCS) Pressure Indication

PFSSD requires RCS pressure indication to be available. RCS pressure indication is provided in the control room using BBPI0405 or BBPI0406. Cables for BBPT0406 and BBPI0406 run through fire area C-11. Therefore, pressure indicator BBPI0406 may not function.

Cables for BBPT0405 are run in a separate fire area and are unaffected by a fire in area C-11. Therefore, RCS pressure indication will be available using BBPI0405 if a fire occurs in area C-11.

References: E-15000, XX-E-013, E-13BB16, E-1F9201, M-12BB04

5.2.7 Centrifugal Charging System

The PFSSD reactivity control and makeup functions require an available centrifugal charging pump (CCP) taking suction from the RWST and injecting through the reactor coolant pump (RCP) seals or through the boron injection tank (BIT). The normal charging pump (NCP) is not credited for PFSSD and is assumed lost.

Cable 14BGB01BB is a control cable associated with Train B CCP motor DPBG05B. Damage to this cable could prevent operation, or cause maloperation, of the CCP. Cables associated with Train A CCP motor DPBG05A are unaffected by a fire in this area.

Power and control cables associated with Train B CCP miniflow valve BGHV8111 are run through area C-11. Cables for Train A CCP miniflow valve BGHV8110 are unaffected by a fire in area C-11.

Valves BGLCV0112B and BGLCV0112C are series installed isolation valves on the discharge side of the VCT. The PFSSD position of these valves is at least one closed with the RWST lined up to the charging header. Both valves are required to be open if the credited charging pump is operating and the RWST is not lined up to the charging header, to ensure a positive suction head on the charging pump. Continued operation in this manner could damage the charging pump due to hydrogen intrusion because makeup to the VCT via the letdown path is not ensured.

Power and control cables associated with valve BGLCV0112C are run in this area. Damage to these cables could prevent closing the valve from the control room. Redundant valve BGLCV0112B is unaffected and will close using the handswitch (BGHIS0112B) in the control room or in response to an automatic signal.

Cable 14BGG12BE provides the permissive for valve BGLCV0112C to close when either a SIS or a VCT low-low level is received coincident with a fully open RWST to CCP valve BNLCV0112E. Cable 14BGG12BD monitors a position switch on BNLCV0112E and provides the permissive for BGLCV0112C to close when BNLCV0112E is fully open. A simultaneous hot short in these cables would bypass the SIS and VCT low-low level contacts as well as the BNLCV0112E position contact and signal valve BGLCV0112C to close. If this occurs prior to the RWST being lined up to the charging header, damage to the operating charging pump could occur.

Calculation XX-E-013, assumption 3-A-22, states that systems and components are in their normal operating position or status prior to the fire. The NCP is the normally operated pump and is assumed to be operating at the time of the fire. Inadvertent closure of valve BGLCV0112C with no suction from the RWST could result in damage to the NCP but the centrifugal charging pumps would remain unaffected.

Power cable 14BGG52BA and control cables 14BGG52BB and 14BGG52BC associated with Train B CCP to RCP seal injection isolation valve BGHV8357B could be affected by a fire in this area. The Train A CCP to RCP seal injection valve BGHV8357A is unaffected by the fire.

Power cable 14BNG01BA and control cables 14BNG01BB, 14BNG01BC and 14BNG01BD associated with RWST to CCP suction header valve BNLCV0112E run in this area. Damage to these cables could prevent opening the valve from the control room or in response to an automatic signal. Cables associated with redundant RWST to CCP suction header valve BNLCV0112D are unaffected by a fire in this area. Therefore, the RWST is available to provide suction to the CCPs.

Cable 14GLG05HA is the power cable for Train B CCP room cooler DSGL12B. Damage to this cable will prevent operation of the cooler. The Train A CCP room cooler is unaffected by a fire in this area.

Based on the above discussion, the Train B CCP may not be available but the Train A CCP is unaffected by a fire in area C-11.

References: E-15000, XX-E-013, E-13BG01A, E-13BG11C, E-13BG12A, E-13BG52, E-13BN01A, E-1F9102, E-1F9302, M-12BG03, M-12BN01

5.2.8 Residual Heat Removal

The residual heat removal (RHR) system is required for decay heat removal during transition from hot shutdown to cold shutdown. At least one train of RHR is requried to be operable for PFSSD.

A control cable associated with Train B RHR pump motor DPEJ01B is run in this area. In addition, cables associated with Train B RHR pump miniflow valve EJFCV0611 and RHR pump B miniflow indicating switch EJFIS0611 are run in this area. Damage to these cables could affect operation of the Train B RHR pump. The Train A RHR pump and miniflow valve are unaffected by a fire in this area and remain available to ensure shutdown cooling.

Terminal box, power and control cables associated with RWST to Train B RHR pump valve BNHV8812B run in this area. Damage to the terminal box and cables could prevent opening the valve or could cause the valve to spuriously open. Maloperation of this valve would prevent establishing a suction source from the RWST to the Train B RHR pump. Cables associated with RWST to Train A RHR pump valve BNHV8812A do not run in this area. Therefore, the RWST is available to provide a suction source to the Train A RHR pump. Spurious operation of BNHV8812B would allow the RWST to drain to the containment sump if containment sump isolation valve EJHV8811B were to spuriously open. Cables associated with EJHV8811B do not run in fire area C-11. In addition, a fire-induced spurious safety injection signal or RWST low-low level signal is not credible. Therefore, containment sump isolation valve EJHV8811B will not spuriously open and the RWST will not drain to the containment sump.

Valve EJHV8804B is the RHR pump B to Safety Injection pump isolation valve. Cable 14EJG04BA is the power cable for valve EJHV8804B. Cables 14EJG04BB and 14EJG04BC are control cables for valve EJHV8804B. Valve EJHV8804B is normally closed and is required to remain closed during RHR Train B operation. Damage to the power cable would cause the valve to remain in its normally closed position. Damage to the control cables could result in the valve spuriously opening. The Train A RHR pump is credited if a fire occurs in this area. Therefore, spurious opening of this valve will not adversely impact PFSSD.

Power cable 14GLG05BA, associated with Train B RHR pump room cooler SGL10B, may be damaged, causing inoperability of the cooler. Train A RHR pump room cooler SGL10A is unaffected.

Based on the above discussion, the Train B RHR system may be affected by a fire in area C-11 but the Train A RHR system is unaffected.

References: E-15000, XX-E-013, E-13BN03A, E-13EJ01, E-13EJ04B, E-13EJ06B, E-13EJ08, E-13GL05, E-1F9102, E-1F9205, E-1F9401A, M-12BN01, M-12EJ01

5.2.9 Essential Service Water

Either the Train A or the Train B essential service water (ESW) system is required to be available to ensure PFSSD. The ESW system supplies water to the following PFSSD components on the associated train:

- CCP room cooler
- RHR pump room cooler
- Class 1E switchgear room A/C condenser
- diesel generator engine cooling
- control room A/C condenser
- auxiliary feedwater pump room cooler
- motor and turbine driven auxiliary feedwater pump suction (backup to CST)
- containment air coolers
- electrical penetration room cooler
- component cooling water pump room cooler
- component cooling water heat exchanger
- component cooling water system makeup

Cables associated with Train B essential service water (ESW) system run in this area. As discussed below, damage to these cables could prevent operation of the Train B ESW system. However, the Train A ESW system remains available.

Cables 14EFB01SA and 14EFB01SB are associated with Train B ESW pump PEF01B. Damage to these cables could prevent operation of the pump. Cables associated with Train A ESW pump PEF01A run in a separate fire area.

The service water to/from ESW system cross connect flowpath needs to be isolated for PFSSD to prevent flow diversion from ESW to service water. Each cross connect has four series valves; two on the supply and two on the return. The following table identifies the valves on each ESW Train.

Series Installed Service Water to/from Essential Service Water Cross-Connect Valves			
Train A ESW Supply From SW	**Train B ESW Supply From SW**	**Train A ESW Return To SW**	**Train B ESW Return To SW**
EFHV0023	EFHV0024	EFHV0041	EFHV0042
EFHV0025	EFHV0026	EFHV0039	EFHV0040

At least one valve on the supply and one on the return needs to be closed. Cables associated with valves EFHV0025, EFHV0026, EFHV0039 and EFHV0040 are run in this area. Cables associated with valves EFHV0023, EFHV0024, EFHV0041 and EFHV0042 are unaffected. Therefore, at least one valve on each line will be available to ensure the flowpath is isolated. In addition, check valve EFV0470 is installed between valves EFHV0023 and EFHV0025 and will prevent flow diversion from Train A ESW to the service water system. Also, check valve EFV0471 is installed between valves EFHV0024 and EFHV0026 and will prevent flow diversion from Train B ESW to the service water system.

The Train B ESW return to ultimate heat sink (UHS) valve EFHV0038 may be affected due to damage to cables 14EFG06BA, 14EFG06BB and 14EFG06BC. However, cables associated with the Train A ESW return valve to the UHS (EFHV0037) are unaffected.

Train B ESW pump discharge pressure transmitter EFPT0002 may be affected due to damage to an instrument cable (14EFI08RB). Train A ESW pump pressure transmitter EFPT0001 is unaffected.

Train B ESW pump flow transmitter EFFT0054 may be affected due to damage to an instrument cable (14EFI11FA). Train A ESW pump flow transmitter EFFT0053 is unaffected.

The Train B ESW pump room supply fan motor DCGD01B may not be available due to damage to cables associated with the fan. The Train A ESW pump room supply fan motor is unaffected.

Cables 14GDI04BA and 14GDI04BF provide ESW B room temperature from temperature element GDTE0011 to temperature controller GDTC0011. Cables 14GDI04BB and 14GDI04BG provide signals from GDTC0011 to outside air intake damper GDTZ0011A. Cables 14GDI04BC and 14GDI04BH provide signals from GDTC0011 to recirculation damper GDTZ0011B. Terminal box TB33106 provides a connection point for these cables. Damage to these cables or terminal box could prevent operation of the dampers. Temperature controls for Train A ESW pump room are unaffected by a fire in area C-11.

Cable 14GDY01BA is associated with the automatic and manual start circuit for the Train B ESW pump room supply fan. Cable 14GDY01BB is associated with the automatic start on the Train B ESW pump room supply fan control circuit. Upon start of the Train B ESW pump, the contacts on this circuit close and energize the ARC relay, which closes a contact to start the supply fan. Cable 14GDY01BD is associated with a bistable element that prevents the fan from starting if the room temperature is below a pre-determined set point. Damage to these cables due to a fire could spuriously start the fan or prevent it from starting. In either case, the Train A ESW pump room ventilation system is unaffected by a fire in area C-10.

Cable 14RPK09BA supplies 125 VDC power to ESW pump motor B interposing relays 1XEF32, 1XEF34, 1XEF36 located in relay rack RP140. Cable 14EFK01SA is a control cable associated with local hand switch EFHIS0056B. The hand switch and interposing relays operate to control the Train B ESW pump locally. Damage to the cables could prevent local operation of the Train B ESW pump and could override control room hand switch signals, preventing operation of the pump. Local control of the Train A ESW pump is unaffected by a fire in area C-11.

Cable 14EFG02SD is a control cable that provides an automatic start signal to the Train B ESW traveling water screen motor DFEF01B when the Train B ESW pump runs. Damage to the cable could prevent automatic operation of the screen. Circuits for Train A traveling water screen do not run through area C-11.

Cable 14EFG03SD is a control cable associated with ESW Train B screen wash water valve EFHV0092. Damage to this cable could prevent operation of the valve. Circuits for Train A screen wash water valve EFHV0091 do not run through area C-11.

Cable 14EFG06SD is associated with Train A ESW pump air release valve EFHV0098. The air release valve purges air from the pump casing upon pump start to ensure pump operability. Damage to the cable could prevent operation of the air release valve. Circuits for Train A ESW pump air release valve EFHV0097 do not run through area C-11.

Based on the above discussion, the Train A ESW pump and associated components are available if a fire occurs in area C-11.

References: XX-E-013, E-15000, E-093-00055, E-13EF02, E-13EF02A, E-13EF03, E-13EF06A, E-13EF11, E-13RP09, E-1F9402A, E-1F9402B, E-1F9403, E-1F9443, E-K3EF01A, E-K3EF02, E-K3EF03, E-K3EF06, E-K3EF08, E-K3GD01A, E-K3GD04, E-K3GD04A, M-12EF01, M-12EF02, M-K2EF01, M-K2GD01

5.2.10 Component Cooling Water

For PFSSD, the component cooling water (CCW) system is used to provide cooling to the centrifugal charging pump (CCP) oil cooler, seal water heat exchanger, the RHR heat exchanger and the RHR pump seal cooler. In addition, the CCW system provides cooling to the RCP thermal barriers and is credited as a backup to RCP seal injection for maintaining seal cooling.

Cables associated with Train B CCW pump motors DPEG01B and DPEG01D run in this area. Damage to these cables could prevent operation of the pumps. Cables associated with Train A CCW pump motors DPEG01A and DPEG01C are run in a different area.

Cable 14EGG05DD, associated with Train B CCW valve EGHV0054, is run in this area. This cable supplies power to auxiliary relay 3XEG10 which provides permissives to open or close valves in the CCW supply to and from the Radwaste building. If Train B CCW is operating at the time of the fire, valve EGHV0054 will be open. Damage to cable 14EGG05DD could cause the control power fuse to blow and prevent closure of EGHV0054 when lining up Train A CCW. A loss of power to NB02, which is possible if a fire occurs in this area, could also prevent closure of valves EGHV0016 and EGHV0054. Operation of Train A CCW with valves EGHV0016 and EGHV0054 open could cause Train A CCW flow to divert to Train B CCW system. Per calculation M-EG-24, the system will continue to operate with no damage to the pumps if the valves in the opposite train are open.

Cable 14GLG06BD, associated with Train B CCW pump room cooler SGL11B, runs in area C-11. Damage to this cable could prevent automatic operation of the unit. The Train A CCW pump room cooler SGL11A is unaffected by a fire in this area.

Based on the above discussion, the Train B CCW system could be affected by a fire in area C-11 but the Train A CCW system is available.

References: XX-E-013, E-15000, E-13EG01C, E-13EG01D, E-13EG05D, E-13GL06, E-1F9401A, E-1F9444, M-12EG01, M-12GL02, Calculation M-EG-24

5.2.11 Safety Injection Pumps

The PFSSD strategy is to prevent operation of the Safety Injection (SI) pumps to ensure an adequate supply of borated water in the RWST. One cable (14EMB01BB) associated with Train B SI pump motor (DPEM01B) is run in area C-11. Damage to this cable could cause the spurious start of the pump and could prevent stopping the pump from the control room.

If the Train B SI pump spuriously starts with the reactor at normal pressure, PFSSD will be assured. The pump will not discharge into the RCS due to the pressure differential between the RCS (2,235 psig nominal per current operating data) and the SI pump shutoff pressure (1,565 psig per the SI pump curve). In addition, the setpoint of the discharge relief valve (EM8853B) to the Recycle Holdup Tank is 1,825 psig. Therefore, no inventory is lost from the RWST. With the SI pump operating with no flow, damage to the pump could occur, which is a commercial concern only since the SI pump is not credited in the PFSSD analysis. If necessary, the pump can be stopped by opening breaker NB0202, but this action is not required for PFSSD.

Based on the above discussion, spurious operation of the Train B SI pump will not adversely impact PFSSD.

References: XX-E-013, E-15000, E-13EM01, E-1F9102, E-1F9302, M-12EM01, WCRE-01

5.2.12 Containment Spray Pumps

Spurious start of the containment spray (CS) pumps may complicate PFSSD due to the possible depletion of inventory in the RWST. Therefore, a spurious start of the CS pumps should be avoided or mitigated. A control cable (14ENB01BB) associated with the Train B CS pump motor DPEN01B runs through area C-11 and could cause a spurious start of the pump. The cable damage could prevent stopping the pump from the control room.

If the Train B CS pump spuriously starts, normally closed valve ENHV0012 will remain closed, since a spurious containment spray actuation signal (CSAS) is not credible for a fire in area C-11. In addition, cables associated with valve ENHV0012 do not run in area C-11. Therefore, if the CS pump operates, inventory will not be lost from the RWST. If necessary, the pump can be stopped by opening breaker NB0203, but this action is not required for PFSSD.

Based on the above discussion, spurious operation of the Train B CS pump will not adversely impact PFSSD.

References: XX-E-013, E-15000, E-13EN01, E-13EN03, E-1F9102, E-1F9302, M-12EN01

5.2.13 Control Room Air Conditioning

Control room air conditioning is required to be available to satisfy the PFSSD support function. Two redundant and independent air conditioning units (SGK04A and SGK04B) are provided to satisfy this function. At least one unit is required to be available for PFSSD.

The power cable (14GKG02BA) that supplies 480 VAC power to panel GK199C runs in this area. Panel GK199C is the power and control panel for Train B control room A/C unit SGK04B. Damage to this cable will prevent operation of SGK04B.

Control cables 14GKY02BA, 14GKY02BB, 14GKY02BC, 14GKY02BD and 14GKY02BE, associated with control room A/C unit SGK04B supply and return dampers GKHZ0040A and GKHZ0040B, are run in this area. Damage to these cables could prevent operation of the dampers.

The Train A control room A/C unit SGK04A is unaffected by a fire in this area. Therefore, control room air conditioning is available if a fire occurs in area C-11.

References: XX-E-013, E-15000, E-13GK02A, E-13GK02C, E-13GK02D, E-1F9442, M-12GK01

5.2.14 Class 1E Electrical Equipment Air Conditioning

The PFSSD support function requires Class 1E electrical equipment air conditioning on the operating train of equipment. Class 1E electrical equipment air conditioning is provided by units SGK05A (Train A) and SGK05B (Train B).

Power cable 14GKG13BA and control cables 14GKG13BG and 14GKG13BH associated with Train B class 1E electrical equipment room A/C unit SGK05B are run in area C-11. Damage to these cables could prevent operation of the unit. Therefore, SGK05B is unavailable if a fire occurs in area C-11.

Power and control cables associated with Train A class 1E electrical equipment room A/C unit SGK05A are unaffected by a fire in this area.

References: XX-E-013, E-15000, E-13GK13A, E-1F9444, M-12GK03

5.2.15 Standby Diesel Generation

PFSSD requires at least one source of electrical power to energize credited PFSSD equipment. The electrical power sources credited for PFSSD include offsite power, where an evaluation shows offsite power is not lost due to a fire, and onsite power using the emergency diesel generators.

Calculation XX-E-013 documents a loss of off-site power evaluation that identifies the fire areas in and around the plant in which a fire could cause a loss of offsite and onsite power. Per XX-E-013 and Section 5.2.16 of this evaluation, a fire in area C-11 could cause a loss of both trains of off-site power and Train B on-site power sources.

Several cables (See Table C-11-3) associated with the Train B diesel engine as well as supporting functions are run in area C-11. Damage to these cables could prevent operation of the Train B diesel engine. The Train A diesel engine/generator is unaffected by a fire in area C-11 and is available to energize PFSSD equipment supplied by NB01.

Based on the above discussion, the Train A emergency diesel generator is available if a fire occurs in area C-11.

References: XX-E-013, E-15000, E-12KJ01, E-13GM01A, E-13GM04A, E-13JE01, E-13JE01A, E-13JE04, E-13KJ03A, E-13NE02, E-13NE11, E-13NE13, E-1F9444, E-1F9411B, E-1F9412B, E-1F9423, E-1F9426, M-12GM01, M-12JE01, M-12KJ04, M-12KJ05, M-12KJ06

5.2.16 Class 1E 4.16 kV Offsite Power

PFSSD requires at least one source of electrical power to energize credited PFSSD equipment. The electrical power sources credited for PFSSD include offsite power, where an evaluation shows offsite power is not lost due to a fire, and onsite power using the emergency diesel generators.

Bus NB02 supplies power to Train B Engineered Safety Features (ESF) components. Cables associated with offsite power feeder breakers NB0209 and NB0212 are run in this area. In addition, cables associated with NB02 breaker control power are run in this area. Damage to these cables due to a fire could cause a loss of offsite power to NB02 and could prevent operation of the PFSSD equipment supplied by NB02. As stated in Section 5.2.15, the Train B emergency diesel generator may not be available if a fire occurs in this area.

Cables associated with transformers XNB01 and XNB02 lockout and phase differential relays are run in fire area C-11. Damage to these cables could cause a loss of offsite power on both trains.

Control cables associated with bus NB02 Synchro-scope and associated switches are run in area C-11. Damage to these cables could disable the synchro-scope for NB02, but would not cause a loss of the NB02 bus.

As stated in Section 5.2.15, Train A emergency diesel generator is available and can be lined up to NB01 to provide power to Train A PFSSD loads. Therefore, a loss of offsite power on both trains due to a fire in area C-11 will not impact the ability to achieve and maintain safe shutdown. For a more detailed evaluation of offsite power availability, refer to Calculation XX-E-013, Appendix 2.

References: XX-E-013, E-15000, E-13NB03, E-13NB04, E-13NB05, E-13NB06, E-13NB10, E-13NB11, E-13NB14, E-13NB15, E-1F9102, E-1F9423, E-1F9425, E-1F9426

5.2.17 Load Shedder / Emergency Load Sequencer

The load shedder and emergency load sequencers are included in the PFSSD design to evaluate the impact of spurious operation or mal-operation. The load shedder/emergency load sequencer operates upon presence of the following conditions:

1. An undervoltage (UV) on a safeguards bus,
2. A safety injection signal (SIS) or a containment spray actuation signal (CSAS), or
3. An undervoltage on a safeguards bus with a SIS or CSAS.

Eight inputs (four undervoltage (UV) inputs and four degraded voltage inputs) on each safeguards bus (NB01 and NB02) monitor voltage conditions on that bus. An undervoltage condition on two of four UV relays on each bus will actuate the load shedder/sequencer and send a signal to start the associated diesel generator. In addition, degraded voltage sensed by two of four degraded voltage potential transformers (PTs) will, after a time delay, provide a signal to open the offsite feeder breakers on the associated bus.

Cables 14NFK01CA and 14NFK01DA associated with one of the four UV relays on each bus are run in fire area C-11. Also, cables 14NFY01EA and 14NFY01FA associated with one of the four degraded voltage PTs on each bus are run in fire area C-11. Cables associated with the remaining three UV relays and PTs do not run in fire area C-11. Therefore, automatic functioning of the bus NB01 and NB02 emergency load shedder/sequencer is unaffected by a fire in area C-11 and a spurious start of the associated diesel generator due to a false undervoltage condition on two of the four circuits is not credible.

Based on the above discussion, the Train A and Train B load shedders/sequencers are unaffected by a fire in area C-11.

References: XX-E-013, E-15000, E-11NB01, E-11NB02, E-12NF01, E-13NF01, E-10NF, E-1F9411A, E-1F9411B, E-1F9412A, E-1F9412B, E-1F9402A, E-1F9402B, E-1F9403, E-1F9425, E-1F9426

5.2.18 Train B 480 Volt Class 1E Load Centers

The 480 Volt Class 1E load centers are required to supply power to PFSSD equipment.

Cables associated with Train B 480 VAC Class 1E load centers NG02, NG04 and motor control center (MCC) NG06E are run in area C-11. In addition, as stated in other sections, loss of power to these load centers and MCCs could occur due to loss of Train B offsite and onsite power. Therefore, Train B load centers and MCCs and associated equipment may not be available if a fire occurs in this area.

Cables 14NGG01AJ and 14NGG01BF supply power to MCCs NG02T and NG04T which power containment cooler fan motors DSGN01B and DSGN01D. Damage to these cables could prevent operation of the fans. Containment cooler fans SGN01A and SGN01C are unaffected. Therefore, sufficient containment cooling will be available.

Cable 14PKK11AA is associated with 480 VAC breaker NG0409. NG0409 supplies 480 VAC power to Train B 125 VDC battery charger PK22, which energizes the PK02 bus. Damage to this cable could disable power to the battery charger but will not de-energize PK02 due to the installed batteries. Battery set PK12 will provide short-term 125 VDC power to PK02. In addition, PK01 is unaffected by a fire in this area.

Redundant Train A components, supplied by NG01, NG03 and MCC NG05E are unaffected by a fire in area C-11. Therefore, loss of power to Train B 480 VAC Class 1E load centers NG02, NG04 and MCC NG06E will not impact the ability to achieve and maintain safe shutdown.

References: XX-E-013, E-15000, E-11NG02, E-13NG01A, E-13NG10A, E-13NG11A, E-13NG11B, E-13PK11, E-K3NG10A, E-1F9422C, E-1F9423, E-1F9424B, E-1F9424D, E-K3NG10A

5.2.19 Class 1E 120 VAC Electrical Distribution System

The Class 1E 120 VAC electrical distribution system provides power to vital instrumentation and control loads for shutdown and normal operation. Under normal conditions, the system is supplied by inverters connected to the 125 VDC NK battery system. Swing inverters allow the primary inverters to be taken out of service for maintainance or repair without disrupting power to the associated vital AC bus. In the event of a loss of power to the inverters, a backup source of power is automatically lined up. The backup power source originates from the 480 VAC electrical distribution system (NG).

Cable 14NNG01AA supplies 480 VAC power from NG0~~0~~2AFF3 to inverter NN14. Cable 14NNG01BA supplies 480 VAC power from NG02ABR1 to inverter NN12. Damage to these cables will disrupt the 480 VAC power source to inverters NN12 and NN14. The 480 VAC power supply to swing inverter NN16 is unaffected.

Cables 14NNK01MA and 14NNK01MB supply 125 VDC power from NK0403 to manual transfer switch NK80. Damage to these cables will disrupt the 125 VDC power supply from NK0403 to swing inverter NN16. The 125 VDC power supply from NK0203 to swing inverter NN16 is unaffected.

Cables 14NNY01HA and 14NNY01HB supply 120 VAC power from swing inverter NN16 to bus NN04 through a manual transfer switch in inverter NN14. Damage to these cables will disrupt the 120 VAC power supply from swing inverter NN16 to NN02. The 120 VAC power supply from inverter NN14 to bus NN04 is unaffected.

As stated in Section 5.2.18, a fire in area C-11 could cause a loss of Train A 480 VAC power. This would cause a loss of 480 VAC power to the Train B NK battery chargers (NK22, NK24 and NK26) which will cause a loss of normal power to the NK02 and NK04 busses. Batteries NK12 and NK14 are unaffected and can supply 125 VDC to busses NK02 and NK04 to provide power to inverters NN12 and NN14 for a limited time.

Train A vital 120 VAC distribution panels NN01 and NN03 are unaffected by a fire in area C-11. Therefore, in the event of a loss of Train B Class 1E 120 VAC electrical distribution system, the Train A Class 1E electrical distribution switchboards are available to supply redundant PFSSD loads.

Based on the above discussion, damage to cables and components associated with Train B vital 120 VAC distribution panels NN02 and NN04 will not adversely impact the ability to achieve and maintain safe shutdown in the event of a fire in area C-11.

5.2.20 Non-Class 1E 120 VAC Electrical Distribution System

The PFSSD function of the non-Class 1E 120 VAC electrical distribution system is to supply 120 VAC power to Main Control Boards (MCBs) RL017/RL018 and RL021/RL022. The power is split at the MCB to supply specific PFSSD components.
