The PFSSD components that depend on non-class 1E 120 VAC power from RL017/RL018 are Residual Heat Removal (RHR) discharge valves EJHCV0606 (Train A) and EJHCV0607 (Train B). Non-class 1E switchboard panel PN07 supplies power from switch PN0736 to solenoid valve EJHY0606 via RL017/RL018. Solenoid valve EJHY0606 controls the position of EJHCV0606 using hand controller EJHIC0606. Non-class 1E switchboard panel PN08 supplies power from switch PN0833 to solenoid valve EJHY0607 via RL017/RL018. Solenoid valve EJHY0607 controls the position of EJHCV0607 using hand controller EJHIC0607.

The PFSSD components that depend on non-class 1E 120 VAC power from RL021/RL022 are temperature recorders BBTR0423, BBTR0433 and BBTR0443. Non-class 1E switchboard panel PN07 supplies power from switch PN0738 to temperature recorder BBTR0423 via RL021/RL022. Non-class 1E switchboard panel PN08 supplies power from switch PN0835 to temperature recorders BBTR0433 and BBTR0443 via RL021/RL022.

Cables 14PNG01AD and 14PNG01AE supply 480 VAC power from NG002BBF1 to 480/120V transformer XPN08A. Damage to either of these cables due to a fire in area C-11 will result in a loss of power to the transformer and loss of non-class 1E 120 VAC feed to PN08 from this power source. Cables associated with the alternate power feed to PN08 from PG20GER5 are unaffected by a fire in area C-11. Therefore, at least one source of power to PN08 is available.

Both power feeds to non-class 1E 120 VAC power to panel PN07 are unaffected by a fire in this area. Therefore, panels PN07 and PN08 and associated PFSSD loads are available if a fire occurs in area C-11.

5.2.21 Process Monitoring Instrumentation

Reliable process monitoring is required to achieve and maintain safe shutdown. Circuits for a number of process instruments are run in area C-11. These circuits run from various process monitoring panels to the auxiliary shutdown panel (ASP) and provide indication at the ASP for control outside the control room. Each cable, along with the effects of fire damage to the cable, is discussed below.

Cable 14SBS16AA provides RCS cold leg loop 2 wide range temperature indication at the ASP on indicator BBTI0423X. Damage to this cable could cause a false temperature indication at the ASP but will not cause a loss of indication in the control room. Therefore, damage to this cable will not adversely impact PFSSD.

Cables 14SBS16BA and 14SBS16YA are associated with steam generator D wide range level indicator AELI0504A located at the ASP. Damage to these cables could cause a false level indication at the ASP but will not cause a loss of indication in the control room. Therefore, damage to these cables will not adversely impact PFSSD.

Cable 14SBS16EA provides RCS hot leg loop 4 wide range temperature indication at the ASP on indicator BBTI0443A. Damage to this cable could cause a false temperature indication at the ASP but will not cause a loss of indication in the control room. Therefore, damage to this cable will not adversely impact PFSSD.

Cable 14SBS16NA provides RCS wide range pressure indication at the ASP on pressure indicator BBPI0406X. Damage to this cable could cause a false pressure indication at the ASP

but will not cause a loss of indication in the control room. Therefore, damage to this cable will not adversely impact PFSSD.

Cable 14SBS16XA provides steam generator B wide range level indication at the ASP on indicator AELI0502A. Damage to this cable could cause a false level indication at the ASP but will not cause a loss of indication in the control room. Therefore, damage to this cable will not adversely impact PFSSD.

Cable 14SBS16ZA provides pressurizer narrow range level indication at the ASP on indicator BBLI0460B. Damage to this cable could cause a false level indication at the ASP but will not cause a loss of indication in the control room. Therefore, damage to this cable will not adversely impact PFSSD.

Based on the above discussion, damage to process instrumentation cables due to a fire in area C-11 will not adversely impact PFSSD.

5.2.22 Lockout Relay Panel RP335

Cable 14RPK09NA provides Class 1E 125 VDC power from NK4419 to panel RP335. Damage to this cable could disrupt power to the loads served by panel RP335, which could prevent operation of the associated equipment. The following table identifies the PFSSD equipment powered by this cable.

Panel RP335 PFSSD Relays	
Relay #	**Description**
86XRP5	Train B MDAFP from CST and ESW Supply Valves (ALHV0034 and ALHV0030)
86XRP6	ESW to TDAFP Supply Valve (ALHV0033)
86XRP7	Train B MDAFP (PAL01B)

As discussed in Section 5.2.4, Train A auxiliary feedwater is available and is unaffected by a fire in area C-11. Therefore, damage to cable 14RPK09NA will have no adverse impact on PFSSD.

Other cables associated with control room lockout relays are run in area C-11. Damage to these cables could prevent operation of associated equipment. Train A equipment, located in a separate fire area, is available and is unaffected by the fire.

References: XX-E-013, E-15000, E-13AL01B, E-13AL02B, E-13AL04B, E-13RP09, E-13RP15, E-093-00095, E-093-00096, E-1F9202, E-1F9204

5.2.23 Miscellaneous Control Room Panels

Cable 14RPY09GA provides 120 VAC power to panel RP147B. Cable 14RPY10BA provides 120 VAC power to panel RP068. The following table identifies the PFSSD components that could be affected by a loss of Train B 120 VAC power to these panels.

Cable	Power Supply	Affected Components
14RPY09GA	NN0404	ABHS0004, ABPIC0004B, ABPT0004, ABPY0004, ALFT0001, ALFY0005B, ALHK0005A, ALHK0005B, ALHK0010A, ALHK0010B, ALHS0005, ALHS0010, ALHV0010, ALHY0010, ALPI0024B, ALPT0024, RP118B
14RPY10BA	NG02ACR136	GDHIS0011A (CGD01B)

All affected components listed in the above table are associated with Train B. Loss of power to these components will not adversely impact PFSSD. Redundant Train A components are unaffected by the fire or the component fails in the desired PFSSD position.

References: XX-E-013, E-15000, E-13AL03B, E-13AL05B, E-13AL07B, E-13AL09, E-13AB20B, E-13RP09, E-13RP10, E-1F9101, E-1F9202, E-1F9203, E-1F9204, E-1F9443, E-K3GD01A, J-110-00592, J-110-00593, J-110-00596, M-12AB01, M-12AL01, M-K2GD01

5.2.24 Reactor Coolant Pumps

The reactor coolant pumps are not credited in the PFSSD analysis. However, the capability to stop the pumps from the control room in the event of a loss of all seal cooling is credited. Westinghouse Technical Bulletin TB-04-22, Rev. 1 recommends that if all seal cooling is lost (RCP seal injection and thermal barrier heat exchanger flow), operators need to stop the pumps before a seal LOCA occurs.

One control cable associated with reactor coolant pumps C and D is run in fire area C-11. Damage to these cables in the event of a fire could prevent operators from stopping the C and D RCPs from the control room. However, a fire in C-11 will not cause a loss of all seal cooling since RCP seal injection and thermal barrier cooling remain available.

Based on the above discussion, the inability to trip the C and D RCPs from the control room will have no adverse impact on PFSSD. The pumps can continue to operate, providing forced flow circulation. If the pumps spuriously stop, natural circulation cooldown can be used.

References: E-15000, XX-E-013, E-13BB01, Westinghouse TB-04-22 Rev. 1

5.2.25 Steam Generator Feedwater Pumps

Main feedwater pump steam supply valves FCFV0005 and FCFV0105 are credited in the PFSSD analysis to trip the main feedwater pumps if the main steam isolation valves (MSIVs) are affected by a fire. Closing the MSIVs stops steam flow to the feedwater pumps' turbines and stops the feedwater pumps. The steam generator feedwater pumps are tripped in the event of a fire to prevent overfilling the steam generators.

Non-Class 1E 120 VAC Inverter PN10 and distribution panel PN10A provide power to FCFV0105 trip relays in panel FC170C. Cable 16RPY10AA supplies power from PN0806 to inverter PN10. Cable 16FCY35AA provides the primary source of 120 VAC power from distribution panel PN010A to panel FC170A. The alternate source of power to panel FC170A is not credited for PFSSD and is assumed lost.

A fire in area C-11 could damage cables 16FCY35AA or 16RPY10AA. If this occurs, operators in the control room would not be able to close valve FCFV0105 to stop steam flow to steam generator feedwater pump PAE01B.

A fire in area C-11 will not affect the ability to close the MSIVs from the control room. All-close hand switches ABHS0079 and ABHS0080 are unaffected and can be used to close the MSIVs from the control room.

Based on the above discussion, valve FCFV0105 may not close if a fire occurs in this area. However, the MSIVs can be closed using either hand switch ABHS0079 or ABHS0080 in the main control room. Therefore, the configuration is acceptable.

References: E-15000, XX-E-013, E-13FC35, E-13RP10, E-1F9103, E-1F9421

5.2.26 Load Center Feeder Breaker PA0207

Load center feeder breaker PA0207 is credited for PFSSD because it supplies power to credited non-safety related loads. Cable 16PGA11AC, associated with PA0207, runs in this area. A fire induced short circuit in this cable will trip the associated breaker.

Breaker PA0207 supplies power to the following PFSSD components:

- PG20GBR217 – MCB Misc. Power Circuits RL023
- PG20GER5 – Instr. Bus Transformer Alt. Feed XPN08D

PFSSD components powered from PG20GBR217 are associated with MSIV downstream components. The MSIVs are unaffected by a fire in this area and can be closed from the control room. Therefore, the MSIV downstream components are not required if a fire occurs in this area.

PG20GER5 is credited as one source of power to PN08. The redundant source of power from NG02BBF1 may also be affected by a fire in this area as discussed in Section 5.2.18. Redundant components powered from inverter PN07 are unaffected by a fire in this area.

Based on the above discussion, loss of breaker PA0207 will not adversely affect PFSSD if a fire occurs in this area.

5.2.27 CVCS Heat Tracing

Heat tracing has been installed to maintain the emergency borate line and other fluid lines above the solidification temperature in the Train A SI pump room. Both safety trains can power the heat tracing; an automatic transfer switch (QJS0001) switches from Train A (primary source) to Train B (alternate source) on loss of A Train.

Fire area C-11 contains one cable (14NGY13BA) associated with the CVCS heat tracing system. Damage to this cable will affect the secondary power feed to the heat tracing system but the primary power feed is unaffected. Therefore, CVCS heat tracing is not affected by a fire in this area.

5.2 PFSSD CABLE EVALUATION 10

1.0 GENERAL AREA DESCRIPTION

Fire area C-12 is located on the 2000 elevation of the Control Building and includes the room listed in Table C-12-1.

Table C-12-1
Rooms Located in Fire Area C-12

ROOM #	DESCRIPTION
3306	North Electrical Chase - 2000 Elevation

Fire area C-12 is protected with an automatic wet-pipe sprinkler system and automatic fire detection. The area is separated from adjacent areas by minimum 3-hour fire resistant construction.

2.0 PRIMARY EQUIPMENT USED FOR PFSSD

Table C-12-2 lists each system credited for post-fire safe shutdown and provides a discussion regarding the availability of the system to perform its Post Fire Safe Shutdown (PFSSD) function if a severe fire occurs in this area. For a summary of the area analysis results, see Section 8.0 of the Fire Area Analysis Narrative section.

Table C-12-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-12

System	System Name	PFSSD Function*	Comments
AB	Main Steam	R, M, H, P, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-12.
AC	Main Turbine	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-12.
AE	Main Feedwater	H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-12.
AL	Aux. Feedwater System	H, P	Train A motor driven auxiliary feedwater pump (MDAFP) PAL01A may be affected. Train B MDAFP and the TDAFP are available.
AP	Condensate Storage System	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-12.
BB	Reactor Coolant System	R, M, H, P, S	Train A pressurizer PORV block valve BBHV8000A may not be isolable from the control room. Pressurizer PORV BBPCV0455A is unaffected and will remain operable. Reactor coolant pumps A and B may not stop using the control room hand switch. RCP seal injection and thermal barrier cooling remain available. Therefore, the inability to stop the RCPs will have no adverse impact on PFSSD. Pressurizer spray valves BBPCV0455B and BBPCV0455C could spuriously open. If this occurs, pressurizer spray can be stopped by closing KAFV0029 using KAHIS0029 in the main control room. Pressurizer pressure indication is available using BBPI0455A, BBPI0456, BBPI0457 or BBPI0458.
BG	Chemical and Volume Control System	R, M, S	A number of Train A components in the CVCS may be affected. Redundant Train B CVCS components are unaffected. Letdown isolation valves BGLCV0459 and BGLCV0460 and letdown orifice isolation valves BGHV8149A, BGHV8149B, and BGHV8149C may need to be failed closed by closing valve KAFV0029 using KAHIS0029 in the main control room.
BM	Steam Generator Blowdown System	R, M, H	The ability to isolate blowdown from Radwaste control room panel BM157 may be affected. Blowdown can be isolated using handswitches in the main control room.
BN	Borated Refueling Water Storage System	R, M, H	Valve BNHV8812A may be affected and may not be isolable from the control room. RWST draindown is prevented by maintaining valve EJHV8811A closed. Train B RWST components are unaffected. Valve BNLCV0112D may be affected. Redundant Train B valve BNLCV0112E is available to ensure a suction source from the RWST to the Train B charging pump.
EF	Essential Service Water System	H, S	Train A ESW may be affected, however Train B ESW is available.

Table C-12-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-12

System	System Name	PFSSD Function*	Comments
EG	Component Cooling Water System	S	Train A CCW may be affected, however Train B CCW is available.
EJ	Residual Heat Removal System	M, H, P	The Train A RHR system may not be available, however the Train B RHR system is unaffected.
EM	High Pressure Coolant Injection	R, M	The Train A SI Pump may spuriously start but the spurious actuation will not adversely impact PFSSD since the pump will be dead headed against RCS pressure. Therefore, no inventory will be lost from the RWST. In this condition, the pump could experience cavitation damage but this is a commercial concern, not a PFSSD concern. Operators can disconnect power to the pump by opening breaker NB0103, but this action is not required for PFSSD. SI test line valve EMHV8882 could be affected. Redundant valves downstream of this valve are unaffected and are available to isolate the SI test line.
EN	Containment Spray	R, M	The Train A containment spray pump may spuriously start but valve ENHV0006 will remain closed to prevent flow of water to the nozzles. Therefore, spurious actuation of the containment spray pump will not adversely impact PFSSD. The pump can be stopped by opening breaker NB0202, but this action is not required for PFSSD.
EP	Safety Injection Accumulators	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-12.
FB	Auxiliary Steam	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-12.
FC	Auxiliary Turbines	R, H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-12.
GD	ESW Pump House HVAC	S	Train A ESW pump room ventilation may be affected. Train B ESW pump room ventilation is unaffected.
GF	AFW Pump Room Coolers	S	Train A AFW room cooler SGF02A may be affected. Train B AFW room cooler SGF02B is unaffected.
GK	Control Room and Class 1E Switchgear Room Coolers	S	Train A control room A/C unit SGK04A may be affected. Train B control room A/C unit SGK04B is unaffected. Train A Class 1E electrical equipment room A/C unit SGK05A may be affected. Train B Class 1E electrical equipment room A/C unit SGK05B is unaffected.

Table C-12-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-12

System	System Name	PFSSD Function*	Comments
GL	Auxiliary Building HVAC	S	Train A RHR pump room cooler SGL10A may be affected. Train B RHR pump room cooler SGL10B is unaffected. Train A centrifugal charging pump (CCP) room cooler SGL12A may be affected. Train B CCP room cooler SGL12B is unaffected. Train A component cooling water (CCW) room cooler SGL11A may be affected. Train B CCW room cooler SGL11B is unaffected.
GM	Emergency Diesel Generator Room HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-12.
GN	Containment Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-12.
JE	Diesel Fuel Oil	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-12.
KA	Instrument Air	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-12.
KC	Fire Protection	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-12.
KH	Service Gas	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-12.
KJ	Standby Diesel Engine	S	Train A diesel engine KKJ01A may be affected by a fire in this area. Train B diesel engine KKJ01B is unaffected.
MA	Main Generation	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-12.
MR	Startup Transformer	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-12.
NB	4.16 kV System	S	Train A Class 1E 4.16 kV switchgear bus NB01 may be affected. Train B Class 1E 4.16 kV switchgear bus NB02 is unaffected. Train A diesel generator output breaker NB0111 may be affected by a fire in this area. Train B diesel generator output breaker NB0211 is unaffected.
NE	Standby Diesel Generator	S	The Train A diesel generator exciter/voltage control cabinet NE107 could be affected. The Train B diesel generator exciter/voltage control cabinet NE106 is unaffected.
NF	Load Shed and Emergency Load Sequencing	S	The Train A emergency load sequencer inputs and outputs could be affected. The Train B emergency load sequencer inputs and outputs are unaffected.

Table C-12-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-12

System	System Name	PFSSD Function*	Comments
NG	480V Load Centers and MCCs	S	Train A 480 VAC load centers and motor control centers may be affected. Train B 480 VAC load centers and motor control centers are unaffected.
NK	125VDC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-12.
NN	120VAC	S	Train A Class 1E 120 VAC electrical distribution system may be affected. The Train B Class 1E electrical distribution system is unaffected.
PA	13.8kV	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-12.
PB	4.16kV	H, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-12.
PG	480V Load Centers and MCCs	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-12.
PK	125VDC	S	125 VDC control power to breaker NG0102 could be affected and could disrupt 480 VAC power to PK21, causing a loss of the normal source of power to non-class 1E 125 VDC bus PK01. Non-class 1E 125 VDC bus PK02 is unaffected.
PL	Local Instrument Panels	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-12.
PN	120VAC	S	Normal power to non-class 1E 120 VAC switchboard PN07 may be affected. However, the alternate power source to PN07 is unaffected. In addition, non-class 1E 120 VAC switchboard PN08 is unaffected.
QB	Standby AC Lighting	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-12.
QD	Emergency Lighting	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-12.
RL	Control Room MCB	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-12.
RP	Miscellaneous Control Panels	R, M, H, P, S	Power supply to Train A auxiliary relay panel RP139 may be affected. Redundant Train B auxiliary relay panel RP140 is unaffected and is available to support associated Train B components. Power to auxiliary relay panel RP211 may be affected, which will cause a loss of power to steam generator blowdown relay 3XBM46. Loss of power to this relay will not affect the ability to isolate blowdown from the main control room.
SA	ESFAS	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-12.

Table C-12-2 Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-12			
System	**System Name**	**PFSSD Function***	**Comments**
SB	Reactor Protection System	R, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-12.
SC	Reactor Instrumentation	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-12.
SE	Ex-Core Neutron Monitoring	R, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-12.
SY	Switchyard	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-12.
UU	Supervisory System	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-12.

* R - Reactivity Control; M - Reactor Coolant Makeup; H - Decay Heat Removal; P - Process Monitoring; S - Support Function

3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD

This section describes operator actions that may need to be performed inside or outside the control room to achieve and maintain hot standby if a fire occurs in area C-12. This section also describes cold shutdown repairs that may need to be made to achieve and maintain cold shutdown conditions. Operator actions are proceduralized in OFN KC-016.

3.1 ACTIONS OUTSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

None

3.2 ACTIONS INSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

3.2.1 Component Cooling Water

Train A CCW could be affected by a fire in this area. If this occurs, swap to Train B CCW using normal operating procedures if Train B CCW is not already running.

3.2.2 Reactor Coolant Pump Seal Cooling

If Train A CCW is operating at the time of the fire, it could be lost causing a temporary loss of thermal barrier cooling. The normal charging pump is not analyzed and is assumed lost. Operators should swap to Train B CCW to restore thermal barrier cooling and line up the Train B CCP to restore RCP seal injection.

3.2.3 Normal Pressurizer Spray

Pressurizer spray valves BBPCV0455B and BBPCV0455C could spuriously open. If this occurs, the spray can be stopped by isolating air to the valves. This can be accomplished by depressing the CLOSE push button on KAHIS0029 to close KAFV0029. KAHIS0029 is located on RL024. Pressurizer pressure indication is available using BBPI0455A, BBPI0456, BBPI0457 and BBPI0458.

3.2.4 Isolation of Letdown

A fire in area C-12 could prevent valves BGLCV0459, BGLCV0460, BGHV8149A, BGHV8149B, and BGHV8149C from being closed using their associated control room hand switches. If this occurs, the valves can be closed by isolating air to the valves. This can be accomplished by depressing the CLOSE push button on KAHIS0029 to close KAFV0029. KAHIS0029 is located on RL024. Pressurizer level indication is available using BBLI0459A and BBLI0460A.

3.3 ACTIONS TO ACHIEVE AND MAINTAIN COLD SHUTDOWN

None

4.0 CONCLUSION

With one exception, redundant Post Fire Safe Shutdown capability exists if a severe fire occurs in area C-12. For the one exception, feasible manual actions are available and are unaffected by the fire. Manual actions are documented in Section 3.0.

5.0 DETAILED ANALYSIS

This section describes the detailed component-by-component and cable-by-cable analysis for a fire in area C-12.

5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA C-12

There are no PFSSD components located in area C-12. This fire area only contains cables associated with PFSSD equipment located in other areas.

5.2 PFSSD CABLE EVALUATION

Table C-12-3 lists all the PFSSD cables (S. in E-15000) located in fire area C-12. The applicable evaluation section is also listed in Table C-12-3.

Table C-12-3
PFSSD Cables Located in Fire Area C-12

Cable #	Location	Primary PFSSD Equipment	Cable Function (P) Power (C) Control (I) Instrumentation	Evaluation Section	Comments
11ALB01AB	3306	DPAL01A	C	5.2.1	AFW Pump A Motor
11ALB01AW	3306	DPAL01A	C	5.2.1	AFW Pump A Motor
11BBG39AF	3306	BBHV8000A	C	5.2.2	Pressurizer PORV BBPCV0455A Inlet Iso

5.2.1 Auxiliary Feedwater

The auxiliary feedwater (AFW) system is required to feed at least two steam generators to ensure PFSSD. The Train A motor driven auxiliary feedwater pump (MDAFP) supplies AFW to steam generators B and C. The Train B MDAFP supplies AFW to steam generators A and D. The turbine driven auxiliary feedwater pump (TDAFP) supplies AFW to all four steam generators.

Cables associated with Train A MDAFP PAL01A are run in this area. Damage to these cables could prevent operation of the pump. Cables associated with redundant Train B MDAFP PAL01B and the TDAFP are run in a different area. Therefore, the Train B MDAFP and TDAFP are available if a fire occurs in this area.

Cable 11GFG01AC is associated with Train A MDAFP room cooler fan motor DSGF02A. Damage to this cable could prevent automatic start of the fan when the Train A MDAFP starts. The Train B MDAFP room cooler DSGF02B is unaffected by a fire in area C-12.

5.2.2 Pressurizer Power Operated Relief Valves and Associated Block Valves

PFSSD requires that either the pressurizer power operated relief valve (PORV) or its associated block valve be closed. Cables associated with block valve BBHV8000A are run through area C-12. Damage to these cables could prevent closing the valve from the control room. Cables and components associated with PORV BBPCV0455A are not located in area C-12. Therefore, the PORV will remain operable if a fire occurs in this area.

References: E-15000, XX-E-013, E-13BB39, E-13BB40, E-1F9301, M-12BB02

5.2.3 Centrifugal Charging System

At least one centrifugal charging pump (CCP) is required for PFSSD to provide RCP seal cooling, reactivity control and inventory control. These functions are accomplished using a CCP taking suction from the refuelling water storage tank (RWST) and injecting through the RCP seals. RCP seal injection provides approximately 20 gpm makeup to the RCS and provides adequate boron concentration to maintain sub-critical reactivity conditions. If RCP seal injection is unavailable, reactivity and inventory control is provided by lining up the CCPs to the boron injection tank (BIT). The normal charging pump (NCP) is not credited and is assumed lost.

Power and control cables associated with Train A CCP are run through area C-12. Damage to these cables could prevent operation of the pump. Redundant Train B CCP cables are run in a separate fire area and are unaffected by a fire in area C-12.

Power and control cables associated with Train A CCP miniflow valve BGHV8110 are run through area C-12. Redundant Train B cables for miniflow valve BGHV8111 are run in a separate fire area and are unaffected by a fire in area C-12.

Power and control cables associated with Train A CCP room cooler SGL12A are run in area C-12. Damage to these cables will prevent operation of the room cooler. Train B CCP room cooler SGL12B circuits are run in a separate fire area and are unaffected by a fire in area C-12.

Power and control cables associated with VCT valve BGLCV0112B run through fire area C-12. Cable damage due to a fire could bypass the BNLCV0112D interlock and cause inadvernent closure of BGLCV0112B. If this occurs prior to establishing suction from the RWST, damage to the operating charging pump could occur due to loss of suction. Calculation XX-E-013,

assumption 3-A-22, states that systems and components are in their normal operating position or status prior to the fire. The Normal Charging Pump (NCP) is the normally operated pump and is assumed to be operating at the time of the fire. Inadvertent closure of valve BGLCV0112B with no suction from the RWST would result in damage to the NCP but the centrifugal charging pumps would remain unaffected. Cables for redundant VCT valve BGLCV0112C are run in a separate fire area and are unaffected by a fire in area C-12.

Power and control cables associated with Train A RCP seal injection flow throttling valve BGHV8357A are run in area C-12. Damage to these cables will prevent operation of the valve from the control room. Cables associated with redundant Train B valve BGHV8357B are run in a separate fire area and are unaffected by a fire in area C-12.

Based on the above discussion, the Train A CCP could be affected but the Train B CCP is available if a fire occurs in area C-12.

References: E-15000, XX-E-013, E-13BG01, E-13BG01A, E-13BG11B, E-13BG12, E-13BG12A, E-13BG52, E-13BN01, E-13GL05, E-1F9102, E-1F9302, E-1F9401A, E-1F9444, M-12BG03, M-12BN01, M-12GL01

5.2.4 RWST to RHR Suction

The RWST is required for PFSSD to ensure an adequate volume of borated water to achieve cold shutdown. Cables associated with RWST to RHR Train A suction valve BNHV8812A are located in this area. Damage to these cables could prevent the valve from closing in response to a signal from the control room, or could cause the valve to spuriously close. Either this valve or containment sump isolation valve EJHV8811A is required to be closed to prevent draindown of the RWST into the containment sump. If using Train A RHR for cold shutdown, valve BNHV8812A is required to be closed.

Cables associated with containment sump isolation valve EJHV8811A are not run in area C-12. Therefore, draindown of the RWST into the containment sump is not a concern. The Train B RHR system is available if a fire occurs in this area, so valve BNHV8812A is not required to be closed.

References: E-15000, XX-E-013, E-13BN03, E-13EJ06A, E-1F9102, E-1F9205, M-12BN01, M-12EJ01

5.2.5 Essential Service Water System

One train of Essential Service Water (ESW) is required to be operable to ensure adequate cooling for essential equipment. A number of cables associated with Train A ESW and Train A ESW pump room cooler are run in this area. Therefore, Train A ESW cannot be relied on for PFSSD if a fire occurs in this area. Cables associated with Train B ESW are run in a different fire area and Train B ESW is available if a fire occurs in area C-12.

Valve EFHV0023 is a normally open isolation valve on the service water system feed to the Train A Essential Service Water System. Either this valve or valve EFHV0025 is required to be closed when operating the Train A ESW system for PFSSD. Power and control cables associated with EFHV0023 are run in this area. Damage to these cables could prevent closing EFHV0023 from the control room. Redundant valve EFHV0025 is unaffected by a fire in area C-12 and can be closed from the control room to isolate this flowpath. In addition, check valve EFV0470 is installed in this line and will prevent flow diversion in the unlikely event valve EFHV0025 cannot be closed.

Valve EFHV0024 is a normally open isolation valve on the service water system feed to the Train B Essential Service Water System. Either this valve or valve EFHV0026 is required to be closed when operating the Train B ESW system for PFSSD. Power and control cables associated with EFHV0024 are run in this area. Damage to these cables could prevent closing

EFHV0024 from the control room. Redundant valve EFHV0026 is unaffected by a fire in area C-12 and can be closed from the control room to isolate this flowpath. In addition, check valve EFV0471 is installed in this line and will prevent flow diversion in the unlikely event valve EFHV0026 cannot be closed.

Valve EFHV0041 is a normally open isolation valve on the return line from the Train A Essential Service Water System to the service water system. Either this valve or valve EFHV0039 is required to be closed when operating the Train A ESW system for PFSSD. Power and control cables associated with EFHV0041 are run in this area. Damage to these cables could prevent closing EFHV0041 from the control room. Redundant valve EFHV0039 is unaffected by a fire in area C-12 and can be closed from the control room to isolate this flowpath.

Valve EFHV0042 is a normally open isolation valve on the return line from the Train B Essential Service Water System to the service water system. Either this valve or valve EFHV0040 is required to be closed when operating the Train B ESW system for PFSSD. Power and control cables associated with EFHV0042 are run in this area. Damage to these cables could prevent closing EFHV0042 from the control room. Redundant valve EFHV0040 is unaffected by a fire in area C-12 and can be closed from the control room to isolate this flowpath.

Valve EFHV0037 is the Train A return isolation valve from ESW to the Ultimate Heat Sink. This valve is required to be open when operating the Train A ESW system for PFSSD. Since the Train A ESW system may not be available if a fire occurs in area C-12, Train B return isolation valve EFHV0038 from ESW to the Ultimate Heat Sink will be used. Circuits for EFHV0038 are not run in area C-12 and will be unaffected by the fire.

Cable 11RPY10BA supplies 120 VAC control power to the automatic and manual start circuits for the Train A ESW pump room supply fan CGD01A. The control power is supplied via this cable to control room panel RP068 and is distributed to a number of fuse blocks including 1FU3, which provides circuit protection for CGD01A control power. If power is lost to the control circuit due to damage to this cable, then the Train A ESW pump room supply fan will not start either automatically, when the ESW pump starts, or manually from the control room. If this occurs, the Train B ESW pump room supply fan remains unaffected by a fire in this area.

Cable 11GDG01AC is associated with the indicator lights on Train A ESW pump room supply fan CGD01A hand switch GDHIS0001B. Damage to this cable could prevent operation of the fan. Cables for Train B ESW pump room supply fan CGD01B are unaffected by a fire in this area.

Cable 11GDI04AA provides ESW A room temperature from temperature element GDTE0001 to temperature controller GDTC0001. Cables 11GDI04AB and 11GDI04AC provide signals from GDTC0001 to outside air intake damper GDTZ0001A and recirculation damper GDTZ0001B, respectively, to change position based on room temperature. Damage to these cables could prevent operation of the dampers. Temperature controls for Train B ESW pump room are unaffected by a fire in area C-12.

PFSSD is assured for a fire in area C-12 using Train B ESW pump PEF01B and associated components.

References: E-15000, XX-E-013, E-13EF02, E-13EF03, E-13EF06, E-13EF11, E-13RP10, E-K3EF01, E-K3EF02, E-K3EF03, E-K3EF06, E-K3EF08, E-K3GD01, E-K3GD01A, E-K3GD04, E-1F9402A, E-1F9402B, E-1F9403, E-1F9443, J-201-00139, M-12EF01, M-12EF02, M-K2EF01, M-K2GD01

5.2.6 Component Cooling Water

For PFSSD, the component cooling water (CCW) system is used to provide cooling to the centrifugal charging pump (CCP) oil cooler, the seal water heat exchanger, the RHR heat exchanger and the RHR pump seal cooler. In addition, the CCW system provides cooling to the RCP thermal barriers and is credited as a backup to RCP seal injection for maintaining seal cooling.

Cables associated with Train A CCW pumps PEG01A and PEG01C are run in this area. In addition, cables associated with Train A CCW pump room cooler SGL11A and associated dampers are run in this area. Damage to these cables could prevent operation of the Train A CCW system.

Cable 11EGG05CD, associated with Train A CCW valve EGHV0053, is run in this area. This cable supplies power to auxiliary relay 3XEG9 which provides permissives to open or close valves in the CCW supply to and from the Radwaste building. If Train A CCW is operating at the time of the fire, valve EGHV0053 will be open. Damage to cable 11EGG05CD could cause the control power fuse to blow and prevent closure of EGHV0053 when lining up Train B CCW. A loss of power to NB01, which is possible if a fire occurs in this area, could also prevent closure of valves EGHV0015 and EGHV0053. Operation of Train B CCW with valves EGHV0015 and EGHV0053 open could cause Train B CCW flow to divert to Train A CCW system. Per calculation M-EG-24, the system will continue to operate with no damage to the pumps if the valves in the opposite train are open.

Control cables associated with Train A CCW Pump Room cooler exhaust dampers GLHZ0080 and GLHZ0081 are run in area C-9. Damage to these cables could prevent operation of the dampers. There are no exhaust dampers associated with Train B CCW pump room cooler.

Cables associated with Train B CCW system are unaffected by a fire in this area. Therefore, the Train B CCW system can be used to supply cooling water to associated Train B equipment.

References: E-15000, XX-E-013, E-13EG01A, E-13EG01B, E-13EG05B, E-13GL06, E-13GL27, E-1F9401A, E-1F9444, M-12EG01, M-12GL01, Calculation M-EG-24

5.2.7 Residual Heat Removal

Cables associated with Train A residual heat removal (RHR) system are run in area C-12. In addition, cables associated with RHR Train A pump room cooler motor DSGL10A are run in this area. Damage to these cables could prevent operation of the Train A RHR system. Cables associated with Train B RHR are run in a different fire area and are unaffected by a fire in area C-12.

The Train B RHR system is available and can be used to achieve cold shutdown if a fire occurs in area C-12.

References: E-15000, XX-E-013, E-13EJ01, E-13EJ08, E-13GL05, E-1F9205, E-1F9401A, E-1F9444, M-12EJ01, M-12GL01

5.2.8 Safety Injection Pumps

The PFSSD strategy is to prevent operation of the Safety Injection (SI) pumps to ensure an adequate supply of borated water in the RWST. A control cable (11EMB01AB) associated with Train A SI pump is run in area C-12. Damage to this cable could cause the spurious start of the pump and could prevent stopping the pump from the control room.

If the Train A SI pump spuriously starts with the reactor at normal pressure, PFSSD will be assured. The pump will not discharge into the RCS due to the pressure differential between the RCS (approximately 2,235 psig) and the SI pump shutoff pressure (approximately 1,565

psig). In addition, the setpoint of the discharge relief valve (EM8853A) to the Recycle Holdup Tank is 1,825 psig. Therefore, no inventory will be lost from the RWST if the SI pumps spuriously start. With the SI pump operating at zero flow, damage to the pump could occur, which is a commercial concern only since the SI pump is not credited in the PFSSD analysis. If necessary, the pump can be stopped by opening breaker NB0103, but this action is not required for PFSSD.

Based on the above discussion, spurious operation of the Train A SI pump will not adversely impact PFSSD.

References: XX-E-013, E-15000, E-13EM01, E-1F9102, E-1F9302, M-12EM01, M-721-00096, WCRE-01

5.2.9 Containment Spray Pumps

Spurious start of the containment spray (CS) pumps may complicate PFSSD due to the possible depletion of inventory in the RWST. Therefore, a spurious start of the CS pumps should be avoided or mitigated. A control cable (11ENB01AB) associated with Train A CS pump PEN01A runs through area C-12 and could cause the spurious start of the pump. The cable damage could prevent stopping the pump from the control room.

If the Train A CS pump spuriously starts, normally closed valve ENHV0006 will remain closed, since a spurious containment spray actuation signal (CSAS) is not credible for a fire in area C-12. This is due to the fact that none of the circuits for containment pressure are run in fire area C-12. In addition, cables associated with valve ENHV0006 do not run in area C-12. Therefore, if the CS pump operates, inventory will not be lost from the RWST. If necessary, the pump can be stopped by opening breaker NB0102, but this action is not required for PFSSD.

Based on the above discussion, the Train A containment spray pump could spuriously start but actual containment spray will not occur since valve ENHV0006 will remain closed.

References: XX-E-013, E-15000, E-13EN01, E-13EN03, E-1F9102, E-1F9302, M-12EN01

5.2.10 Control Room Air Conditioning

Cables associated with Train A control room A/C unit SGK04A are run in this area. Damage to these cables could prevent operation of this unit. Cables associated with Train B control room A/C unit SGK04B are run in a separate area. Therefore, the Train B control room A/C unit is unaffected by a fire in this area.

References: XX-E-013, E-15000, E-13GK02B, E-13GK02C, E-1F9442, M-12GK01

5.2.11 Class 1E Electrical Equipment Air Conditioning

Cables associated with Train A Class 1E A/C unit SGK05A are run in this area. Damage to these cables could prevent operation of this unit. Cables associated with Train B Class 1E A/C unit SGK05B are run in a separate area. Therefore, the Train B Class 1E A/C unit is unaffected by a fire in this area.

References: XX-E-013, E-15000, E-13GK13, E-1F9444, M-12GK03

5.2.12 Standby Diesel Generation

Cables associated with the Train A diesel engine are run in this area. Damage to these cables could prevent operation of the Train A diesel engine and/or cause the Train A load shedder/sequencer to malfunction.

A fire in area C-12 could cause a loss of off-site power on the Train A bus. Therefore, Train A equipment could be completely de-energized if a fire occurs in this area. Train B off-site power bus and Train B diesel engine are unaffected by a fire in this area. Therefore, loss of the Train A diesel engine will have no adverse impact on PFSSD.

References: XX-E-013, E-15000, E-12KJ01, E-13KJ01A, E-13NE12, E-13NF01, E-1F9411A, E-1F9411B, E-1F9412A, E-1F9412B, E-1F9423, M-12KJ01, M-12KJ02, M-12KJ03

5.2.13 Train A Class 1E 4.16 kV ESF Switchgear Bus NB01

Several cables associated with class 1E 4.16 kV switchgear bus NB01 are located in this area. Damage to these cables could prevent operation of Train A equipment powered by NB01. Cables associated with class 1E 4.16 kV switchgear bus NB02 are located in a different fire area. Therefore, Train B 4.16 kV switchgear is unaffected by a fire in area C-12.

References: XX-E-013, E-15000, E-13NB01, E-13NB02, E-13NB03, E-13NB10, E-13NB12, E-13NB13, E-13NE01, E-1F9423, E-1F9425, E-1F9426

5.2.14 Train A 480 VAC Load Centers

Cables associated with 480 VAC load centers NG01, NG03 and motor control center (MCC) NG05E are run in area C-12. Damage to these cables could de-energize the load centers and MCC, preventing operation of the associated Train A equipment.

Cables 11PKK10AA and 11PKK10AB are associated with the 125 VDC control circuit for 125 VDC control power to breaker NG0102, which supplies 480 VAC to battery charger PK21. Damage to these cables could disrupt power to PK21, which would deenergize the normal source of power to non-class 1E 125 VDC bus PK01.

Train B 480 VAC load centers NG02, NG04 and MCC NG06E are unaffected by a fire in this area and are available to supply power to redundant Train B equipment. In addition, power to non-class 1E 125 VDC bus PK02 is unaffected by a fire in area C-12. Therefore, a fire in area C-12 will not impact the ability to supply power to required Train B 480 VAC equipment.

References: XX-E-013, E-15000, E-11NG01, E-11PK01, E-13NG01, E-13NG10, E-13NG11, E-13PK10, E-1F9422C, E-1F9423, E-1F9424A, E-1F9424B, E-1F9424C, E-1F9424D, E-K3NG01, E-K3NG10, J-200-00176

5.2.15 Class 1E 120 VAC Electrical Distribution System

The Class 1E 120 VAC electrical distribution system provides power to vital instrumentation and control loads for shutdown and normal operation. Under normal conditions, the system is supplied by inverters connected to the 125 VDC NK battery system. Swing inverters allow the primary inverters to be taken out of service for maintenance or repair without disrupting power to the associated vital AC bus. In the event of a loss of power to the inverters, a backup source of power is automatically lined up. The backup power source originates from the 480 VAC electrical distribution system (NG).

Cable 11NNG01AA supplies 480 VAC power from NG0~~0~~1ACR3 to inverter NN11. Cable 11NNG01CA supplies 480 VAC power from NG01AGF3 to inverter NN13. Damage to these cables will disrupt the 480 VAC power source to inverters NN11 and NN13. The 480 VAC power supply to swing inverter NN15 is unaffected.

Cables 11NNK01JA and 11NNK01JB supply 125 VDC power from NK0103 to manual transfer switch NK79. Damage to these cables will disrupt the 125 VDC power supply from NK0103 to swing inverter NN15. The 125 VDC power supply from NK0303 to swing inverter NN15 is unaffected.

Cables 11NNY01EA and 11NNY01EB supply 120 VAC power from swing inverter NN15 to bus NN01 through a manual transfer switch in inverter NN11. Damage to these cables will disrupt the 120 VAC power supply from swing inverter NN15 to NN01. The 120 VAC power supply from inverter NN11 to bus NN01 is unaffected.

As stated in Section 5.2.14, a fire in area C-12 could cause a loss of Train A 480 VAC power. This would cause a loss of 480 VAC power to the Train A NK battery chargers (NK21, NK23 and NK25) which will cause a loss of normal power to the NK01 and NK03 busses. Batteries NK11 and NK13 are unaffected and can supply 125 VDC to busses NK01 and NK03 to provide power to inverters NN11 and NN13 for a limited time.

Train B vital 120 VAC distribution panels NN02 and NN04 are unaffected by a fire in area C-12. Therefore, in the event of a loss of Train A Class 1E 120 VAC electrical distribution system, the Train B Class 1E electrical distribution switchboards are available to supply redundant PFSSD loads.

Based on the above discussion, damage to cables and components associated with Train A vital 120 VAC distribution panels NN01 and NN03 will not adversely impact the ability to achieve and maintain safe shutdown in the event of a fire in area C-12.

References: XX-E-013, E-15000, E-11NK01, E-13NN01, E-1F9421

5.2.16 Non-Class 1E 120 VAC Electrical Distribution System

The PFSSD function of the non-Class 1E 120 VAC electrical distribution system is to supply 120 VAC power to Main Control Boards (MCBs) RL017/RL018 and RL021/RL022. The power is split at the MCB to supply specific PFSSD components.

The PFSSD components that depend on non class 1E 120 VAC power from RL017/RL018 are Residual Heat Removal (RHR) discharge valves EJHCV0606 (Train A) and EJHCV0607 (Train B). Non-class 1E switchboard panel PN07 supplies power from switch PN0736 to valve positioner EJHY0606. Valve positioner EJHY0606 controls the position of EJHCV0606 using hand controller EJHIC0606. Non-class 1E switchboard panel PN08 supplies power from switch PN0833 to valve positioner EJHY0607. Valve positioner EJHY0607 controls the position of EJHCV0607 using hand controller EJHIC0607.

The PFSSD components that depend on non class 1E 120 VAC power from RL021/RL022 are temperature recorders BBTR0423, BBTR0433 and BBTR0443. Non-class 1E switchboard

panel PN07 supplies power from switch PN0738 to temperature recorder BBTR0423. Non-class 1E switchboard panel PN08 supplies power from switch PN0835 to temperature recorders BBTR0433 and BBTR0443.

Cables 11PNG01AD and 11PNG01AE supply 480 VAC power from NG001BEF4 to 480/120V transformer XPN07A. Damage to either of these cables due to a fire in area C-12 will result in a loss of power to the transformer and loss of 120 VAC feed to PN07 from this power source. An alternate source of power to PN07 exists, and originates from PG019GFR3 (480 VAC). Cables associated with the alternate power feed to PN07, through transformer XPN07D, do not run in area C-12 and are unaffected by the fire. Therefore, the PFSSD loads supplied by PN07 are available if a fire occurs in area C-12.

Both the normal and alternate power sources for non-class 1E 120 VAC distribution switchboard PN08 are unaffected by a fire in this area. Therefore, the PFSSD loads supplied by PN08 are available if a fire occurs in area C-12.

Based on the above discussion, both non-class 1E electrical distribution switchboards PN07 and PN08 are available if a fire occurs in area C-12.

References: XX-E-013, E-15000, E-13PN01, E-13PN01A, E-13RL04, E-13RL06, E-1F9201, E-1F9205, E-1F9421

5.2.17 Auxiliary Relay Rack RP139

Auxiliary relay rack RP139 contains a number of PFSSD relays used for operation of Train A equipment. A fire in area C-12 could damage cables supplying 125 VDC and 120 VAC power to the various relays within RP139. Damage to the power cables could prevent operation of the associated equipment, or could cause the component to spuriously operate.

Cables associated with redundant Train B auxiliary relay panel RP140 do not run through area C-12. Therefore, PFSSD is assured using Train B components controlled by auxiliary relay panel RP140.

References: XX-E-013, E-15000, E-13BB39, E-13EG01A, E-13EG01B, E-13GK02C, E-13GK13, E-13RP09, E-1F9401A, E-1F9401B, E-1F9402A, E-1F9301, E-1F9442, E-1F9444, E-K3EF01

5.2.18 Letdown Isolation Valves

Valves BGLCV0459 and BGLCV0460 are isolation valves installed in series on the inlet side of the regenerative heat exchanger. PFSSD requires that either of these valves be closed.

Cables 15BGK10AA and 15BGK10AD are power/control cables for the BGLCV0459 solenoid valve (BGHY0459). Air supplied by an open (energized) solenoid valve will open valve BGLCV0459. A closed (de-energized) solenoid valve will cause loss of air pressure and closure of valve BGLCV0459.

Cables 15BGK10BA and 15BGK10BD are power/control cables for the BGLCV0460 solenoid valve (BGHY0460). Air supplied by an open (energized) solenoid valve will open valve BGLCV0460. A closed (de-energized) solenoid valve will cause loss of air pressure and closure of valve BGLCV0460.

Either BGLCV0459 or BGLCV0460 must be closed or letdown orifice isolation valves BGHV8149A, BGHV8149B, and BGHV8149C must be closed. The cables for BGLCV0459 or BGLCV0460 are routed in a common enclosure in cable trays. A hot short on the cables could cause the valves to open. A hot short on cables 15BGK10AA and 15BGK10BA prevents closing BGLCV0459 and BGLCV0460 from the control room. Other cables routed in the cable trays have the proper voltage for hot shorts which can bypass MCB hand switches for

BGLCV0459 and BGLCV0460. BGLCV0459 and BGLCV0460 constitute a high/low pressure interface. Therefore, multiple simultaneous hot shorts must be considered.

Letdown orifice isolation valves BGHV8149A, BGHV8149B, and BGHV8149C are listed as PFSSD components because of the interlock between these valves and BGLCV0459 and BGLCV0460. The interlock prevents closure of the letdown valves when any one or more orifice isolation valves are open. Cables associated with all three letdown orifice isolation valves are located in this fire area. Damage to these cables could prevent closure of the valves from the control room. Therefore, a fire in area C-12 will prevent closure of all three letdown orifice isolation valves (BGHV8149A, BGHV8149B, and BGHV8149C) as well as the two letdown isolation valves (BGLCV0459 and BGLCV0460).

Valves BGLCV0459, BGLCV0460, BGHV8149A, BGHV8149B, and BGHV8149C are air operated and fail in the closed position. The valves are located in containment. Instrument air to containment is controlled by valve KAFV0029, which is unaffected by a fire in area C-12. Hand switch KAHIS0029 can be used to close the valve from the control room and isolate instrument air to containment. Pressurizer level indication is available using BBLI0459A and BBLI0460A.

Based on the above discussion, letdown valves BGLCV0459 and BGLCV0460 and letdown orifice valves BGHV8149A, BGHV8149B, and BGHV8149C can be closed from the control room if a fire occurs in area C-12.

References: E-15000, XX-E-013, E-13BG10, E-13BG35, E-13KA02, E-1F9301, M-12BG01, M-12KA01

5.2.19 Steam Generator Blowdown to Blowdown Flash Tank Isolation Valves

The reactivity control function requires the steam generator blowdown to blowdown flash tank valves (BMHV0001, BMHV0002, BMHV0003, and BMHV0004) be closed to prevent reactivity addition from uncontrolled cooldown.

Cables 15BMK06AB, 15BMK06BB, 15BMK06CB and 15BMK06DB are associated with the BM157 panel mounted handswitches for each of the BMHV valves. Damage to these cables could impact the ability to close the valves from BM157 in the Radwaste Control Room. However, the normal means of closing these valves using the RL024 mounted handswitches in the Main Control Room remains available. Therefore, a fire in area C-12 will not prevent the closure of valves BMHV0001, BMHV0002, BMHV0003, and BMHV0004.

Panel RP211 is an auxiliary relay rack located in room 1101. Power to this panel is supplied by PK5129 through cable 15RPK09EA. Loss of power to the relay panel will result in loss of power to relay 3XBM46. The function of this relay is to close valves BMHV0001, BMHV0002, BMHV0003, and BMHV0004 if a blowdown and sample process isolation signal is received. Under normal conditions the relay is de-energized, the auxiliary contacts are closed, and valves BMHV0001, BMHV0002, BMHV0003, and BMHV0004 are open.

Relay 3XBM46 is associated with the BM157 control circuit. Failure of this relay or associated cable will not prevent closing the blowdown valves from the control room.

5.2.20 Boron Injection Downstream Test Line Isolation Valves

To prevent CCP flow diversion through the SIS test line when charging through the BIT, valves EMHV8843 and EMHV8882 need to be closed. If either or both of these valves cannot be closed, then closing or maintaining closed either valve EMHV8871 or EMHV8964 will accomplish the PFSSD objective.

Cable 15EMK05EA is a control cable for EMHV8882. A hot short in cable 15EMK05EA will energize the solenoid and open valve EMHV8882. The cable is run in raceways with cables carrying the proper voltage and polarity for a cable to cable hot short. The hot short would bypass the control room handswitch (EMHIS8882) on RL018 and control of this valve from the control room would be lost.

CCP flow diversion through the SIS test line is prevented by valves EMHV8871 or EMHV8964. Cables associated with EMHV8871 and EMHV8964 are run in a different fire area. Therefore, the flow path can be isolated using either EMHV8871 or EMHV8964.

References: E-15000, XX-E-013, E-13EM05A, E-1F9302, M-12EM01, M-12EM02

5.2.21 Reactor Coolant Pumps

The reactor coolant pumps are not credited in the PFSSD analysis. However, the capability to stop the pumps from the control room in the event of a loss of all seal cooling or spuriously open pressurizer spray is credited. Westinghouse Technical Bulletin TB-04-22, Rev. 1 recommends that if all seal cooling is lost (RCP seal injection and thermal barrier heat exchanger flow), operators need to stop the pumps before a seal LOCA occurs. Calculation WCNOC-CP-002 shows that if pressurizer spray spuriously actuates, the spray flow needs to be stopped within 50 minutes.

One control cable associated with reactor coolant pumps A and B is run in fire area C-12. Damage to these cables in the event of a fire could prevent operators from stopping the A and B RCPs from the control room. However, a fire in C-12 will not cause a loss of all seal cooling since RCP seal injection and thermal barrier cooling remain available. As discussed in Section 5.2.22, if pressurizer spray spuriously operates, operators can stop the spray by isolating air to the valve from the control room. Therefore, tripping the RCPs is not required to mitigate spurious pressurizer spray.

Based on the above discussion, the inability to trip RCPs A and B from the control room will have no adverse impact on PFSSD. If pressurizer spray spuriously actuates, the valves can be closed by isolating air to the valves from the control room. In addition, seal injection and thermal barrier cooling are unaffected by a fire in area C-12. Therefore, the RCPs do not have to be tripped in the event of a fire in area C-12.

References: E-15000, XX-E-013, E-13BB01, Westinghouse TB-04-22 Rev. 1, WCNOC-CP-002, CR 25002

5.2.22 Normal Pressurizer Spray

The normal pressurizer spray valves are included in the PFSSD design because spurious operation of pressurizer sprays can cause a decrease in pressure which can lead to boiling in the core. The pressurizer spray valves are part of the pressurizer pressure control system.

The pressurizer normal spray valves (BBPCV0455B and BBPCV0455C) operate off a signal from the Ovation pressurizer pressure control system. The operation of the pressure control system is discussed in Calculation XX-E-013.

Cable 15BBI19AA associated with pressurizer spray valve BBPCV0455B, and cable 15BBI19BA associated with pressurizer spray valve BBPCV0455C are run in this area. Damage to these cables could cause the spurious opening of the spray valves.

The pressurizer spray valves are electro/pneumatic operated and loss of air pressure will close the valves. The air supply comes from the compressed air system. Closing valve KAFV0029 using KAHIS0029 on RL024 will isolate compressed air to containment which will cause the pressurizer spray valves to close or prevent them from opening. Based on WCNOC-CP-002, spray flow needs to be stopped within 50 minutes. Since this is a control room action, this can be completed well within 50 minutes.

Based on the above discussion, the pressurizer spray valves could spuriously open if a fire occurs in this area. Pressurizer spray can be stopped by closing valve KAFV0029 from the main control room. Pressurizer pressure indication is available using BBPI0455A, BBPI0456, BBPI0457 and BBPI0458.

5.2.23 Boron Injection Tank (BIT) Flowpath

The Boron Injection Tank (BIT) flowpath is credited for reactivity control and reactor coolant makeup. For reactivity control, the BIT flowpath is credited as an alternate source of boration in the event RCP seal injection is unavailable. Based on Calculation XX-E-013, RCP seal injection will provide sufficient boration to achieve and maintain cold shutdown reactivity conditions. Therefore, the BIT flowpath is not required for reactivity control if RCP seal injection is available.

Since RCP seal injection is limited to 5 gpm per seal or 20 gpm total injection to the RCS, an additional RCS charging flowpath is required for adequate RCS makeup during plant transition from hot standby to cold shutdown. The BIT injection path is the additional RCS charging flowpath. A fire in area C-12 relies on CCP B, since circuits and support systems for CCP A may be affected by the fire. Also, based on the discussion in Section 5.2.18, a fire in area C-12 has the potential to cause a momentary loss of inventory through the letdown flow path until the letdown isolation valves close automatically or are failed closed.

Train A BIT outlet valve EMHV8801A cable 11EMG02CF is run in this area. Cable 11EMG02CF is a fire resistive cable and is not susceptible to fire induced damage. The Train A BIT inlet valve EMHV8803A and the Train B BIT outlet and inlet valves EMHV8801B and EMHV8803B, respectively, do not have cables in area C-12. Therefore, the BIT inlet and outlet valves for both trains are unaffected by a fire in area C-12.

Based on the above discussion, the BIT flowpath is unaffected by a fire in area C-12.

1.0 GENERAL AREA DESCRIPTION

Fire area C-13 is located on the 2016 elevation of the Control Building and includes the room listed in Table C-13-1.

Table C-13-1
Rooms Located in Fire Area C-13

ROOM #	DESCRIPTION
3415	Train B Access Control and Class 1E Elec Equip Room A/C Units

Fire area C-13 is protected with automatic fire detection throughout. There is no automatic suppression installed in this area. The area is separated from all adjacent areas by minimum 3-hour fire rated construction.

2.0 PRIMARY EQUIPMENT USED FOR PFSSD

Table C-13-2 lists each system credited for post-fire safe shutdown and provides a discussion regarding the availability of the system to perform its Post Fire Safe Shutdown (PFSSD) function if a severe fire occurs in this area. For a summary of the area analysis results, see Section 8.0 of the Fire Area Analysis Narrative section.

Table C-13-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-13

System	System Name	PFSSD Function*	Comments
AB	Main Steam	R, M, H, P, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-13.
AC	Main Turbine	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-13.
AE	Main Feedwater	H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-13.
AL	Aux. Feedwater System	H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-13.

3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD

This section describes operator actions that may need to be performed inside or outside the control room to achieve and maintain hot standby if a fire occurs in area C-13. This section also describes cold shutdown repairs that may need to be made to achieve and maintain cold shutdown conditions. Operator actions are proceduralized in OFN KC-016.

3.1 ACTIONS OUTSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

None

3.2 ACTIONS INSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

None

3.3 ACTIONS TO ACHIEVE AND MAINTAIN COLD SHUTDOWN

None

4.0 CONCLUSION

Post-fire safe shutdown is unaffected by a fire in area C-13.

5.0 DETAILED ANALYSIS

This section describes the detailed component-by-component and cable-by-cable analysis for a fire in area C-13.

5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA C-13

PFSSD components (S. in E-15000) located in fire area C-13 are shown in Table C-13-3. An evaluation of each component and associated cables is provided in the sections that follow. The applicable evaluation section is listed in Table C-13-3.

Table C-13-3
PFSSD Equipment Located in Fire Area C-13

Room #	PFSSD Equipment	Description	Evaluation Section	Comments
3415	GK196A	Class 1E Elec Equip Room A/C Unit SGK05B Control Panel	5.1.1	
3415	GK196B	Class 1E Elec Equip Room A/C Unit SGK05B Power Panel	5.1.1	
3415	GK196C	Class 1E Elec Equip Room A/C Unit SGK05B Pwr/Ctrl Panel	5.1.1	
3415	SGK05B	Train B Class 1E Elec Equip Room A/C Unit	5.1.1	
3415	TB34118	SGK05B Terminal Box	5.1.1	

5.1.1 Class 1E Electrical Equipment Room Air Conditioning

Class 1E electrical equipment room air conditioning is required to satisfy the PFSSD support function of maintaining cooling within the Class 1E electrical equipment rooms. Fire area C-13 contains the Train B Class 1E electrical equipment room A/C unit SGK05B as well as a number of associated cables. A fire in this area could damage the unit and/or associated cables and prevent operation of the unit. Therefore, SGK05B is unavailable if a fire occurs in area C-13.

Cable 14SAZ20HA associated with SGK05B is run in fire area C-13. Damage to this cable could prevent operation of SGK05B. Cables associated with SGK05A are unaffected by a fire in area C-13.

Train A Class 1E electrical equipment room air conditioning unit SGK05A is located in a separate fire area and is unaffected by a fire in area C-13. Therefore, Class 1E electrical equipment room cooling is available to Train A components if a fire occurs in fire area C-13.

3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD

This section describes operator actions that may need to be performed inside or outside the control room to achieve and maintain hot standby if a fire occurs in area C-14. This section also describes cold shutdown repairs that may need to be made to achieve and maintain cold shutdown conditions. Operator actions are proceduralized in OFN KC-016.

3.1 ACTIONS OUTSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

None

3.2 ACTIONS INSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

None

3.3 ACTIONS TO ACHIEVE AND MAINTAIN COLD SHUTDOWN

None

4.0 CONCLUSION

Post-fire safe shutdown is unaffected by a fire in area C-14.

5.0 DETAILED ANALYSIS

This section describes the detailed component-by-component and cable-by-cable analysis for a fire in area C-14.

5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA C-14

PFSSD components (S. in E-15000) located in fire area C-14 are shown in Table C-14-3. An evaluation of each component and associated cables is provided in the sections that follow. The applicable evaluation section is listed in Table C-14-3.

Table C-14-3 PFSSD Equipment Located in Fire Area C-14				
Room #	**PFSSD Equipment**	**Description**	**Evaluation Section**	**Comments**
3416	GK195A	Class 1E Elec Equip Room A/C Unit SGK05A Control Panel	5.1.1	
3416	GK195B	Class 1E Elec Equip Room A/C Unit SGK05A Power Panel	5.1.1	
3416	GK195C	Class 1E Elec Equip Room A/C Unit SGK05A Pwr/Ctrl Panel	5.1.1	
3416	SGK05A	Train A Class 1E Elec Equip Room A/C Unit	5.1.1	
3416	TB34117	SGK05A Terminal Box	5.1.1	

5.1.1 Class 1E Electrical Equipment Air Conditioning

Class 1E electrical equipment room air conditioning is required to satisfy the PFSSD support function of maintaining cooling within the Class 1E electrical equipment rooms. Fire area C-14 contains the Train A Class 1E electrical equipment room A/C unit SGK05A as well as a number of associated cables. A fire in this area could damage the unit and/or associated cables and prevent operation of the unit. Therefore, SGK05A is unavailable if a fire occurs in area C-14.

Cable 11SAZ19KA associated with SGK05A is run in fire area C-14. Damage to this cable could prevent operation of SGK05A. Cables associated with SGK05B are unaffected by a fire in area C-14.

Train B Class 1E electrical equipment room air conditioning unit SGK05B is located in a separate fire area and is unaffected by a fire in area C-14. Therefore, Class 1E electrical equipment room cooling is available to Train B components if a fire occurs in fire area C-14.

5.2 PFSSD CABLE EVALUATION 28

1.0 GENERAL AREA DESCRIPTION

Fire area C-15 is located on the 2016 elevation of the Control Building and includes the rooms listed in Table C-15-1.

Table C-15-1
Rooms Located in Fire Area C-15

ROOM #	DESCRIPTION
3403	Non-Vital Swgr & Xfmr Room No. 1
3404	Switchboard Room No. 4
3405	Battery Room No. 4
3410	Switchboard Room No. 2
3411	Battery Room No. 2

Fire area C-15 is protected with an automatic Halon fire suppression system. In addition, automatic fire detection is installed throughout. The fire area is separated from adjacent fire areas by minimum 3-hour fire resistant construction.

2.0 PRIMARY EQUIPMENT USED FOR PFSSD

Table C-15-2 lists each system credited for post-fire safe shutdown and provides a discussion regarding the availability of the system to perform its Post Fire Safe Shutdown (PFSSD) function if a severe fire occurs in this area. For a summary of the area analysis results, see Section 8.0 of the Fire Area Analysis Narrative section.

Table C-15-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-15

System	System Name	PFSSD Function*	Comments
AB	Main Steam	R, M, H, P, S	Power to steam generators B and D ARVs ABPV0002 and ABPV0004 could be lost, preventing control of the ARVs from the control room and failing the ARVs closed. Steam generators A and C ARVs are unaffected. As stated in the AL system comments, only the Train A MDAFP is available to supply steam generator B and C. Per Calculation WCNOC-CP-002, hot standby can be maintained using a single steam generator. Main steam to TDAFP valves ABHV0005 and ABHV0006 could lose power and fail open, which is the desired PFSSD position. See AL System discussion for additional information on auxiliary feedwater. Power to main steam isolation bypass valves auxiliary relay 94XAB6 could be lost, which will fail the bypass valves closed which is the desired PFSSD position. Train B MSFIS cabinet SA075B could lose power, causing the MSIVs to fail closed, which is the desired PFSSD position.
AC	Main Turbine	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-15.
AE	Main Feedwater	H, P	Train B MSFIS cabinet SA075B could lose power, causing the MFIVs to fail closed, which is the desired PFSSD position.
AL	Aux. Feedwater System	H, P	The turbine driven auxiliary feedwater pump could be affected due to loss of 125 VDC power to ABHV0005, ABHV0006, FCFV0313 and FCHV0312. The Train B motor driven auxiliary feedwater pump (MDAFP) may not be available due to loss of control power to NB02. The Train A MDAFP is unaffected. ESFAS LSP signals from ALPT0038 and ALPT0039 could be affected, preventing swapover to ESW on low suction pressure from the condensate storage tank. Pressure transmitter ALPT0037 is unaffected. Operators can manually swap to ESW if necessary.
AP	Condensate Storage System	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-15.
BB	Reactor Coolant System	R, M, H, P, S	Cold leg temperature indication on all four RCS loops could be unavailable. Hot leg temperature indication on RCS loops 3 and 4 could be unavailable. Hot leg temperature indication on RCS loops 1 and 2 is available. This is acceptable as discussed in Section 5.2.2. Pressurizer PORV BBPCV0456A could lose 125 VDC power and fail closed, which is the desired PFSSD position. Reactor head vent valves BBHV8001B and BBHV8002B could lose power, failing the valves closed which is the desired PFSSD position.

Table C-15-2 Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-15			
System	**System Name**	**PFSSD Function***	**Comments**
BG	Chemical and Volume Control System	R, M, S	The Train B CCP may not be available due to loss of control power to NB02. The Train A CCP is available. Excess letdown valves BGHV8153B and BGHV8154B could lose power, causing the valves to fail closed which is the desired PFSSD position. RCP seal injection total flow indicator BGFI0215B may be affected due to loss of 120 VAC power to SB041. Flow indicator BGFI0215A is unaffected.
BM	Steam Generator Blowdown System	R, M, H	Steam generator blowdown valves BMHV0001, BMHV0002, BMHV0003 and BMHV0004 could lose power, failing the valves closed which is the desired PFSSD position.
BN	Borated Refueling Water Storage System	R, M, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-15.
EF	Essential Service Water System	H, S	The Train B ESW pump could be affected. The Train A ESW pump is unaffected.
EG	Component Cooling Water System	S	The Train B component cooling water pumps (DPEG01B and DPEG01D) may not be available due to loss of control power to NB02. Power to Train B temperature control valve EGTV0030 could be lost, failing the valve closed. This would prevent temperature control on the Train B CCW system but will not prevent the system from performing it's PFSSD functions. Train A CCW system is unaffected. CCW to RCP flow indicator EGFI0129 may be affected due to loss of 120 VAC power to RP053B. Flow indicator EGFI0128 is unaffected.
EJ	Residual Heat Removal System	M, H, P	The Train B RHR system may not be available due to loss of control power to NB02. The Train A RHR system is available. Train B RHR discharge valve EJHCV0607 could be affected. Train A RHR discharge valve EJHCV0606 is unaffected.
EM	High Pressure Coolant Injection	R, M	Valves EMHV8843 and EMHV8871 could lose power, failing the valves closed which is the desired PFSSD position.
EN	Containment Spray	R, M	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-15.
EP	Safety Injection Accumulators	H	Position indication for accumulator injection valves EPHV8808B and EPHV8808D could be affected due to loss of 125 VDC power to the hand switch indicating lights. This will not affect the ability to close the valves from the control room using the respective hand switches.

Table C-15-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-15

System	System Name	PFSSD Function*	Comments
FB	Auxiliary Steam	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-15.
FC	Auxiliary Turbines	R, H, P	Control power to FCHV0312 could be lost, preventing operation of the turbine driven auxiliary feedwater pump. TDAFP steam trap valve FCFY0310 could lose power, failing the valve closed which is the desired PFSSD position. Valve FCFV0105 may be affected. The MSIVs can be closed using all-close hand switches ABHS0079 or ABHS0080.
GD	ESW Pump House HVAC	S	Train B ESW pump house temperature element GDTE0011, temperature switch GDTSL0011 and damper actuator GDTZ0011A could be affected. Train A ESW pump house HVAC is unaffected.
GF	AFW Pump Room Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-15.
GK	Control Room and Class 1E Switchgear Room Coolers	S	The Train B control room cooler SGK04B supply and return dampers GKHZ0040A and GKHZ0040B are affected. Train A control room cooler SGK04A supply and return dampers GKHZ0029B and GKHZ0029A are unaffected. The Train B Class 1E electrical equipment room cooler SGK05B is affected. The Train A Class 1E electrical equipment room cooler SGK05A may shut down due to a spurious fire isolation signal. The fire isolation signal can be bypassed from the main control room using GKHS0101 on panel RP068 and SGK05A can be started.
GL	Auxiliary Building HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-15.
GM	Emergency Diesel Generator Room HVAC	S	Train B diesel generator room exhaust damper GMHZ0019 could lose power, failing the damper open which is the desired PFSSD position.
GN	Containment Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-15.
JE	Diesel Fuel Oil	S	Train B emergency diesel generator day tank low level switch JELSL0021C and day tank level transmitter JELT0021 could be affected. Train A emergency diesel generator day tank components are unaffected.
KA	Instrument Air	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-15.
KC	Fire Protection	S	A fire in this area could cause a spurious fire isolation signal causing SGK05A to shut down. See GK System discussion for additional information.
KH	Service Gas	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-15.

Table C-15-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-15

System	System Name	PFSSD Function*	Comments
KJ	Standby Diesel Engine	S	Train B diesel engine control panel KJ122 could lose power, preventing operation of the Train B diesel generator. Train B off-site power and the Train A diesel generator are unaffected by a fire in this area.
MA	Main Generation	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-15.
MR	Startup Transformer	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-15.
NB	4.16 kV System	S	Train B 125 VDC control power to NB02 could be lost. Train A 125 VDC control power to NB01 is unaffected.
NE	Standby Diesel Generator	S	Train B diesel generator may not be available due to loss of 125 VDC control power to NE106. Offsite power to NB02 is unaffected and the Train A diesel generator is unaffected.
NF	Load Shed and Emergency Load Sequencing	S	Train B load shed/emergency load sequencing may be affected due to loss of 125 VDC control power to NF039C. Train A load shed/emergency load sequencing is unaffected.
NG	480V Load Centers and MCCs	S	Train B 125 VDC control power to NG02 and NG04 could be lost. Train A 125 VDC control power to NG01 and NG03 is unaffected.
NK	125VDC	S	Train B Class 1E 125 VDC power could be affected. Train A Class 1E 125 VDC power is unaffected.
NN	120VAC	S	Train B Class 1E 120 VAC power could be affected. Train A Class 1E 120 VAC power is unaffected.
PA	13.8kV	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-15.
PB	4.16kV	H, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-15.
PG	480V Load Centers and MCCs	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-15.
PK	125VDC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-15.
PL	Local Instrument Panels	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-15.
PN	120VAC	S	Non-class 1E 120 VAC switchboard panel PN08 is affected. Non-class 1E 120 VAC switchboard panel PN07 is unaffected.
QB	Standby AC Lighting	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-15.

Table C-15-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-15

System	System Name	PFSSD Function*	Comments
QD	Emergency Lighting	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-15.
RL	Control Room MCB	S	Train B Class 1E 125 VDC power to the following MCB panels could be affected: RL001/RL002, RL005/RL006, RL017/RL018, RL019/RL020, RL021/RL022 and RL023/RL024. This will not affect PFSSD as discussed in Section 5.1.2.
RP	Miscellaneous Control Panels	R, M, H, P, S	Loss of 125 VDC power to control room lockout relay racks RP334 and RP335 could occur. A fire in C-15 does not require evacuation and isolation of the control room. Therefore, loss of DC power to these relay racks will not impact PFSSD.
SA	ESFAS	S	Train B MSFIS cabinet SA075B could lose power, causing the MSIVs and MFIVs to fail closed, which is the desired PFSSD position.
SB	Reactor Protection System	R, S	Train B reactor trip switchgear cabinet SB102B could lose power. Train A reactor trip switchgear cabinet SB102A is unaffected. 125 VDC power to SB032D could be lost, preventing operation of the Train B reactor protection system. The Train A reactor protection system remains available. 120 VAC power to SB032D, SB041 and SB042 could be lost. Reactor protection system panels SB037 and SB038 are unaffected.
SC	Reactor Instrumentation	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-15.
SE	Ex-Core Neutron Monitoring	R, P	Source range monitors SENI0032B and SENY0061A/B could lose power. Source range monitors SENI0031B and SENI0060A/B are unaffected.
SY	Switchyard	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-15.
UU	Supervisory System	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-15.

* R - Reactivity Control; M - Reactor Coolant Makeup; H - Decay Heat Removal; P - Process Monitoring; S - Support Function

3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD

This section describes operator actions that may need to be performed inside or outside the control room to achieve and maintain hot standby if a fire occurs in fire area C-15. This section also describes cold shutdown repairs that may need to be made to achieve and maintain cold shutdown conditions. Operator actions are proceduralized in OFN KC-016.

3.1 ACTIONS OUTSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

None

3.2 ACTIONS INSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

3.2.1 Class 1E Electrical Equipment Room Cooler SGK05A

If a fire occurs in area C-15, SGK05A may not respond to an automatic start signal or may shut down due to a fire isolation signal. If this occurs, start SGK05A by placing GKHS0101 in bypass and start the unit normally. GKHS0101 is located on panel RP068 in the main control room.

3.3 ACTIONS TO ACHIEVE AND MAINTAIN COLD SHUTDOWN

None

4.0 CONCLUSION

Post Fire Safe Shutdown is assured if a fire occurs in fire area C-15.

5.0 DETAILED ANALYSIS

This section describes the detailed component-by-component and cable-by-cable analysis for a fire in area C-15.

5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA C-15

PFSSD components (S. in E-15000) located in fire area C-15 are shown in Table C-15-3. An evaluation of each component and associated cables is provided in the sections that follow. The applicable evaluation section is listed in Table C-15-3.

Table C-15-3 PFSSD Equipment Located in Fire Area C-15

5.1.1 Non-Class 1E 120 VAC Electrical Distribution System

The PFSSD function of the non-Class 1E 120 VAC electrical distribution system is to supply 120 VAC power to Main Control Boards (MCBs) RL017/RL018 and RL021/RL022. The power is split at the MCB to supply specific PFSSD components. The other PFSSD function of the non-Class 1E 120 VAC electrical distribution system is to supply power to steam generator feedwater pump controller cabinets FC169A/C and FC170A/C. See Section 5.2.3 for a detailed discussion about the steam generator feedwater pumps.

The PFSSD components that depend on 120 VAC power from RL017/RL018 are Residual Heat Removal (RHR) discharge valves EJHCV0606 (Train A) and EJHCV0607 (Train B). Non-class 1E 120 VAC switchboard panel PN07 supplies power from switch PN0736 to solenoid valve EJHY0606. Solenoid valve EJHY0606 controls the position of EJHCV0606 using hand controller EJHIC0606. Non-class 1E 120 VAC switchboard panel PN08 supplies power from switch PN0833 to solenoid valve EJHY0607. Solenoid valve EJHY0607 controls the position of EJHCV0607 using hand controller EJHIC0607.

The PFSSD components that depend on 120 VAC power from RL021/RL022 are temperature recorders BBTR0423, BBTR0433 and BBTR0443. Non-class 1E switchboard panel PN07 supplies power from switch PN0738 to temperature recorder BBTR0423. Non-class 1E switchboard panel PN08 supplies power from switch PN0835 to temperature recorders BBTR0433 and BBTR0443.

Non-class 1E 120 VAC switchboard panel PN08 and several associated cables and components (PN08A, PN08B, PN08C, TB34103, TB34104, XPN08A, XPN08D) are located in fire area C-15. Therefore, solenoid valve EJHY0607 and temperature recorders BBTR0433 and BBTR0443 could lose power if a fire occurs in this area. A loss of power to EJHY0607 will fail valve EJHCV0607 open and will prevent control of EJHCV0607 from the control room. Loss of power to temperature recorders BBTR0433 and BBTR0443 will result in a loss of RCS loops 3 and 4 temperature indication.

Non-class 1E 120 VAC power to panel PN07 is unaffected by a fire in this area. Train A RHR valve EJHCV0606 is unaffected by a fire in area C-15, so Train A RHR can be used for shutdown cooling. For a detailed discussion on PFSSD impact on loss of RCS temperature indication, see Section 5.2.2.

Based on the above discussion, a loss of non-class 1E 120 VAC distribution switchboard PN08 will not adversely impact safe shutdown.

References: XX-E-013, E-15000, E-13PN01, E-13PN01A, E-13RL01, E-13RL04, E-13RL06, E-1F9201, E-1F9205, E-1F9421, E-1F9424E

5.1.2 Class 1E 125 VDC Electrical Distribution System

The PFSSD function of the Class 1E 125 VDC electrical distribution system is to provide a reliable source of DC power to the Class 1E DC loads for control and switching of the Class 1E systems. The DC system is separated into four subsystems, two per load group. Subsystems 1 and 3 (Train A) belong to one load group while subsystems 2 and 4 (Train B) belong to the second load group. The safety actions provided by one load group are independent of the safety actions provided by its redundant counterpart.

The battery chargers for each DC subsystem are energized by Class 1E 480 VAC power, which provides the normal source of power to each bus. Each load group is provided with a swing battery charger that is energized by Class 1E 480 VAC power as well as an alternate source of power from non-Class 1E 480 VAC power. The non-Class 1E 480 VAC power to the swing battery chargers is not modeled in the PFSSD analysis.

A fire in area C-15 could damage multiple cables and components associated with Train B Class 1E 125 VDC electrical distribution system. A number of components and cables that are required to energize Train B Class 1E 125 VDC electrical distribution buses NK02 and NK04 are located in this area. The following table identifies the PFSSD components that will be affected by a loss of Train B Class 1E 125 VDC electrical distribution system as well as the potential impact on PFSSD if power is lost.

Potential Impact on Loss of Train B Class 1E 125 VDC Electrical Distribution System		
Switch(es)	**Component**	**Impact**
NKHS0012	125 VDC Bus NK02	This is a transfer switch used to transfer the NK02 power source from battery charger NK22 to swing battery charger NK26. Damage to this switch could prevent battery charger NK22 from energizing NK02. The impact on PFSSD upon loss of this component is discussed in the individual switch discussions below.
NKHS0014	125 VDC Bus NK04	This is a transfer switch used to transfer the NK04 power source from battery charger NK24 to swing battery charger NK26. Damage to this switch could prevent battery charger NK24 from energizing NK04. The impact on PFSSD upon loss of this component is discussed in the individual switch discussions below.
NKHS0262 NKHS0264	125 VDC Buses NK02 and NK04	These are transfer switches used to transfer the swing battery charger to either NK02 or NK04. Damage to this component by itself will not cause a loss of power on either NK02 or NK04 since battery chargers NK22 and NK24 would be available.
NK72	Battery Charger NK22	Damage to this switch could prevent battery charger NK22 from energizing NK02. The impact on PFSSD upon loss of this component is discussed in the individual switch discussions below.
NK74	Battery Charger NK24	Damage to this switch could prevent battery charger NK24 from energizing NK04. The impact on PFSSD upon loss of this component is discussed in the individual switch discussions below.
N/A	NK0200	This is the incoming line to NK02 from battery set NK12. The impact on PFSSD upon loss of this component is discussed in the individual switch discussions below.

Potential Impact on Loss of Train B Class 1E 125 VDC Electrical Distribution System		
Switch(es)	**Component**	**Impact**
NK0201	125 VDC Bus NK02	Damage to this component will prevent battery set NK12 from energizing the NK02 bus. Battery chargers NK22 and NK26 could also be affected by a fire in this area, disabling all power to NK02. The impact on PFSSD is discussed in the individual switch discussions below.
NK0202	125 VDC Bus NK02	This switch controls the main power feed to NK02 from battery chargers NK22 and NK26. Battery set NK12 could also be affected by a fire in this area, disabling all power to NK02. The impact on PFSSD is discussed in the individual switch discussions below.
NK0203	Swing Inverter NN16	This switch controls one of two 125 VDC power feeds to swing inverter NN16 through transfer switch NK80. Loss of swing inverter NN16 will not adversely impact PFSSD as discussed in Section 5.1.3.
NK0204	NK42 NK4200	This is on the incoming line to 125 VDC distribution switchboard NK42. Damage to this component will de-energize NK42. The PFSSD switches and components that are affected are discussed below.
NK4201	Auxiliary Relay Rack RP334	The only relays in RP334 that are required for PFSSD are 86XRP1, 86XRP2 and 86XRP3. These are lockout relays used to isolate the control room if a fire occurs in the control room. Loss of DC power to the relays will prevent isolating the control room but will not cause a spurious control room isolation signal. Control room isolation is not required if a fire occurs in area C-15. Therefore, loss of DC power will not impact PFSSD.
NK4205	ESFAS Cabinet SA036C	SA036C is the Channel II logic and termination cabinet. Panel SA036C controls automatic safety features associated with auxiliary feedwater. Loss of DC power will not prevent manual operation of auxiliary feedwater. Therefore, loss of DC power will not impact PFSSD.
NK4206	Main Control Board Panels RL005/RL006	The PFSSD components on RL005/RL006 supplied by NK4206 are ABHV0005 and ABHV0006. Loss of power will fail the valves open, which is desired for operation of the turbine driven auxiliary feedwater pump (TDAFP). Therefore, loss of DC power will not impact PFSSD.

Potential Impact on Loss of Train B Class 1E 125 VDC Electrical Distribution System		
Switch(es)	**Component**	**Impact**
NK4208	Auxiliary Relay Rack RP266	There are no PFSSD relays in RP266. However, power is supplied to the control circuit for PFSSD components FCHV0312 and FCFV0313 through RP266. Valve FCHV0312 is the trip and throttle valve for the TDAFP. Valve FCFV0313 is the speed governing valve for the TDAFP. Loss of power could prevent operation of the TDAFP but the Train A MDAFP is unaffected by a fire in this area.
NK0211	Inverter NN12	See Section 5.1.3 for PFSSD impact on loss of Class 1E 120 VAC electrical distribution.
N/A	NK0400	This is the incoming line to NK04 from battery set NK14. The impact on PFSSD upon loss of this component is discussed in the individual switch discussions below.
NK0401	125 VDC Bus NK04	Damage to this component will prevent battery set NK14 from energizing the NK04 bus. Battery chargers NK24 and NK26 could also be affected by a fire in this area, disabling all power to NK04. The impact on PFSSD is discussed in the individual switch discussions below.
NK0402	125 VDC Bus NK04	This switch controls the main power feed to NK04 from battery chargers NK24 and NK26. Battery set NK14 could also be affected by a fire in this area, disabling all power to NK04. The impact on PFSSD is discussed in the individual switch discussions below.
NK0403	Swing Inverter NN16	This switch controls one of two 125 VDC power feeds to swing inverter NN16 through transfer switch NK80. Loss of swing inverter NN16 will not adversely impact PFSSD as discussed in Section 5.1.3.
NK0404	NK44 NK4400	This is on the incoming line to 125 VDC distribution switchboard NK44. Damage to this component will de-energize NK44. The PFSSD switches and components that are affected are discussed below.
NK4401	NB02 Breaker Control Power	Loss of control power for NB02 breakers will prevent operation of the associated equipment from the control room. Redundant Train A components fed from NB01 are available. Therefore, loss of DC power will not impact PFSSD.
NK4402	Load Center NG04 Breaker Control	Loss of control power for NG04 breakers will prevent operation of the associated equipment from the control room. Redundant Train A components fed from NG01 and NG03 are available. Therefore, loss of DC power will not impact PFSSD.

Potential Impact on Loss of Train B Class 1E 125 VDC Electrical Distribution System		
Switch(es)	**Component**	**Impact**
NK4407	RC and Support System Control Panel RL001/RL002	The PFSSD components on RL001/RL002 supplied by NK4407 are solenoid valves BGHV8153B and BGHV8154B on the excess letdown line. Loss of DC power will fail the valves closed which is the desired PFSSD position. Therefore, loss of DC power will not impact PFSSD.
NK4409	Turbine Generator and Feedwater Control Panel RL005/RL006	The PFSSD component on RL005/RL006 supplied by NK4409 is solenoid valve FCFY0310 which is the TDAFP steam trap drain valve. Loss of DC power will fail the valve closed which is the desired PFSSD position. Therefore, loss of DC power will not impact PFSSD.
NK4411	Turbine Generator and Feedwater Control Panel RL023/RL024	The PFSSD components on RL023/RL024 supplied by NK4411 are solenoid valves BMHV0001, BMHV0002, BMHV0003 and BMHV0004 which are steam generator blowdown valves. Loss of DC power will fail the valves closed which is the desired PFSSD position. Therefore, loss of DC power will not impact PFSSD.
NK4412	ESF Control Panel RL017/RL018	The PFSSD components on RL017/RL018 supplied by NK4412 are EMHV8843, EMHV8871, EPHIS8808B and EPHIS8808D. Valves EMHV8843 and EMHV8871 are solenoid valves on boron injection and SI test lines. Loss of DC power will fail the valves closed which is the desired PFSSD position. Hand switches EPHIS8808B and EPHIS8808D are associated with accumulator injection isolation valves EPHV8808B and EPHV8808D, respectively. Loss of 125 VDC power to the switches will affect position indication but will not affect operation of the valves. Therefore, loss of DC power will not impact PFSSD.
NK4413	ESF Control Panel RL019/RL020	The PFSSD components on RL019/RL020 supplied by NK4413 are solenoid valve EGTV0030 and damper GMHZ0019. Loss of DC power to EGTV0030 will fail the valve closed and prevent temperature control on the Train B CCW heat exchanger. Loss of temperature control will not affect operation of the Train B CCW system for PFSSD. Damper GMHZ0019 is the Train B diesel generator room exhaust damper. Loss of DC power will fail the damper open which is the desired PFSSD position. Therefore, loss of DC power will not impact PFSSD.

Potential Impact on Loss of Train B Class 1E 125 VDC Electrical Distribution System		
Switch(es)	**Component**	**Impact**
NK4414	Reactor Auxiliary Control Panel RL021/RL022	The PFSSD components on RL021/RL022 supplied by NK4414 are solenoid valves BBHV8001B and BBHV8002B which are reactor head vent valves. Loss of DC power will fail the valves closed which is the desired PFSSD position. Therefore, loss of DC power will not impact PFSSD.
NK4415	Auxiliary Relay Rack RP140	The PFSSD relays located in RP140 that are powered by NK4415 are 1XEF32, 1XEF34 and 1XEF36. These relays are associated with the Train B ESW pump. Loss of DC power could prevent operation of the Train B ESW pump motor but the Train A ESW pump is unaffected by the fire. Therefore, loss of DC power will not impact PFSSD.
NK4416	Solid State Protection Cabinet SB032D	Loss of DC power to SB032D will prevent operation of the Train B SSPS. Redundant Train A SSPS is available using SB029A through SB029E. Therefore, loss of DC power will not impact PFSSD.
NK4417	Auxiliary Relay Rack RP210	The only PFSSD relay in RP210 supplied by NK4417 is 94XAB6, which is the MSIV bypass valves auxiliary relay. The MSIV bypass valves fail closed on loss of power to the relay which is the desired PFSSD position. Therefore, loss of DC power will not impact PFSSD.
NK4419	Auxiliary Relay Rack RP335	The only relays in RP335 that are required for PFSSD are 86XRP5, 86XRP6 and 86XRP7. These are lockout relays used to isolate the control room if a fire occurs in the control room. Loss of DC power to the relays will prevent isolating the control room but will not cause a spurious control room isolation signal. Control room isolation is not required if a fire occurs in area C-15. Therefore, loss of DC power to these relays will not impact PFSSD.
NK4421	Pressurizer PORV BBPCV0456A	The pressurizer PORV fails closed on loss of DC power which is the desired PFSSD position. Therefore, loss of DC power will not impact PFSSD.
NK0405	NK54 NK5400	This is on the incoming line to 125 VDC distribution switchboard NK54. Damage to this component will de-energize NK54. The PFSSD switches and components that are affected are discussed below.

Potential Impact on Loss of Train B Class 1E 125 VDC Electrical Distribution System		
Switch(es)	**Component**	**Impact**
NK5401	Load Center NG02 Breaker Control	Loss of control power for NG02 breakers will prevent operation of the associated equipment from the control room. Redundant Train A components fed from NG01 and NG03 are available. Therefore, loss of DC power will not impact PFSSD.
NK5409	ESFAS Cabinet SA036B	SA036B is the Channel IV termination cabinet. Loss of DC power will prevent operation of associated Channel IV ESFAS signals but will not prevent operation of PFSSD equipment from the control room. Therefore, loss of DC power will not impact PFSSD.
NK5410	Reactor Trip Switchgear Cabinet SB102B	SB102B is the Train B reactor trip switchgear cabinet. Loss of power will prevent operation of the Train B reactor trip functions but redundant Train A reactor trip switchgear cabinet SB102A remains available. Therefore, loss of DC power will not impact PFSSD.
NK5412	Channel 1 and 4 Load Shed/Sequencer Panel NF039C	Loss of DC power from NK5412 to NF039C will prevent operation of the Train B load shedder/sequencer. Offsite power is available on Train B based on XX-E-013, Appendix 2. Therefore, loss of DC power will not impact PFSSD.
NK5414	Diesel Generator Control Panel KJ122	Panel KJ122 is the Train B emergency diesel generator control panel. Loss of DC power will prevent operation of the Train B emergency diesel generator. Train B offsite power is available based on XX-E-013, Appendix 2. Therefore, loss of DC power will not impact PFSSD.
NK5423	Main Steam and Feedwater Isolation Cabinet SA075B	SA075B is the Train B MSFIS cabinet. Loss of DC power to SA075B will cause the MSIVs and MFIVs to close, which is the desired PFSSD position. Therefore, loss of DC power will not impact PFSSD.
NK5424	Diesel Generator Panel NE106	Panel NE106 is the Train B emergency diesel generator control and relay panel. Loss of DC power will prevent operation of the Train B emergency diesel generator. Train B offsite power is available based on XX-E-013, Appendix 2. Therefore, loss of DC power will not impact PFSSD.
NK0411	Inverter NN14	See Section 5.1.3 for PFSSD impact on loss of Class 1E 120 VAC electrical distribution.

Based on the above discussion, a loss of Train B Class 1E 125 VDC power will not adversely impact safe shutdown. In addition, Train A Class 1E 125 VDC power is unaffected by a fire in this area.

5.1.3 Class 1E 120 VAC Electrical Distribution System

The PFSSD function of the Class 1E 120 VAC system is to supply a reliable source of 120 VAC power to vital PFSSD equipment. Four Class 1E 120 VAC distribution switchboards are provided, two per train. The primary power source to each switchboard is from the Class 1E 125 VDC system through an inverter. Each inverter has a backup 480 VAC power supply from the Class 1E 480 VAC system. Two swing inverters, one per safety Train, are installed as a backup to the primary inverter and can be placed in service in the event of a failure or for maintenance of the primary inverter. The swing inverters are powered from the Class 1E 125 VDC system and Class 1E 480 VAC system.

Terminal box TB34120 provides a termination point for the power cable from NG02AFF3 to inverter NN14. The impact on PFSSD due to loss of power to NN14 is discussed in the table below.

A fire in area C-15 can cause a loss of Train B Class 1E 120 VAC switchboards NN02 and NN04. The following table identifies the PFSSD components that will be affected by a loss of Train B Class 1E 120 VAC electrical distribution system as well as the potential impact on PFSSD if power is lost.

Potential Impact on Loss of Train B Class 1E 120 VAC Electrical Distribution System		
Switch(es)	**Component**	**Impact**
N/A	NN12	Damage to 7.5kVA inverter NN12 will prevent the primary power source from energizing NN02. The alternate power source from swing inverter NN16 may also be affected. The PFSSD impact on loss of NN02 is discussed in the individual switch evaluations below.
N/A	NN14	Damage to 7.5kVA inverter NN14 will prevent the primary power source from energizing NN04. The alternate power source from swing inverter NN16 may also be affected. The PFSSD impact on loss of NN04 is discussed in the individual switch evaluations below.
NN0201	120 VAC Switchboard NN02 Power Supply	Damage to this switch will prevent energizing NN02 from both inverter NN12 and swing inverter NN16. The PFSSD impact on loss of NN02 is discussed in the individual switch evaluations below.

Potential Impact on Loss of Train B Class 1E 120 VAC Electrical Distribution System		
Switch(es)	**Component**	**Impact**
NN0401	120 VAC Switchboard NN04 Power Supply	Damage to this switch will prevent energizing NN04 from both inverter NN14 and swing inverter NN16. The PFSSD impact on loss of NN04 is discussed in the individual switch evaluations below.
NN0203	BOP Instrument Rack RP147A	The only PFSSD component affected by a loss of NN0203 is ABPV0002. PFSSD is assured using the Train A MDAFP to supply steam generator C (See Calculation WCNOC-CP-002). Therefore, loss of AC power will not impact PFSSD.
NN0204 NN0405	LSELS Panel NF039B	Panel NF039B has four sources of Class 1E 120 VAC power, each from separate 120 VAC distribution switchboards, two on Train A and two on Train B. The LSELS system operates when a degraded voltage condition exists on 2 out of 4 sensors on a single 4,160 volt Class 1E bus. Loss of AC power from NN0204 and NN0405 to NF039B will have no adverse impact on PFSSD since 120 VAC power remains available from NN0106 and NN0303 to NF039B to ensure operation of Train B LSELS. Therefore, loss of AC power will not impact PFSSD.
NN0205	ESFAS Panel SA036C	SA036C is the Channel II logic and termination cabinet. Panel SA036C controls automatic safety features associated with both trains of auxiliary feedwater. Loss of AC power will not prevent manual operation of auxiliary feedwater. Therefore, loss of AC power will not impact PFSSD.
NN0206 NN0407	LSELS Panel NF039A	Panel NF039A has four sources of Class 1E 120 VAC power, each from separate 120 VAC distribution switchboards, two on Train A and two on Train B. The LSELS system operates when a degraded voltage condition exists on 2 out of 4 sensors on a single 4,160 volt Class 1E bus. Loss of AC power from NN0206 and NN0407 to NF039A will have no adverse impact on PFSSD since 120 VAC power remains available from NN0108 and NN0305 to NF039A to ensure operation of Train A LSELS. Therefore, loss of AC power will not impact PFSSD.

Potential Impact on Loss of Train B Class 1E 120 VAC Electrical Distribution System		
Switch(es)	**Component**	**Impact**
NN0208	BOP Instrument Rack RP053DA	The PFSSD components that are affected by a loss of 120 VAC power to RP053DA are ALPT0038, ALPT0026 and ABPV0002. Loss of power to ALPT0038 will not affect PFSSD due to the availability of ALPT0037 and ALPT0039 to ensure ESFAS LSP swapover. However, as discussed below for switches NN0416 and NN0418, ALPT0039 could also lose power. This could prevent swapover to ESW on low CST level. This is acceptable since the CST is unaffected by the fire and contains sufficient volume to maintain PFSSD hot standby conditions. In addition, pressure indicators ALPI0025A and ALPI0037 are available to indicate low suction pressure in the control room and operators can swap to ESW from the control room. Loss of power to ALPT0026 will not affect PFSSD due to the availability of Train A MDAFP. Loss of power to ABPV0002 will not affect PFSSD since ABPV0003 is available to control cooldown and the local controller for ABPV0002 can be used if necessary for cold shutdown. Therefore, loss of AC power will not impact PFSSD.
NN0209 NN0410	SSPS Train B Input Panel SB032A	Panel SB032A has four sources of Class 1E 120 VAC input power, one source per channel. NN0209 provides 120 VAC power to channel II and NN0410 provides 120 VAC power to channel IV. Loss of two sources of power will render these channels inoperable but the remaining two channels remain operable. The SSPS operates on a 2/3 or 2/4 logic. Therefore, loss of two channels on a train will not prevent the SSPS from performing it's function. The loss of power will send a general warning signal for the train and place the SSPS in a partial trip condition. Loss of power on the other train will actuate the SSPS and trip the plant, which is acceptable for PFSSD. Therefore, loss of AC power will not impact PFSSD.

Potential Impact on Loss of Train B Class 1E 120 VAC Electrical Distribution System		
Switch(es)	**Component**	**Impact**
NN0210 NN0409	SSPS Train A Input Panel SB029A	Panel SB029A has four sources of Class 1E 120 VAC input power, one source per channel. NN0210 provides 120 VAC power to channel II and NN0409 provides 120 VAC power to channel IV. Loss of two sources of power will render these channels inoperable but the remaining two channels remain operable. The SSPS operates on a 2/3 or 2/4 logic. Therefore, loss of two channels on a train will not prevent the SSPS from performing it's function. The loss of power will send a general warning signal for the train and place the SSPS in a partial trip condition. Loss of power on the other train will actuate the SSPS and trip the plant, which is acceptable for PFSSD. Therefore, loss of AC power will not impact PFSSD.
NN0211 NN0406 NN0408	NIS2 Panel SE054B Source Range Monitor SENY0061A/B	Panel SE054B is associated with source range neutron monitor SENI0032B. Loss of power to the panel will prevent SENI0032B from operating. In addition, power to source range monitor SENY0061A/B could be lost. Source range monitoring remains available using SENI0031B and SENI0060A. Therefore, loss of AC power will not impact PFSSD.

Potential Impact on Loss of Train B Class 1E 120 VAC Electrical Distribution System		
Switch(es)	**Component**	**Impact**
NN0212 NN0414	Process Protection Set 2 Panel SB042 Process Protection Set 4 Panel SB041	Panel SB042 is the Channel II process protection rack. Panel SB041 is the Channel IV process protection rack. Loss of 120 VAC power will prevent operation of Channels II and IV inputs to the reactor protection system. The remaining two channels will remain operable. The SSPS operates on a 2/3 or 2/4 logic. Therefore, loss of two channels will not prevent the SSPS from performing it's function. PFSSD transmitters powered from NN0212 are ABPT0515, ABPT0525, ABPT0535, ABPT0545, AELT0519, AELT0549, AELT0552, AELT0553, BBPT0403, BBPT0456, BBTE0413B, BBTE0433A, BNLT0931 and GNPT0936. PFSSD transmitters powered from NN0414 are ABPT0516, ABPT0546, AELT0517, AELT0527, AELT0537, AELT0547, BBPT0458, BGFT0215B, BGLT0185, BNLT0933 and GNPT0934. These transmitters and associated control room indicators are not credited in the event of a fire in this area. Redundant instrumentation powered from alternate sources of power is available. Therefore, loss of AC power will not impact PFSSD. Also see Section 5.2.2 for discussion on loss of RCS temperature indication.
NN0217	Fire Isolation Panel SB148A	Panel SB148A receives signals from certain field transmitters (BBLT0460, BBTE0423, AELT0502 and BBTE0443) and sends the signals to the control room and the auxiliary shutdown panel (ASP). This ensures reliable diagnostic instrumentation is available at the ASP if a fire occurs in the control room. Loss of 120 VAC power to SB148A will prevent signals from these transmitters from reaching the control room and the ASP. However, redundant diagnostic instrumentation remains available in the control room. Therefore, loss of AC power will not impact PFSSD.
NN0403	ESFAS Panel SA036B	SA036B is the Channel IV termination cabinet. Loss of AC power will prevent operation of associated Channel IV ESFAS signals but will not prevent operation of PFSSD equipment from the control room. Therefore, loss of AC power will not impact PFSSD.

Potential Impact on Loss of Train B Class 1E 120 VAC Electrical Distribution System		
Switch(es)	**Component**	**Impact**
NN0404	BOP Instrument Rack RP147B	The PFSSD components controlled by instrument rack RP147B are ABPV0004, ALHV0005, ALHV0010, ALFT0001 and ALPT0024. Loss of 120 VAC power to RP147B will not impact PFSSD since these components are not credited if a fire occurs in this area. Therefore, loss of AC power will not impact PFSSD.
NN0412	SSPS Train B #2 Output Panel SB032D	Loss of 120 VAC power to SB032D will prevent operation of the Train B SSPS. The Train A output panels are unaffected by a fire in this area. Therefore, loss of AC power will not impact PFSSD.
NN0416 NN0418	BOP Instrument Rack RP053BC	The PFSSD components affected by a loss of 120 VAC power to RP053BC are ABPV0004, ALFT0007, ALHV0005, ALHV0007, ALHV0010, ALHV0012, ALPI0024A, ALPT0039, EFFT0054, EFPT0002, EGFT0129, EGPT0078, GDTE0011 and JELT0021. Loss of power to ALPT0039 is discussed above for switch NN0208. Loss of power to the remaining components will not adversely impact PFSSD since these components are not credited if a fire occurs in this area. Therefore, loss of AC power will not impact PFSSD.
NN0420	Fire Isolation Panel SB148B	Panel SB148B receives signals from certain field transmitters (AELT0504, BBPT0406) and sends the signals to the control room and the auxiliary shutdown panel (ASP). This ensures reliable diagnostic instrumentation is available at the ASP if a fire occurs in the control room. Loss of 120 VAC power to SB148B will prevent signals from these transmitters from reaching the control room and the ASP. However, redundant diagnostic instrumentation remains available in the control room. Therefore, loss of AC power will not impact PFSSD.
NN0422	Train B Control Room A/C Unit Inlet & Discharge Dampers GKHZ0040A & GKHZ0040B	Loss of 120 VAC power from NN0422 will impact only Train B inlet & discharge dampers GKHZ0040A & 40B. Train A dampers are unaffected by a fire in this area. Therefore, loss of AC power will not affect PFSSD.

The only potential PFSSD impact identified in the above discussion is that steam generator B ARV ABPV0002 could fail closed. Only the Train A motor driven auxiliary feedwater pump (MDAFP) is available to supply steam generators B and C. The Train B MDAFP and the TDAFP may be unavailable. Per Calculation WCNOC-CP-002, hot standby can be maintained using a single steam generator ARV. Therefore, the configuration is acceptable.

Based on the above discussion, a loss of Class 1E 120 VAC power will not adversely impact PFSSD.

5.2.1 Class 1E Electrical Equipment Room Air Conditioning

Class 1E electrical equipment room air conditioning is required to satisfy the PFSSD support function of maintaining cooling within the Class 1E electrical equipment rooms. Either the Train A or Train B (depending on the credited train) room cooler is required to be operable to ensure adequate room cooling.

Power and control cables associated with Train B Class 1E electrical equipment room A/C unit SGK05B are run in fire area C-15. Damage to these cables could prevent operation of SGK05B. In addition, a fire in this area will initiate the fire detection and Halon actuation system, causing SGK05B to shut down. Therefore, the Train B Class 1E electrical equipment room A/C unit SGK05B is unavailable if a fire occurs in area C-15.

Cables 16KCQ21FA and 16KCQ21JA are associated with the fire detection and Halon actuation system for Train A Class 1E switchboard rooms 3414 and 3408, respectively. A hot short in either of these cables will cause a Halon actuation in the respective room and shut down, or prevent from starting, the Train A Class 1E electrical equipment room A/C unit SGK05A. As stated throughout this document, a number of Train B components could be affected by a fire in this area but Train A components are available. Therefore, the Train A Class 1E electrical equipment room A/C unit is required to be operable in the event of a fire in this area.

If a fire occurs in area C-15 that causes SGK05A to shut down, or prevent it from being started, operators can bypass the fire isolation signal by placing GKHS0101 in bypass then starting the unit normally. GKHS0101 is located on panel RP068 in the main control room.

Based on the above discussion, the Train A Class 1E electrical equipment room A/C unit SGK05A is available in the event of a fire in area C-15.

5.2.2 RCS Temperature Indication

Reactor coolant system (RCS) hot and cold leg temperature indication is required to verify that RCS decay heat removal has been established, either by forced circulation or natural circulation. The PFSSD methodology requires wide range hot leg and cold leg temperature indication to be available on at least one RCS loop. The following table identifies the hot and cold leg temperature components credited for PFSSD as well as the components power supply.

RCS Loop	Hot Leg Temperature	Power Supply	Cold Leg Temperature	Power Supply
1	BBTE0413A/BBTI0413A	NN0111	BBTE0413B/BBTI0413B	NN0212
2	BBTE0423A/BBTI0423A BBTR0423	NN0111 PN0738	BBTE0423B/BBTI0423B	NN0217
3	BBTE0433A BBTR0433	NN0212 PN0835	BBTE0433B BBTR0433	NN0111 PN0835
4	BBTE0443A BBTR0443	NN0212 PN0835	BBTE0443B BBTR0443	NN0111 PN0835

Class 1E 120 VAC power from NN0212 to process rack SB042 (Cable 12SBY09DA) and from NN0217 to fire isolation rack SB148A (Cable 12SBY09GA) could be disrupted as discussed in Section 5.1.3. In addition, non-class 1E power from PN0835 to temperature recorders BBTR0433 and BBTR0443 (Cable 16RLY01EA) could be disrupted as discussed in Section

5.1.1. If this occurs, cold leg temperature indication on all four loops and hot leg temperature indication on loops 3 and 4 will be lost. Hot leg temperature indication on loops 1 and 2 remains available.

EMG ES-04 provides alternate indication that may be used. One of these methods verifies that steam generator pressure is stable or decreasing. As stated earlier, the Train A MDAFP is available to supply steam generators B and C. Steam generator B pressure instruments ABPT524 and ABPT526 and steam generator C pressure instruments ABPT0003, ABPT0534 and ABPT0536 are unaffected by a fire in C-15 and can be used per EMG ES-04 to verify heat removal in loops 2 and 3.

The configuration is acceptable because, in the event of a fire in fire area C-15, cooldown will be performed using RCS loops 2 and 3. RCS loop 2 wide range hot leg temperature element BBTE423A as well as steam generators B and C pressure transmitters ABPT0003, ABPT524, ABPT526, ABPT0534 and ABPT0536 will provide indication.

References: E-15000, XX-E-013, E-13RL06, E-13BB15, E-1F9201, M-12AB01, M-12BB01, EMG ES-04

5.2.3 Steam Generator Feedwater Pumps

Main feedwater pump steam supply valves FCFV0005 and FCFV0105 are credited in the PFSSD analysis to trip the main feedwater pumps if the main steam isolation valves (MSIVs) are affected by a fire. Closing the MSIVs stops steam flow to the feedwater pumps' turbines and stops the feedwater pumps. The steam generator feedwater pumps are tripped in the event of a fire to prevent overfilling the steam generators.

Non-Class 1E 120 VAC Inverter PN10 and distribution panel PN10A provide power to FCFV0105 trip relays in panel FC170C. Cable 16RPY10AA supplies power from PN0806 to inverter PN10. Damage to this cable could prevent the ability to close valve FCFV0105 to stop steam flow to steam generator feedwater pump PAE01B.

A fire in area C-15 will not affect the ability to close the MSIVs from the control room. All-close hand switches ABHS0079 and ABHS0080 are unaffected and can be used to close the MSIVs from the control room.

Based on the above discussion, valve FCFV0105 may not close if a fire occurs in this area. However, the MSIVs can be closed using either hand switch ABHS0079 or ABHS0080 in the main control room. Therefore, the configuration is acceptable.

References: E-15000, XX-E-013, E-13RP10, E-1F9103, E-1F9421

5.2.4 Control Room Air Conditioning

Power cables associated with Train B Control Room A/C unit supply and return dampers GKHZ0040A and GKHZ0040B are run in area C-15. Damage to these cables could prevent operation of the associated dampers. Circuits for Train A Control Room A/C unit dampers do not run in area C-15.

Based on the above discussion, Control Room environmental conditions will be unaffected by a fire in area C-15.

5.2 PFSSD CABLE EVALUATION 24

1.0 GENERAL AREA DESCRIPTION

Fire area C-16 is located on the 2016 elevation of the Control Building and includes the rooms listed in Table C-16-1.

Table C-16-1
Rooms Located in Fire Area C-16

ROOM #	DESCRIPTION
3407	Battery Room No. 1
3408	Switchboard Room No. 1
3409	Non-Vital Swgr & Xfmr Room No. 1
3413	Battery Room No. 3
3414	Switchboard Room No. 3

Fire area C-16 is protected with an automatic Halon fire suppression system. In addition, automatic fire detection is installed throughout. The fire area is separated from adjacent fire areas by minimum 3-hour fire resistant construction.

2.0 PRIMARY EQUIPMENT USED FOR PFSSD

Table C-16-2 lists each system credited for post-fire safe shutdown and provides a discussion regarding the availability of the system to perform its Post Fire Safe Shutdown (PFSSD) function if a severe fire occurs in this area. For a summary of the area analysis results, see Section 8.0 of the Fire Area Analysis Narrative section.

Table C-16-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-16

System	System Name	PFSSD Function*	Comments
AB	Main Steam	R, M, H, P, S	Power to steam generators A and C ARVs ABPV0001 and ABPV0003 could be lost, preventing control of the ARVs from the control room and failing the ARVs closed. Steam generators B and D ARVs are unaffected. As stated in the AL system comments, the Train B MDAFP is available to supply steam generator D and the TDAFP is available to supply steam generator B. Train A MSFIS cabinet SA075A could lose power, causing the MSIVs to fail closed, which is the desired PFSSD position.
AC	Main Turbine	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-16.
AE	Main Feedwater	H, P	Train A MSFIS cabinet SA075A could lose power, causing the MFIVs to fail closed, which is the desired PFSSD position.
AL	Aux. Feedwater System	H, P	The Train A motor driven auxiliary feedwater pump (MDAFP) may not be available due to loss of control power to NB01. The Train B MDAFP and the turbine driven auxiliary feedwater pump (TDAFP) are unaffected. ESFAS LSP signals from ALPT0037 could be affected. ESFAS LSP signals from ALPT0038 and ALPT0039 are unaffected, which will ensure swapover to ESW on low suction pressure from the condensate storage tank.
AP	Condensate Storage System	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-16.
BB	Reactor Coolant System	R, M, H, P, S	Cold leg temperature indication on RCS loops 3 and 4 could be unavailable. Hot leg temperature indication on RCS loops 1 and 2 could be unavailable. Pressurizer PORV BBPCV0455A could lose 125 VDC power and fail closed, which is the desired PFSSD position. Reactor head vent valves BBHV8001A and BBHV8002A could lose power, failing the valves closed which is the desired PFSSD position.
BG	Chemical and Volume Control System	R, M, S	The Train A CCP may not be available due to loss of control power to NB01. The Train B CCP is available. Excess letdown valves BGHV8153A and BGHV8154A could lose power, causing the valves to fail closed which is the desired PFSSD position. RCP seal injection total flow indicator BGFI0215A may be affected due to loss of 120 VAC power to SB038. Flow indicator BGFI0215B is unaffected.
BM	Steam Generator Blowdown System	R, M, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-16.

Table C-16-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-16

System	System Name	PFSSD Function*	Comments
BN	Borated Refueling Water Storage System	R, M, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-16.
EF	Essential Service Water System	H, S	The Train A ESW pump could be affected. The Train B ESW pump is unaffected.
EG	Component Cooling Water System	S	The Train A component cooling water pumps (DPEG01A and DPEG01C) may not be available due to loss of control power to NB02. Power to Train A temperature control valve EGTV0029 could be lost, failing the valve closed. This would prevent temperature control on the Train A CCW system but will not prevent the system from performing it's PFSSD functions. Train B CCW system is unaffected. CCW to RCP flow indicator EGFI0128 may be affected due to loss of 120 VAC power to RP053A. Flow indicator EGFI0129 is unaffected.
EJ	Residual Heat Removal System	M, H, P	The Train A RHR system may not be available due to loss of control power to NB01. The Train B RHR system is available. Train A RHR discharge valve EJHCV0606 could be affected. Train B RHR discharge valve EJHCV0607 is unaffected.
EM	High Pressure Coolant Injection	R, M	Valve EMHV8964 could lose power, failing the valve closed which is the desired PFSSD position.
EN	Containment Spray	R, M	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-16.
EP	Safety Injection Accumulators	H	Position indication for accumulator injection valves EPHV8808A and EPHV8808C could be affected due to loss of 125 VDC power to the hand switch indicating lights. This will not affect the ability to close the valves from the control room using the respective hand switches.
FB	Auxiliary Steam	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-16.
FC	Auxiliary Turbines	R, H, P	Valve FCFV0005 may be affected. The MSIVs can be closed using all-close hand switches ABHS0079 or ABHS0080.
GD	ESW Pump House HVAC	S	Train A ESW pump house temperature element GDTE0001, temperature switch GDTSL0001 and damper actuator GDTZ0001A could be affected. Train B ESW pump house HVAC is unaffected.
GF	AFW Pump Room Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-16.

Table C-16-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-16

System	System Name	PFSSD Function*	Comments
GK	Control Room and Class 1E Switchgear Room Coolers	S	Train A control room cooler SGK04A supply and return dampers GKHZ0029B and GKHZ0029A are affected. The Train B control room cooler SGK04B supply and return dampers GKHZ0040A and GKHZ0040B are unaffected. The Train A Class 1E electrical equipment room cooler SGK05A is affected. The Train B Class 1E electrical equipment room cooler SGK05B is unaffected.
GL	Auxiliary Building HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-16.
GM	Emergency Diesel Generator Room HVAC	S	Train A diesel generator room exhaust damper GMHZ0009 could lose power, failing the damper open which is the desired PFSSD position. Train B diesel generator room exhaust damper is unaffected.
GN	Containment Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-16.
JE	Diesel Fuel Oil	S	Train A emergency diesel generator day tank low level switch JELSL0001C and day tank level transmitter JELT0001 could be affected. Train B emergency diesel generator day tank components are unaffected.
KA	Instrument Air	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-16.
KC	Fire Protection	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-16.
KH	Service Gas	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-16.
KJ	Standby Diesel Engine	S	Train A diesel engine control panel KJ121 could lose power, preventing operation of the Train A diesel generator. Train A and B off-site power and the Train B diesel generator are unaffected by a fire in this area.
MA	Main Generation	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-16.
MR	Startup Transformer	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-16.
NB	4.16 kV System	S	Train A 125 VDC control power to NB01 could be lost. Train B 125 VDC control power to NB02 is unaffected.
NE	Standby Diesel Generator	S	Train A diesel generator may not be available due to loss of 125 VDC control power to NE107. Offsite power to NB01 and NB02 is unaffected and the Train B diesel generator is unaffected.
NF	Load Shed and Emergency Load Sequencing	S	Train A load shed/emergency load sequencing may be affected due to loss of 125 VDC control power to NF039C. Train B load shed/emergency load sequencing is unaffected.

Table C-16-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-16

System	System Name	PFSSD Function*	Comments
NG	480V Load Centers and MCCs	S	Train A 125 VDC control power to NG01 and NG03 could be lost. Train B 125 VDC control power to NG02 and NG04 is unaffected.
NK	125VDC	S	Train A Class 1E 125 VDC power could be affected. Train B Class 1E 125 VDC power is unaffected.
NN	120VAC	S	Train A Class 1E 120 VAC power could be affected. Train B Class 1E 120 VAC power is unaffected.
PA	13.8kV	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-16.
PB	4.16kV	H, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-16.
PG	480V Load Centers and MCCs	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-16.
PK	125VDC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-16.
PL	Local Instrument Panels	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-16.
PN	120VAC	S	Non-class 1E 120 VAC switchboard panel PN07 is affected. Non-class 1E 120 VAC switchboard panel PN08 is unaffected.
QB	Standby AC Lighting	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-16.
QD	Emergency Lighting	S	Control room emergency lighting may be affected. Self-contained battery powered units are available to provide illumination in the control room.
RL	Control Room MCB	S	Train A Class 1E 125 VDC power to the following MCB panels could be affected: RL001/RL002, RL017/RL018, RL019/RL020 and RL021/RL022. This will not affect PFSSD as discussed in Section 5.1.1.
RP	Miscellaneous Control Panels	R, M, H, P, S	Train A 125 VDC power to RP139 and RP209 could be lost. Train A 120 VAC power to RP053AC and RP053DB could be lost. This is acceptable as discussed in Sections 5.1.1 and 5.1.2.
SA	ESFAS	S	Train A MSFIS cabinet SA075A could lose power, causing the MSIVs and MFIVs to fail closed, which is the desired PFSSD position.

Table C-16-2 Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-16			
System	**System Name**	**PFSSD Function***	**Comments**
SB	Reactor Protection System	R, S	Train A reactor trip switchgear cabinet SB102A could lose power. Train B reactor trip switchgear cabinet SB102B is unaffected. 125 VDC power to SB029D could be lost, preventing operation of the Train A reactor protection system. The Train B reactor protection system remains available. Train A 120 VAC power to SB029A, SB029D, SB032A, SB037 and SB038 could be lost. Redundant Train B reactor protection system panels are unaffected.
SC	Reactor Instrumentation	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-16.
SE	Ex-Core Neutron Monitoring	R, P	Source range monitors SENI0031B and SENY0060A/B could lose power. Source range monitors SENI0032B and SENI0061A/B are unaffected.
SY	Switchyard	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-16.
UU	Supervisory System	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-16.

* R - Reactivity Control; M - Reactor Coolant Makeup; H - Decay Heat Removal; P - Process Monitoring; S - Support Function

3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD

This section describes operator actions that may need to be performed inside or outside the control room to achieve and maintain hot standby if a fire occurs in fire area C-16. This section also describes cold shutdown repairs that may need to be made to achieve and maintain cold shutdown conditions. Operator actions are proceduralized in OFN KC-016.

3.1 ACTIONS OUTSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

None

3.2 ACTIONS INSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

None

3.3 ACTIONS TO ACHIEVE AND MAINTAIN COLD SHUTDOWN

None

4.0 CONCLUSION

Post Fire Safe Shutdown is assured if a fire occurs in fire area C-16.

5.0 DETAILED ANALYSIS

This section describes the detailed component-by-component and cable-by-cable analysis for a fire in area C-16.

5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA C-16

PFSSD components (S. in E-15000) located in fire area C-16 are shown in Table C-16-3. An evaluation of each component and associated cables is provided in the sections that follow. The applicable evaluation section is listed in Table C-16-3.

5.1.1 Class 1E 125 VDC Electrical Distribution System

The PFSSD function of the Class 1E 125 VDC electrical distribution system is to provide a reliable source of DC power to the Class 1E DC loads for control and switching of the Class 1E systems. The DC system is separated into four subsystems, two per load group. Subsystems 1 and 3 (Train A) belong to one load group while subsystems 2 and 4 (Train B) belong to the second load group. The safety actions provided by one load group are independent of the safety actions provided by its redundant counterpart.

The battery chargers for each DC subsystem are energized by Class 1E 480 VAC power, which provides the normal source of power to each bus. Each load group is provided with a swing battery charger that is energized by Class 1E 480 VAC power as well as an alternate source of power from non-Class 1E 480 VAC power. The non-Class 1E 480 VAC power to the swing battery chargers is not modeled in the PFSSD analysis.

A fire in area C-16 could damage multiple cables and components associated with Train A Class 1E 125 VDC electrical distribution system. A number of components and cables that are required to energize Train A Class 1E 125 VDC electrical distribution buses NK01 and NK03 are located in this area. The following table identifies the PFSSD components that will be affected by a loss of Train A Class 1E 125 VDC electrical distribution system as well as the potential impact on PFSSD if power is lost.

Potential Impact on Loss of Train A Class 1E 125 VDC Electrical Distribution System		
Switch(es)	**Component**	**Impact**
NKHS0011	125 VDC Bus NK01	This is a transfer switch used to transfer the NK01 power source from battery charger NK21 to swing battery charger NK25. Damage to this switch could prevent battery charger NK21 from energizing NK01. The impact on PFSSD upon loss of this component is discussed in the individual switch discussions below.
NKHS0013	125 VDC Bus NK03	This is a transfer switch used to transfer the NK03 power source from battery charger NK23 to swing battery charger NK25. Damage to this switch could prevent battery charger NK23 from energizing NK03. The impact on PFSSD upon loss of this component is discussed in the individual switch discussions below.
NKHS0251 NKHS0253	125 VDC Buses NK01 and NK03	These are transfer switches used to transfer the swing battery charger to either NK01 or NK03. Damage to this component by itself will not cause a loss of power on either NK01 or NK03 since battery chargers NK21 and NK23 would be available.
NK71	Battery Charger NK21	Damage to this switch could prevent battery charger NK21 from energizing NK01. The impact on PFSSD upon loss of this component is discussed in the individual switch discussions below.

Potential Impact on Loss of Train A Class 1E 125 VDC Electrical Distribution System		
Switch(es)	**Component**	**Impact**
NK73	Battery Charger NK23	Damage to this switch could prevent battery charger NK23 from energizing NK01. The impact on PFSSD upon loss of this component is discussed in the individual switch discussions below.
N/A	NK0100	This is the incoming line to NK01 from battery set NK11. The impact on PFSSD upon loss of this component is discussed in the individual switch discussions below.
NK0101	125 VDC Bus NK01	Damage to this component will prevent battery set NK11 from energizing the NK01 bus. Battery chargers NK21 and NK25 could also be affected by a fire in this area, disabling all power to NK01. The impact on PFSSD is discussed in the individual switch discussions below.
NK0102	125 VDC Bus NK01	This switch controls the main power feed to NK01 from battery chargers NK21 and NK25. Battery set NK11 could also be affected by a fire in this area, disabling all power to NK01. The impact on PFSSD is discussed in the individual switch discussions below.
NK0103	Swing Inverter NN15	This switch controls one of two 125 VDC power feeds to swing inverter NN15 through transfer switch NK79. Loss of swing inverter NN15 will not adversely impact PFSSD as discussed in Section 5.1.2.
NK0104	NK41 NK4100	This is on the incoming line to 125 VDC distribution switchboard NK41. Damage to this component will de-energize NK41. The PFSSD switches and components that are affected are discussed below.
NK0105	NK51 NK5100	This is on the incoming line to 125 VDC distribution switchboard NK51. Damage to this component will de-energize NK51. The PFSSD switches and components that are affected are discussed below.
NK0111	Inverter NN11	See Section 5.1.2 for PFSSD impact on loss of Class 1E 120 VAC electrical distribution.
NK4101	NB01 Breaker Control Power	Loss of control power for NB01 breakers will prevent operation of the associated equipment from the control room. Redundant Train B components fed from NB02 are available. Therefore, loss of DC power will not impact PFSSD.

Potential Impact on Loss of Train A Class 1E 125 VDC Electrical Distribution System		
Switch(es)	**Component**	**Impact**
NK4108	Diesel Generator Panel NE107	Panel NE107 is the Train A emergency diesel generator control and relay panel. Loss of DC power will prevent operation of the Train A emergency diesel generator. Train A offsite power is available based on XX-E-013, Appendix 2. Therefore, loss of DC power will not impact PFSSD.
NK4112	ESF Control Panel RL017/RL018	The PFSSD components on RL017/RL018 supplied by NK4112 are EMHV8964, EPHIS8808A and EPHIS8808C. Valve EMHV8964 is a test line isolation valve on boron injection and SI flowpaths. Loss of DC power will fail the valve closed which is the desired PFSSD position. Hand switches EPHIS8808A and EPHIS8808C are associated with accumulator injection isolation valves EPHV8808A and EPHV8808C, respectively. Loss of 125 VDC power to the switches will affect position indication but will not affect operation of the valves. Therefore, loss of DC power will not impact PFSSD.
NK4113	ESF Control Panel RL019/RL020	The PFSSD components on RL019/RL020 supplied by NK4113 are solenoid valve EGTV0029 and damper GMHZ0009. Loss of DC power to EGTV0029 will fail the valve closed and prevent temperature control on the Train A CCW heat exchanger. Loss of temperature control will not affect operation of the Train A CCW system for PFSSD. Damper GMHZ0009 is the Train A diesel generator room exhaust damper. Loss of DC power will fail the damper open which is the desired PFSSD position. Therefore, loss of DC power will not impact PFSSD.
NK4116	Reactor Trip Switchgear Cabinet SB102A	SB102A is the Train A reactor trip switchgear cabinet. Loss of power will prevent operation of the Train A reactor trip functions but redundant Train B reactor trip switchgear cabinet SB102B remains available. Therefore, loss of DC power will not impact PFSSD.
NK4117	Channel 1 and 4 Load Shed/Sequencer Panel NF039C	Loss of DC power from NK4117 to NF039C will prevent operation of the Train A load shedder/sequencer. Offsite power is available on Train A based on XX-E-013, Appendix 2. Therefore, loss of DC power will not impact PFSSD.

Potential Impact on Loss of Train A Class 1E 125 VDC Electrical Distribution System		
Switch(es)	**Component**	**Impact**
NK4118	Solid State Protection Cabinet SB029D	Loss of DC power to SB029D will prevent operation of the Train A SSPS. Redundant Train B SSPS is available using SB032A through SB032E. Therefore, loss of DC power will not impact PFSSD.
NK4119	RC and Support System Control Panel RL001/RL002	The PFSSD components on RL001/RL002 supplied by NK4119 are solenoid valves BGHV8153A and BGHV8154A on the excess letdown line. Loss of DC power will fail the valves closed which is the desired PFSSD position. Therefore, loss of DC power will not impact PFSSD.
NK4122	Auxiliary Relay Rack RP139	The PFSSD relays located in RP139 that are powered by NK4122 are 1XEF31, 1XEF33 and 1XEF35. These relays are associated with the Train A ESW pump. Loss of DC power could prevent operation of the Train A ESW pump motor but the Train B ESW pump is unaffected by the fire. Therefore, loss of DC power will not impact PFSSD.
NK5101	Load Center NG03 Breaker Control	Loss of control power for NG03 breakers will prevent operation of the associated equipment from the control room. Redundant Train B components fed from NG02 and NG04 are available. Therefore, loss of DC power will not impact PFSSD.
NK5102	Load Center NG01 Breaker Control	Loss of control power for NG01 breakers will prevent operation of the associated equipment from the control room. Redundant Train B components fed from NG02 and NG04 are available. Therefore, loss of DC power will not impact PFSSD.
NK5108	Pressurizer PORV BBPCV0455A	The pressurizer PORV fails closed on loss of DC power which is the desired PFSSD position. Therefore, loss of DC power will not impact PFSSD.
NK5109	Reactor Auxiliary Control Panel RL021/RL022	The PFSSD components on RL021/RL022 supplied by NK5109 are solenoid valves BBHV8001A and BBHV8002A which are reactor head vent valves. Loss of DC power will fail the valves closed which is the desired PFSSD position. Therefore, loss of DC power will not impact PFSSD.
NK5110	ESFAS Cabinet SA036A	SA036A is the Channel I termination cabinet. Loss of DC power will prevent operation of associated Channel I ESFAS signals but will not prevent operation of PFSSD equipment from the control room. Therefore, loss of DC power will not impact PFSSD.

Potential Impact on Loss of Train A Class 1E 125 VDC Electrical Distribution System		
Switch(es)	**Component**	**Impact**
NK5111	Diesel Generator Control Panel KJ121	Panel KJ121 is the Train A emergency diesel generator control panel. Loss of DC power will prevent operation of the Train A emergency diesel generator. Train A offsite power is available based on XX-E-013, Appendix 2. Therefore, loss of DC power will not impact PFSSD.
NK5113	Auxiliary Relay Rack RP209	The only PFSSD relay in RP209 supplied by NK5113 is 94XAB5, which is the MSIV bypass valves auxiliary relay. The MSIV bypass valves fail closed on loss of power to the relay which is the desired PFSSD position. Therefore, loss of DC power will not impact PFSSD.
NK5119	Main Steam and Feedwater Isolation Cabinet SA075A	SA075A is the Train A MSFIS cabinet. Loss of DC power to SA075A will cause the MSIVs and MFIVs to close, which is the desired PFSSD position. Therefore, loss of DC power will not impact PFSSD.
NK5120	Control Room Emergency Lighting	Switch NK5120 supplies power to control room emergency lighting distribution switchboard NK51A which energizes switch NK51A01. Loss of control room emergency lights will not affect PFSSD since self-contained battery powered lighting is available. Also see Section 5.2.3.
N/A	NK0300	This is the incoming line to NK03 from battery set NK13. The impact on PFSSD upon loss of this component is discussed in the individual switch discussions below.
NK0301	125 VDC Bus NK03	Damage to this component will prevent battery set NK13 from energizing the NK03 bus. Battery chargers NK23 and NK25 could also be affected by a fire in this area, disabling all power to NK03. The impact on PFSSD is discussed in the individual switch discussions below.
NK0302	125 VDC Bus NK03	This switch controls the main power feed to NK03 from battery chargers NK23 and NK25. Battery set NK13 could also be affected by a fire in this area, disabling all power to NK03. The impact on PFSSD is discussed in the individual switch discussions below.
NK0303	Swing Inverter NN15	This switch controls one of two 125 VDC power feeds to swing inverter NN15 through transfer switch NK79. Loss of swing inverter NN15 will not adversely impact PFSSD as discussed in Section 5.1.2.
NK0311	Inverter NN13	See Section 5.1.2 for PFSSD impact on loss of Class 1E 120 VAC electrical distribution.

Based on the above discussion, a loss of Train A Class 1E 125 VDC power will not adversely impact safe shutdown. In addition, Train B Class 1E 125 VDC power is unaffected by a fire in this area.

5.1.2 Class 1E 120 VAC Electrical Distribution System

The PFSSD function of the Class 1E 120 VAC system is to supply a reliable source of 120 VAC power to vital PFSSD equipment. Four Class 1E 120 VAC distribution switchboards are provided, two per train. The primary power source to each switchboard is from the Class 1E 125 VDC system through an inverter. Each inverter has a backup 480 VAC power supply from the Class 1E 480 VAC system. Two swing inverters, one per safety Train, are installed as a backup to the primary inverter and can be placed in service in the event of a failure or for maintenance of the primary inverter. The swing inverters are powered from the Class 1E 125 VDC system and Class 1E 480 VAC system.

Terminal box TB34119 provides a termination point for the power cable from NG01ACR3 to inverter NN11. The impact on PFSSD due to loss of power to NN11 is discussed in the table below.

A fire in area C-16 can cause a loss of Train A Class 1E 120 VAC switchboards NN01 and NN03. The following table identifies the PFSSD components that will be affected by a loss of Train A Class 1E 120 VAC electrical distribution system as well as the potential impact on PFSSD if power is lost.

Potential Impact on Loss of Train A Class 1E 120 VAC Electrical Distribution System		
Switch(es)	**Component**	**Impact**
N/A	NN11	Damage to 7.5kVA inverter NN11 will prevent the primary power source from energizing NN01. The alternate power source from swing inverter NN15 may also be affected. The PFSSD impact on loss of NN01 is discussed in the individual switch evaluations below.
N/A	NN13	Damage to 7.5kVA inverter NN13 will prevent the primary power source from energizing NN03. The alternate power source from swing inverter NN15 may also be affected. The PFSSD impact on loss of NN03 is discussed in the individual switch evaluations below.
NN0101	120 VAC Switchboard NN01 Power Supply	Damage to this switch will prevent energizing NN01 from both inverter NN11 and swing inverter NN15. The PFSSD impact on loss of NN01 is discussed in the individual switch evaluations below.
NN0301	120 VAC Switchboard NN03 Power Supply	Damage to this switch will prevent energizing NN03 from both inverter NN13 and swing inverter NN15. The PFSSD impact on loss of NN03 is discussed in the individual switch evaluations below.

Potential Impact on Loss of Train A Class 1E 120 VAC Electrical Distribution System		
Switch(es)	**Component**	**Impact**
NN0103	ESFAS Cabinet SA036A	SA036A is the Channel I termination cabinet. Loss of AC power will prevent operation of associated Channel I ESFAS signals but will not prevent operation of PFSSD equipment from the control room. Therefore, loss of AC power will not impact PFSSD.
NN0105 NN0107 NN0113	Neutron Flux Monitor SENY0060A/B NIS1 Panel SE054A	Panel SE054A is associated with source range neutron monitor SENI0031B. Loss of power to the panel will prevent SENI0031B from operating. In addition, power to source range monitor SENY0060A/B could be lost. Source range monitoring remains available using SENI0032B and SENI0061A/B. Therefore, loss of AC power will not impact PFSSD.
NN0106 NN0303	LSELS Panel NF039B	Panel NF039B has four sources of Class 1E 120 VAC power, each from separate 120 VAC distribution switchboards, two on Train A and two on Train B. The LSELS system operates when a degraded voltage condition exists on 2 out of 4 sensors on a single 4,160 volt Class 1E bus. Loss of AC power from NN0106 and NN0303 to NF039B will have no adverse impact on PFSSD since 120 VAC power remains available from NN0204 and NN0405 to NF039B to ensure operation of Train B LSELS. Therefore, loss of AC power will not impact PFSSD.
NN0108 NN0305	LSELS Panel NF039A	Panel NF039A has four sources of Class 1E 120 VAC power, each from separate 120 VAC distribution switchboards, two on Train A and two on Train B. The LSELS system operates when a degraded voltage condition exists on 2 out of 4 sensors on a single 4,160 volt Class 1E bus. Loss of AC power from NN0108 and NN0305 to NF039A will have no adverse impact on PFSSD since 120 VAC power remains available from NN0206 and NN0407 to NF039A to ensure operation of Train A LSELS. Therefore, loss of AC power will not impact PFSSD.
NN0109 NN0310	SSPS Train B Input Panel SB032A	Panel SB032A has four sources of Class 1E 120 VAC input power, one source per channel. NN0109 provides 120 VAC power to channel I and NN0310 provides 120 VAC power to channel III. Loss of two sources of power will render these channels inoperable but the remaining two channels remain operable. The SSPS operates on a 2/3 or 2/4 logic. Therefore, loss of two channels on a train will not prevent the SSPS from

Potential Impact on Loss of Train A Class 1E 120 VAC Electrical Distribution System		
Switch(es)	**Component**	**Impact**
		performing it's function. The loss of power will send a general warning signal for the train and place the SSPS in a partial trip condition. Loss of power on the other train will actuate the SSPS and trip the plant, which is acceptable for PFSSD. Therefore, loss of AC power will not impact PFSSD.
NN0110 NN0309	SSPS Train A Input Panel SB029A	Panel SB029A has four sources of Class 1E 120 VAC input power, one source per channel. NN0110 provides 120 VAC power to channel I and NN0309 provides 120 VAC power to channel III. Loss of two sources of power will render these channels inoperable but the remaining two channels remain operable. The SSPS operates on a 2/3 or 2/4 logic. Therefore, loss of two channels on a train will not prevent the SSPS from performing it's function. The loss of power will send a general warning signal for the train and place the SSPS in a partial trip condition. Loss of power on the other train will actuate the SSPS and trip the plant, which is acceptable for PFSSD. Therefore, loss of AC power will not impact PFSSD.
NN0111 NN0311	Process Protection Set 1 Panel SB038 Process Protection Set 3 Panel SB037	Panel SB038 is the Channel I process protection rack. Panel SB037 is the Channel III process protection rack. Loss of 120 VAC power will prevent operation of Channels I and III inputs to the reactor protection system. The remaining two channels will remain operable. The SSPS operates on a 2/3 or 2/4 logic. Therefore, loss of two channels will not prevent the SSPS from performing it's function. PFSSD transmitters powered from NN0111 are ABPT0514, ABPT0524, ABPT0534, ABPT0544, AELT0501, AELT0529, AELT0539, AELT0551, AELT0554, BBLT0459, BBPT0405, BBPT0455, BBTE0413A, BBTE0423A, BBTE0433B, BBTE0443B, BGFT0215A, BGLT0112, BNLT0930 and GNPT0937. PFSSD transmitters powered from NN0311 are ABPT0526, ABPT0536, AELT0503, AELT0518, AELT0528, AELT0538, AELT0548, BBPT0457, BNLT0932 and GNPT0935. These transmitters and associated control room indicators are not credited in the event of a fire in this area. Redundant instrumentation powered from alternate sources of power is available. Therefore, loss of AC power will not impact PFSSD. Also see Section 5.2.2 for discussion

Potential Impact on Loss of Train A Class 1E 120 VAC Electrical Distribution System		
Switch(es)	**Component**	**Impact**
		on loss of RCS temperature indication.
NN0112	SSPS Train A #2 Output Panel SB029D	Loss of 120 VAC power to SB029D will prevent operation of the Train A SSPS. The Train B output panels are unaffected by a fire in this area. Therefore, loss of AC power will not impact PFSSD.
NN0116 NN0120	BOP Instrument Rack RP053AC	Loss of 120 VAC power from NN0116 to RP053AC will cause a loss of the following PFSSD components: ABPV0001, ALHV0006, ALHV0008, ALHV0009, ALHV0011, ALPT0025, EFFT0053, EFPI0001, JELSL0001C, JELT0001. Loss of power to ABPV0001 will fail the valve closed. The Train B MDAFP can be used to supply steam generator D with temperature control using ABPV0004. The TDAFP can be used to supply steam generators B and C with temperature control using ABPV0002 and ABPV0003. However, as discussed below for switch NN0307, ABPV0003 could fail closed. The remaining components are not credited for a fire in this area so loss of AC power will not adversely impact PFSSD. Loss of 120 VAC power from NN0120 to RP053AC will cause a loss of the following PFSSD components: ALFT0009, ALFT0011, ALPT0037, EFPI0001, EFPT0001, EGPSL0077, EGFT0128, EGPT0077, GDTE0001, GDTSL0001, GDTZ0001A. Loss of power to ALPT0037 will not affect PFSSD due to the availability of ALPT0038 and ALPT0039 to ensure ESFAS LSP swapover. The remaining components are not credited for a fire in this area so loss of AC power will not adversely impact PFSSD.
NN0121	Train A Control Room A/C Unit Inlet & Discharge Dampers GKHZ0029A & GKHZ0029B	Loss of 120 VAC power from NN0121 will impact only Train A inlet & discharge dampers GKHZ0029A & 29B. Train B dampers are unaffected by a fire in this area. Therefore, loss of AC power will not affect PFSSD.
NN0307	BOP Instrument Rack RP053DB	The only PFSSD component affected by a loss of 120 VAC power from NN0307 to RP053DB is steam generator C ARV ABPV0003. A loss of power will cause the ARV to fail closed. As stated above for switches NN0116 and NN0120, steam generator A ARV ABPV0001 could also fail closed. Steam generators B and D ARVs are unaffected by a fire in this area. The Train B MDAFP is available to supply steam generator

Potential Impact on Loss of Train A Class 1E 120 VAC Electrical Distribution System		
Switch(es)	**Component**	**Impact**
		D and the TDAFP is available to supply steam generator B.

The potential PFSSD impacts identified in the above discussion are that steam generators A and C ARVs ABPV0001 and ABPV0003 could fail closed. The Train B motor driven auxiliary feedwater pump (MDAFP) is available to supply steam generator D and the turbine driven auxiliary feedwater pump (TDAFP) is available to supply steam generator B. Therefore, temperature control is achieved using at least two steam generators.

Based on the above discussion, a loss of Class 1E 120 VAC power will not adversely impact PFSSD.

5.1.3 Non-Class 1E 120 VAC Electrical Distribution System

The PFSSD function of the non-Class 1E 120 VAC electrical distribution system is to supply 120 VAC power to Main Control Boards (MCBs) RL017/RL018 and RL021/RL022. The power is split at the MCB to supply specific PFSSD components. The other PFSSD function of the non-Class 1E 120 VAC electrical distribution system is to supply power to steam generator feedwater pump controller cabinets FC169A/C and FC170A/C. See Section 5.2.4 for a detailed discussion about the steam generator feedwater pumps.

The PFSSD components that depend on 120 VAC power from RL017/RL018 are Residual Heat Removal (RHR) discharge valves EJHCV0606 (Train A) and EJHCV0607 (Train B). Non-class 1E 120 VAC switchboard panel PN07 supplies power from switch PN0736 to solenoid valve EJHY0606. Solenoid valve EJHY0606 controls the position of EJHCV0606 using hand controller EJHIC0606. Non-class 1E 120 VAC switchboard panel PN08 supplies power from switch PN0833 to solenoid valve EJHY0607. Solenoid valve EJHY0607 controls the position of EJHCV0607 using hand controller EJHIC0607.

The PFSSD components that depend on 120 VAC power from RL021/RL022 are temperature recorders BBTR0423, BBTR0433 and BBTR0443. Non-class 1E switchboard panel PN07 supplies power from switch PN0738 to temperature recorder BBTR0423. Non-class 1E switchboard panel PN08 supplies power from switch PN0835 to temperature recorders BBTR0433 and BBTR0443.

Non-class 1E 120 VAC switchboard panel PN07 and several associated cables and components (PN07A, PN07B, PN07C, TB34101, TB34102, XPN07A and XPN07D) are located in fire area C-16. Therefore, solenoid valve EJHY0606 and temperature recorder BBTR0423 could lose power if a fire occurs in this area. A loss of power to EJHY0606 will fail valve EJHCV0606 open and will prevent control of EJHCV0606 from the control room. Loss of power to temperature recorder BBTR0423 will result in a loss of one of the two RCS loop 2 hot leg temperature indicators.

Non-class 1E 120 VAC power to panel PN08 is unaffected by a fire in this area. Train B RHR valve EJHCV0607 is unaffected by a fire in area C-16, so Train B RHR can be used for

shutdown cooling. For a detailed discussion on PFSSD impact on loss of RCS temperature indication, see Section 5.2.2.

Based on the above discussion, a loss of non-class 1E 120 VAC distribution switchboard PN07 will not adversely impact safe shutdown.

5.2.1 Class 1E Electrical Equipment Room Air Conditioning

Class 1E electrical equipment room air conditioning is required to satisfy the PFSSD support function of maintaining cooling within the Class 1E electrical equipment rooms. Either the Train A or Train B room cooler is required to be operable to ensure adequate room cooling.

Power and control cables associated with Train A Class 1E electrical equipment room A/C unit SGK05A are run in fire area C-16. Damage to these cables could prevent operation of SGK05A. In addition, a fire in this area will initiate the fire detection and Halon actuation system, causing SGK05A to shut down. Damage to cable 15GKK31CB could cause SGK05A to spuriously shut down due to a false fire isolation signal. Therefore, the Train A Class 1E electrical equipment room A/C unit SGK05A is unavailable if a fire occurs in area C-16.

Cable 11SAZ19KA associated with SGK05A is run in fire area C-16. Damage to this cable could prevent operation of SGK05A. Cables associated with SGK05B are unaffected by a fire in area C-16.

Power and control cables associated with Train B Class 1E electrical equipment room A/C unit SGK05B are not run in fire area C-16. Therefore, SGK05B is available in the event of a fire in this area.

Based on the above discussion, the Train B Class 1E electrical equipment room A/C unit SGK05B is available in the event of a fire in area C-16.

References: XX-E-013, E-15000, E-13GK13, E-13GK31, E-13SA19, M-622.1A-00002

5.2.2 RCS Temperature Indication

Reactor coolant system (RCS) hot and cold leg temperature indication is required to verify that RCS decay heat removal has been established, either by forced circulation or natural circulation. The PFSSD methodology requires wide range hot leg and cold leg temperature indication to be available on at least one RCS loop. The following table identifies the hot and cold leg temperature components credited for PFSSD as well as the components power supply.

RCS Loop	Hot Leg Temperature	Power Supply	Cold Leg Temperature	Power Supply
1	BBTE0413A/BBTI0413A	NN0111	BBTE0413B/BBTI0413B	NN0212
2	BBTE0423A/BBTI0423A BBTR0423	NN0111 PN0738	BBTE0423B/BBTI0423B	NN0217
3	BBTE0433A BBTR0433	NN0212 PN0835	BBTE0433B BBTR0433	NN0111 PN0835
4	BBTE0443A BBTR0443	NN0212 PN0835	BBTE0443B BBTR0443	NN0111 PN0835

Class 1E 120 VAC power from NN0111 to process rack SB038 (Cable 11SBY09CA) could be disrupted as discussed in Section 5.1.2. In addition, non-class 1E power from PN0738 to temperature recorder BBTR0423 (Cable 15RLY01EA) could be disrupted as discussed in Section 5.1.3. If this occurs, hot leg temperature indication on loops 1 and 2 will be lost and cold leg temperature indication on loops 3 and 4 will be lost. Hot leg temperature indication on loops 3 and 4 and cold leg temperature indication on loops 1 and 2 remain available.

EMG ES-04 provides alternate indication that may be used. One of these methods verifies that steam generator pressure is stable or decreasing. As stated earlier, the Train B MDAFP is

available to supply steam generators A and D. Steam generator A pressure instruments ABPT515 and ABPT516 and steam generator D pressure instruments ABPT0545 and ABPT0546 are unaffected by a fire in C-16 and can be used per EMG ES-04 to verify heat removal in loops 1 and 4.

The configuration is acceptable because, in the event of a fire in fire area C-16, cooldown will be performed using RCS loops 1 and 4. RCS loop 1 wide range cold leg temperature element BBTE0413B, RCS loop 4 wide range hot leg temperature element BBTE0443A as well as steam generators A and D pressure transmitters ABPT515, ABPT516, ABPT0545 and ABPT0546 will provide indication.

References: E-15000, XX-E-013, E-13RL06, E-13BB15, E-1F9201, E-1F9431, M-12AB01, M-12BB01, EMG ES-04

5.2.3 Control Room Emergency Lights

Emergency lighting is provided in the control room to ensure adequate lighting during a station blackout and in the event a fire damages cables associated with the normal and standby lighting system. Emergency lights are supplied power from Class 1E 125 VDC breaker NK5120.

The control room has four sources of lighting; 1) Normal; 2) Standby; 3) Emergency; and Self-contained battery units. The normal lighting system is not evaluated in the PFSSD analysis and is assumed lost.

The standby lighting system is supplied by the 480 VAC Class 1E electrical system through breakers NG01AHF1 and NG01AHF2. Power availability on NG01AHF1 and NG01AHF2 is monitored by auxiliary relays 27XQB1 and 27XQB2 in panel RP330. Upon loss of power to both NG01AHF1 and NG01AHF2, the relay coils are de-energized and the normally open contacts close. This energizes the contactor control relay which closes a contact and energizes the control room emergency lighting panel NK051A, which automatically illuminates the 125 VDC (QD System) emergency lights in the control room.

Cable 11QBY03CA is a control cable that runs from NK051 to RP330 and provides control power to energize the contactor control relay to illuminate control room emergency lights upon loss of Class 1E power. A short in this cable due to a fire will illuminate emergency lights in the control room even though Class 1E power is available. An open in cable 11QBY03CA will prevent the control room emergency lights from illuminating upon loss of Class 1E power.

Cable 11QDK01AA is a power cable that runs from NK051A to control room emergency lights. Damage to this cable will prevent operation of the emergency lights.

Based on Calculation XX-E-013, Appendix 2, a fire in area C-16 will not result in a loss of offsite power so it is likely that normal lighting in the control room will be available. In the unlikely event control room lighting is lost, self-contained Appendix R battery units are provided in the control room to provide minimum lighting for post-fire safe shutdown. Operations has indicated that installed Appendix R lights are sufficient to perform control room actions to achieve hot standby.

Based on the above discussion, the control room will have sufficient lighting to achieve and maintain PFSSD.

5.2.4 Steam Generator Feedwater Pumps

Main feedwater pump steam supply valves FCFV0005 and FCFV0105 are credited in the PFSSD analysis to trip the main feedwater pumps if the main steam isolation valves (MSIVs) are affected by a fire. Closing the MSIVs stops steam flow to the feedwater pumps' turbines and stops the feedwater pumps. The steam generator feedwater pumps are tripped in the event of a fire to prevent overfilling the steam generators.

Non-Class 1E 120 VAC Inverter PN09 and distribution panel PN09A provide power to FCFV0005 trip relays in panel FC169C. Cable 15RPY10AA supplies power from PN0712 to inverter PN09. Cable 15FCY35AA provides the primary source of 120 VAC power from distribution panel PN09A to panel FC169A, which distributes power to the trip relays in panel FC169C. The alternate source of power to panel FC169A is not credited for PFSSD and is assumed lost.

A fire in area C-16 could damage cables 15FCY35AA and 15RPY10AA. If this occurs, operators in the control room would not be able to close valve FCFV0005 to stop steam flow to steam generator feedwater pump PAE01A.

A fire in area C-16 will not affect the ability to close the MSIVs from the control room. All-close hand switches ABHS0079 and ABHS0080 are unaffected and can be used to close the MSIVs from the control room.

Based on the above discussion, valve FCFV0005 may not close if a fire occurs in this area. However, the MSIVs can be closed using either hand switch ABHS0079 or ABHS0080 in the main control room. Therefore, the configuration is acceptable.

References: E-15000, XX-E-013, E-13FC35, E-13RP10, E-1F9103, E-1F9421

5.2.5 Control Room Air Conditioning

Power cables associated with Train A Control Room A/C unit supply and return dampers GKHZ0029A and GKHZ0029B are run in area C-16. Damage to these cables could prevent operation of the associated dampers. Circuits for Train B Control Room A/C unit dampers do not run in area C-16.

Based on the above discussion, Control Room environmental conditions will be unaffected by a fire in area C-16.

1.0 GENERAL AREA DESCRIPTION

Fire area C-17 is located on the 2016 elevation of the Control Building and includes the room listed in Table C-17-1.

Table C-17-1
Rooms Located in Fire Area C-17

ROOM #	DESCRIPTION
3418	South Electrical Chase - 2016 Elevation

Fire area C-17 is protected with an automatic wet-pipe sprinkler system and automatic fire detection. The area is separated from adjacent areas by minimum 3-hour fire resistant construction.

2.0 PRIMARY EQUIPMENT USED FOR PFSSD

Table C-17-2 lists each system credited for post-fire safe shutdown and provides a discussion regarding the availability of the system to perform its Post Fire Safe Shutdown (PFSSD) function if a severe fire occurs in this area. For a summary of the area analysis results, see Section 8.0 of the Fire Area Analysis Narrative section.

Table C-17-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-17

System	System Name	PFSSD Function*	Comments
AB	Main Steam	R, M, H, P, S	Cables associated with S/G ARV ABPV0004 may be damaged, preventing control of this valve from the control room. The ARV can be isolated by closing air supply valve KAV1429 and nitrogen supply valve KAV1365, then bleeding air from the regulator. The capability to isolate the MSIVs and bypass valves using handswitch ABHS0079 may be affected. The MSIVs and bypass valves can be isolated using handswitch ABHS0080.
AC	Main Turbine	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-17.
AE	Main Feedwater	H, P	The capability to isolate the MFIVs using handswitch AEHS0081 may be affected. Isolate the MFIVs using handswitch AEHS0080. Steam generator D wide range level indicator AELI0504 in the main control room (MCR) may be affected. Steam generators B and D wide range level indication at the auxiliary shutdown panel (ASP) may be affected. All four narrow range level indicators in the (MCR) are unaffected.
AL	Aux. Feedwater System	H, P	Train B motor driven auxiliary feedwater pump (MDAFP) may be affected. Train A MDAFP is available to supply auxiliary feedwater to SGs B and C. The turbine driven auxiliary feedwater pump will operate, but it may be limited to supplying only steam generators A and D. Steam generator D flow transmitter ALFT0001 may be affected. Steam generator A flow transmitter ALFT0007 may be affected. Steam generators B and C flow transmitters are unaffected. Valves ALHV0005 (MDAFP B to SG D), ALHV0007 (MDAFP B to SG A), ALHV0010 (TDAFP to SG B) and ALHV0012 (TDAFP to SG C) may be affected. Valves from MDAFP A to SGs B and C and from the TDAFP to SGs A and D are unaffected. MDAFP B suction pressure transmitter ALPT0024 may be affected. MDAFP A suction pressure transmitter ALPT0025 is unaffected. TDAFP suction pressure transmitter ALPT0026 is unaffected.
AP	Condensate Storage System	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-17.

Table C-17-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-17

System	System Name	PFSSD Function*	Comments
BB	Reactor Coolant System	R, M, H, P, S	Block valve BBHV8000B may fail to respond to a close signal. A cable associated with redundant PORV BBPCV0456A runs in this area but cable damage will not cause the PORV to spuriously open. RCS pressure transmitter BBPT0406 may be affected and pressure indicator BBPI0406 may not function. Pressure transmitter/indicator BBPT0405/BBPI0405 is unaffected. Main control room RCS temperature recorders BBTR0433 and BBTR0443 on loops 3 and 4 could lose power. Loops 2 and 4 RCS temperature indicators BBTI0423X and BBTI0443A, located at the ASP, could be affected. Loop 2 cold leg temperature element BBTE0423B and loop 4 hot leg temperature element BBTE0443A may be affected. Loop 1 cold leg and hot leg temperature indicators BBTI0413B and BBTI0413A in the MCR remain available. Power to reactor head vent valves BBHV8001B and BBHV8002B may be lost. If this occurs, the valves will fail closed which is the desired PFSSD position. Pressurizer level indicator BBLI0460B located at the ASP may be affected. Pressurizer level transmitter BBLT0460 may be affected. Pressurizer level indication in the MCR using BBLI0459A is unaffected. Reactor coolant pumps C and D may not stop using the control room hand switch. RCP seal injection and thermal barrier cooling remain available. Therefore, the inability to stop the RCPs will have no adverse impact on PFSSD.
BG	Chemical and Volume Control System	R, M, S	VCT outlet valve BGLCV0112C may not close in response to a control room signal. Redundant valve BGLCV0112B is unaffected and will close in response to a control room signal or a low-low level in the VCT. Train B centrifugal charging pump (CCP) to RCP seal injection isolation valve BGHV8357B could spuriously close. The Train A RCP seal injection valve BGHV8357A is unaffected. Power to excess letdown isolation valves BGHV8153B and BGHV8154B may be disrupted, causing the valves to fail closed which is the desired PFSSD position. RCP seal injection total flow indicator BGFI0215B may be affected due to loss of 120 VAC power to SB041. Flow indicator BGFI0215A is unaffected.
BM	Steam Generator Blowdown System	R, M, H	Power to steam generator blowdown valves BMHV0001, BMHV0002, BMHV0003 and BMHV0004 could be disrupted, causing the valves to fail closed which is the desired PFSSD position.
BN	Borated Refueling Water Storage System	R, M, H	The Train B RWST to CCP suction valve BNLCV0112E may spuriously close. The Train A RWST to CCP suction valve BNLCV0112D is unaffected. RWST to Train B RHR pump valve BNHV8812B may not open, which would prevent a suction source to the Train B RHR pump. RWST to Train A RHR pump valve BNHV8812A is unaffected.
EF	Essential Service Water System	H, S	Train B ESW system may be affected. Train A ESW system is unaffected.

Table C-17-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-17

System	System Name	PFSSD Function*	Comments
EG	Component Cooling Water System	S	Train B CCW pumps PEG01B and PEG01D may be affected. Train A CCW pumps PEG01A and PEG01C are unaffected. Train B CCW temperature control valve EGTV0030 may be affected. Train A CCW temperature control valve EGTV0029 is unaffected. Train B CCW pumps discharge pressure transmitter EGPT0078 and low pressure switch EGPSL0078 may be affected. Train A CCW pumps discharge pressure transmitter EGPT0077 and low pressure switch EGPSL0077 are unaffected. CCW to RCP flow indicator EGFI0129 may be affected due to loss of 120 VAC power to RP053B. Flow indicator EGFI0128 is unaffected.
EJ	Residual Heat Removal System	M, H, P	The Train B RHR system may be affected. Train A RHR is unaffected.
EM	High Pressure Coolant Injection	R, M	The Train B SI pump may spuriously start and may not be able to be stopped from the control room. Actual safety injection will not occur until the RCS pressure decreases below that of the pump shutoff pressure. The pump can be stopped, if necessary, by opening breaker NB0202, but this action is not required for PFSSD. Power to SI test line isolation valves EMHV8843 and EMHV8871 could be affected, causing the valves to fail closed which is the desired PFSSD position.
EN	Containment Spray	R, M	The Train B CS pump may spuriously start. Valve ENHV0012 will remain closed, preventing flow from the CS nozzles. The pump can be stopped, if necessary, by opening breaker NB0203, but this action is not required for PFSSD.
EP	Safety Injection Accumulators	H	Position indication for accumulator injection valves EPHV8808B and EPHV8808D may be affected.
FB	Auxiliary Steam	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-17.
FC	Auxiliary Turbines	R, H, P	Solenoid valve FCFY0310 associated with Turbine Driven Auxiliary Feedwater Pump steam trap valve FCHV0310 could lose power causing the valve to fail closed which is the desired PFSSD position. Valve FCFV0105 may be affected. The MSIVs can be closed using all-close hand switch ABHS0080.
GD	ESW Pump House HVAC	S	Train B ESW pump room ventilation may be affected. Train A ESW pump room ventilation is unaffected.
GF	AFW Pump Room Coolers	S	Train B motor driven auxiliary feedwater pump room cooler SGF02B may be affected. Train A motor driven auxiliary feedwater pump room cooler SGF02A is unaffected.

Table C-17-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-17

System	System Name	PFSSD Function*	Comments
GK	Control Room and Class 1E Switchgear Room Coolers	S	Train B control room A/C unit SGK04B may be affected. Train A control room A/C unit SGK04A is unaffected. Both Train A and Train B class 1E electrical equipment room A/C units (SGK05A and SGK05B) may be affected. If SGK05A spuriously shuts down or cannot be started, the spurious fire isolation signal can be bypassed by placing hand switch GKHS0101 in bypass position and the unit can be started using GKHIS0100. Hand switches GKHIS0100 and GKHS0101 are located on panel RP068 in the main control room.
GL	Auxiliary Building HVAC	S	Train B CCW pump room cooler SGL11B may be affected. Train A CCW pump room cooler SGL11A is unaffected.
GM	Emergency Diesel Generator Room HVAC	S	Cables associated with Train B diesel generator room exhaust damper GMHZ0019 are run in this area. Train A diesel generator room ventilation is unaffected.
GN	Containment Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-17.
JE	Diesel Fuel Oil	S	Train B emergency diesel fuel oil transfer pump DPJE01B may be affected. Level indication for the Train B fuel oil storage tank may be lost. Train A emergency diesel fuel oil transfer pump DPJE01A and Train A fuel oil storage tank level transmitter are unaffected.
KA	Instrument Air	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-17.
KC	Fire Protection	S	Cables associated with Halon protection in class 1E electrical equipment switchboard rooms 3408 and 3414 could be damaged by a fire in area C-17, causing Halon release in these rooms and subsequent shutdown of SGK05A. This will not adversely impact PFSSD (See GK discussion).
KH	Service Gas	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-17.
KJ	Standby Diesel Engine	S	Train B emergency diesel engine may not be available. The Train A emergency diesel engine is unaffected.
MA	Main Generation	S	A cable associated with phase differential relay 287/T1 in transformer protection relay panel MA104F could be affected. This could cause a loss of offsite power to NB01. Cables associated with MA104E are unaffected.
MR	Startup Transformer	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-17.
NB	4.16 kV System	S	A loss of off-site power to NB01 and NB02 may occur. The Train A diesel generator is available to energize the NB01 bus if this occurs.
NE	Standby Diesel Generator	S	Train B emergency diesel generator may not be available. The Train A emergency diesel generator is unaffected.

Table C-17-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-17

System	System Name	PFSSD Function*	Comments
NF	Load Shed and Emergency Load Sequencing	S	Some cables associated with the load shedder/sequencer on both trains could be affected. However, damage to these cables will not prevent the equipment from performing its intended function.
NG	480V Load Centers and MCCs	S	A loss of off-site power to the Train A and B 480 Volt load centers may occur. The Train A diesel generator is available to energize the Train A load centers if this occurs.
NK	125VDC	S	Loss of power to a number of PFSSD components powered from the Train B NK system could occur. These components fail in the desired PFSSD position upon loss of power or the redundant Train A component is available.
NN	120VAC	S	A loss of Train B Class 1E 120 VAC electrical distribution system may occur. The Train A Class 1E electrical distribution switchboards are unaffected.
PA	13.8kV	S	Cables associated with PA0201 phase differential relay 287/T2 could be affected, causing a loss of off-site power to NB02. In addition, the Train B EDG may not be available. The Train A EDG is available to supply power to Train A PFSSD loads. Breaker PA0207 could be affected by a fire in this area. Redundant capability is available.
PB	4.16kV	H, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-17.
PG	480V Load Centers and MCCs	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-17.
PK	125VDC	S	Battery charger PK22 may be affected. Battery set PK12 will maintain 125 VDC power to PK02. Also, Train A non-class 1E 125 VDC system is unaffected.
PL	Local Instrument Panels	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-17.
PN	120VAC	S	Power to non-class 1E 120 VAC switchboard PN08 may be affected. Non-class 1E 120 VAC switchboard PN07 is unaffected.
QB	Standby AC Lighting	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-17.
QD	Emergency Lighting	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-17.

Table C-17-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-17

System	System Name	PFSSD Function*	Comments
RL	Control Room MCB	S	Separation group 5 non class 1E 120 VAC power could be disrupted to control room panels RL017/RL018 and RL021/RL022. Separation group 6 non class 1E 120 VAC power remains available.
RP	Miscellaneous Control Panels	R, M, H, P, S	Panel RP140 could lose Class 1E 125 VDC power from NK4415. This affects three relays associated with Train B ESW system. Train A ESW remains available. Panel RP210 could lose Class 1E 125 VDC power from NK4417. This affects the MSIV bypass valves and would cause them to fail closed which is the desired PFSSD position. Panel RP335 could lose Class 1E 125 VDC power from NK4419. This affects control room lockout relays associated with Train B motor driven and turbine driven auxiliary feedwater. Train A motor driven auxiliary feedwater remains available. Train B 120 VAC power to control room panels RP053BA, RP053BB, RP053BC, RP147B and RP068 could be lost. Train A 120 VAC power remains available to supply redundant PFSSD loads.
SA	ESFAS	S	Class 1E 125 VDC and 120 VAC power to panel SA036B could be lost, resulting in a loss of Channel 4 Engineered Safety Features Actuation System (ESFAS). Redundant Channels 1 and 2 ESFAS are unaffected. Class 1E 125 VDC power to Train B MSFIS cabinet SA075B could be affected. Redundant Train A MSFIS cabinet SA075A is unaffected. Status panel input from SGK05B to SA066B could be affected. Status panel input from SGK05A to SA066A is unaffected.
SB	Reactor Protection System	R, S	A loss of power to input channel 4 in SB029A and SB032A could occur. Input channels 1, 2 and 3 remain available. Train B output cabinet 2 and Train B reactor trip switchgear cabinet could lose power. Train A output cabinets and Train A reactor trip switchgear cabinet are unaffected. A number of cables from SB148A and SB148B to the ASP could be affected, causing a loss of process monitoring at the ASP. Process monitoring in the main control room remains available.
SC	Reactor Instrumentation	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-17.
SE	Ex-Core Neutron Monitoring	R, P	SR monitor signal processor SENY0061B and SR monitor amplifier SENY0061A could be affected. Source Range monitoring remains available using SENE0031, SENE0032 and SENY0060A/B
SY	Switchyard	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-17.
UU	Supervisory System	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-17.

* R - Reactivity Control; M - Reactor Coolant Makeup; H - Decay Heat Removal; P - Process Monitoring; S - Support Function

3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD

This section describes operator actions that may need to be performed inside or outside the control room to achieve and maintain hot standby if a fire occurs in area C-17. This section also describes cold shutdown repairs that may need to be made to achieve and maintain cold shutdown conditions. Operator actions are proceduralized in OFN KC-016.

3.1 ACTIONS OUTSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

Operator Manual Actions (OMAs) are those actions outside the main control room required to achieve and maintain hot standby. OMAs are identified in E-1F9900 and were determined from thermal hydraulic analysis WCNOC-CP-002. Applicable E-1F9900 OMAs are annotated herein. All other actions outside the control room are desirable for plant control in support of hot standby but not required to achieve and maintain hot standby.

3.1.1 Steam Generator Atmospheric Relief Valves

Cables associated with S/G ARV ABPV0004 may be damaged, preventing control of this valve from the control room. The ARV can be isolated by closing air supply valve KAV1429 and nitrogen supply valve KAV1365, then bleeding air from the regulator. The air and nitrogen supply valves are located in fire area A-23 and access is available without having to traverse area C-17.

3.2 ACTIONS INSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

3.2.1 Main Steam Isolation Valves

A cable associated with hand switch ABHS0079 may be damaged by the fire. Cables for redundant hand switch ABHS0080 are unaffected. Use ABHS0080 in the main control room to close the MSIVs and MSIV bypass valves.

3.2.2 Main Feedwater Isolation Valves

A cable associated with hand switch AEHS0081 may be damaged. Cables for redundant hand switch AEHS0080 are unaffected. Use AEHS0080 in the main control room to close the MFIVs.

3.2.3 Class 1E A/C Unit SGK05A

Class 1E electrical equipment room A/C unit SGK05A may be affected due to damage to cables associated with the fire detection system. If SGK05A spuriously shuts down or cannot be started, the spurious fire isolation signal can be bypassed by placing hand switch GKHS0101 in bypass position and the unit can be started using GKHIS0100. Hand switches GKHIS0100 and GKHS0101 are located on panel RP068 in the main control room.

3.2.4 Component Cooling Water

Train B CCW could be affected by a fire in this area. If this occurs, swap to Train A CCW using normal operating procedures if Train A CCW is not already running. CCW to RCP flow indicator EGFI0128 is available to diagnose a loss of flow to the RCP thermal barriers.

3.2.5 Reactor Coolant Pump Seal Cooling

If Train B CCW is operating at the time of the fire, it could be lost causing a temporary loss of thermal barrier cooling. The normal charging pump is not analyzed and is assumed lost. Operators should swap to Train A CCW to restore thermal barrier cooling and line up the Train A CCP to restore RCP seal injection. RCP seal injection total flow indicator BGFI0215A is

available to diagnose a loss of RCP seal injection. CCW to RCP flow indicator EGFI0128 is available to diagnose a loss of flow to the RCP thermal barriers.

3.3 ACTIONS TO ACHIEVE AND MAINTAIN COLD SHUTDOWN

3.3.1 Residual Heat Removal

Train B RHR may not be available for shutdown cooling. Train A RHR is unaffected.

4.0 CONCLUSION

With some exceptions, redundant Post Fire Safe Shutdown capability exists if a severe fire occurs in area C-17. For those exceptions, feasible manual actions are available and are unaffected by the fire. Manual actions are documented in Section 3.0.

5.0 DETAILED ANALYSIS

This section describes the detailed component-by-component and cable-by-cable analysis for a fire in area C-17.

5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA C-17

There are no PFSSD components located in area C-17. This fire area only contains cables associated with PFSSD equipment located in other areas.

5.2 PFSSD CABLE EVALUATION

Table C-17-3 lists all the PFSSD cables (S. in E-15000) located in fire area C-17. The applicable evaluation section is also listed in Table C-17-3.

Table C-17-3
PFSSD Cables Located in Fire Area C-17

Cable #	Location	Primary PFSSD Equipment	Cable Function (P) Power (C) Control (I) Instrumentation	Evaluation Section	Comments
14ABI20HE	3418	ABPV0004	I	5.2.1	SG D ARV I/P Converter (ABPY0004)

5.2.1 Steam Generator Atmospheric Relief Valves

PFSSD requires at least two steam generator atmospheric relief valves (ARV) be controlled and the other two closed. The ARVs are pneumatically operated using air from the compressed air system (KA) or nitrogen from the nitrogen accumulators. The valves open by pneumatic pressure and close by spring action. A pressure transmitter installed on the outlet side of the steam generator sends a signal to a controller and automatically controls the associated ARV position. Alternatively, each ARV can be controlled manually from the control room or the auxiliary shutdown panel by placing the pressure indicating controller (PIC) in manual.

Cables associated with steam generator D ARV ABPV0004 are run in area C-17. Damage to these cables could prevent control or closure of the ARV. Cables associated with the remaining ARVs are run in a different fire area.

If steam generator D ARV ABPV0004 spuriously opens, operators can isolate air and nitrogen to fail the ARV closed. Air is isolated by closing valve KAV1429 and nitrogen is isolated by closing valve KAV1365. The air and nitrogen supply valves are located in fire area A-23 and access is available without having to traverse area C-17.

Up to three ARVs can fail closed or open without impacting ability to achieve and maintain hot standby according to thermal hydraulic analysis WCNOC-CP-002. With at least one ARV unaffected, no E-1F9900 OMA is required to address ARV closure or control. Reference Attachment 4, MSO Evaluation Scenario ID PWROG 23.

References: E-15000, XX-E-013, E-13AB20B, E-1F9101, M-12AB01, M-12KA04, M-12KA05

5.2.2 Main Steam and Feedwater Isolation Actuation Cabinet

The Class 1E 125 VDC power supply cable to Train B MSFIS Cabinet SA075B is run in area C-17. Damage to this cable could prevent closure of the MSIVs and MFIVs using handswitches ABHS0079 and AEHS0081, respectively.

The Class 1E 125 VDC power supply cable to redundant Train A MSFIS cabinet SA075A is not run in area C-17. Therefore, the MSIVs and MFIVs can be closed using handswitches ABHS0080 and AEHS0080, respectively.

References: E-15000, XX-E-013, E-13AB26, E-13AB27, E-13AB30, E-13AE14, E-13AE15, E-1F9101, E-1F9201, M-12AB02, M-12AE02

5.2.3 Steam Generator Level Indication

An instrument cable associated with steam generator D wide range level transmitter AELT0504 is run in this area. Damage to this cable could prevent wide range indication of steam generator D level in the control room. However, cables associated with all four steam generator D narrow range level transmitters are run in a different fire area and are unaffected by a fire in C-17. Therefore, level indication on the D steam generator is available.

References: E-15000, XX-E-013, E-1F9203, E-13AE08, M-12AE02

5.2.4 Auxiliary Feedwater

The PFSSD design requires the use of one auxiliary feedwater pump (AFP) supplying water to at least two steam generators. The turbine driven auxiliary feedwater pump (TDAFP) is normally aligned to supply all four steam generators. The Train A motor driven auxiliary feedwater pump (MDAFP) is aligned to supply steam generators B and C. The Train B MDAFP is aligned to supply steam generators A and D.

Cables associated with Train B auxiliary feedwater pump are run in area C-17. Damage to these cables could prevent operation of the pump. The Train A motor driven auxiliary feedwater pump (MDAFP) and the turbine driven auxiliary feedwater pump (TDAFP) remain available to ensure auxiliary feedwater.

The suction isolation valve from the condensate storage tank (CST) to the Train B MDAFP (ALHV0034) may be affected such that the valve spuriously closes. Therefore, the CST may not be able to provide a suction source to the Train B MDAFP. In addition, the essential service water (ESW) source to Train B MDAFP may be affected due to damage to cables associated with ALHV0030. The CST and ESW supply to the Train A MDAFP are unaffected. Also, the CST supply to the TDAFP and the Train A ESW supply to the TDAFP are available. The Train B ESW supply valve to the TDAFP (ALHV0033) may not be available.

The Train B MDAFP to steam generator (SG) D control valve (ALHV0005) may spuriously close or may not operate properly. The TDAFP is available to supply SG D through valve ALHV0006, which is unaffected by a fire in area C-17.

Valve ALHV0010 could be affected such that the valve cannot be controlled from the control room or the valve may spuriously close. This valve controls auxiliary feedwater flow from the TDAFP to SG B. Valve ALHV0009 is unaffected by a fire in area C-17 and is available to ensure an adequate auxiliary feedwater supply from the Train A MDAFP to SG B.

As discussed in Section 5.2.24, the TDAFP to SG C control valve (ALHV0012) may be affected. Therefore, this valve cannot be relied on to ensure a supply of AFW from the TDAFP to SG C.

Auxiliary feedwater to SG D flow transmitter ALFT0001 may be affected. Auxiliary feedwater to SG A flow transmitter ALFT0007 may be affected (See Section 5.2.24). Auxiliary feedwater to SG A flow transmitter ALFT0002 is unaffected. Flow transmitters on SGs B and C supply lines are unaffected.

Train B MDAFP suction pressure transmitter (ALPT0024) may be affected. Suction pressure transmitters on Train A MDAFP and TDAFP suction lines are unaffected.

A cable associated with the Train B MDAFP room cooler (SGF02B) is run in this area. Damage to this cable could prevent operation of the cooler. The Train A MDAFP room cooler (SGF02A) is unaffected.

In summary, the Train A MDAFP is available to supply auxiliary feedwater to SGs B and C using either the CST or the ESW as the supply. In addition, the TDAFP is available to supply auxiliary feedwater to steam generators A and D using either the CST or the ESW as the supply, however the flow transmitter for SG D may not be available.

References: E-15000, XX-E-013, E-13AL01B, E-13AL02B, E-13AL03B, E-13AL04B, E-13AL05B, E-13AL07B, E-13AL09, E-13GF01, E-1F9202, E-1F9203, E-1F9204, E-1F9444, M-12AL01, M-12GF01

5.2.5 Pressurizer Power Operated Relief Valves and Associated Block Valves

PFSSD requires that either the pressurizer power operated relief valve (PORV) or its associated block valve be closed. Cables associated with PORV BBPCV0456A and associated block valve BBHV8000B are located in area C-17. Cables associated with BBPCV0455A and BBHV8000A are run in a different fire area.

A fire in area C-17 could damage cables for block valve BBHV8000B such that the block valve fails to respond to a close signal. Only one cable associated with PORV BBPCV0456A runs in area C-17. This cable (14BBK40BL) provides 125 VDC power from NK4421 to the control

circuit for the valve. Damage to this cable could disrupt power to the PORV and prevent it from opening but will not cause the PORV to spuriously open. Power failure will fail the valve closed, which is the desired PFSSD position.

Based on the above discussion, both pressurizer relief flow paths will remain isolated in the event of a fire in area C-17.

References: E-15000, XX-E-013, E-13BB39, E-13BB40, E-1F9301, M-12BB02

5.2.6 Reactor Coolant System (RCS) Pressure Indication

PFSSD requires RCS pressure indication to be available. RCS pressure indication is provided in the control room using BBPI0405 or BBPI0406. Cables for BBPT0406 run through fire area C-17. Therefore, pressure indicator BBPI0406 may not function.

Cables for BBPT0405 are run in a separate fire area and are unaffected by a fire in area C-17. Therefore, RCS pressure indication will be available using BBPI0405 if a fire occurs in area C-17.

References: E-15000, XX-E-013, E-13BB15, E-13BB16, E-1F9201, E-1F9205, M-12BB04

5.2.7 Centrifugal Charging System

At least one centrifugal charging pump (CCP) is required for PFSSD to provide RCP seal cooling, reactivity control and inventory control. These functions are accomplished using a CCP taking suction from the refuelling water storage tank (RWST) and injecting through the RCP seals. RCP seal injection provides approximately 20 gpm makeup to the RCS and provides adequate boron concentration to maintain sub-critical reactivity conditions. If RCP seal injection is unavailable, reactivity and inventory control is provided by lining up the CCPs to the boron injection tank (BIT). The normal charging pump (NCP) is not credited and is assumed lost.

Cables associated with Train B charging system are run in area C-17. Damage to these cables could prevent operation of the system. The Train A charging system is unaffected by the fire.

Volume control tank (VCT) outlet valve BGLCV0112C may not close in response to a control room signal. Redundant valve BGLCV0112B is unaffected and will close using the handswitch (BGHIS0112B) in the control room or in response to a low-low level in the VCT.

Cable 14BGG12BE provides the permissive for valve BGLCV0112C to close when either a SIS or a VCT low-low level is received. A hot short in this cable would bypass the SIS and VCT low-low level contacts. However, the valve will not spuriously close because cable 14BGG12BD is unaffected by the fire. This cable provides the permissive to complete the circuit and close BGLCV0112C when RWST to charging pump valve BNLCV0112E is fully open. Therefore BGLCV0112C will not spuriously close, unless the RWST is aligned to the charging header, in which case a loss of suction to charging will not occur.

Train B centrifugal charging pump (CCP) to RCP seal injection isolation valve BGHV8357B could be affected by a fire in this area. The Train A RCP seal injection valve BGHV8357A is unaffected by the fire. Therefore, seal injection can be accomplished using Train A charging system.

Cables associated with RWST to Train B CCP valve BNLCV0112E run in this area. Damage to these cables could prevent opening the valve, which would prevent a suction source to the CCP. Cables associated with RWST to Train A CCP valve BNLCV0112D do not run in this area. Therefore, the RWST is available to provide a suction source to the Train A CCP.

Based on the above discussion, the Train B CCP may not be available but the Train A CCP is unaffected by a fire in area C-17.

References: E-15000, XX-E-013, E-13BG01A, E-13BG11B, E-13BG12A, E-13BG52, E-13BN01, E-1F9102, E-1F9302, E-1F9401A, M-12BG03, M-12BN01

5.2.8 Residual Heat Removal

Cables associated with various components in the Train B residual heat removal (RHR) system run in this area. Damage to these cables could affect operation of the Train B RHR system. The Train A RHR system is unaffected by a fire in this area and remains available to ensure shutdown cooling.

Cable 14BNG03BC associated with RWST to Train B RHR pump valve BNHV8812B run in this area. Damage to this cable could prevent opening the valve, which would prevent a suction source to the Train B RHR pump. Cables associated with RWST to Train A RHR pump valve BNHV8812A do not run in this area. Therefore, the RWST is available to provide a suction source to the Train A RHR pump.

References: E-15000, XX-E-013, E-13BN03A, E-13EJ01, E-13EJ04B, E-13EJ08A, E-1F9102, E-1F9205, E-1F9401A, M-12BN01, M-12EJ01

5.2.9 Essential Service Water

Cables associated with Train B essential service water (ESW) system run in this area. As discussed below, damage to these cables could prevent operation of the Train B ESW system. However, the Train A ESW system remains available.

Cables 14EFB01SA and 14EFB01SB are associated with Train B ESW pump PEF01B. Damage to these cables could prevent operation of the pump. Cables associated with Train A ESW pump PEF01A run in a separate fire area.

The service water to/from ESW system cross connect flowpath needs to be isolated for PFSSD to prevent flow diversion from ESW to service water. Each cross connect has four series valves; two on the supply and two on the return. The following table identifies the valves on each ESW Train.

Series Installed Service Water to/from Essential Service Water Cross-Connect Valves			
Train A ESW Supply From SW	**Train B ESW Supply From SW**	**Train A ESW Return To SW**	**Train B ESW Return To SW**
EFHV0023	EFHV0024	EFHV0041	EFHV0042
EFHV0025	EFHV0026	EFHV0039	EFHV0040

At least one valve on the supply and one on the return needs to be closed. Cables associated with valves EFHV0025, EFHV0026, EFHV0039 and EFHV0040 are run in this area. Cables associated with valves EFHV0023, EFHV0024, EFHV0041 and EFHV0042 are unaffected. Therefore, at least one valve on each line will be available to ensure the flowpath can be isolated. In addition, check valve EFV0470 is installed between valves EFHV0023 and EFHV0025 and will prevent flow diversion from Train A ESW to the service water system. Also, check valve EFV0471 is installed between valves EFHV0024 and EFHV0026 and will prevent flow diversion from Train B ESW to the service water system.

The Train B ESW return to ultimate heat sink (UHS) valve EFHV0038 may be affected due to damage to a cable (14EFG06BC) associated with this valve. However, cables associated with the Train A ESW return valve to the UHS (EFHV0037) are unaffected.

Train B ESW pump discharge pressure transmitter EFPT0002 may be affected due to damage to an instrument cable (14EFI08RB). Train A ESW pump pressure transmitter EFPT0001 is unaffected.

Train B ESW pump flow transmitter EFFT0054 may be affected due to damage to an instrument cable (14EFI11FA). Train A ESW pump flow transmitter EFFT0053 is unaffected.

The Train B ESW pump room supply fan may not be available due to damage to cables associated with the fan and dampers. The Train A ESW pump room supply fan is unaffected.

Cable 14RPK09BA supplies 125 VDC power to ESW pump motor B interposing relays 1XEF32, 1XEF34, 1XEF36 located in relay rack RP140. Damage to the cable could prevent operation of the Train B ESW pump. As stated throughout this section, the Train A ESW system is unaffected if a fire occurs in this area.

Cables 14GDY01BA, 14GDY01BB and 14GDY01BD are associated with Train B ESW pump room supply fan CGD01B. Damage to these cables could prevent operation of the supply fan. Train A ESW pump room supply fan CGD01A is unaffected by a fire in this area.

Based on the above discussion, the Train A ESW pump and associated components are available if a fire occurs in area C-17.

References: XX-E-013, E-15000, E-093-00054, E-093-00055, E-13EF02, E-13EF02A, E-13EF03, E-13EF06A, E-13EF11, E-13RP09, E-1F9402A, E-1F9402B, E-1F9403, E-1F9443, E-K3EF01A, E-K3EF08, E-K3GD01A, E-K3GD04, E-K3GD04A, M-12EF01, M-12EF02, M-K2EF01, M-K2GD01

5.2.10 Component Cooling Water

The component cooling water system is required for PFSSD to provide cooling water to the CCP oil coolers, seal water heat exchanger, RHR heat exchanger, RHR pump seal cooler and RCP thermal barriers (to maintain RCP seal cooling in the event RCP seal injection is lost). In addition, the CCW system provides cooling to the RCP thermal barriers and is credited as a backup to RCP seal injection for maintaining seal cooling.

Cables associated with Train B CCW pumps PEG01B and PEG01D run in this area. Damage to these cables could prevent operation of the pumps. Cables associated with Train A CCW pumps PEG01A and PEG01C are run in a different area.

Cable 14EGG05DD, associated with Train B CCW valve EGHV0054, is run in this area. This cable supplies power to auxiliary relay 3XEG10 which provides permissives to open or close valves in the CCW supply to and from the Radwaste building. If Train B CCW is operating at the time of the fire, valve EGHV0054 will be open. Damage to cable 14EGG05DD could cause the control power fuse to blow and prevent closure of EGHV0054 when lining up Train A CCW. A loss of power to NB02, which is possible if a fire occurs in this area, could also prevent closure of valves EGHV0016 and EGHV0054. Operation of Train A CCW with valves EGHV0016 and EGHV0054 open could cause Train A CCW flow to divert to Train B CCW system. Per calculation M-EG-24, the system will continue to operate with no damage to the pumps if the valves in the opposite train are open.

Cable 14GLG06BD, associated with Train B CCW pump room cooler SGL11B, runs in this area. Damage to this cable could prevent automatic operation of the unit. The Train A CCW pump room cooler SGL11A is unaffected by a fire in this area.

Based on the above discussion, the Train B CCW system could be affected by a fire in area C-17 but the Train A CCW system is available.

References: XX-E-013, E-15000, E-13EG01C, E-13EG01D, E-13EG05D, E-13GL06, E-1F9401A, E-1F9444, M-12EG01, M-12GL02, Calculation M-EG-24

5.2.11 Safety Injection Pumps

The PFSSD strategy is to prevent operation of the Safety Injection (SI) pumps to ensure an adequate supply of borated water in the RWST. One cable (14EMB01BB) associated with Train B SI pump is run in area C-17. Damage to this cable could cause the spurious start of the pump and could prevent stopping the pump from the control room.

If the Train B SI pump spuriously starts with the reactor at normal pressure, PFSSD will be assured. The pump will not discharge into the RCS due to the pressure differential between the RCS (2,235 psig) and the SI pump shutoff pressure (1,565 psig). In addition, the setpoint of the discharge relief valve (EM8853B) to the Recycle Holdup Tank is 1,825 psig. Therefore, no inventory is lost from the RWST. With the SI pump operating with no flow, damage to the pump could occur, which is a commercial concern only since the SI pump is not credited in the PFSSD analysis. If necessary, the pump can be stopped by opening breaker NB0202, but this action is not required for PFSSD.

Based on the above discussion, spurious operation of the Train B SI pump will not adversely impact PFSSD.

References: XX-E-013, E-15000, E-13EM01, E-1F9102, E-1F9302, M-12EM01, WCRE-01

5.2.12 Containment Spray Pumps

Spurious start of the containment spray (CS) pumps may complicate PFSSD due to the possible depletion of inventory in the RWST. Therefore, a spurious start of the CS pumps should be avoided or mitigated. A control cable (14ENB01BB) associated with the Train B CS pump PEN01B runs through area C-17 and could cause the spurious start of the pump. The cable damage could prevent stopping the pump from the control room.

If the Train B CS pump spuriously starts, normally closed valve ENHV0012 will remain closed, since a spurious containment spray actuation signal (CSAS) is not credible for a fire in area C-17. In addition, cables associated with valve ENHV0012 do not run in area C-17. Therefore, if the CS pump operates, inventory will not be lost from the RWST. If necessary, the pump can be stopped by opening breaker NB0203, but this action is not required for PFSSD.

Based on the above discussion, spurious operation of the Train B CS pump will not adversely impact PFSSD.

References: XX-E-013, E-15000, E-13EN01, E-13EN03, E-1F9102, E-1F9302, M-12EN01

5.2.13 Control Room Air Conditioning

The power cable that supplies 480 VAC power to panel GK199C runs in this area. Panel GK199C is the power and control panel for Train B control room A/C unit SGK04B. Damage to this cable will prevent operation of SGK04B.

Cables associated with control room A/C unit SGK04B supply and return dampers GKHZ0040A and GKHZ0040B are run in this area. Damage to these cables could prevent operation of the dampers.

The Train A control room A/C unit SGK04A is unaffected by a fire in this area. Therefore, control room air conditioning is available if a fire occurs in area C-17.

References: XX-E-013, E-15000, E-13GK02A, E-13GK02C, E-13GK02D, E-1F9442, M-12GK01

5.2.14 Class 1E Electrical Equipment Air Conditioning

A number of cables associated with Train B class 1E electrical equipment room A/C unit SGK05B are run in area C-17. Damage to these cables could prevent operation of the unit. Therefore, SGK05B is unavailable if a fire occurs in area C-17.

Power and control cables associated with Train A class 1E electrical equipment room A/C unit SGK05A are unaffected by a fire in this area. However, cables associated with the fire detection alarm panel that initiates shutdown of SGK05A are run in fire area C-17. Cables 16KCQ21FA and 16KCQ21JA run from the main fire alarm panel (KC275) to Halon releasing panel KC230, located on the 2016 elevation of the control building in fire area C-35. Panel KC275 monitors smoke detectors in Halon protected switchboard rooms that are conditioned by SGK05A. Upon receipt of the proper detection sequence at KC275, a normally open auxiliary relay contact in KC275 closes and sends a short circuit signal over cables 16KCQ21FA or 16KCQ21JA to KC230. The short circuit signal received at KC230 initiates actuation of Halon in the affected room and shuts down SGK05A. If the cables are damaged in a fire and short circuit, Halon will be released into the Train A class 1E electrical equipment rooms and class 1E A/C unit SGK05A will shut down.

If SGK05A spuriously shuts down or cannot be started, the spurious fire isolation signal can be bypassed by placing hand switch GKHS0101 in bypass position and the unit can be started using GKHIS0100. Hand switches GKHIS0100 and GKHS0101 are located on panel RP068 in the main control room.

References: XX-E-013, E-15000, E-13GK13, E-13GK13A, E-13GK31, E-13KC21, E-13SA20, E-1F9444, M-12GK03, M-655-00009, M-658-00042, M-658-00043, M-658-00044, DCP 12169

5.2.15 Standby Diesel Generation

Several cables associated with the Train B diesel engine as well as supporting functions are run in area C-17. Damage to these cables could prevent operation of the Train B diesel. Calculation XX-E-013 documents a loss of off-site power evaluation that identifies the fire areas in and around the plant in which a fire could cause a loss of off-site and on-site power. Per XX-E-013 and Section 5.2.16 of this evaluation, a fire in area C-17 could cause a loss of both trains of off-site power and Train B on-site power. The Train A on-site power source remains available.

Damage to cables associated with Train B diesel engine will not adversely affect PFSSD due to the availability of the Train A emergency diesel.

References: XX-E-013, E-15000, E-12KJ01, E-13GM01A, E-13GM04A, E-13JE01, E-13JE04, E-13KJ03A, E-13NE02, E-13NE11, E-13NE13, E-1F9444, E-1F9411B, E-1F9412B, E-1F9423, E-1F9426, M-12GM01, M-12JE01, M-12KJ04, M-12KJ05, M-12KJ06

5.2.16 Class 1E 4.16 kV Offsite Power

Bus NB02 supplies power to Train B Engineered Safety Features (ESF) components. Cables associated with offsite power feeder breakers NB0209 and NB0212 are run in this area. In addition, cables associated with NB02 breaker control power are run in this area. Damage to these cables due to a fire could cause a loss of offsite power to NB02 and could prevent operation of the PFSSD equipment supplied by NB02. As stated in Section 5.2.15, the Train B emergency diesel generator may not be available if a fire occurs in this area.

Cables associated with transformers XNB01 and XNB02 lockout and phase differential relays are run in fire area C-17. Damage to these cables could cause a loss of offsite power on both trains.

Control cables associated with bus NB02 Synchro-scope and associated switches are run in area C-17. Damage to these cables could prevent some of the monitoring functions for NB02, but would not cause a loss of the NB02 bus.

As stated in Section 5.2.15, Train A emergency diesel generator is available and can be lined up to NB01 to provide power to Train A PFSSD loads. Therefore, a loss of offsite power on both trains due to a fire in area C-17 will not impact the ability to achieve and maintain safe shutdown. For a more detailed evaluation of offsite power availability, refer to Calculation XX-E-013.

References: XX-E-013, E-15000, E-1F9425, E-1F9426, E-13NB03, E-13NB04, E-13NB05, E-13NB06, E-13NB10, E-13NB11, E-13NB14, E-13NB15, E-1F9102, E-1F9423, E-1F9425, E-1F9426

5.2.17 Load Shedder / Emergency Load Sequencer

The load shedder and emergency load sequencers are included in the PFSSD design to evaluate the impact of spurious operation or mal-operation. The load shedder/emergency load sequencer operates upon presence of the following conditions:

1. An undervoltage (UV) on a safeguards bus,
2. A safety injection signal (SIS) or a containment spray actuation signal (CSAS), or
3. An undervoltage on a safeguards bus with a SIS or CSAS.

Eight inputs (four undervoltage (UV) inputs and four degraded voltage inputs) on each safeguards bus (NB01 and NB02) monitor voltage conditions on that bus. An undervoltage condition on two of four UV relays on each bus will actuate the load shedder/sequencer and send a signal to start the associated diesel generator. In addition, degraded voltage sensed by two of four degraded voltage potential transformers (PTs) will, after a time delay, provide a signal to open the offsite feeder breakers on the associated bus.

Cables 14NFK01CA and 14NFK01DA for one of the four UV relays on each bus are run in fire area C-17. Also, cables 14NFY01EA and 14NFY01FA associated with one of the four degraded voltage PTs on each bus are run in fire area C-17. Cables associated with the remaining three UV relays and PTs do not run in fire area C-17. Therefore, automatic functioning of the bus NB01 and NB02 emergency load shedder / sequencer is unaffected by a fire in area C-17 and a spurious start of the associated diesel generator due to a false undervoltage condition on two of the four circuits is not credible.

Cable 14NFK01AA is a DC power cable that runs from NK5412 to NF039C. Damage to this cable could prevent an auto start of the Train B emergency diesel generator upon degraded voltage on 2/4 Train B undervoltage relays or 2/4 input of Train B degraded voltage PTs.

Separation group 4 power cables 14NFY01GA and 14NFY01HA associated with NF039A, NF039B and NF039C are run in this area. Separation groups 1, 2 and 3 power cables associated with these panels are unaffected. Therefore, power to the load shedder/sequencer panels is available.

Based on the above discussion, the Train B emergency diesel generator may not be available if a fire occurs in this area but the Train A load shedder/sequencer is unaffected.

References: XX-E-013, E-15000, E-11NB01, E-11NB02, E-12NF01, E-13NF01, E-10NF, E-1F9411A, E-1F9411B, E-1F9412A, E-1F9412B, E-1F9402A, E-1F9402B, E-1F9403, E-1F9425, E-1F9426

5.2.18 Train B 480 Volt Class 1E Load Centers

Cables associated with Train B 480 VAC Class 1E load centers NG02, NG04 and motor control center (MCC) NG06E are run in area C-17. In addition, as stated in other sections, loss of power to these load centers and MCCs could occur due to loss of Train B off-site and on-site power. Therefore, Train B load centers and MCCs and associated equipment may not be available if a fire occurs in this area.

Cable 14PKK11AA is associated with controlling 480 VAC breaker NG0409. NG0409 supplies 480 VAC power to Train B 125 VDC battery charger PK22, which energizes the PK02 bus. Damage to this cable could disable power to the battery charger but will not de-energize PK02 due to the installed batteries. Battery set PK12 will maintain 125 VDC power to PK02.

Redundant Train A components, supplied by NG01, NG03 and MCC NG05E are unaffected by a fire in area C-17. Therefore, loss of power to Train B 480 VAC Class 1E load centers NG02, NG04 and MCC NG06E will not impact the ability to achieve and maintain safe shutdown.

References: XX-E-013, E-15000, E-11NG02, E-13NG01A, E-13NG10A, E-13NG11A, E-13NG11B, E-13PK11, E-1F9422C, E-1F9423, E-1F9424B, E-1F9424D, E-K3NG10A

5.2.19 Class 1E 120 VAC Electrical Distribution System

The Class 1E 120 VAC electrical distribution system provides power to vital instrumentation and control loads for shutdown and normal operation. Under normal conditions, the system is supplied by inverters connected to the 125 VDC NK battery system. Swing inverters allow the primary inverters to be taken out of service for maintenance or repair without disrupting power to the associated vital AC bus. In the event of a loss of power to the inverters, a backup source of power is automatically lined up. The backup power source originates from the 480 VAC electrical distribution system (NG).

Cable 14NNG01AA supplies 480 VAC power from NG0~~0~~2AFF3 to inverter NN14. Cable 14NNG01BA supplies 480 VAC power from NG02ABR1 to inverter NN12. Damage to these cables will disrupt the 480 VAC power source to inverters NN12 and NN14. The 480 VAC power supply to swing inverter NN16 is unaffected.

Cables 14NNK01MA and 14NNK01MB supply 125 VDC power from NK0403 to manual transfer switch NK80. Damage to these cables will disrupt the 125 VDC power supply from NK0403 to swing inverter NN16. The 125 VDC power supply from NK0203 to swing inverter NN16 is unaffected.

Cables 14NNY01HA and 14NNY01HB supply 120 VAC power from swing inverter NN16 to bus NN04 through a manual transfer switch in inverter NN14. Damage to these cables will disrupt the 120 VAC power supply from swing inverter NN16 to NN02. The 120 VAC power supply from inverter NN14 to bus NN04 is unaffected.

As stated in Section 5.2.18, a fire in area C-17 could cause a loss of Train A 480 VAC power. This would cause a loss of 480 VAC power to the Train B NK battery chargers (NK22, NK24 and NK26) which will cause a loss of normal power to the NK02 and NK04 busses. Batteries NK12 and NK14 are unaffected and can supply 125 VDC to busses NK02 and NK04 to provide power to inverters NN12 and NN14 for a limited time.

Train A vital 120 VAC distribution panels NN01 and NN03 are unaffected by a fire in area C-17. Therefore, in the event of a loss of Train B Class 1E 120 VAC electrical distribution system, the Train A Class 1E electrical distribution switchboards are available to supply redundant PFSSD loads.

Based on the above discussion, damage to cables and components associated with Train B vital 120 VAC distribution panels NN02 and NN04 will not adversely impact the ability to achieve and maintain safe shutdown in the event of a fire in area C-17.

References: XX-E-013, E-15000, E-13NN01, E-1F9421

5.2.20 Non-Class 1E 120 VAC Electrical Distribution System

The PFSSD function of the non-Class 1E 120 VAC electrical distribution system is to supply 120 VAC power to Main Control Boards (MCBs) RL017/RL018 and RL021/RL022. The power is split at the MCB to supply specific PFSSD components.

The PFSSD components that depend on 120 VAC power from RL017/RL018 are Residual Heat Removal (RHR) discharge valves EJHCV0606 (Train A) and EJHCV0607 (Train B). Non-class 1E switchboard panel PN07 supplies power from switch PN0736 to valve positioner EJHY0606. Valve positioner EJHY0606 controls the position of EJHCV0606 using hand controller EJHIC0606. Non-class 1E switchboard panel PN08 supplies power from switch PN0833 to valve positioner EJHY0607. Valve positioner EJHY0607 controls the position of EJHCV0607 using hand controller EJHIC0607.

The PFSSD components that depend on 120 VAC power from RL021/RL022 are temperature recorders BBTR0423, BBTR0433 and BBTR0443. Non-class 1E switchboard panel PN07 supplies power from switch PN0738 to temperature recorder BBTR0423. Non-class 1E switchboard panel PN08 supplies power from switch PN0835 to temperature recorders BBTR0433 and BBTR0443.

Cables 14PNG01AD and 14PNG01AE supply 480 VAC power from NG002BBF1 to 480/120V transformer XPN08A. Damage to either of these cables due to a fire in area C-17 will result in a loss of power to the transformer and loss of 120 VAC feed to PN08 from this power source.

Cable 16PNY01AR provides an alternate power feed to switchboard PN08 from PG20GER5. Cables 16PNY01AW, 16PNY01AX, 16PNY01AY and 16PNY01AZ are also associated with the alternate power supply to PN08. Damage to these cables will result in a loss of the alternate power feed to PN08.

A loss of power to PN08 will result in a loss of power to EJHY0607, which will fail valve EJHCV0607 open and will prevent control of the valve from the control room. Loss of power to PN08 will also result in a loss of loops 3 and 4 temperature recorders BBTR0433 and BBTR0443, respectively.

Non-Class 1E 120 VAC power to panel PN07 is unaffected by a fire in this area. Train A RHR valve EJHCV0606 is unaffected by a fire in area C-17, so Train A RHR can be used for shutdown cooling. Also, operators can use available temperature indication on loops 1 and 2 if a loss of loops 3 and 4 temperature indication occurs.

References: XX-E-013, E-15000, E-13PN01, E-13PN01A, E-13RL01, E-13RL04, E-13RL06, E-1F9201, E-1F9205, E-1F9421, E-1F9424E

5.2.21 Class 1E 125 VDC Distribution System

Power cables associated with the Class 1E 125 VDC electrical distribution system are run in area C-17. These cables supply 125 VDC power to various PFSSD loads. The cables and supplied PFSSD equipment are summarized in the following table.

CABLE	NK BREAKER	PFSSD Components
14RLK01AA	NK04407	BGHV8153B, BGHV8154B
14RLK01BA	NK04409	FCFY0310
14RLK01CA	NK04412	EMHV8843, EMHV8871, EPHIS8808B, EPHIS8808D
14RLK01DA	NK04413	EGTV0030, GMHZ0019
14RLK01EA	NK04414	BBHV8001B, BBHV8002B
14RLK01FA	NK04411	BMHV0001, BMHV0002, BMHV0003, BMHV0004

Damage to these cables could cause a loss of power to the indicated components. This is acceptable for PFSSD since the components fail in the desired PFSSD position upon loss of power, or the redundant Train A component is available to perform the PFSSD function.

Damage to cable 14RLK01CA could cause a loss of position indication for accumulator injection valves EPHV8808B and EPHV8808D. Loss of position indication for these valves will not impact PFSSD since the valves will continue to perform their intended function without indication.

References: XX-E-013, E-15000, E-13BB30, E-13BG48, E-13BM06A, E-13EG16, E-13EM04, E-13EM04A, E-13EP02A, E-13FC21, E-13GM04A, E-13RL01, E-13RL02, E-13RL03, E-13RL04, E-13RL05, E-13RL06, E-13RL07, E-1F9101, E-1F9201, E-1F9301, E-1F9302, E-1F9401A, E-1F9422B, E-1F9444, M-12BB04, M-12BG01, M-12BM01, M-12EG02, M-12EM01, M-12EM02, M-12EP01, M-12FC02, M-12GM01

5.2.22 Main Steam Isolation Bypass Valves

Cable 14RPK09AA supplies 125 VDC power from NK4417 to auxiliary relay panel RP210. The PFSSD loads supplied by this cable are as follows:

- Relay 94XAB06
- Solenoid valve ABHY0012B
- Solenoid valve ABHY0015B
- Solenoid valve ABHY0018B
- Solenoid valve ABHY0021B

The solenoid valves listed above are associated with MSIV bypass valves ABHV0012, ABHV0015, ABHV0018 and ABHV0021. Each MSIV bypass valve is normally closed and is required to remain closed for PFSSD. Two (2) redundant solenoid valves (one on each train) are installed on the air supply line and control air to the pneumatic actuator. Both solenoids on the associated valve are required to be energized to open the valve.

Damage to cable 14RPK09AA will cause a loss of power to the relay and solenoids and fail the valves closed, which is the desired PFSSD position. Therefore, damage to this cable will not adversely impact PFSSD.

References: E-15000, XX-E-013, E-13AB23B, E-13BM06A, E-13RP09, E-1F9101, E-1F9422B, E-093-00050, E-093-00051

5.2.23 Lockout Relay Panel RP335

Cable 14RPK09NA provides Class 1E 125 VDC power from NK4419 to panel RP335. Damage to this cable could disrupt power to the loads served by panel RP335, which could prevent operation of the associated equipment. The following table identifies the PFSSD equipment powered by this cable.

Panel RP335 PFSSD Relays	
Relay #	**Description**
86XRP5	Train B MDAFP from CST and ESW Supply Valves (ALHV0034 and ALHV0030)
86XRP6	ESW to TDAFP Supply Valve (ALHV0033)
86XRP7	Train B MDAFP (PAL01B)

As discussed in Section 5.2.4, Train A auxiliary feedwater is available and is unaffected by a fire in area C-17. Therefore, damage to cable 14RPK09NA will have no adverse impact on PFSSD.

Other cables associated with control room lockout relays are run in area C-17. Damage to these cables could prevent operation of associated equipment. Train A equipment, located in a separate fire area, is available and is unaffected by the fire.

References: XX-E-013, E-15000, E-13AL01B, E-13AL02B, E-13AL04B, E-13RP09, E-13RP15, E-093-00095, E-093-00096, E-1F9202, E-1F9204

5.2.24 Miscellaneous Control Room Panels

Cables 14RPY09BA and 14RPY09CA provide 120 VAC power to control room panels RP053BA, RP053BB and RP053BC. Cable 14RPY09GA provides 120 VAC power to panel RP147B. Cable 14RPY10BA provides 120 VAC power to panel RP068. The following table identifies the PFSSD components that could be affected by a loss of Train B 120 VAC power to these panels.

Cable	Power Supply	Affected Components
14RPY09BA	NN0416	ABHS0004, ABPIC0004A, ALFT0007, ALFY0007B, ALHK0005A, ALHK0007A, ALHK0010A, ALHK0012A, ALHS0007, ALHS0012, ALHV0012, ALPI0024A, EFFI0054, EFFT0054, EFPI0002, EFPT0002, JELSL0021C, JELT0021, RP118B
14RPY09CA	NN0418	ALHY0012, ALPT0039, ALPY0039A, EGFT0129, EGPSL0078, EGPT0078, GDTE0011, GDTSL0011, GDTZ0011A
14RPY09GA	NN0404	ABHS0004, ABPIC0004B, ABPT0004, ABPY0004, ALFT0001, ALFY0005B, ALHK0005A, ALHK0005B, ALHK0010A, ALHK0010B, ALHS0005, ALHS0010, ALHV0010, ALHY0010, ALPI0024B, ALPT0024, RP118B
14RPY10BA	NG02ACR136	GDHIS0011A (CGD01B)

Loss of power to these components will not adversely impact PFSSD. Redundant Train A components are unaffected by the fire or the component fails in the desired PFSSD position.

References: XX-E-013, E-15000, E-13AL03A, E-13AL03B, E-13AL05A, E-13AL05B, E-13AL07A, E-13AL07B, E-13AL08, E-13AL09, E-13AB20B, E-13EF11, E-13EG01C, E-13EG01D, E-13EG13, E-13EG19, E-13GK07, E-13JE01, E-13JE04, E-13RP09, E-13RP10, E-1F9101, E-1F9202, E-1F9203, E-1F9204, E-1F9401B, E-1F9402B, E-1F9411B, E-1F9421, E-1F9424B, E-1F9443, E-K3GD01A, E-K3GD04, E-K3GD04A, E-K3EF08, E-K3GD01A, J-110-00592, J-110-00593, J-110-00596, M-12AB01, M-12AL01, M-12EF01, M-12EG01, M-12JE01, M-K2EF01, M-K2GD01

5.2.25 ESFAS Actuation Cabinet SA036B

Cables 14SAK21BA and 14SAY21BA provide 125 VDC and 120 VAC power, respectively, to panel SA036B. Panel SA036B houses the controls for Channel 4 Engineered Safety Features Actuation System (ESFAS). Damage to these cables could prevent operation of the Channel 4 ESFAS. However, Channels 1 and 2 ESFAS are unaffected by the fire and will remain operable to perform the required PFSSD functions.

References: XX-E-013, E-15000, E-13SA21, E-1F9202, E-1F9402A, E-1F9402B

5.2.26 Reactor Protection System

The Reactor Protection System (RPS) monitors specified input parameters and initiates reactor protection features whenever those parameters are outside specified limits. Field installed transmitters continuously monitor various parameters and report the results to one of four process cabinets, one per channel. Signals are then sent from the process cabinets to both solid state protection cabinets, one on each train. The cabinets and associated channel are listed below:

<u>Process Cabinets</u>

- Cabinet SB038 - Channel 1
- Cabinet SB042 - Channel 2
- Cabinet SB037 - Channel 3
- Cabinet SB041 - Channel 4

<u>Solid State Protection Cabinets</u>

- Cabinet SB029A - Train A Input Cabinet
- Cabinet SB029B - Train A Logic Cabinet
- Cabinet SB029C - Train A Output Cabinet 1
- Cabinet SB029D - Train A Output Cabinet 2
- Cabinet SB032A - Train B Input Cabinet
- Cabinet SB032B - Train B Logic Cabinet
- Cabinet SB032C - Train B Output Cabinet 1
- Cabinet SB032D - Train B Output Cabinet 2

The RPS is actuated upon 2/3 or 2/4 coincident logic, depending on the input parameter. This ensures that a loss of a single channel will not prevent the system from performing its function.

Power cables for certain RPS cabinets are run in area C-17. These cables originate from the separation group 4 (Train B) source. Power cables originating from the separation group 1 source (Train A) are unaffected by a fire in area C-17. The following table summarizes the RPS power cables that could be affected by a fire in this area, as well as the power supply and component served by the cable, and identifies the available power source or component.

RPS POWER CABLES RUN IN AREA C-17			
CABLE	**POWER SUPPLY**	**RPS COMPONENT SERVED**	**AVAILABLE POWER SOURCE(s)**
14SBS01DC	NN0409	SB029A - Train A Input Channel 4	NN0110 - Channel 1 NN0210 - Channel 2 NN0309 - Channel 3
14SBS02DC	NN0410	SB032A - Train B Input Channel 4	NN0109 - Channel 1 NN0209 - Channel 2 NN0310 - Channel 3
14SBS05BE	NN0412	SB032D - Train B Output Cabinet 2	NN0112 powers redundant Train A output cabinet SB029D
14SBS05BF	NK4416	SB032D - Train B Output Cabinet 2	Cable damage will cause main steam dumps to close, which is the desired PFSSD position. Otherwise, the MSIVs are available to isolate steam flow. NK4118 powers redundant Train A output cabinet SB029D
14SBS10BB	NK5410	SB102B - Reactor Trip Swgr Train B	NK4116 powers redundant Train A cabinet SB102A
14SBY09FA	NN0414	SB041 - Process Protection Rack Channel 4	NN0111 powers SB038 (CH 1) NN0212 powers SB042 (CH 2) NN0311 powers SB037 (CH 3)

Based on the above table, a fire in this area could result in a loss of power to input channel 4 in SB029A and SB032A, but will not result in a loss of input channels 1, 2 and 3. In addition, Train B output cabinet 2 and Train B reactor trip switchgear cabinet could lose power. Train A output cabinets and Train A reactor trip switchgear cabinet are unaffected. Power to channel 4 process protection rack SB041 could be affected but channels 1, 2 and 3 process protection racks remain available.

5.2.27 Process Monitoring Instrumentation

Circuits for a number of process instruments are run in area C-17. These circuits run from various process monitoring panels to the auxiliary shutdown panel (ASP) and provide indication at the ASP for control outside the control room. Each cable, along with the effects of fire damage to the cable, is discussed below.

Cable 14SBS16AA provides RCS cold leg loop 2 wide range temperature indication at the ASP on indicator BBTI0423X. Damage to this cable could cause a false temperature indication at the ASP but will not cause a loss of indication in the control room. Therefore, damage to this cable will not adversely impact PFSSD.

Cables 14SBS16BA and 14SBS16YA are associated with steam generator D wide range level indicator AELI0504A located at the ASP. Damage to these cables could cause a false level

indication at the ASP but will not cause a loss of indication in the control room. Therefore, damage to these cables will not adversely impact PFSSD.

Cable 14SBS16EA provides RCS hot leg loop 4 wide range temperature indication at the ASP on indicator BBTI0443A. Damage to this cable could cause a false temperature indication at the ASP but will not cause a loss of indication in the control room. Therefore, damage to this cable will not adversely impact PFSSD.

Cable 14SBS16NA provides RCS wide range pressure indication at the ASP on pressure indicator BBPI0406X. Damage to this cable could cause a false pressure indication at the ASP but will not cause a loss of indication in the control room. Therefore, damage to this cable will not adversely impact PFSSD.

Cable 14SBS16XA provides steam generator B wide range level indication at the ASP on indicator AELI0502A. Damage to this cable could cause a false level indication at the ASP but will not cause a loss of indication in the control room. Therefore, damage to this cable will not adversely impact PFSSD.

Cable 14SBS16ZA provides pressurizer narrow range level indication at the ASP on indicator BBLI0460B. Damage to this cable could cause a false level indication at the ASP but will not cause a loss of indication in the control room. Therefore, damage to this cable will not adversely impact PFSSD.

Based on the above discussion, damage to process instrumentation cables due to a fire in area C-17 will not adversely impact PFSSD.

References: XX-E-013, E-15000, E-13AE08, E-13BB15, E-13BB16, E-13SB16, E-1F9201, E-1F9203, E-1F9301, M-12AE02, M-12BB01, M-12BB02, M-12BB04

5.2.28 Source Range Monitoring

PFSSD requires source range (SR) flux monitoring to be available. Source range monitoring is provided by source range monitors SENE0031, SENE0032, SENY0060A & B, and SENY0061A & B.

Cable 14SES07BA is a power cable associated with SR monitor signal processor SENY0061B. Cable 14SES07CA is a power cable associated with SR monitor amplifier SENY0061A. Damage to these cables could prevent operation of the associated source range monitor. Source Range monitoring remains available for a fire in area C-17 using SENE0031, SENE0032 and SENY0060A/B.

For a more detailed evaluation on Source Range monitoring, see Calculation XX-E-013.

References: E-15000, XX-E-013, E-13SE07, E-1F9101

5.2.29 Process Monitoring Fire Isolation Cabinets SB148A and SB148B

The PFSSD function of cabinets SB148A and SB148B is to provide reliable process monitoring instrumentation at the auxiliary shutdown panel (ASP) in the event of a fire in the control room. This allows operators the ability to monitor critical process variables during shutdown from outside the control room. Process variables that can be monitored at the ASP as well as in the main control room (MCR) are as follows:

- AELT0502 – Steam Generator B Wide Range Water Level (SB148A)
- AELT0504 – Steam Generator D Wide Range Water Level (SB148B)
- BBLT0460 – Pressurizer Level Transmitter Narrow Range (SB148A)
- BBTE0423B – RCS Loop 2 Cold Leg Temperature Element (SB148A)
- BBTE0443A – RCS Loop 4 Hot Leg Temperature Element (SB148A)

- BBPT0406 – RCS Wide Range Hot Leg Pressure Transmitter (SB148B)

The instrument cable from each transmitter or temperature element runs to the SB148 cabinet indicated above. The signal is split and runs to the ASP and MCR via independent instrument cables. Cable 14SBY09HA is a power cable that provides 120 VAC to cabinet SB148B. A loss of power to SB148B could result in a loss of capability to monitor AELT0504 and BBPT0406 from the ASP and the MCR.

A loss of capability to monitor AELT0504 and BBPT0406 from the MCR will not adversely impact PFSSD. Redundant capability exists to monitor these variables as described below:

- AELT0547, AELT0548, AELT0549 and AELT0554 are available to provide level indication (narrow range) for steam generator D to associated indicators in the control room.
- BBPT0405 is available to provide RCS pressure to pressure indicator BBPI0405.

Based on the above discussion, a fire in area C-17 that affects the process monitoring instrumentation associated with cabinet SB148B will not impact the ability to achieve and maintain PFSSD due to the availability of redundant process monitoring instrumentation in the control room.

References: XX-E-013, E-15000, E-13AE08, E-13BB15, E-13BB16, E-13SB09, E-13SB16, E-13NN01, E-1F9201, E-1F9203, E-1F9205, E-1F9301, E-1F9421, M-12AE02, M-12BB01, M-12BB04

5.2.30 Reactor Coolant Pumps

The reactor coolant pumps are not credited in the PFSSD analysis. However, the capability to stop the pumps from the control room in the event of a loss of all seal cooling is credited. Westinghouse Technical Bulletin TB-04-22, Rev. 1 recommends that if all seal cooling is lost (RCP seal injection and thermal barrier heat exchanger flow), operators need to stop the pumps before a seal LOCA occurs.

One control cable associated with reactor coolant pumps C and D is run in fire area C-17. Damage to these cables in the event of a fire could prevent operators from stopping the C and D RCPs from the control room. However, a fire in C-17 will not cause a loss of all seal cooling since RCP seal injection and thermal barrier cooling remain available.

Based on the above discussion, the inability to trip the C and D RCPs from the control room will have no adverse impact on PFSSD. The pumps can continue to operate, providing forced flow circulation. If the pumps spuriously stop, natural circulation cooldown can be used.

References: E-15000, XX-E-013, E-13BB01, Westinghouse TB-04-22 Rev. 1

5.2.31 Steam Generator Feedwater Pumps

Main feedwater pump steam supply valves FCFV0005 and FCFV0105 are credited in the PFSSD analysis to trip the main feedwater pumps if the main steam isolation valves (MSIVs) are affected by a fire. Closing the MSIVs stops steam flow to the feedwater pumps' turbines and stops the feedwater pumps. The steam generator feedwater pumps are tripped in the event of a fire to prevent overfilling the steam generators.

Non-Class 1E 120 VAC Inverter PN10 and distribution panel PN10A provide power to FCFV0105 trip relays in panel FC170C. Cable 16RPY10AA supplies power from PN0806 to inverter PN10. Cable 16FCY35AA provides the primary source of 120 VAC power from distribution panel PN010A to panel FC170A. The alternate source of power to panel FC170A is not credited for PFSSD and is assumed lost.

A fire in area C-17 could damage cables 16FCY35AA or 16RPY10AA. If this occurs, operators in the control room would not be able to close valve FCFV0105 to stop steam flow to steam generator feedwater pump PAE01B.

A fire in area C-17 will not affect the ability to close the MSIVs from the control room. All-close hand switch ABHS0080 is unaffected and can be used to close the MSIVs from the control room.

Based on the above discussion, valve FCFV0105 may not close if a fire occurs in this area. However, the MSIVs can be closed using hand switch ABHS0080 in the main control room. Therefore, the configuration is acceptable.

References: E-15000, XX-E-013, E-13FC35, E-13RP10, E-1F9103, E-1F9421

5.2.32 Load Center Feeder Breaker PA0207

Load center feeder breaker PA0207 is credited for PFSSD because it supplies power to credited non-safety related loads. Cable 16PGA11AC, associated with PA0207, runs in this area. A fire induced short circuit in this cable will trip the associated breaker.

Breaker PA0207 supplies power to the following PFSSD components:

- PG20GBR217 – MCB Misc. Power Circuits RL023
- PG20GER5 – Instr. Bus Transformer Alt. Feed XPN08D

PFSSD components powered from PG20GBR217 are associated with MSIV downstream components. The MSIVs are unaffected by a fire in this area and can be closed from the control room. Therefore, the MSIV downstream components are not required if a fire occurs in this area.

PG20GER5 is credited as one source of power to PN08. The redundant source of power from NG02BBF1 may also be affected by a fire in this area as discussed in Section 5.2.18. Redundant components powered from inverter PN07 are unaffected by a fire in this area.

Based on the above discussion, loss of breaker PA0207 will not adversely affect PFSSD if a fire occurs in this area.

5.2 PFSSD CABLE EVALUATION 11

1.0 GENERAL AREA DESCRIPTION

Fire area C-18 is located on the 2016 elevation of the Control Building and includes the room listed in Table C-18-1.

Table C-18-1
Rooms Located in Fire Area C-18

ROOM #	DESCRIPTION
3419	North Electrical Chase - 2016 Elevation

Fire area C-18 is protected with an automatic wet-pipe sprinkler system and automatic fire detection. The area is separated from adjacent areas by minimum 3-hour fire resistant construction.

2.0 PRIMARY EQUIPMENT USED FOR PFSSD

Table C-18-2 lists each system credited for post-fire safe shutdown and provides a discussion regarding the availability of the system to perform its Post Fire Safe Shutdown (PFSSD) function if a severe fire occurs in this area. For a summary of the area analysis results, see Section 8.0 of the Fire Area Analysis Narrative section.

Table C-18-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-18

System	System Name	PFSSD Function*	Comments
AB	Main Steam	R, M, H, P, S	Steam generator A ARV control may be lost. Cooldown is assured using Aux Feedwater Pump B supplying steam generator D and the Turbine Driven Auxiliary Feedwater Pump supplying steam generators B and C. Steamline pressure indicators ABPI0514A, ABPI0524A, ABPI0534A and ABPI0544A may not be available. Monitor steamline pressure on loops 2, 3 and 4 using pressure indicators ABPI0525A, ABPI0526A, ABPI0535A, ABPI0536A, ABPI0545A and ABPI0546A. ABHS0080 may not be available to close the MSIVs and MSIV bypass valves. ABHS0079 is available to close the MSIVs and MSIV bypass valves.
AC	Main Turbine	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-18.
AE	Main Feedwater	H, P	All PFSSD functions associated with the main feedwater system are satisfied. Steam generator (SG) level indication is available on SG A using narrow range level transmitters AELT0517, AELT0518, and AELT0519. Steam generator level indication is available on SG D using wide range level transmitter AELT0504 and narrow range level transmitters AELT0547, AELT0548, and AELT0549. AEHS0080 may not be available to close the MFIVs. Isolate all four MFIVs using hand switch AEHS0081.
AL	Aux. Feedwater System	H, P	All PFSSD functions associated with the auxiliary feedwater system are satisfied. Train B MDAFP is available to supply SGs A and D, however SG A ARV ABPV0001 could spuriously open and may need to be failed closed. The TDAFP is available to supply SGs B and C. Pressure transmitter/indicator ALPT0037/ALPI0037 may be affected. Auxiliary feedwater suction pressure indication is available using pressure transmitters/indicators ALPT0038/ALPI0038A and ALPT0039/ALPI0039A.
AP	Condensate Storage System	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-18.

Table C-18-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-18

System	System Name	PFSSD Function*	Comments
BB	Reactor Coolant System	R, M, H, P, S	Pressurizer PORV BBPCV0455A may open and block valve BBHV8000A may not close. If this occurs, Operators can close the PORV by placing BBHIS0455A in the CLOSE position. RCS pressure transmitter BBPT0405 could be affected. RCS pressure indication is available using BBPI0406. Pressurizer level transmitter BBLT0459 could be affected. Pressurizer level indication is available using BBLI0460A. Pressurizer pressure transmitter BBPT0455 could be affected. Pressurizer pressure transmitters BBPT0456, BBPT0457 and BBPT0458 are unaffected. Therefore, pressurizer pressure indication is available using BBPI0456, BBPI0457 or BBPI0458. RCS Loop 1 Wide Range Cold Leg Temperature Element BBTE413B and RCS Loop 4 Wide Range Hot Leg Temperature Element BBTE443A are available. Loss of inventory through the head vent valves is prevented by maintaining valves BBHV8002A and either BBHV8001B or BBHV8002B closed. RCP thermal barrier cooling could be affected due to spurious closure of BBHV0013, BBHV0014, BBHV0015 and BBHV0016. Reactor coolant pumps A and B may not stop using the control room hand switch. RCP seal injection remains available. Therefore, the inability to stop the RCPs will have no adverse impact on PFSSD. Pressurizer spray valves BBPCV0455B and BBPCV0455C could spuriously open. If this occurs, pressurizer spray can be stopped by closing KAFV0029 using KAHIS0029 in the main control room.
BG	Chemical and Volume Control System	R, M, S	All PFSSD functions associated with the chemical and volume control system are satisfied. Train B Centrifugal Charging Pump (CCP) is available to provide charging flow from the RWST to the RCP seals through valve BGHV8357B. VCT level indicator BGLI0112 could be affected. Level indicator BGLI0185 should be used to determine VCT level. Normal charging is isolated using BGHIS8105 to close valve BGHV8105. Cables for valve BGHV8106 could be damaged. Valve BGHV8153A and either BGHV8153B or BGHV8154B are maintained closed to isolate excess letdown. Letdown isolation valves BGLCV0459 and BGLCV0460 and letdown orifice isolation valves BGHV8149A, BGHV8149B, and BGHV8149C may need to be failed closed by closing valve KAFV0029 using KAHIS0029 in the main control room. RCP seal flow indication is available using BGFI0215B. RCP seal flow indicator BGFI0215A may be affected.
BM	Steam Generator Blowdown System	R, M, H	All PFSSD functions associated with the steam generator blowdown system are satisfied. Steam generator blowdown is isolated by closing valves BMHV0001, BMHV0002, BMHV0003 and BMHV0004 using BMHIS0001A, BMHIS0002A, BMHIS0003A and BMHIS0004A, located on the RL024 panel in the main control room.

Table C-18-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-18

System	System Name	PFSSD Function*	Comments
BN	Borated Refueling Water Storage System	R, M, H	The RWST is available to provide a suction source to Centrifugal Charging Pump B via valve BNLCV0112E.
EF	Essential Service Water System	H, S	All PFSSD functions associated with the essential service water system are satisfied. Train A ESW is unavailable due to damage to a number of associated components. Train B ESW is unaffected.
EG	Component Cooling Water System	S	All PFSSD functions associated with the component cooling water system are satisfied. A number of Train A CCW system components could be affected. The Train B CCW system is unaffected. CCW flow to the RCP thermal barriers could be affected as discussed in BB System comments above. CCW to RCP flow indicator EGFI0128 could be affected. CCW to RCP flow indicator EGFI0129 is unaffected. Valve EGHV0101 could be affected, preventing operation of Train A RHR. Valve EGHV0102 is unaffected.
EJ	Residual Heat Removal System	M, H, P	A number of Train A RHR components may be affected. The Train B RHR pump is unaffected but valve EJHV8701B may need to be manually opened or a cold shutdown repair made when aligning Train B RHR for shutdown cooling. The Train A RHR system could be affected. The Train B RHR system is unaffected.
EM	High Pressure Coolant Injection	R, M	All PFSSD functions associated with the high pressure coolant injection system are satisfied. BIT inlet valve EMHV8803A may be affected but valves EMHV8801A, EMHV8801B and EMHV8803B are available to ensure an available BIT flowpath using Train B CCP. The Train A SI Pump may spuriously start but the spurious actuation will not adversely impact PFSSD since the pump will be dead headed against RCS pressure. Therefore, no inventory will be lost from the RWST. In this condition, the pump could experience cavitation damage but this is a commercial concern, not a PFSSD concern. Operators can disconnect power to the pump by opening breaker NB0103, but this action is not required for PFSSD. SI test line valves EMHV8882 and EMHV8964 could be affected. The SI test line can be isolated by closing valve EMHV8871.
EN	Containment Spray	R, M	Containment spray pump PEN01A could spuriously start and valve ENHV0006 could open, causing flow to the containment spray nozzles. Pump PEN01A can be stopped by opening breaker NB0102 in area C-9.
EP	Safety Injection Accumulators	H	A containment entry may be required to close SI Accumulator injection valves EPHV8808A and EPHV8808C if these valves are unresponsive from the control room. The SI accumulators need to be isolated during cold shutdown, prior to the RCS reaching 1000 psig.
FB	Auxiliary Steam	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-18.
FC	Auxiliary Turbines	R, H, P	Valve FCFV0005 may be affected. The MSIVs can be closed using all-close hand switch ABHS0079.

Table C-18-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-18

System	System Name	PFSSD Function*	Comments
GD	ESW Pump House HVAC	S	Train A ESW pump room ventilation system could be affected. Train B ESW pump room ventilation system is unaffected.
GF	AFW Pump Room Coolers	S	Train A AFW pump room cooler SGF02A could be affected. Train B AFW pump room cooler is unaffected.
GK	Control Room and Class 1E Switchgear Room Coolers	S	Train A control room A/C unit SGK04A may be affected. Train B control room A/C unit SGK04B is unaffected. Train A Class 1E electrical equipment room A/C unit SGK05A may be affected. Train B Class 1E electrical equipment room A/C unit SGK05B is unaffected.
GL	Auxiliary Building HVAC	S	Train A RHR pump room cooler SGL10A could be affected. Train B RHR pump room cooler SGL10B is unaffected. Train A CCP room cooler SGL12A could be affected. Train B CCP room cooler SGL12B is unaffected. Train A CCW pump room cooler SGL11A and associated dampers could be affected. Train B CCW pump room cooler SGL11B is unaffected.
GM	Emergency Diesel Generator Room HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-18.
GN	Containment Coolers	S	Containment pressure transmitter GNPT0937 could be affected. Containment pressure transmitters GNPT0934, GNPT0935 and GNPT0936 are unaffected. Train A containment cooler fans SGN01A and SGN01C could be affected. Train B containment cooler fans SGN01B and SGN01D are unaffected.
JE	Diesel Fuel Oil	S	Low standpipe level switch JELSL0001C may be affected due to loss of power to RP053AC. This could prevent operation of the Train A diesel fuel oil transfer pump PJE01A on low standpipe level. The Train B diesel fuel oil transfer pump PJE01B is unaffected by a fire in this area. Train A emergency fuel oil transfer pump could be affected. Train B emergency fuel oil transfer pump is unaffected.
KA	Instrument Air	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-18.
KC	Fire Protection	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-18.
KH	Service Gas	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-18.
KJ	Standby Diesel Engine	S	Train A diesel engine may be affected by a fire in this area. Train B diesel engine is unaffected.
MA	Main Generation	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-18.

Table C-18-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-18

System	System Name	PFSSD Function*	Comments
MR	Startup Transformer	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-18.
NB	4.16 kV System	S	Train A Class 1E 4.16 kV switchgear bus NB01 may be affected. Train B Class 1E 4.16 kV switchgear bus NB02 is unaffected.
NE	Standby Diesel Generator	S	Train A diesel generator may be affected by a fire in this area. Train B diesel generator is unaffected.
NF	Load Shed and Emergency Load Sequencing	S	The PFSSD function associated with the load shed/emergency load sequencing system is satisfied. Cables associated with one of the four undervoltage relays and degraded voltage potential transformers on Trains A and B are run in area C-18. Emergency load shed/sequencer operates when 2/4 UV relays sense undervoltage on the bus. Therefore, Trains A and B Load Shed and Emergency Load Sequencing will be available.
NG	480V Load Centers and MCCs	S	Loss of power to NB01 will result in a loss of power to Train A 480 V load centers and MCCs. Redundant Train B 480 V load centers and MCCs are unaffected.
NK	125VDC	S	Train A class 1E 125 VDC power could be disrupted to control room panels RL001/RL002, RL017/RL018, RL019/RL020 and RL021/RL022. The normal source of power to NK01 and NK03, through the Train A 480 V distribution system, could be disrupted. 125 VDC battery sets NK011 and NK013 are unaffected. Train B class 1E 125 VDC power is unaffected.
NN	120VAC	S	Train A Class 1E 120 VAC electrical distribution system may be affected. Train B Class 1E 120 VAC electrical distribution system is unaffected.
PA	13.8kV	S	Breakers PA0105 and PA0106 could be affected by a fire in this area. Redundant capability is available.
PB	4.16kV	H, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-18.
PG	480V Load Centers and MCCs	S	Loss of all power on bus NB01 will result in Separation Group 5 PG busses losing power. Off-site and on-site power to NB02 and Separation Group 6 PG busses are unaffected. Breaker PG1901 could be affected. Redundant capability is available.
PK	125VDC	S	Battery charger PK21 could be affected. Battery charger PK22 is unaffected.
PL	Local Instrument Panels	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-18.
PN	120VAC	S	Power to non-class 1E 120 VAC switchboard PN07 may be affected. Non-class 1E 120 VAC switchboard PN08 is unaffected.

Table C-18-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-18

System	System Name	PFSSD Function*	Comments
QB	Standby AC Lighting	S	Standby AC lighting in the main control room could be affected due to loss of Train A off-site power and the Train A emergency diesel generator. Self-contained battery powered lighting units are available to provide lighting in the control room.
QD	Emergency Lighting	S	The 125 VDC emergency lights in the control room could be affected. Self-contained battery powered lighting units are available to provide lighting in the control room.
RL	Control Room MCB	S	Train A class 1E 125 VDC power could be disrupted to control room panels RL001/RL002, RL017/RL018, RL019/RL020 and RL021/RL022. Train B class 1E 125 VDC power is unaffected. Non class 1E 120 VAC power from separation group 5 to RL017/RL018 and RL021/RL022 could be affected. Non class 1E 120 VAC power from separation group 6 to RL017/RL018 and RL021/RL022 is unaffected.
RP	Miscellaneous Control Panels	R, M, H, P, S	Train A components and cables associated with this system could be affected. Train B components and cables associated with this system are unaffected. 120 VAC power to panel RP053A could be affected. Power to panels RP053B, RP053D and RP147 is unaffected. Certain PFSSD functions associated with panels RP068, RP139, RP209, RP211 and RP330 could be affected. Redundant capability exists and is unaffected by a fire in this area.
SA	ESFAS	S	Auxiliary feedwater low suction pressure (LSP) signal monitored by panel SA036A could be affected. Auxiliary feedwater LSP signals monitored by panels SA036B and SA036C are unaffected. Status indication of Train A class 1E electrical equipment A/C unit SGK05A at status panel SA066A could be affected. Status indication of Train B class 1E electrical equipment A/C unit SGK05B is unaffected.
SB	Reactor Protection System	R, S	A loss of power to input channel 1 in SB029A and SB032A could occur. Input channels 2, 3 and 4 remain available. Train A output cabinet 2 and Train A reactor trip switchgear cabinet could lose power. Train B output cabinets and Train B reactor trip switchgear cabinet are unaffected.
SC	Reactor Instrumentation	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-18.
SE	Ex-Core Neutron Monitoring	R, P	Source range monitor SENE0031, SR monitor signal processor SENY0060B and SR monitor amplifier SENY0060A could be affected. Source range monitoring remains available using SENE0032 and SENY0061A/B.
SY	Switchyard	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-18.
UU	Supervisory System	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-18.

* R - Reactivity Control; M - Reactor Coolant Makeup; H - Decay Heat Removal; P - Process Monitoring; S - Support Function

3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD

This section describes operator actions that may need to be performed inside or outside the control room to achieve and maintain hot standby if a fire occurs in area C-18. This section also describes cold shutdown repairs that may need to be made to achieve and maintain cold shutdown conditions. Operator actions are proceduralized in OFN KC-016.

3.1 ACTIONS OUTSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

Operator Manual Actions (OMAs) are those actions outside the main control room required to achieve and maintain hot standby. OMAs are identified in E-1F9900 and were determined from thermal hydraulic analysis WCNOC-CP-002. Applicable E-1F9900 OMAs are annotated herein. All other actions outside the control room are desirable for plant control in support of hot standby but not required to achieve and maintain hot standby.

3.1.1 Steam Generator ARVs

To prevent uncontrolled cooldown due to a spuriously opened ARV ABPV0001, fail the ARV closed by isolating air and nitrogen to the valve using KAV1435 (air) and KAV1364 (nitrogen), and venting air from the regulator. These valves are located in area A-23 and access is available without having to traverse fire area C-18.

3.1.2 Containment Spray (OMA, refer to E-1F9900)

Containment spray pump PEN01A could spuriously start and valve ENHV0006 could open, causing containment spray. The pump can be stopped by opening breaker NB0102 in area C-9.

3.2 ACTIONS INSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

3.2.1 Main Steam Isolation Valves and MSIV Bypass Valves

The capability to isolate the MSIVs and bypass valves using hand switch ABHS0080 may be affected. The MSIVs and bypass valves can be isolated using hand switch ABHS0079.

3.2.2 Main Feedwater Isolation Valves

The capability to isolate the MFIVs using hand switch AEHS0080 may be affected. Isolate the MFIVs using hand switch AEHS0081.

3.2.3 Component Cooling Water

Train A CCW could be affected by a fire in this area. If this occurs, swap to Train B CCW using normal operating procedures if Train B CCW is not already running. Loss of CCW flow to the RCP thermal barriers can be diagnosed using flow indicator EGFI0129 on panel RL020.

3.2.4 Reactor Coolant Pump Seal Cooling

Thermal barrier cooling could be affected. RCP seal injection could temporarily be disrupted until the Train B CCP is lined up. The Train B CCP can be started and lined up from the control room. RCP seal flow indication is available using BGFI0215B.

3.2.5 Pressurizer PORV/Block Valve

Pressurizer PORV BBPCV0455A could spuriously open and block valve BBHV8000A may not close. If this occurs, Operators can close the PORV by placing BBHIS0455A in the CLOSE position. Pressurizer pressure indication is available using BBPI0456, BBPI0457 and BBPI0458 located on RL002.

3.2.6 Normal Pressurizer Spray

Pressurizer spray valves BBPCV0455B and BBPCV0455C could spuriously open. If this occurs, the spray can be stopped by isolating air to the valves. This can be accomplished by depressing the CLOSE push button on KAHIS0029 to close KAFV0029. KAHIS0029 is located on RL024. Pressurizer pressure indication is available using BBPI0456, BBPI0457 and BBPI0458.

3.2.7 Isolation of Letdown

A fire in area C-18 could prevent valves BGLCV0459, BGLCV0460, BGHV8149A, BGHV8149B, and BGHV8149C from being closed using their associated control room hand switches. If this occurs, the valves can be closed by isolating air to the valves. This can be accomplished by depressing the CLOSE push button on KAHIS0029 to close KAFV0029. KAHIS0029 is located on RL024. Pressurizer level indication is available using BBLI0460A.

3.3 ACTIONS TO ACHIEVE AND MAINTAIN COLD SHUTDOWN

3.3.1 Residual Heat Removal

Valve EJHV8701B may need to be manually opened or a cold shutdown repair made when aligning Train B RHR for shutdown cooling.

3.3.2 Safety Injection Accumulators

A fire in area C-18 may require a containment entry to close SI Accumulator injection valves EPHV8808A and EPHV8808C if these valves are unresponsive from the control room. The SI accumulators need to be isolated during cold shutdown, prior to the RCS reaching 1000 psig.

4.0 CONCLUSION

With some exceptions, redundant Post Fire Safe Shutdown capability exists if a severe fire occurs in area C-18. For those exceptions, feasible manual actions are available and are unaffected by the fire. Manual actions are documented in Section 3.0.

5.0 DETAILED ANALYSIS

This section describes the detailed component-by-component and cable-by-cable analysis for a fire in area C-18.

5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA C-18

There are no PFSSD components located in area C-18. This fire area only contains cables associated with PFSSD equipment located in other areas.

5.2 PFSSD CABLE EVALUATION

Table C-18-3 lists all the PFSSD cables (S. in E-15000) located in fire area C-18. The applicable evaluation section is also listed in Table C-18-3.

Table C-18-3
PFSSD Cables Located in Fire Area C-18

Cable #	Location	Primary PFSSD Equipment	Cable Function (P) Power (C) Control (I) Instrumentation	Evaluation Section	Comments
11ABI20EA	3419	ABPT0001	I	5.2.1	SG A ARV ABPV0001 Pressure Transmitter

5.2.1 Steam Generator Atmospheric Relief Valves

PFSSD requires at least two steam generator atmospheric relief valves (ARVs) be controlled and the other two closed. The ARVs are pneumatically operated using air from the compressed air system (KA) or nitrogen from the nitrogen accumulators. The valves open by pneumatic pressure and close by spring action. The valves are automatically controlled by a pressure transmitter input signal from a pressure transmitter installed on the outlet side of the steam generator. Alternatively, each valve can be controlled manually from the control room or the auxiliary shutdown panel by placing the pressure indicating controller (PIC) in manual.

As discussed in Section 5.2.7, a fire in area C-18 could damage cables and equipment associated with the Train A Motor Driven Auxiliary Feedwater Pump (MDAFP). The Turbine Driven Auxiliary Feedwater Pump (TDAFP) and the Train B MDAFP are available. The TDAFP can be lined up to feed steam generators B and C while the Train B MDAFP can be used to supply auxiliary feedwater to Steam Generators A and D.

Cables associated with steam generator A ARV ABPV0001 are run in this area. Damage to these cables could prevent control or isolation of the ARV. A single open ARV is bounded by the main steamline break analysis. If necessary, ABPV0001 can be failed closed by isolating air and nitrogen to the valve using KAV1435 (air) and KAV1364 (nitrogen) then venting air from the regulator. These valves are located in area A-23 and emergency lighting is available.

Cables associated with ARVs ABPV0002 (SG B), ABPV0003 (SG C) and ABPV0004 (SG D) do not run through fire area C-18. Therefore, these three ARVs can be controlled from the control room.

Based on the above discussion, PFSSD can be achieved by controlling ARVs ABPV0002, ABPV0003 and ABPV0004 and locally isolating ARV ABPV0001. The TDAFP can be used to supply steam generators B and C the Train B MDAFP can be used to supply steam generator D.

Up to three ARVs can fail closed or open without impacting ability to achieve and maintain hot standby according to thermal hydraulic analysis WCNOC-CP-002. With at least one ARV unaffected, no E-1F9900 OMA is required to address ARV closure or control. Reference Attachment 4, MSO Evaluation Scenario ID PWROG 23.

5.2.2 Safety Injection and Containment Spray

A spurious safety injection signal (SIS) could cause the safety injection pumps to operate. A spurious containment spray actuation signal (CSAS) could cause the containment spray pumps to operate, depleting inventory in the RWST. These conditions are not desirable for PFSSD at Wolf Creek.

Safety injection (SI) is initiated automatically by any of the following conditions:

1. Two out of three high containment pressures monitored by pressure transmitters GNPT0934, GNPT0935 and GNPT0936.
2. Two out of four low pressurizer pressures monitored by pressure transmitters BBPT0455, BBPT0456, BBPT0457 and BBPT0458.
3. Two out of three low steam line pressures on any steam generator monitored by ABPT0514, ABPT0515 and ABPT0516 on SG A; ABPT0524, ABPT0525 and ABPT0526 on SG B; ABPT0534, ABPT0535 and ABPT0536 on SG C; and ABPT0544, ABPT0545 and ABPT0546 on SG D. Two out of three logic must be satisfied on a

single steam generator line. Low pressure on a single pressure transmitter co-incident with low pressure on another pressure transmitter on a different steam generator line will not initiate SIS.

Containment spray (CS) is initiated automatically by two out of four high containment pressures monitored by pressure transmitters GNPT0934, GNPT0935, GNPT0936 and GNPT0937.

Cables associated with steamline pressure transmitters ABPT0514, ABPT0524, ABPT0534 and ABPT0544, pressurizer pressure transmitter BBPT0455 and containment pressure transmitter GNPT0937 run in area C-18. Cables for the remaining components associated with SIS and CSAS do not run in area C-18. Consequently, a spurious SIS or CSAS cannot occur due to a fire in area C-18.

References: E-15000, XX-E-013, E-13AB21, E-13BB16, E-13GN05, E-1F9431, E-1F9432, E-1F9433, M-12AB01, M-12BB02, M-12GN01

5.2.3 Steam Generator Main Steam Isolation Bypass Valves

Each of the four Steam Generator Main Steam Isolation Valve (MSIV) bypass valves (ABHV0012, ABHV0015, ABHV0018 and ABHV0021) has two redundant solenoids that control the position of the associated bypass valve. The bypass valves are normally closed with the solenoids de-energized. Both solenoids need to be energized to open the valve. One of the solenoids on each valve is on separation group 1 (Train A) and are controlled by handswitch ABHS0080. The other solenoids on each valve are on separation group 4 (Train B) and are controlled by handswitch ABHS0079.

Cable 11ABK23AE is associated with steam line isolation signal relay K627. Upon receipt of a steam line isolation signal, the relay contact opens and the bypass valves close. An open circuit in one of the two conductors will produce the same result as a steam line isolation signal, which is desired for PFSSD. A hot short between the conductors will bypass the contact and prevent a steam line isolation signal from closing the valves.

Cable 11ABK23AF is associated with handswitch ABHS0080 on the Train A MSIV bypass valve control circuit. An open circuit in one of the two conductors will de-energize the respective solenoid and close the bypass valves. A hot short between the conductors will bypass the handswitch contact and prevent closure of the valves using the handswitch.

Cable 11ABK23AG is associated with MSIV bypass valves ABHV0012, ABHV0015, ABHV0018 and ABHV0021. The bypass valves are normally closed, which is the desired PFSSD position. In order for the valves to spuriously open, both solenoids on the air line need to be energized. An external cable hot short on cable 11ABK23AG could energize the Train A solenoids but the Train B solenoids are unaffected by a fire in area C-18. In addition, hand switch ABHS0079 is available to ensure the bypass valves are closed. Therefore, a fire in area C-18 will not affect the ability to isolate the MSIV bypass valves.

Cable 11RPK09CA supplies 125 VDC to relay panel RP209 from NK5113 and energizes the Train A control circuit for all four MSIV bypass valves. Damage to this cable will result in a loss of power to the control circuit and fail all four MSIV bypass valves closed, which is the desired PFSSD position.

Redundant means are available to ensure the MSIV bypass valves are closed. Handswitch ABHS0079 is unaffected by the fire and can be used to ensure one of the two solenoids on each bypass valve is de-energized.

References: E-15000, XX-E-013, E-093-00048, E-13AB23A, E-13AB23B, E-13RP09, E-1F9101, M-12AB02

5.2.4 Steam Generator Main Steam Isolation Valves (MSIVs)

PFSSD requires the MSIVs be closed to prevent reactivity addition due to uncontrolled cooldown. The MSIVs are closed from the control room using all close hand switches ABHS0079 or ABHS0080.

Each MSIV is designed to utilize system fluid (main steam) as the motive force to open and close. The valve actuation (open or close) is accomplished through positioning a series of six electric solenoid pilot valves to either direct the system fluid to the Upper Piston Chamber (UPC) and/or the Lower Piston Chamber (LPC), or vent either or both piston chambers. The six solenoid pilot valves are divided into two trains (3 per train) that are independently powered and controlled. Either train can independently perform the PFSSD function to close the valve and isolate main steam. This is done by actuating either all close hand switch ABHS0079 (separation group 4) or ABHS0080 (separation group 1) to de-energize the associated solenoid valves.

The following table identifies the solenoids and associated control cables for each hand switch.

MSIV	ABHS0079 (Sep Group 4)		ABHS0080 (Sep Group 1)	
	Solenoids	Cable	Solenoids	Cable
ABHV0011	MV2, MV4, MV6	14ABK28BH	MV1, MV3, MV5	11ABK29BH
ABHV0014	MV2, MV4, MV6	14ABK29AH	MV1, MV3, MV5	11ABK28AH
ABHV0017	MV2, MV4, MV6	14ABK28AH	MV1, MV3, MV5	11ABK29AH
ABHV0020	MV2, MV4, MV6	14ABK29BH	MV1, MV3, MV5	11ABK28BH

All 4 cables associated with the 12 separation group 1 solenoid valves are run in area C-18. Cable damage due to a fire will likely result in disruption of power to the solenoids, which will close the valves. The four separation group 4 cables associated with hand switch ABHS0079 are unaffected by a fire in area C-18. Therefore, hand switch ABHS0079 is available to close the four MSIVs.

Cable 11ABK30BB provides 125 VDC power to Train A main steam and feedwater isolation system (MSFIS) actuation cabinet SA075A from NK5119. Damage to this cable would disrupt power to the separation group 1 solenoids and close the MSIVs, which is the desired PFSSD position. In addition, the Train B MSFIS is unaffected by the fire and ABHS0079 is unaffected by the fire and is available to close the MSIVs.

Based on the above discussion, hand switch ABHS0079 is available to close the MSIVs in the event of a fire in area C-18.

References: E-15000, XX-E-013, E-13AB23A, E-13AB23B, E-13AB26, E-13AB27, E-13AB28, E-13AB29, E-1F9101, J-104-00295, J-104-00296, M-12AB02

5.2.5 Steam Generator Level Indication

The decay heat removal function for PFSSD requires the use of two RCS loops and two Steam Generators. Steam generator (SG) level indication is required to support this function. A fire in area C-18 credits MDAFP B supplying SG D and the TDAFP supplying either SG B or C. As discussed in Section 5.2.1, steam generator A ARV ABPV0001 control could be lost.

Cables associated with SG level transmitters AELT0501 (SG A WR), AELT0551 (SG A NR), AELT0529 (SG B NR), AELT0539 (SG C NR) and AELT0554 (SG D NR) are run in area C-18. Damage to these cables due to a fire will prevent indication on the associated level indicators in the control room. Alternate level indication remains available on all four SGs using the following level indicators:

Steam Generator	Available Level Indication
A	AELI0517 (NR), AELI0518 (NR), AELI0519 (NR)
B	AELI0502 (WR), AELI0527 (NR), AELI0528 (NR), AELI0552 (NR)
C	AELI0503 (WR), AELI0537 (NR), AELI0538 (NR), AELI0553 (NR)
D	AELI0504 (WR), AELI0547 (NR), AELI0548 (NR), AELI0549 (NR)

Based on the above discussion, level indication on all four steam generators is assured if a fire occurs in area C-18.

References: E-15000, XX-E-013, E-13AE08, E-13AE12, E-1F9203, M-12AE02

5.2.6 Steam Generator Main Feedwater Isolation Valves

PFSSD requires that either the main feedwater isolation valves (MFIVs) be closed or the main feedwater pumps be stopped to prevent overfilling the steam generators. Flow diversion from auxiliary feedwater (AFW) to the main feedwater system piping is prevented by check valves AEV0420, AEV0421, AEV0422 and AEV0423. Closure of the main feedwater isolation valves is not required to prevent AFW flow diversion.

Each MFIV is designed to utilize system fluid (feedwater) as the motive force to open and close. The valve actuation (open or close) is accomplished through positioning a series of six electric solenoid pilot valves to either direct the system fluid to the Upper Piston Chamber (UPC) and/or the Lower Piston Chamber (LPC), or vent either or both piston chambers. The six solenoid pilot valves are divided into two trains (3 per train) that are independently powered and controlled. Either train can independently perform the PFSSD function to close the valve and isolate main feedwater. This is done by actuating either all close hand switch AEHS0080 (separation group 1) or AEHS0081 (separation group 4) to de-energize the associated solenoid valves.

The following table identifies the solenoids and associated control cables for each hand switch.

MFIV	AEHS0080 (Sep Group 1)		AEHS0081 (Sep Group 4)	
	Solenoids	Cable	Solenoids	Cable
AEFV0039	MV1, MV3, MV5	11AEK16AH	MV2, MV4, MV6	14AEK17AH
AEFV0040	MV1, MV3, MV5	11AEK17AH	MV2, MV4, MV6	14AEK16AH
AEFV0041	MV1, MV3, MV5	11AEK16BH	MV2, MV4, MV6	14AEK17BH
AEFV0042	MV1, MV3, MV5	11AEK17BH	MV2, MV4, MV6	14AEK16BH

All 4 cables associated with the 12 separation group 1 solenoid valves are run in area C-18. Cable damage due to a fire will likely result in disruption of power to the solenoids, which will close the valves. The four separation group 4 cables associated with hand switch AEHS0081 are unaffected by a fire in area C-18. Therefore, hand switch AEHS0081 is available to close the four MFIVs.

Cable 11ABK30BB provides 125 VDC power to Train A main steam and feedwater isolation system (MSFIS) actuation cabinet SA075A from NK5119. Damage to this cable would disrupt power to the separation group 1 solenoids and close the MFIVs, which is the desired PFSSD position. In addition, the Train B MSFIS is unaffected by the fire and AEHS0081 is available to close the MFIVs.

Based on the above discussion, MFIV isolation is assured using hand switch AEHS0081.

References: E-15000, XX-E-013, E-13AE14, E-13AE15, E-13AE16, E-13AE17, E-1F9201, J-104-00295, J-104-00296, M-12AE02

5.2.7 Auxiliary Feedwater

The PFSSD design requires the use of one auxiliary feedwater pump (AFP) supplying water to at least two steam generators. The turbine driven auxiliary feedwater pump (TDAFP) is normally aligned to supply all four steam generators. The Train A motor driven auxiliary feedwater pump (MDAFP) is aligned to supply steam generators B and C. The Train B MDAFP is aligned to supply steam generators A and D.

The normal source of water to the AFPs is the condensate storage tank (CST). The emergency supply is from the essential service water (ESW) system. For commercial concerns, the CST is the preferred source and contains sufficient volume to supply the entire AFW demand to achieve cold shutdown.

Motor operated valves (MOVs) in the system allow operators to line up the auxiliary feedwater system as required to achieve and maintain safe shutdown. Damage to the MOV circuits due to a fire could prevent operators from lining up the system from the control room.

Several PFSSD cables associated with various components of the auxiliary feedwater system (AL) run through fire area C-18. These cables are identified in Table C-18-3. All cables are associated with Train A (separation group 1). There are no Train B (separation group 4) cables associated with the AFW system running through area C-18.

Damage to the Train A cables listed in Table C-18-3 could prevent operation of Train A MDAFP. However, Train B MDAFP and the TDAFP are unaffected by a fire in area C-18. The suction source to the Train B MDAFP is available from the CST and Train B ESW. The suction source to the TDAFP is available from Train B ESW only. The TDAFP is available to supply AFW to steam generators B and C but the capability of the TDAFP to supply steam generators A and D could be affected.

Condensate storage tank pressure transmitters ALPT0037, ALPT0038 and ALPT0039 are included in the PFSSD design because they initiate swapover to ESW upon 2/3 low CST pressure indications. Panels SA036A, SA036B and SA036C monitor pressure transmitter signals on ALPT0037, ALPT0039 and ALPT0038, respectively. A spurious low CST pressure due to fire damage to cables associated with two of these pressure transmitters could swap the water source to ESW. This is only a commercial concern and should be prevented if possible.

Cable 11ALI08AA is an instrument cable associated with ALPT0037. Cables associated with the remaining two pressure transmitters are not run in C-18. Therefore, swapover to ESW due to spurious low CST pressure is not feasible if a fire occurs in this area.

Cable 11SAK21AA supplies 125 VDC power to panel SA036A from NK5110. Cable 11SAY21AA supplies 120 VAC power to panel SA036A from NN0103. Damage to these cables could result in a loss of power to the panel and could prevent automatic operation of Train A low suction pressure (LSP) swapover. Power cables associated with LSP signals controlled by panels SA036B and SA036C are unaffected by a fire in this area.

Based on the above discussion, auxiliary feedwater is assured if a fire occurs in fire area C-18 using Train B MDAFP supplying auxiliary feedwater to steam generators A and D and the TDAFP supplying AFW to steam generators B and C. However, as discussed in Section 5.2.1, steam generator A ARV could be affected. Therefore, the assured method to achieve PFSSD if a fire occurs in this area is the Train B MDAFP supplying steam generator D and the TDAFP supplying steam generators B and C.

References: E-15000, XX-E-013, E-13AL01A, E-13AL01B, E-13AL02A, E-13AL02B, E-13AL03A, E-13AL03B, E-13AL04A, E-13AL04B, E-13AL05A, E-13AL05B, E-13AL07A, E-13AL08, E-13AL09, E-13GF01, E-13SA21, E-1F9202, E-1F9203, E-1F9204, E-1F9402A, E-1F9402B, E-1F9444, J-10SA, M-12AL01, M-12GF01

5.2.8 Pressurizer PORVs and Block Valves

PFSSD requires that either the pressurizer power operated relief valve (PORV) or its associated block valve be closed. Cables and components associated with PORV BBPCV0455A and associated block valve BBHV8000A are run through area C-18. Cables and components associated with PORV BBPCV0456A and associated block valve BBHV8000B are not located in area C-18.

The pressurizer PORVs are not considered high/low pressure interfaces. The valves are supplied power by an ungrounded 125 VDC system. Therefore, based on GL 86-10, consideration of multiple proper polarity hot shorts is not required. A single proper polarity hot short still needs to be considered.

If a fire causes BBPCV0455A to open and damages BBHV8000A cables, Operators can close BBPCV0455A by placing hand switch BBHIS0455A, located on RL021, in the close position. Pressurizer level and RCS pressure indication are available to diagnose a failed open PORV using BBLI0460A and BBPI0406, respectively. In addition, pressurizer pressure indication is available using BBPI0456, BBPI0457 and BBPI0458.

Instrument cable 11BBI16KB associated with pressurizer pressure transmitter BBPT0455 is run in fire area C-18. Damage to this cable could send a spurious high-pressure signal to the pressurizer master controller. However, as discussed in Calculation XX-E-013, Appendix 1, damage to a single pressure channel will not cause the spurious operation of the pressurizer PORVs.

Based on the above discussion, pressurizer PORV BBPCV0455A could spuriously open due to damage to the PORV control cables and valve BBHV8000A may not close due to cable damage. The PORV can be closed using hand switch BBHIS0455A in the main control room.

References: E-15000, XX-E-013, E-13BB16, E-13BB39, E-13BB40, E-1F9301, M-12BB02, M-744-00028, OFN KC-016, CR 13079, DCP 12944, DCP 13324

5.2.9 Reactor Coolant System (RCS) Pressure Indication

The PFSSD design requires RCS pressure indication to be available. RCS pressure indication is provided in the control room using BBPI0405 or BBPI0406. Cable 11BBI15EB, associated with BBPT0405, runs through fire area C-18 and could be damaged by a fire.

Redundant RCS pressure transmitter BBPT0406 is unaffected by a fire in area C-18. Therefore, RCS pressure indication is available using BBPI0406.

References: E-15000, XX-E-013, E-13BB15, E-13BB16, E-1F9201, E-1F9205, M-12BB04

5.2.10 RCS Hot and Cold Leg Temperature Elements

PFSSD requires RCS hot and cold leg temperature indication on at least one loop to verify flow through the steam generators. The temperature elements used for this purpose are listed in the following table.

As identified in Table C-18-3, cables associated with RCS temperature elements BBTE0413A, BBTE0423A, BBTE0433B and BBTE0443B are run in area C-18. A fire could damage these cables and cause temperature indication on the four temperature elements to be unavailable. Consequently, temperature indication on at least one leg on each loop could be lost, which is not in accordance with the PFSSD methodology at Wolf Creek.

RCS Hot and Cold Leg Temperature Elements Used for PFSSD	
COMPONENT	**FUNCTION**
BBTE0413A	RCS Hot Leg Temperature Element (WR) Loop 1
BBTE0413B	RCS Cold Leg Temperature Element (WR) Loop 1
BBTE0423A	RCS Hot Leg Temperature Element (WR) Loop 2
BBTE0423B	RCS Cold Leg Temperature Element (WR) Loop 2
BBTE0433A	RCS Hot Leg Temperature Element (WR) Loop 3
BBTE0433B	RCS Cold Leg Temperature Element (WR) Loop 3
BBTE0443A	RCS Hot Leg Temperature Element (WR) Loop 4
BBTE0443B	RCS Cold Leg Temperature Element (WR) Loop 4

Cable 15RLY01EA supplies 120 VAC power from PN0738 to RL021/RL022. The power splits at RL021/RL022 and supplies power to temperature recorder BBTR0423 as well as some non-PFSSD components. This temperature recorder provides indication of RCS hot and cold leg temperature on loop 2.

Procedure EMG ES-04, Attachment B Section B1 provides alternate indication in the control room that may be used to verify natural circulation flow. One of these methods verifies that steam generator pressure is stable or decreasing. Based on Sections 5.2.1 and 5.2.7, cooldown can be performed using loops 2, 3 and 4. Based on Section 5.2.2, S/G B pressure instruments ABPT0525 and ABPT0526; S/G C pressure instruments ABPT0535 and ABPT0536; and S/G D pressure instruments ABPT0545 and ABPT0546 are unaffected by a fire in C-18. These pressure instruments, along with their respective indicators in the control room, can be used, per EMG ES-04, to verify heat removal in loops 2, 3 and 4.

The configuration is acceptable because, in the event of a fire in area C-18, cooldown can be performed using RCS loops 2, 3 and 4. The associated indicating devices for RCS wide range hot and cold leg temperature elements (BBTE0423B, BBTE0433A and BBTE0443A) as well as ABPT0525, ABPT0526, ABPT0535, ABPT0536, ABPT0545 and ABPT0546 will provide indication of flow through the steam generators.

References: E-15000, XX-E-013, E-13BB15, E-13RL01, E-13RL06, E-1F9201, M-12AB01, M-12BB01, EMG ES-04

5.2.11 Pressurizer Level Transmitters

PFSSD requires pressurizer level indication to be available. Pressurizer level indication is provided by level transmitters BBLT0459 and BBLT0460. A cable associated with BBLT0459 runs through area C-18 and could be damaged, causing inoperability of BBLT0459 and its associated level indicator (BBLI0459A). Cables for BBLT0460/BBLI0460A do not run through fire area C-18.

Pressurizer level indication is available using BBLT0460/BBLI0460A if a fire occurs in area C-18.

References: E-15000, XX-E-013, E-13BB16, E-1F9301, M-12BB02

5.2.12 Reactor Head Vent Valves

PFSSD requires that one of the two reactor vessel head vent valves on each flow path (2 flow paths total) be closed to prevent uncontrolled depressurization of the RCS. Either BBHV8001A or BBHV8002A and either BBHV8001B or BBHV8002B needs to be closed.

A cable associated with head vent valve BBHV8001A runs through C-18. Cables for the remaining valves are unaffected. Therefore, the reactor head vent flow path will remain isolated throughout the event.

References: E-15000, XX-E-013, E-1F9301, E-13BB30, M-12BB04

5.2.13 Centrifugal Charging System

At least one centrifugal charging pump (CCP) is required for PFSSD to provide RCP seal cooling, reactivity control and inventory control. These functions are accomplished using a CCP taking suction from the refuelling water storage tank (RWST) and injecting through the RCP seals. RCP seal injection provides approximately 20 gpm makeup to the RCS and provides adequate boron concentration to maintain sub-critical reactivity conditions. If RCP seal injection is unavailable, reactivity and inventory control is provided by lining up the CCPs to the boron injection tank (BIT). The normal charging pump (NCP) is not credited and is assumed lost.

A control cable associated with Train A Centrifugal Charging Pump (CCP) runs through area C-18. Damage to this cable could prevent operation of the pump. Redundant Train B CCP cables are run in a separate fire area and are unaffected by a fire in this area. Therefore, PFSSD is assured using Train B CCP if a fire occurs in area C-18.

Power and control cables associated with Train A CCP miniflow valve BGHV8110 are run through area C-18. Redundant Train B cables for miniflow valve BGHV8111 are run in a different area and are unaffected by a fire in area C-18. Therefore, PFSSD is assured using Train B CCP miniflow valve if a fire occurs in area C-18.

The power cable associated with Train A CCP room cooler motor DSGL12A runs in area C-18. Damage to this cable will prevent operation of the room cooler. Train B CCP room cooler SGL12B circuits do not run in area C-18 and are unaffected by a fire. Therefore, Train B CCP room cooler will be available.

Based on the above discussion, the Train A CCP could be affected but the Train B CCP is available if a fire occurs in area C-18.

References: XX-E-013, E-15000, E-13BG01, E-13BG11B, E-13GL05, E-1F9102, E-1F9302, E-1F9401A, E-1F9444, M-12BG03, M-12GL01

5.2.14 Charging Flow to Regenerative Heat Exchanger Isolation Valves

PFSSD requires charging flow to be directed to the RCP seals. To ensure adequate flow to RCP seals, flow diversion to the regenerative heat exchanger needs to be prevented. Valves BGHV8105 and BGHV8106 are included in the PFSSD design to accomplish this task. Manual valve BG8402B is also included to provide an alternate means of closing this flow path if either BGHV8105 or BGHV8106 are unavailable, and is also used during alternate safe shutdown per OFN RP-017.

Cables associated with BGHV8106 are run in area C-18 and could be damaged by a fire, preventing valve BGHV8106 from being closed from the control room. Cables associated with redundant valve BGHV8105 do not run in area C-18. Consequently, valve BGHV8105 can be isolated from the control room if a fire occurs in area C-18.

References: E-15000, XX-E-013, E-13BG11A, E-1F9102, E-1F9302, M-12BG03

5.2.15 Volume Control Tank (VCT)

Power and control cables associated with VCT valve BGLCV0112B run through fire area C-18. Cables for redundant VCT valve BGLCV0112C are run in a separate fire area and are unaffected by a fire in area C-18. The PFSSD position of these valves is at least one closed. Therefore, PFSSD can be accomplished by isolation of BGLCV0112C.

A hot short involving cables 11BGG12AD and 11BGG12AE could bypass the BNLCV0112D interlock as well as the SIS and VCT low-low level interlocks and cause inadvertent closure of BGLCV0112B. If this occurs prior to establishing suction from the RWST, damage to the operating charging pump could occur due to loss of suction. The assumptions in calculation XX-E-013 state that systems and components are in their normal operating position or status prior to the fire. The Normal Charging Pump (NCP) is the normally operated pump and is assumed to be operating at the time of the fire. Inadvertent closure of valve BGLCV0112B with no suction from the RWST would result in damage to the NCP but the centrifugal charging pumps would remain unaffected. As stated in 5.2.13, the A Train CCP could be unavailable but the B Train CCP is unaffected by the fire.

A cable (11BGI51CA) associated with VCT level transmitter BGLT0112 runs through area C-18. A false low-low level signal associated with this level transmitter could initiate refueling water sequence, which is the desired PFSSD lineup. Damage to this cable could also cause a spurious VCT level indication on BGLI0112 in the control room. Cables associated with BGLT0185 are unaffected by the fire and BGLI0185 will provide reliable level indication in the control room.

Based on the above discussion, a fire in area C-18 that affects components associated with the VCT will not adversely impact the ability to achieve and maintain PFSSD.

References: XX-E-013, E-15000, E-13BG12, E-13BG12A, E-13BG51, E-13BN01, E-1F9102, E-1F9302, M-12BG03

5.2.16 RCP Seal Injection

PFSSD requires RCP seal injection to provide a boron injection path, provide makeup to the RCS and provide cooling to the RCP seals. The redundant boron injection and makeup path is through the boron injection tank (BIT). The redundant seal cooling method uses thermal barrier cooling.

Power and control cables associated with RCP seal injection flow throttling valve BGHV8357A are run in area C-18. Damage to these cables will prevent operation of the valve from the control room. PFSSD requires RCP seal injection using an available centrifugal charging pump and flowing through the associated throttling valve. Cables associated with redundant Train B valve BGHV8357B are run in a separate fire area and are unaffected by a fire in area C-18.

Cable 11BGI51AA is associated with RCP seal total flow transmitter BGFT0215A. Damage to this cable could prevent operation of the flow transmitter and could prevent operators from determining total RCP seal flow using flow indicator BGFI0215A. Flow indicator BGFI0215B is unaffected by a fire in area C-18 and can be used by operators to determine if seal flow is functioning.

Based on the above discussion, PFSSD is assured using Train B charging pump and aligning RCP seal injection flow through BGHV8357B. Operators can use flow indicator BGFI0215B to diagnose a loss of RCP seal injection in the event of a loss of the operating charging pump. Therefore, the configuration is acceptable.

References: E-15000, XX-E-013, E-13BG51, E-13BG52, E-1F9102, E-1F9302, M-12BG03

5.2.17 Excess Letdown

PFSSD requires the excess letdown path be isolated to prevent uncontrolled depressurization of the RCS. To accomplish this, either normally closed valve BGHV8153A or BGHV8154A must be maintained closed and either normally closed valve BGHV8153B or BGHV8154B must be maintained closed.

One cable associated with BGHV8154A runs through fire area C-18. The remaining valves are unaffected since their cables do not run through this area. Therefore, the remaining valves are unaffected by a fire in area C-18 and will remain closed.

References: E-15000, XX-E-013, E-13BG48, E-1F9301, M-12BG01

5.2.18 Refueling Water Storage Tank (RWST) to Charging Pumps Suction Isolation Valves

Cables associated with RWST to CCP A valve BNLCV0112D run through fire area C-18. As stated earlier, the Train A CCP may not be available if a fire occurs in area C-18. Therefore, the Train B CCP is used, taking suction from the RWST. Cables associated with valve BNLCV0112E are unaffected by a fire in area C-18. Therefore, BNLCV0112E can be opened from the control room to provide the necessary suction from the RWST to the Train B CCP.

A fire in area C-18 will use CCP B taking suction from the RWST through valve BNLCV0112E.

References: E-15000, XX-E-013, E-13BN01, E-1F9102, E-1F9302, M-12BN01

5.2.19 Refueling Water Storage Tank (RWST) and Containment Sump Isolation Valves

To prevent draindown of the RWST into the containment sump, PFSSD requires that either valve BNHV8812A or valve EJHV8811A and valve BNHV8812B or valve EJHV8811B be closed during hot standby. For cold shutdown, the operating train containment sump valve (EJHV8811A or EJHV8811B) must be maintained closed to prevent flow diversion from the RCS to the containment sump. Valves BNHV8812A and BNHV8812B are normally open and valves EJHV8811A and EJHV8811B are normally closed.

Power and control cables for valve BNHV8812A run through fire area C-18. Damage to these cables could prevent closing this valve from the control room or could cause the valve to spuriously close. In addition, cable damage could prevent the valve from automatically closing when valve EJHV8811A reaches full open position.

A control cable (11EJG06AC) associated with valve EJHV8811A runs through fire area C-18. Damage to this cable will not result in valve EJHV8811A opening as long as valve BNHV8812A remains open. If valve BNHV8812A is fully closed, it will provide a permissive for valve EJHV8811A to open. If valve EJHV8811A opens due to damage to cable 11EJG06AC, draindown will not occur since valve BNHV8812A is closed.

Based on the above discussion, draindown of the RWST to the containment sump is not credible if a fire occurs in area C-18.

References: E-15000, XX-E-013, E-13BN03, E-13BN03A, E-13EJ06A, E-13EJ06B, E-1F9102, E-1F9205, M-12BN01, M-12EJ01, M-10BN

5.2.20 Essential Service Water System

One train of Essential Service Water (ESW) is required to be operable to ensure adequate cooling for essential equipment. A number of cables associated with Train A ESW components are run in this area. Therefore, Train A ESW cannot be relied on for PFSSD if a fire occurs in this area. Cables associated with Train B ESW are run in a different fire area. Therefore, Train B ESW is available if a fire occurs in area C-18.

Valve EFHV0023 is a normally open isolation valve on the service water system feed to the Train A Essential Service Water System. Either this valve or valve EFHV0025 is required to be closed when operating the Train A ESW system for PFSSD. Power and control cables associated with EFHV0023 are run in this area. Damage to these cables could prevent closing EFHV0023 from the control room. Redundant valve EFHV0025 is unaffected by a fire in area C-18 and can be closed from the control room to isolate this flowpath. In addition, check valve EFV0470 is installed in this line and will prevent flow diversion in the unlikely event valve EFHV0025 cannot be closed.

Valve EFHV0024 is a normally open isolation valve on the service water system feed to the Train B Essential Service Water System. Either this valve or valve EFHV0026 is required to be closed when operating the Train B ESW system for PFSSD. Power and control cables associated with EFHV0024 are run in this area. Damage to these cables could prevent closing EFHV0024 from the control room. Redundant valve EFHV0026 is unaffected by a fire in area C-18 and can be closed from the control room to isolate this flowpath. In addition, check valve EFV0471 is installed in this line and will prevent flow diversion in the unlikely event valve EFHV0026 cannot be closed.

Valve EFHV0041 is a normally open isolation valve on the return line from the Train A Essential Service Water System to the service water system. Either this valve or valve EFHV0039 is required to be closed when operating the Train A ESW system for PFSSD. Power and control cables associated with EFHV0041 are run in this area. Damage to these

cables could prevent closing EFHV0041 from the control room. Redundant valve EFHV0039 is unaffected by a fire in area C-18 and can be closed from the control room to isolate this flowpath.

Valve EFHV0042 is a normally open isolation valve on the return line from the Train B Essential Service Water System to the service water system. Either this valve or valve EFHV0040 is required to be closed when operating the Train B ESW system for PFSSD. Power and control cables associated with EFHV0042 are run in this area. Damage to these cables could prevent closing EFHV0042 from the control room. Redundant valve EFHV0040 is unaffected by a fire in area C-18 and can be closed from the control room to isolate this flowpath.

Valve EFHV0037 is the Train A return isolation valve from ESW to the Ultimate Heat Sink. This valve is required to be open when operating the Train A ESW system for PFSSD. A cable (11EFG06AC) associated with this valve is run in this area and damage could cause the valve to spuriously close. Circuits for redundant Train B valve EFHV0038 are not run in area C-18 and will be unaffected by the fire.

Cable 11GDI04AA provides ESW A room temperature from temperature element GDTE0001 to temperature controller GDTC0001. Cables 11GDI04AB and 11GDI04AC provide signals from GDTC0001 to outside air intake damper GDTZ0001A and recirculation damper GDTZ0001B, respectively, to change position based on room temperature. Damage to these cables could prevent operation of the dampers. Temperature controls for Train B ESW pump room are unaffected by a fire in area C-18.

Cable 11RPY10BA supplies 120 VAC control power to the automatic and manual start circuits in panel RP068 from NG01ACR1 for Train A ESW pump room supply fan CGD01A. Cables 11GDY01AA and 11GDY01AB are associated with the Train A ESW pump room supply fan CGD01A control circuit. Damage to these cables could prevent operation of the unit, which could prevent continuous operation of the Train A ESW pump. If this occurs, the Train B ESW pump room supply fan is unaffected by the fire.

Cable 11GDG01AC is associated with the indicator lights on Train A ESW pump room supply fan CGD01A hand switch GDHIS0001B. Damage to this cable could prevent operation of the fan. Cables for Train B ESW pump room supply fan CGD01B are unaffected by a fire in this area.

Cable 11RPK09AA supplies class 1E 125 VDC power from NK4122 to certain relays in panel RP139. These relays (1XEF31, 1XEF33 and 1XEF35) are associated with Train A ESW Pump. Damage to this cable could prevent operation of the Train A ESW pump.

PFSSD is assured for a fire in area C-18 using Train B ESW pump PEF01B and associated components.

References: E-15000, XX-E-013, E-093-00052, E-093-00053, E-13EF02, E-13EF03, E-13EF04, E-13EF06, E-13EF07, E-13EF08, E-13EF09, E-13RP09, E-13RP10, E-13EF11, E-K3EF08, E-K3GD01, E-K3GD04, E-1F9402A, E-1F9402B, E-1F9403, E-1F9424A, E-1F9443, E-K3EF01, J-201-00139, M-12EF01, M-12EF02, M-K2EF01, M-K2GD01

5.2.21 Component Cooling Water

For PFSSD, the component cooling water (CCW) system is used to provide cooling to the centrifugal charging pump (CCP) oil cooler, the RHR heat exchanger and the RHR pump seal cooler. In addition, the CCW system provides cooling to the RCP thermal barriers and is credited as a backup to RCP seal injection for maintaining seal cooling. Cables associated with Train A CCW pumps PEG01A and PEG01C are run in this area. In addition, cables associated with Train A CCW pump room cooler SGL11A and associated dampers are run in this area. Damage to these cables could prevent operation of the Train A CCW system.

Cables associated with a number of valves in the Train A CCW system are run in area C-18. These cables and associated valves are listed in Table C-18-3. Cables associated with valves in the Train B CCW system do not run in area C-18 and are unaffected by a fire in this area.

Valves BBHV0013, BBHV0014, BBHV0015, BBHV0016, EGHV0058, EGHV0061, EGHV0126 and EGHV0132 provide isolation capability for CCW flow to/from the RCP thermal barriers. Cables associated with these components are located in area C-18. If the valves fail to the open position, CCW would continue to flow to the RCP components, including the thermal barrier. This continued flow of water will not adversely impact PFSSD. If the valves fail to the closed position, CCW flow to the thermal barrier could be lost. This is acceptable since RCP seal injection is available.

Flow transmitters BBFT0017, BBFT0018, BBFT0019 and BBFT0020 are associated with valves BBHV0013, BBHV0014, BBHV0015 and BBHV0016, respectively. The flow transmitters monitor flow in the CCW piping and shut the valves on high CCW flow. Cables associated with these flow transmitters are run in this area. Damage to these cables could cause a spurious high CCW flow signal and close the valves. Damage to the valve cables could prevent re-opening the valves.

Cable 11EGI19AB is associated with CCW to RCP flow transmitter EGFT0128. Damage to this cable could prevent operators from diagnosing a loss of CCW flow to the RCP thermal barriers using flow indicator EGFI0128. CCW to RCP flow indicator EGFI0129 is unaffected by a fire in area C-18 and can be used to diagnose a loss of CCW flow to the RCP thermal barriers.

Based on the above discussion, a fire in area C-18 could affect CCW flow to/from the RCP thermal barriers. The Train B CCW system is available to supply cooling to the remaining Train B PFSSD components. Loss of CCW flow to the RCP thermal barriers can be diagnosed using flow indicator EGFI0129. RCP seal injection is unaffected.

References: E-15000, XX-E-013, E-13BB03, E-13BB28, E-13EG01A, E-13EG01B, E-13EG05A, E-13EG05B, E-13EG07, E-13EG09, E-13EG09A, E-13EG16, E-13EG17A, E-13EG18, E-13EG19, E-13GL06, E-13GL27, E-1F9303, E-1F9401A, E-1F9444, M-12EG01, M-12EG02, M-12EG03, M-12GL01

5.2.22 Residual Heat Removal System

PFSSD requires one train of residual heat removal (RHR) to be available for shutdown cooling. The RHR system is not used for hot standby. A number of cables associated with the RHR system run in area C-18. These cables are discussed in the following paragraphs.

Valve EGHV0101 is the Train A CCW to RHR Heat Exchanger control valve. Valve EGHV0102 is the Train B CCW to RHR Heat Exchanger control valve. These valves are normally closed during power operation. PFSSD requires that the valve on the operating train of CCW be closed until shutdown cooling mode is entered, at which time the valve on the operating train of RHR needs to be open. Cables 11EGG07AA and 11EGG07AB are power and control cables associated with valve EGHV0101. Damage to these cables would not cause the spurious opening of the valve but could prevent operation when lining up for shutdown cooling. Valve EGHV0102 is unaffected by a fire in this area.

Cable 11EJB01AB is a control cable associated with Train A RHR pump feeder breaker NB00101. Damage to this cable could prevent operation of the pump from the control room or could cause the pump to spuriously operate. If the pump fails to operate, the Train B RHR pump is available. If the pump spuriously operates with no suction source, it will likely become damaged and the Train B RHR system will be used.

Cables 11EJG04AA and 11EJG04AB are power and control cables, respectively, associated with normally closed valve EJHV8804A. This valve is required to remain closed when aligning Train A RHR for cold shutdown. For hot standby, the valve can be in any position. Based on a review of the schematic diagram, damage to these cables will not cause the valve to spuriously open. Since this valve is not a high-low pressure interface boundary, consideration of a three-phase cable-to-cable hot short is not required. Train B valve EJHV8804B is unaffected by a fire in area C-18.

Cables associated with normally closed valves EJHV8701A (Train A) and EJHV8701B (Train B) run in area C-18. These valves are required to be open when aligning the respective RHR Train for cold shutdown. Cable damage could prevent opening the associated valve from the control room. Therefore, a fire in area C-18 may require a cold shutdown repair to be made within 72 hours per 10CFR50, Appendix R or a containment entry to manually open EJHV8701B when using RHR Train B.

Cables associated with Train A RHR pump mini-flow valve EJFCV0610 are run in area C-18. The mini-flow valve protects the Train A RHR pump during low-flow in the system. Damage to the cables could prevent operation of the valve. Cables associated with Train B RHR mini-flow valve EJFCV0611 do not run in area C-18. Therefore, the Train B RHR pump mini-flow valve is unaffected by a fire in area C-18.

The RHR pump discharge to RCS cold leg isolation valve (EJHV8809A or EJHV8809B) needs to be open on the operating train. Damage to cables 11EJG09CC and 11EJG09CD would likely result in valve EJHV8809A remaining in its as-is normally open position, which is the preferred PFSSD position. However, two proper intra-cable hot shorts in cable 11EJG09CD or one intra-cable hot short in cable 11EJG09CD combined with a short to ground on conductor 31 would spuriously close the valve.

Cable 11GLG05AA is the power cable for the RHR A room cooler SGL10A. Damage to this cable will prevent the RHR A room cooler from operating, and could impair the Train A RHR system. The B Train RHR room cooler is unaffected by a fire in area C-18.

Cable 15EJI12AA is an instrument AC power cable associated with Train A RHR flow control valve EJHCV0606. Cable 15RLY01DA supplies 120 VAC power from PN00736 to RL017/RL018, where the power splits and feeds EJHCV0606 via cable 15EJI12AA. Damage

to these cables will cause a loss of power to the valve controller, failing the valve open, which is the desired position if using Train A RHR. Train B RHR flow control valve EJHCV0607 is unaffected by a fire in this area.

Based on the above discussion, a number of Train A RHR components could be affected by a fire in area C-18 but Train B RHR is unaffected.

References: E-15000, XX-E-013, E-13EG07, E-13EJ01, E-13EJ04A, E-13EJ04B, E-13EJ05A, E-13EJ05B, E-13EJ08, E-13EJ09A, E-13EJ12, E-13GL05, E-13RL01, E-13RL04, E-1F9205, E-1F9301, E-1F9401A, E-1F9444, M-12EJ01, M-12GL01

5.2.23 Safety Injection Pumps

The PFSSD strategy is to prevent operation of the Safety Injection (SI) pumps to ensure an adequate supply of borated water in the RWST. One cable (11EMB01AB) associated with Train A SI pump is run in area C-18. Damage to this cable could cause the spurious start of the pump and could prevent stopping the pump from the control room.

If the Train A SI pump spuriously starts with the reactor at normal pressure, PFSSD will be assured. The pump will not discharge into the RCS due to the pressure differential between the RCS (approximately 2,235 psig) and the SI pump shutoff pressure (approximately 1,565 psig). In addition, the setpoint of the discharge relief valve (EM8853A) to the Recycle Holdup Tank is 1,825 psig. Therefore, no inventory will be lost from the RWST if the SI pumps spuriously start. With the SI pump operating at zero flow, damage to the pump could occur, which is a commercial concern only since the SI pump is not credited in the PFSSD analysis. If necessary, the pump can be stopped by opening breaker NB0103, but this action is not required for PFSSD.

Based on the above discussion, spurious operation of the Train A SI pump will not adversely impact PFSSD.

References: E-15000, XX-E-013, E-13EM01, E-1F9102, E-1F9302, M-12EM01, M-721-00096, WCRE-01

5.2.24 Boron Injection Tank Flowpath

The Boron Injection Tank (BIT) flowpath is credited for reactivity control and reactor coolant makeup. For reactivity control, the BIT flowpath is credited as an alternate source of boration in the event RCP seal injection is unavailable. Based on Calculation XX-E-013, RCP seal injection will provide sufficient boration to achieve and maintain cold shutdown reactivity conditions. Therefore, the BIT flowpath is not required for reactivity control if RCP seal injection is available. Since RCP seal injection is limited to 5 gpm per seal or 20 gpm total injection to the RCS, an additional RCS charging flowpath is required for adequate RCS makeup during plant transition from hot standby to cold shutdown. The BIT injection path was selected as the additional RCS charging flowpath.

A fire in area C-18 uses CCP B, since circuits and support systems for CCP A may be affected by the fire. Also, based on the discussion in 5.2.41, a fire in area C-18 has the possibility to cause a momentary loss of inventory through the letdown flow path until the letdown isolation valves close automatically or are failed closed.

Cables 11EMG02AC, associated with EMHV8803A, and 11EMG02CF, associated with EMHV8801A, are run in this area. Cable 11EMG02CF is fire resistive and not susceptible to fire induced damage. Damage to cable 11EMG02AC could prevent opening valve EMHV8803A and could prevent a flowpath from Train A CCP to the RCS via the BIT.

Redundant Train B valve EMHV8803B is unaffected by a fire in this area so the Train B CCP flowpath to the RCS via the BIT is available.

To prevent CCP flow diversion through the SIS test line when charging through the BIT, valves EMHV8843 and EMHV8882 need to be closed. If either or both of these valves cannot be closed, then closing or maintaining closed either valve EMHV8871 or EMHV8964 will accomplish the PFSSD objective.

Cable 11EMK12BA is a control cable for EMHV8964. A hot short in cable 11EMK12BA will energize the solenoid and open valve EMHV8964. The cable is run in raceways with cables carrying the proper voltage and polarity for a cable-to-cable hot short. The hot short would bypass the control room handswitch (EMHIS8964) on RL017 and control of this valve from the control room would be lost.

Cable 15EMK05EA is a control cable associated with EMHV8882. A hot short in cable 15EMK05EA will energize the solenoid and open valve EMHV8882. The cable is run in raceways with cables carrying the proper voltage and polarity for a cable-to-cable hot short. The hot short would bypass the control room handswitch (EMHIS8882) on RL018 and control of this valve from the control room would be lost.

Redundant valve EMHV8871 is unaffected by the fire and is available to ensure the SIS test line remains isolated. Therefore, a fire in area C-18 will not adversely impact the ability to isolate the SIS test line flow path.

Based on the above discussion, charging through the BIT is unaffected by a fire in this area using Train B CCP and valves EMHV8801B and EMHV8803B. The SI test line can be isolated using valve EMHV8871.

References: E-15000, XX-E-013, E-13EM02, E-13EM02A, E-13EM02B, E-13EM02C, E-13EM05A, E-13EM12, E-1F9302, M-12EM01, M-12EM02

5.2.25 Containment Spray Pumps

Spurious start of the containment spray (CS) pumps may complicate PFSSD due to the possible depletion of inventory in the RWST. Therefore, a spurious start of the CS pumps should be avoided or mitigated. A control cable (11ENB01AB) associated with Train A CS pump PEN01A runs through area C-18 and could cause a spurious start of the pump if damaged. The cable damage could prevent stopping the pump from the control room.

Normally closed valve ENHV0006 could open due to damage to associated control cables. If this occurs, water would flow from the containment spray nozzles, depleting inventory in the RWST.

The total flow in the containment spray system during injection phase with one pump operating is 3,165 gpm (M-10EN). Based on calculation XX-E-013, Appendix 1, a maximum of 214,260 gallons of water can be lost from the RWST to maintain sufficient volume to achieve cold shutdown.

Level indication in the RWST is available, so operators have the ability to diagnose a reducing RWST inventory. The time available to mitigate containment spray is:

214,260 gallons / 3,165 gpm = 67.7 minutes

A fire in this area could also result in the inability to isolate letdown, as discussed in Section 5.2.41. The maximum inventory loss through letdown is 195 gpm through all three orifice valves. If a multiple spurious operation scenario exists where containment spray spuriously

operates concurrent with failed open letdown valves, the available time to mitigate this condition is as follows:

3,165 gpm + 195 gpm = 3,360 gpm

At this flowrate, the amount of time available to mitigate RWST inventory loss is:

214,260 gallons / 3,360 gpm = 63.7 minutes

Based on the above discussion, there is 63.7 minutes available to mitigate containment spray. Pump PEN01A can be stopped by opening breaker NB0102 in fire area C-9. This is an OMA. Refer to E-1F9900 for details. Reference Attachment 4, MSO Evaluation Scenario ID PWROG 16.

References: XX-E-013, E-15000, E-13EN01, E-13EN03, E-1F9102, E-1F9302, E-1F9424A, E-1F9433, M-10BG, M-10EN, M-12EN01, M-721-00093

5.2.26 Safety Injection Accumulator Isolation Valves

PFSSD requires isolation of the SI accumulators prior to reducing RCS pressure below the injection pressure to avoid unnecessary accumulator discharge. This is accomplished by closing valves EPHV8808A, EPHV8808B, EPHV8808C and EPHV8808D. These valves are normally open with the MCC breaker administratively locked in the open position. Cables for valves EPHV8808A and EPHV8808C are run in area C-18.

Since the breakers for these valves are normally open, damage to these cables will not cause the valves to spuriously change position. However, damage to the cables will prevent closing the associated valve from the control room after power is restored.

The SI accumulators need to be isolated during cold shutdown, prior to the RCS reaching 1000 psig. If necessary, a containment entry can be made to manually close the valves.

References: E-15000, XX-E-013, M-12EP01, E-13EP02A, E-1F9201, CKL EP-120

5.2.27 Control Room Air Conditioning

Cables associated with Train A control room A/C unit SGK04A are run in this area. Damage to these cables could prevent operation of this unit. Cables associated with Train B control room A/C unit SGK04B are run in a separate area. Therefore, the Train B control room A/C unit is unaffected by a fire in this area.

Power and control cables associated with Train A Control Room A/C unit supply and return dampers GKHZ0029A and GKHZ0029B are run in area C-18. Damage to these cables could prevent operation of the associated dampers. Circuits for Train B Control Room A/C unit dampers do not run in area C-18.

Based on the above discussion, Control Room environmental conditions will be unaffected by a fire in area C-18.

References: XX-E-013, E-15000, E-13GK02A, E-13GK02B, E-13GK02C, E-1F9442, M-12GK01

5.2.28 Class 1E Electrical Equipment Room A/C Unit

Power and control cables associated with Train A class 1E Electrical Equipment room A/C unit SGK05A are run in area C-18. A fire could damage these circuits and prevent operation of the unit. Circuits for Train B class 1E Electrical Equipment A/C unit SGK05B do not run in area C-18.

Cable 11SAZ19KA associated with SGK05A is run in fire area C-18. Damage to this cable could prevent operation of SGK05A. Cables associated with SGK05B are unaffected by a fire in area C-18.

Cables 15GKK31CA and 15GKK31CB are associated with the fire isolation signal on SGK05A. Damage to these cables could cause the unit to stop and prevent a re-start. Cable 15RPK09NA is the power cable from PK5126 to separation group 5 relays in RP330. Damage to this cable could cause a loss of power to relay 95XGK07 and shut down SGK05A. Fire isolation signal cables associated with Train B class 1E A/C unit SGK05B are unaffected.

Based on the above discussion, Train B class 1E electrical equipment room cooling is available and is unaffected by a fire in area C-18.

References: XX-E-013, E-15000, E-13GK13, E-13GK31, E-13RP09, E-13SA19, E-1F9444, M-12GK03, M-622.1A-00002

5.2.29 Containment Coolers

PFSSD requires containment cooling to maintain the containment environment within EQ limits. Cables associated with Train A containment coolers are run in area C-18. Damage to these cables could prevent operation of the Train A containment coolers if a fire occurs in this area. Circuits for the Train B containment coolers are run in a separate fire area and are unaffected by a fire in area C-18.

As discussed earlier, Train B ESW is available if a fire occurs in area C-18. Therefore, the Train B containment coolers will have the necessary service water flow to ensure proper operation.

References: E-15000, XX-E-013, E-13GN02, E-13GN02A, E-1F9441, M-12GN01

5.2.30 Load Shedder / Emergency Load Sequencer

The load shedder and emergency load sequencers are included in the PFSSD design to evaluate the impact of spurious operation or mal-operation. The load shedder/emergency load sequencer operates upon presence of the following conditions:

1. An undervoltage (UV) on a safeguards bus,
2. A safety injection signal (SIS) or a containment spray actuation signal (CSAS), or
3. An undervoltage on a safeguards bus with a SIS or CSAS.

Eight inputs (four undervoltage (UV) inputs and four degraded voltage inputs) on each safeguards bus (NB01 and NB02) monitor voltage conditions on that bus. An undervoltage condition on two of four UV relays on each bus will actuate the load shedder/sequencer and send a signal to start the associated diesel generator. In addition, degraded voltage sensed by two of four degraded voltage potential transformers (PTs) will, after a time delay, provide a signal to open the offsite feeder breakers on the associated bus.

Cables 11NFK01CA and 11NFK01DA associated with one of the four undervoltage relays on each bus run in area C-18. Also, cables 11NFY01EA and 11NFY01FA associated with the

degraded voltage PTs on each bus are run in fire area C-18. Cables associated with the remaining UV relays and PTs do not run in fire area C-18. Therefore, automatic functioning of the bus NB01 and NB02 emergency load shed/sequencer is unaffected by a fire in area C-18 due to the availability of at least two UV relay inputs.

Separation group 1 power supply cables for load shedder/sequencer logic and input cabinets NF039A, NF039B and NF039C run in area C-18. Damage to these cables could cause a loss of separation group 1 DC and AC power to the panels. Redundant separation group 3 and Train B DC and AC power is unaffected by a fire in area C-18.

Based on the above discussion, the load shedder/sequencer is not adversely affected by a fire in area C-18.

References: XX-E-013, E-15000, E-11NB01, E-11NB02, E-12NF01, E-13NF01, E-10NF, E-1F9411A, E-1F9411B, E-1F9412A, E-1F9412B, E-1F9402A, E-1F9402B, E-1F9403, E-1F9425, E-1F9426

5.2.31 Train A Class 1E 4.16 kV ESF Switchgear Bus NB01

Several cables associated with Class 1E 4.16 kV switchgear bus NB01 are located in this area. Damage to these cables could prevent operation of Train A equipment powered by NB01. Cables associated with class 1E 4.16 kV switchgear bus NB02 are located in a different fire area and are unaffected by a fire in area C-18.

References: XX-E-013, E-15000, E-13NB01, E-13NB02, E-13NB03, E-13NB10, E-13NB12, E-13NB13, E-13NG01A, E-1F9423, E-1F9425

5.2.32 Train A 480 VAC Load Centers

Cables associated with 480 VAC load centers NG01, NG03 and motor control center (MCC) NG05E are run in area C-18. Damage to these cables could de-energize the load centers and MCCs, preventing operation of the associated Train A equipment.

Cables 11PKK10AA and PKK10AB are associated with the 125 VDC control circuit for breaker NG0102, which supplies 480 VAC power to battery charger PK021. Damage to these cables could prevent closing NG0102 and supplying power to PK021. Battery charger PK022 is unaffected by a fire in this area.

Train B 480 VAC load centers NG02, NG04 and MCC NG06E are unaffected by a fire in this area and are available to supply power to redundant Train B equipment. Therefore, a fire in area C-18 will not impact the ability to supply power to required Train B 480 VAC equipment.

References: XX-E-013, E-15000, E-13NG01A, E-13NG10, E-13NG11, E-13PK10, E-1F9423, E-1F9424A, E-1F9424B, E-1F9424C, E-1F9424D, E-K3NG10

5.2.33 Class 1E 120 VAC Electrical Distribution System

The Class 1E 120 VAC electrical distribution system provides power to vital instrumentation and control loads for shutdown and normal operation. Under normal conditions, the system is supplied by inverters connected to the 125 VDC NK battery system. Swing inverters allow the primary inverters to be taken out of service for maintenance or repair without disrupting power to the associated vital AC bus. In the event of a loss of power to the inverters, a backup source of power is automatically lined up. The backup power source originates from the 480 VAC electrical distribution system (NG).

Cable 11NNG01AA supplies 480 VAC power from NG01ACR3 to inverter NN11. Cable 11NNG01CA supplies 480 VAC power from NG01AGF3 to inverter NN13. Damage to these cables will disrupt the 480 VAC power source to inverters NN11 and NN13. The 480 VAC power supply to swing inverter NN15 is unaffected.

Cables 11NNK01JA and 11NNK01JB supply 125 VDC power from NK0103 to manual transfer switch NK79. Damage to these cables will disrupt the 125 VDC power supply from NK0103 to swing inverter NN15. The 125 VDC power supply from NK0303 to swing inverter NN15 is unaffected.

Cables 11NNY01EA and 11NNY01EB supply 120 VAC power from swing inverter NN15 to bus NN01 through a manual transfer switch in inverter NN11. Damage to these cables will disrupt the 120 VAC power supply from swing inverter NN15 to NN01. The 120 VAC power supply from inverter NN11 to bus NN01 is unaffected.

As stated in Section 5.2.32, a fire in area C-18 could cause a loss of Train A 480 VAC power. This would cause a loss of 480 VAC power to the Train A NK battery chargers (NK21, NK23 and NK25) which will cause a loss of normal power to the NK01 and NK03 busses. Batteries NK11 and NK13 are unaffected and can supply 125 VDC to busses NK01 and NK03 to provide power to inverters NN11 and NN13 for a limited time.

Train B vital 120 VAC distribution panels NN02 and NN04 are unaffected by a fire in area C-18. Therefore, in the event of a loss of Train A Class 1E 120 VAC electrical distribution system, the Train B Class 1E electrical distribution switchboards are available to supply redundant PFSSD loads.

Based on the above discussion, damage to cables and components associated with Train A vital 120 VAC distribution panels NN01 and NN03 will not adversely impact the ability to achieve and maintain safe shutdown in the event of a fire in area C-18.

References: XX-E-013, E-15000, E-11NK01, E-13NN01, E-1F9421

5.2.34 Non-Class 1E 120 VAC Electrical Distribution System

The PFSSD function of the non-Class 1E 120 VAC electrical distribution system is to supply 120 VAC power to Main Control Boards (MCBs) RL017/RL018 and RL021/RL022. The power is split at the MCB to supply specific PFSSD components.

The PFSSD components that depend on non-class 1E 120 VAC power from RL017/RL018 are Residual Heat Removal (RHR) discharge valves EJHCV0606 (Train A) and EJHCV0607 (Train B). Non-class 1E switchboard panel PN07 supplies power from switch PN0736 to valve positioner EJHY0606. Valve positioner EJHY0606 controls the position of EJHCV0606 using hand controller EJHIC0606. Non-class 1E switchboard panel PN08 supplies power from switch PN0833 to valve positioner EJHY0607. Valve positioner EJHY0607 controls the position of EJHCV0607 using hand controller EJHIC0607.

The PFSSD components that depend on non-class 1E 120 VAC power from RL021/RL022 are temperature recorders BBTR0423, BBTR0433 and BBTR0443. Non-class 1E switchboard panel PN07 supplies power from switch PN0738 to temperature recorder BBTR0423. Non-class 1E switchboard panel PN08 supplies power from switch PN0835 to temperature recorders BBTR0433 and BBTR0443.

Cables 11PNG01AD and 11PNG01AE supply 480 VAC power from NG01BEF4 to 480/120V transformer XPN07A. Damage to either of these cables due to a fire in area C-18 will result in a loss of power to the transformer and loss of 120 VAC feed to PN07 from this power source.

Cable 15PNY01AR provides an alternate power feed to switchboard PN07 from PG19GFR3. Damage to this cable will result in a loss of the alternate power feed to PN07. The primary source of power to PN07 from transformer XPN07A could also be affected due to the loss of NG01, as discussed in Section 5.2.32. Therefore, PN07 may not be available if a fire occurs in this area.

Switchboard PN08 is unaffected by a fire in this area. Therefore, power to PFSSD loads supplied by PN08 is available. Loss of PN07 will have no adverse impact on PFSSD due to the availability of PN08.

References: XX-E-013, E-15000, E-13PN01, E-13PN01A, E-13RL04, E-13RL06, E-1F9201, E-1F9205, E-1F9421, E-1F9424E

5.2.35 Control Room Emergency Lights

Emergency lighting is provided in the control room to ensure adequate lighting during a station blackout and in the event a fire damages cables associated with the normal and standby lighting system. Emergency lights are supplied power from Class 1E 125 VDC breaker NK5120.

The control room has four sources of lighting; 1) Normal (QA); 2) Standby (QB); 3) Emergency (QD); and 4) Self-contained battery units. The normal lighting system is not evaluated in the PFSSD analysis and is assumed lost.

The control building standby lighting system is powered by the Train A 480 VAC Class 1E electrical system through breakers NG01AHF1 and NG01AHF2. Power availability on NG01AHF1 and NG01AHF2 is monitored by auxiliary relays 27XQB1 and 27XQB2 in panel RP330. Upon loss of power to both NG01AHF1 and NG01AHF2, the relay coils are de-energized and the normally open contacts close. This energizes the contactor control relay which closes a contact and energizes the control room emergency lighting panel NK051A, which automatically illuminates the 125 VDC (QD System) emergency lights in the control room.

Cable 11QBY03CA is a control cable that runs from NK051 to RP330 and provides control power to energize the contactor control relay to illuminate control room emergency lights upon loss of Class 1E power. A short in this cable due to a fire will illuminate emergency lights in the control room even though Class 1E power is available. This will have no impact on PFSSD.

An open in cable 11QBY03CA will prevent the control room emergency lights from illuminating upon loss of Class 1E power. Based on Calculation XX-E-013, Appendix 2, a fire in area C-18 can result in the loss of Train A off-site power and Train A emergency diesel generator. Therefore, the possibility exists for a fire in area C-18 to result in a loss of normal, standby and emergency lighting in the control room.

Cable 11QDK01AA is a 125 VDC power cable that runs from NK051A to the control room emergency lights. Damage to this cable will prevent operation of the emergency lights.

Self-contained Appendix R battery units are provided in the control room to provide minimum lighting for post-fire safe shutdown. Three units are provided in the front panel area, each with two light heads, to provide illumination on the main control boards. Two additional units are provided in the corridor area and two units are provided in the back panel area, each with two light heads. The Appendix R battery units are capable of providing minimum illumination for 8 hours, during which time action can be taken by maintenance to restore the normal or standby lighting system.

Based on the above discussion, sufficient lighting exists in the control room to achieve and maintain PFSSD.

References: E-15000, XX-E-013, E-093-00064, E-11NK01, E-13QB03, E-13QD01, E-1L3604, E-1L8900, E-1F9422A

5.2.36 Class 1E 125 VDC Power to Main Control Boards

Several cables that supply Class 1E 125 VDC power to the main control boards are run in area C-18. The cables run from the power supply to the control panel where the power is split to supply specific loads. The cables, power supply, control panel and affected PFSSD components are summarized in the following table.

CABLE	POWER SUPPLY	CONTROL PANEL	PFSSD EQUIPMENT	POSITION ON LOSS OF POWER	REQUIRED PFSSD POSITION
11RLK01AA	NK4119	RL001/002	BGHV8153A BGHV8154A	Closed Closed	Closed Closed
11RLK01CA	NK4112	RL017/018	EMHV8964	Closed	Closed
11RLK01DA	NK4113	RL019/020	EGTV0029 GMHZ0009	Closed Open	Closed Open
11RLK01EA	NK5109	RL021/022	BBHV8001A BBHV8002A	Closed Closed	Closed Closed

Based on the above table, the PFSSD equipment fails to the desired position upon loss of power. Therefore, damage to the cables will not adversely impact PFSSD.

References: E-15000, XX-E-013, E-13BB30, E-13BG48, E-13EG16, E-13EM12, E-13GM04, E-13RL01, E-13RL02, E-13RL03, E-13RL04, E-13RL05, E-13RL06, E-1F9301, E-1F9302, E-1F9401A, E-1F9422A, E-1F9444, M-12BB04, M-12BG01, M-12EG02, M-12EM01, M-12GM01

5.2.37 Steam Generator Blowdown to Blowdown Flash Tank Isolation Valves

Blowdown valves BMHV0001, BMHV0002, BMHV0003 and BMHV0004 are required to be closed for PFSSD. The valves are air operated and each valve is controlled by three solenoid valves. All three solenoid valves are required to be energized to open the valve. If any one solenoid is de-energized, the associated valve will close or remain closed. Only two of the three solenoids for each valve are considered in the PFSSD analysis, so the third solenoid is assumed energized throughout the event.

Cable 11RPK09CA supplies 125 VDC to relay panel RP209 from NK5113 and energizes Train A control circuit relays 3XBM13, 3XMB14, 3XBM15 and 3XBM16 associated with all four blowdown isolation valves. Damage to this cable could prevent closing the blowdown valves from BM157 in the Radwaste control room but will not affect the ability to close the valves from the main control room. Therefore, the blowdown valves can be closed using BMHIS0001A, BMHIS0002A, BMHIS003A and BMHIS0004A on main control board RL024.

Cable 15BMK16AA is the 125 VDC power feed to BM157. Cables 15BMK06AB, 15BMK06BB, 15BMK06CB and 15BMK06DB are associated with the BM157 panel mounted handswitches for each of the BMHV valves. Damage to these cables could impact the ability to close the valves from BM157 in the Radwaste Control Room. However, as stated in the previous paragraph, the normal means of closing these valves using the RL024 mounted handswitches

in the main control room remains available. Therefore, a fire in area C-18 will not prevent the closure of valves BMHV0001, BMHV0002, BMHV0003, and BMHV0004.

Cable 15RPK09EA supplies non-class 1E 125 VDC power to panel RP211 from PK5129. Loss of power to the relay panel will result in loss of power to relay 3XBM46. The function of this relay is to close valves BMHV0001, BMHV0002, BMHV0003, and BMHV0004 if a blowdown and sample process isolation signal is received. Under normal conditions the relay is de-energized, the auxiliary contacts are closed, and valves BMHV0001, BMHV0002, BMHV0003, and BMHV0004 are open. Damage to cable 15RPK09EA could result in the relay remaining de-energized which would prevent a blowdown and sample process isolation signal from closing the valves. The capability to close the blowdown valves using BMHIS0001A, BMHIS0002A, BMHIS003A and BMHIS0004A in the main control room is unaffected.

Based on the above discussion, isolation of the Steam Generator Blowdown valves is achievable if a fire occurs in area C-18.

References: E-15000, XX-E-013, E-093-00048, E-13BM04, E-13BM06A, E-13BM06B, E-13BM06C, E-13BM06D, E-13BM16, E-13RP09, E-1F9101, E-1F9422A, E-1F9422C, M-12BM01

5.2.38 BOP Instrument Racks

BOP instrument racks RP053A, RP053B, RP053D and RP147 are credited in the PFSSD analysis. The following table identifies the PFSSD components served by each instrument rack.

Instrument Rack	PFSSD Components
RP053A (RP053AA, RP053AB, RP053AC)	ALHV0009 ALHV0011 ALPY037A EGFT0128 EGPSL0077 GDTSL0001 JELSL0001C
RP053B (RP053BA, RP053BB, RP053BC)	ALHV0007 ALPY0039A EGFT0129 EGPSL0078 GDTSL0011 JELSL0021C
RP053D (RP053DA, RP053DB)	ALPY0038A
RP147 (RP147A, RP147B)	ALHV0005

Cables 11RPY09CA and 11RPY09DA supply 120 VAC power to Train A BOP instrument rack RP053A. Damage to these cables could cause a loss of function of panel RP053A and associated PFSSD components.

Instrument racks RP053B, RP053D and RP147B are unaffected by the fire. Therefore, loss of PFSSD components associated with RP053A will not adversely impact PFSSD.

5.2.39 Reactor Protection System

The Reactor Protection System (RPS) monitors specified input parameters and initiates reactor protection features whenever those parameters are outside specified limits. Field installed transmitters continuously monitor various parameters and report the results to one of four process cabinets, one per channel. Signals are then sent from the process cabinets to both solid state protection cabinets, one on each train. The cabinets and associated channel are listed in the following table.

Process Cabinets	Solid State Protection Cabinets
Cabinet SB038 - Channel 1 Cabinet SB042 - Channel 2 Cabinet SB037 - Channel 3 Cabinet SB041 - Channel 4	Cabinet SB029A - Train A Input Cabinet Cabinet SB029B - Train A Logic Cabinet Cabinet SB029C - Train A Output Cabinet 1 Cabinet SB029D - Train A Output Cabinet 2 Cabinet SB032A - Train B Input Cabinet Cabinet SB032B - Train B Logic Cabinet Cabinet SB032C - Train B Output Cabinet 1 Cabinet SB032D - Train B Output Cabinet 2

The RPS is actuated upon 2/3 or 2/4 coincident logic, depending on the input parameter. This ensures that a loss of a single channel will not prevent the system from performing its function. Loss of power to a single cabinet will render the channel or Train inoperative.

Cables associated with RPS channel 1 run through this area. These cables supply power from separation group 1 power supplies to panels SB029A, SB029D, SB032A and SB038. Power cables associated with RPS channels 2, 3 and 4 are run in a separate fire area.

Cable 11SBS12AC is a control cable associated with reactor trip switchgear cabinet SB102A. Damage to this cable could cause a reactor trip or could prevent a trip on Train A. Cables associated with Train B reactor trip switchgear cabinet SB102B are unaffected by a fire in this area.

References: XX-E-013, E-15000, E-11NK01, E-11NK02, E-13NN01, E-13SB01, E-13SB02, E-13SB05, E-13SB09, E-13SB10, E-13SB12A, E-1F9101, E-1F9102, E-1F9431, E-1F9432, E-1F9433

5.2.40 Source Range Monitoring

PFSSD requires source range (SR) flux monitoring to be available. Source range monitoring is provided by source range monitors SENE0031, SENE0032, SENY0060A & B, and SENY0061A & B.

Cable 11SES01AA is a power cable associated with panel SE054A, which is associated with SR monitor SENE0031. Cable 11SES07BA is a power cable associated with SR monitor SENY0060B. Cable 11SES07BB is an instrument cable associated with SENY0060B. Cable 11SES07CA is a power cable associated with SR monitor amplifier SENY0060A. Damage to these cables could prevent operation of the associated source range monitor. Source Range monitoring remains available for a fire in area C-18 using SENE0032 and SENY0061A/B.

For a more detailed evaluation on Source Range monitoring, see Calculation XX-E-013.

References: E-15000, XX-E-013, E-13NN01, E-13SE01, E-13SE05, E-13SE07, E-1F9101, E-1F9421

5.2.41 Letdown Isolation Valves

Valves BGLCV0459 and BGLCV0460 are isolation valves installed in series on the inlet side of the regenerative heat exchanger. PFSSD requires that either of these valves be closed.

Cables 15BGK10AA and 15BGK10AD are power/control cables for the BGLCV0459 solenoid valve (BGHY0459). Air supplied by an open (energized) solenoid valve will open valve BGLCV0459. A closed (de-energized) solenoid valve will cause loss of air pressure and closure of valve BGLCV0459.

Cables 15BGK10BA and 15BGK10BD are power/control cables for the BGLCV0460 solenoid valve (BGHY0460). Air supplied by an open (energized) solenoid valve will open valve BGLCV0460. A closed (de-energized) solenoid valve will cause loss of air pressure and closure of valve BGLCV0460.

Either BGLCV0459 or BGLCV0460 must be closed or letdown orifice isolation valves BGHV8149A, BGHV8149B, and BGHV8149C must be closed. The cables for BGLCV0459 or BGLCV0460 are run in a common enclosure in cable trays. A hot short on the cables could cause the valves to open. A hot short on cables 15BGK10AA and 15BGK10BA prevents closing BGLCV0459 and BGLCV0460 from the control room. Other cables run in the cable trays have the proper voltage for hot shorts which can bypass MCB handswitches for BGLCV0459 and BGLCV0460. BGLCV0459 and BGLCV0460 constitute a high/low pressure interface. Therefore, multiple simultaneous hot shorts must be considered.

Letdown orifice isolation valves BGHV8149A, BGHV8149B, and BGHV8149C are listed as PFSSD components because of the interlock between these valves and BGLCV0459 and BGLCV0460. The interlock prevents closure of the letdown valves when any one or more orifice isolation valves are open. Cables associated with all three letdown orifice isolation valves are located in this fire area. Damage to these cables could prevent closure of the valves from the control room. Therefore, a fire in area C-18 could prevent closure of all three letdown orifice isolation valves (BGHV8149A, BGHV8149B, and BGHV8149C) as well as the two letdown isolation valves (BGLCV0459 and BGLCV0460) using their respective hand switches in the control room.

Valves BGLCV0459, BGLCV0460, BGHV8149A, BGHV8149B, and BGHV8149C are air operated and fail in the closed position. The valves are located in containment. Instrument air to containment is controlled by valve KAFV0029, which is unaffected by a fire in area C-18. Hand switch KAHIS0029 can be used to close the valve from the control room and isolate instrument air to containment. Pressurizer level indication is available using BBLI0459A and BBLI0460A.

Based on the above discussion, letdown valves BGLCV0459 and BGLCV0460 and letdown orifice valves BGHV8149A, BGHV8149B, and BGHV8149C can be closed from the control room if a fire occurs in area C-18.

References: E-15000, XX-E-013, E-13BG10, E-13BG35, E-13KA02, E-1F9301, M-12BG01, M-12KA01

5.2.42 Standby Diesel Generation

Cable 11KJK01AA is associated with the Train A Diesel Engine start/stop circuit. Cables 11NEB10AA and 11NEB10AD are associated with Train A diesel generator to NB01 feeder breaker NB0111. Cable 11NEK12AA is associated with Train A Diesel Generator Exciter Control. Cable 11JEG01AD is associated with the Train A fuel oil transfer pump. Damage to these cables could prevent operation and line up of the Train A diesel generator to the NB01 bus.

Calculation XX-E-013 documents a loss of off-site power evaluation that identifies the fire areas in and around the plant in which a fire could cause a loss of off-site and on-site power. Per XX-E-013 and Section 5.2.31 of this evaluation, a fire in area C-18 could cause a loss of off-site power on Train A. Train B off-site power and Train B diesel generator are unaffected by a fire in this area. Therefore, loss of the Train A diesel generator and off-site power to Train A will have no adverse impact on PFSSD.

References: XX-E-013, E-15000, E-13JE01, E-13KJ01, E-13KJ01A, E-13NE10, E-13NE12, E-1F9411A, E-1F9411B, E-1F9412A, E-1F9412B

5.2.43 Reactor Coolant Pumps

The reactor coolant pumps are not credited in the PFSSD analysis. However, the capability to stop the pumps from the control room in the event of a loss of all seal cooling is credited. Westinghouse Technical Bulletin TB-04-22, Rev. 1 recommends that if all seal cooling is lost (RCP seal injection and thermal barrier heat exchanger flow), operators need to stop the pumps before a seal LOCA occurs.

One control cable associated with reactor coolant pumps A and B is run in fire area C-18. Damage to these cables in the event of a fire could prevent operators from stopping the A and B RCPs from the control room. However, a fire in C-18 will not cause a loss of all seal cooling since RCP seal injection remains available.

Based on the above discussion, the inability to trip the A and B RCPs from the control room will have no adverse impact on PFSSD. The pumps can continue to operate, providing forced flow circulation. If the pumps spuriously stop, natural circulation cooldown can be used.

References: E-15000, XX-E-013, E-13BB01, Westinghouse TB-04-22 Rev. 1

5.2.44 Normal Pressurizer Spray

The normal pressurizer spray valves are included in the PFSSD design because spurious operation of pressurizer sprays can cause a decrease in pressure which can lead to boiling in the core. The pressurizer spray valves are part of the pressurizer pressure control system.

The pressurizer normal spray valves (BBPCV0455B and BBPCV0455C) operate off a signal from the Ovation pressurizer pressure control system. The operation of the pressure control system is discussed in Calculation XX-E-013.

Cable 11BBI16KB associated with BBPT0455 is run in this area. Damage to this cable could cause a spurious high-pressure signal. As discussed in Calculation XX-E-013, Appendix 1, damage to a single pressure input channel will not cause the spurious operation of the pressurizer spray valves due to the Ovation 4-channel validation logic, which uses the 2nd highest signal as the validated signal and has built-in logic to detect and ignore a failed input.

Cable 15BBI19AA associated with pressurizer spray valve BBPCV0455B, and cable 15BBI19BA associated with pressurizer spray valve BBPCV0455C are run in this area. Damage to these cables could cause the spurious opening of the spray valves.

The pressurizer spray valves are electro/pneumatic operated and loss of air pressure will close the valves. The air supply comes from the compressed air system. Closing valve KAFV0029 using KAHIS0029 on RL024 will isolate compressed air to containment which will cause the pressurizer spray valves to close or prevent them from opening. Based on WCNOC-CP-002, spray flow needs to be stopped within 50 minutes. Since this is a control room action, this can be completed well within 50 minutes.

Based on the above discussion, the pressurizer spray valves could spuriously open if a fire occurs in this area. Pressurizer spray can be stopped by closing valve KAFV0029 from the main control room. Pressurizer pressure indication is available using BBPI0456, BBPI0457 and BBPI0458.

References: E-15000, XX-E-013, E-13BB19, E-13KA02, M-744-00028, DCP 13324

5.2.45 Steam Generator Feedwater Pumps

Main feedwater pump steam supply valves FCFV0005 and FCFV0105 are credited in the PFSSD analysis to trip the main feedwater pumps if the main steam isolation valves (MSIVs) are affected by a fire. Closing the MSIVs stops steam flow to the feedwater pumps' turbines and stops the feedwater pumps. The steam generator feedwater pumps are tripped in the event of a fire to prevent overfilling the steam generators.

Non-Class 1E 120 VAC Inverter PN09 and distribution panel PN09A provide power to FCFV0005 trip relays in panel FC169C. Cable 15FCY35AA provides the primary source of 120 VAC power from distribution panel PN09A to panel FC169A, which distributes power to the trip relays in panel FC169C. The alternate source of power to panel FC169A is not credited for PFSSD and is assumed lost.

A fire in area C-18 could damage cable 15FCY35AA. If this occurs, operators in the control room would not be able to close valve FCFV0005 to stop steam flow to steam generator feedwater pump PAE01A.

A fire in area C-18 will not affect the ability to close the MSIVs from the control room. All-close hand switch ABHS0079 is unaffected and can be used to close the MSIVs from the control room.

Based on the above discussion, valve FCFV0005 may not close if a fire occurs in this area. However, the MSIVs can be closed using hand switch ABHS0079 in the main control room. Therefore, the configuration is acceptable.

References: E-15000, XX-E-013, E-13FC35, E-1F9103, E-1F9421

5.2.46 Load Center Feeder Breakers PA0105 and PA0106 and Load Center PG19 Incoming Feeder Breaker PG1901

Load center feeder breakers PA0105 and PA0106 are credited for PFSSD because they supply power to credited non-safety related loads. Cables 15PGA10AA, associated with PA0105, and 15PGA10BA and 15PGA10BB associated with PA0106, run in this area. Cables 15PGG13DA and 15PGG13DC associated with PG1901 are also run in this area. A fire induced short circuit in these cables will trip the associated breaker.

Load center feeder breaker PA0105 is credited for PFSSD because it supplies power to credited non-safety related loads. Cable 15PGA10AA is a control cable associated with breaker PA0105. An intra-cable hot short in this cable will trip the breaker. Breaker PA0105 supplies power to the following PFSSD components:

- PG11JFR2 – Main Steam Supply to 2nd Stage Reheat Valve ABHV0031
- PG11KBR3 – Auxiliary Steam System Control Valve FBHV0081

PG11JFR2 and PG11KBR3 supply power to components downstream of the MSIVs. The MSIVs are unaffected by a fire in this area and can be closed from the control room using hand switch ABHS0079. Therefore, the MSIV downstream components are not required if a fire occurs in this area.

Based on the above discussion, loss of breaker PA0105 will not adversely affect PFSSD if a fire occurs in this area.

Breakers PA0106 and PG1901 supply power to the following PFSSD components:

- PG19GCR217 – MCB Misc. Power Circuits RL023
- PG19GFR3 – Instr. Bus Transformer Alt. Feed XPN07D

PFSSD components supplied power from PG19GCR217 are associated with MSIV downstream components. The MSIVs are unaffected by a fire in this area and can be closed from the control room. Therefore, the MSIV downstream components are not required if a fire occurs in this area.

PG19GFR3 is credited as the backup source of power to PN07. The primary source of power to PN07 is from NG01BEF4. As discussed in Section 5.2.32 the primary source of power to PN07 could also be affected. However, as discussed in Section 5.2.34, switchboard PN08 is available to supply power to redundant PFSSD loads.

Based on the above discussion, loss of breakers PA0105, PA0106 or PG1901 will not adversely affect PFSSD if a fire occurs in this area.

1.0 GENERAL AREA DESCRIPTION

Fire area C-19 is located on the 2016 elevation of the Control Building and includes the room listed in Table C-19-1.

Table C-19-1
Rooms Located in Fire Area C-19

ROOM #	DESCRIPTION
C19	North Small Elec Chase 2016 Elevation

Fire area C-19 is protected with an automatic fire suppression and detection system. The area is bounded on all sides by minimum 3-hour fire resistance rated construction.

2.0 PRIMARY EQUIPMENT USED FOR PFSSD

Table C-19-2 lists each system credited for post-fire safe shutdown and provides a discussion regarding the availability of the system to perform its Post Fire Safe Shutdown (PFSSD) function if a severe fire occurs in this area. For a summary of the area analysis results, see Section 8.0 of the Fire Area Analysis Narrative section.

Table C-19-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-19

System	System Name	PFSSD Function*	Comments
AB	Main Steam	R, M, H, P, S	Power to steam generator ARV ABPV0003 controller could be lost. This will fail the valve in the closed position and prevent opening from the control room. The remaining steam generator ARVs are unaffected.
AC	Main Turbine	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-19.
AE	Main Feedwater	H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-19.
AL	Aux. Feedwater System	H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-19.
AP	Condensate Storage System	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-19.
BB	Reactor Coolant System	R, M, H, P, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-19.
BG	Chemical and Volume Control System	R, M, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-19.
BM	Steam Generator Blowdown System	R, M, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-19.
BN	Borated Refueling Water Storage System	R, M, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-19.
EF	Essential Service Water System	H, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-19.
EG	Component Cooling Water System	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-19.
EJ	Residual Heat Removal System	M, H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-19.
EM	High Pressure Coolant Injection	R, M	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-19.
EN	Containment Spray	R, M	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-19.

Table C-19-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-19

System	System Name	PFSSD Function*	Comments
EP	Safety Injection Accumulators	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-19.
FB	Auxiliary Steam	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-19.
FC	Auxiliary Turbines	R, H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-19.
GD	ESW Pump House HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-19.
GF	AFW Pump Room Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-19.
GK	Control Room and Class 1E Switchgear Room Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-19.
GL	Auxiliary Building HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-19.
GM	Emergency Diesel Generator Room HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-19.
GN	Containment Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-19.
JE	Diesel Fuel Oil	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-19.
KA	Instrument Air	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-19.
KC	Fire Protection	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-19.
KH	Service Gas	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-19.
KJ	Standby Diesel Engine	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-19.
MA	Main Generation	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-19.
MR	Startup Transformer	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-19.

Table C-19-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-19

System	System Name	PFSSD Function*	Comments
NB	4.16 kV System	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-19.
NE	Standby Diesel Generator	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-19.
NF	Load Shed and Emergency Load Sequencing	S	All PFSSD functions associated with load shed/emergency load sequencing system are satisfied. Separation group 3 power supply cables for load shedder/sequencer logic and input cabinets NF039A and NF039B could be affected. Redundant AC power is available from separation groups 1, 2 and 4 power supplies.
NG	480V Load Centers and MCCs	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-19.
NK	125VDC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-19.
NN	120VAC	S	One of two sources of 125 VDC power to swing inverter NN15 could be affected. The remaining source is unaffected. Swing inverter NN15 may not be able to supply power to bus NN03. Inverter NN13 is unaffected and can supply 120 VAC power to NN03.
PA	13.8kV	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-19.
PB	4.16kV	H, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-19.
PG	480V Load Centers and MCCs	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-19.
PK	125VDC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-19.
PL	Local Instrument Panels	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-19.
PN	120VAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-19.
QB	Standby AC Lighting	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-19.
QD	Emergency Lighting	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-19.

Table C-19-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-19

System	System Name	PFSSD Function*	Comments
RL	Control Room MCB	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-19.
RP	Miscellaneous Control Panels	R, M, H, P, S	Power to panel RP053DB could be affected, which will prevent opening steam generator ARV ABPV0003. The remaining RP panels are unaffected.
SA	ESFAS	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-19.
SB	Reactor Protection System	R, S	RPS Channel 3 could be affected. RPS Channels 1, 2 and 4 are unaffected.
SC	Reactor Instrumentation	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-19.
SE	Ex-Core Neutron Monitoring	R, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-19.
SY	Switchyard	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-19.

3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD

This section describes operator actions that may need to be performed inside or outside the control room to achieve and maintain hot standby if a fire occurs in area C-19. This section also describes cold shutdown repairs that may need to be made to achieve and maintain cold shutdown conditions. Operator actions are proceduralized in OFN KC-016.

3.1 ACTIONS OUTSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

None

3.2 ACTIONS INSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

None

3.3 ACTIONS TO ACHIEVE AND MAINTAIN COLD SHUTDOWN

None

4.0 CONCLUSION

Redundant post-fire safe shutdown capability is unaffected by a fire in area C-19.

5.0 DETAILED ANALYSIS

This section describes the detailed component-by-component and cable-by-cable analysis for a fire in area C-19.

5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA C-19

There are no PFSSD components located in fire area C-19. This fire area only contains cables associated with PFSSD equipment located in other areas.

5.2 PFSSD CABLE EVALUATION

Table C-19-3 lists all the PFSSD cables (S. in E-15000) located in fire area C-19. The applicable evaluation section is also listed in Table C-19-3.

Table C-19-3
PFSSD Cables Located in Fire Area C-19

Cable #	Location	Primary PFSSD Equipment	Cable Function (P) Power (C) Control (I) Instrumentation	Evaluation Section	Comments
13NFK01CA	C19	127-3/DG	C	5.2.1	NB01 Undervoltage Relay
13NFK01DA	C19	127-3/DG	C	5.2.1	NB02 Undervoltage Relay
13NFY01EA	C19	127-3/DG PTNB117/B	P	5.2.1	NB01 UV Relay and Degraded Voltage Potential Transformer

5.2.1 Load Shedder / Emergency Load Sequencer

The load shedder and emergency load sequencers are included in the PFSSD design to evaluate the impact of spurious operation or mal-operation. The load shedder/emergency load sequencer operates upon presence of the following conditions:

1. An undervoltage (UV) on a safeguards bus,
2. A safety injection signal (SIS) or a containment spray actuation signal (CSAS), or
3. An undervoltage on a safeguards bus with a SIS or CSAS.

Eight inputs (four undervoltage (UV) inputs and four degraded voltage inputs) on each safeguards bus (NB01 and NB02) monitor voltage conditions on that bus. An undervoltage condition on two of four UV relays on each bus will actuate the load shedder/sequencer and send a signal to start the associated diesel generator. In addition, degraded voltage sensed by two of four degraded voltage potential transformers (PTs) will, after a time delay, provide a signal to open the offsite feeder breakers on the associated bus.

The outputs from each safeguards bus (NB01 and NB02) are divided into 4 separation groups; 1, 2, 3 and 4 and routed to two control panels, NF039A and NF039B. The input section of each control panel also receives group 1, 2, 3 and 4 instrument power (120VAC). The inputs then pass through isolation devices, at which point all inputs to NF039A become separation group 1 and all inputs to NF039B become separation group 4. Interruption of either the inputs or the instrument power from one separation group would impact the associated input channel, but would not impact the other 3 input channels.

Cables 13NFK01CA and 13NFK01DA are associated with separation group 3 UV relays on buses NB01 and NB02, respectively. Cables 13NFY01GA and 13NFY01HA are associated with separation group 3 degraded voltage PTs on buses NB01 and NB02, respectively. Cables associated with the remaining three UV relays and PTs from separation groups 1, 2 and 4 do not run in fire area C-19.

Separation group 3 120VAC instrument power supply cables 13NFY01EA and 13NFY01FA for load shedder/sequencer logic and input cabinets NF039A and NF039B, respectively, run in fire area C-19. Damage to these cables could cause a loss of separation group 3 120 VAC instrument power to the group 3 input panels, and therefore loss of input channel 3. Channels 1, 2 and 4 instrument AC power remains available from separation groups 1, 2 and 4 power supplies.

Based on the above discussion, the Train A and Train B load shed/sequencers are available if a fire occurs in this area. Off-site power to both trains is unaffected based on Calculation XX-E-013, Appendix 2.

5.2.2 Steam Generator Atmospheric Relief Valves

PFSSD requires at least two steam generator atmospheric relief valves (ARV) be controlled and the other two closed. The ARVs are pneumatically operated using air from the compressed air system (KA) or nitrogen from the nitrogen accumulators. The valves open by pneumatic pressure and close by spring action. A pressure transmitter installed on the outlet side of the steam generator sends a signal to a controller and automatically controls the associated ARV position. Alternatively, each ARV can be controlled manually from the control room or the auxiliary shutdown panel by placing the pressure indicating controller (PIC) in manual.

Cable 13RPY09AA supplies 120 VAC power to Train A BOP instrument rack RP053DB. The only PFSSD components controlled by RP053DB are ABPIC0003A, ABPIC0003B, ABHS0003,

ABPT0003 and ABPY0003. These components are associated with steam generator C ARV ABPV0003. Loss of power to these components due to damage to cable 13RPY09AA will cause ABPV0003 to fail closed, which is the desired PFSSD position for a fire in this area.

Calculation WCNOC-CP-002 demonstrates that sufficient heat removal capability exists using three steam generator ARVs. Therefore, failure of the fourth ARV to open will have no adverse impact on PFSSD.

Based on the above discussion, damage to the cable associated with ARV ABPV0003 in this area will not adversely impact PFSSD.

5.2.3 Reactor Protection System

The Reactor Protection System (RPS) monitors specified input parameters and initiates reactor protection features whenever those parameters are outside specified limits. Field installed transmitters continuously monitor various parameters and report the results to one of four process cabinets, one per channel. Signals are then sent from the process cabinets to both solid state protection cabinets, one on each train. The cabinets and associated channel are listed in the following table.

Process Cabinets	Solid State Protection Cabinets
Cabinet SB038 - Channel 1 Cabinet SB042 - Channel 2 Cabinet SB037 - Channel 3 Cabinet SB041 - Channel 4	Cabinet SB029A - Train A Input Cabinet Cabinet SB029B - Train A Logic Cabinet Cabinet SB029C - Train A Output Cabinet 1 Cabinet SB029D - Train A Output Cabinet 2 Cabinet SB032A - Train B Input Cabinet Cabinet SB032B - Train B Logic Cabinet Cabinet SB032C - Train B Output Cabinet 1 Cabinet SB032D - Train B Output Cabinet 2

The RPS is actuated upon 2/3 or 2/4 coincident logic, depending on the input parameter. This ensures that a loss of a single channel will not prevent the system from performing it's function.

Cables associated with reactor protection system channel 3 run through this area. These cables supply power from separation group 3 power supplies to panels SB029A, SB032A and SB037. Damage to these cables could cause a loss of RPS channel 3, but channels 1, 2 and 4 remain available. Therefore, the RPS is available if a fire occurs in this area.

5.2.4 Class 1E 120 VAC Electrical Distribution System

The Class 1E 120 VAC electrical distribution system provides power to vital instrumentation and control loads for shutdown and normal operation. Under normal conditions, the system is supplied by inverters connected to the 125 VDC NK battery system. Swing inverters allow the primary inverters to be taken out of service for maintainance or repair without disrupting power to the associated vital AC bus. In the event of a loss of power to the inverters, a backup source of power is automatically lined up. The backup power source originates from the 480 VAC electrical distribution system (NG).

Cables 13NNK01KA and 13NNK01KB supply 125 VDC power from NK0303 to manual transfer switch NK79. Damage to these cables will disrupt the 125 VDC power supply from NK0303 to swing inverter NN15. 125 VDC power from NK0103 to swing inverter NN15 is unaffected.

Cables 13NNY01FA and 13NNY01FB supply 120 VAC power from swing inverter NN15 to bus NN03 through a manual transfer switch in inverter NN13. Damage to these cables will disrupt the 120 VAC power supply from swing inverter NN15 to NN03.

Inverters NN11 and NN13 and 120 VAC vital distribution buses NN01 and NN03 are located in a separate fire area and are unaffected by a fire in area C-19. The 125 VDC and 480 VAC power supply to inverters NN11 and NN13 are unaffected by a fire in area C-19.

Based on the above discussion, the Train A and Train B vital 120 VAC electrical distribution system is unaffected by a fire in this area.

1.0 GENERAL AREA DESCRIPTION

Fire area C-20 is located on the 2016 elevation of the Control Building and includes the room listed in Table C-20-1.

Table C-20-1
Rooms Located in Fire Area C-20

ROOM #	DESCRIPTION
C20	South Small Elec Chase 2016 Elevation

Fire area C-20 is protected with an automatic fire suppression and detection system. The area is bounded on all sides by minimum 3-hour fire rated construction.

2.0 PRIMARY EQUIPMENT USED FOR PFSSD

Table C-20-2 lists each system credited for post-fire safe shutdown and provides a discussion regarding the availability of the system to perform its Post Fire Safe Shutdown (PFSSD) function if a severe fire occurs in this area. For a summary of the area analysis results, see Section 8.0 of the Fire Area Analysis Narrative section.

Table C-20-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-20

System	System Name	PFSSD Function*	Comments
AB	Main Steam	R, M, H, P, S	It may be necessary to isolate SG B ARV using local control station ABFHC0002. Steam generators A, C and D ARVs are unaffected. Valves ABHV0005 and ABHV0006 could be affected, preventing operation of the turbine driven auxiliary feedwater pump. Both motor driven auxiliary feedwater pumps are available.
AC	Main Turbine	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-20.
AE	Main Feedwater	H, P	Steam generator B wide range water level transmitter AELT0502 may be affected. Remaining steam generator level transmitters are unaffected.
AL	Aux. Feedwater System	H, P	All PFSSD functions associated with the auxiliary feedwater system are satisfied. The turbine driven auxiliary feedwater pump (TDAFP) may not be available. The motor driven auxiliary feedwater pumps are unaffected.
AP	Condensate Storage System	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-20.
BB	Reactor Coolant System	R, M, H, P, S	Pressurizer level transmitter BBLT0460 may be affected. Redundant pressurizer level transmitter BBLT0459 is unaffected. RCS Temperature elements BBTE0423B and BBTE0443A, as well as associated temperature indicators, could be affected by a fire in this area. The remaining temperature elements/indicators are unaffected.
BG	Chemical and Volume Control System	R, M, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-20.
BM	Steam Generator Blowdown System	R, M, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-20.
BN	Borated Refueling Water Storage System	R, M, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-20.
EF	Essential Service Water System	H, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-20.
EG	Component Cooling Water System	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-20.

Table C-20-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-20

System	System Name	PFSSD Function*	Comments
EJ	Residual Heat Removal System	M, H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-20.
EM	High Pressure Coolant Injection	R, M	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-20.
EN	Containment Spray	R, M	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-20.
EP	Safety Injection Accumulators	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-20.
FB	Auxiliary Steam	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-20.
FC	Auxiliary Turbines	R, H, P	The TDAFP speed control valve FCFV0313 and trip and throttle valve FCHV0312 could be affected. The motor driven auxiliary feedwater pumps are available.
GD	ESW Pump House HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-20.
GF	AFW Pump Room Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-20.
GK	Control Room and Class 1E Switchgear Room Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-20.
GL	Auxiliary Building HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-20.
GM	Emergency Diesel Generator Room HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-20.
GN	Containment Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-20.
JE	Diesel Fuel Oil	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-20.
KA	Instrument Air	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-20.
KC	Fire Protection	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-20.

Table C-20-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-20

System	System Name	PFSSD Function*	Comments
KH	Service Gas	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-20.
KJ	Standby Diesel Engine	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-20.
MA	Main Generation	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-20.
MR	Startup Transformer	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-20.
NB	4.16 kV System	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-20.
NE	Standby Diesel Generator	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-20.
NF	Load Shed and Emergency Load Sequencing	S	All PFSSD functions associated with load shed/emergency load sequencing system are satisfied. Separation group 2 power supply cables for load shedder/sequencer logic and input cabinets NF039A and NF039B could be affected. Redundant AC power is available from separation groups 1, 3 and 4 power supplies.
NG	480V Load Centers and MCCs	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-20.
NK	125VDC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-20.
NN	120VAC	S	One of two sources of 125 VDC power to swing inverter NN16 could be affected. The remaining source is unaffected. Swing inverter NN16 may not be able to supply power to bus NN02. Inverter NN12 is unaffected and can supply 120 VAC power to NN02.
PA	13.8kV	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-20.
PB	4.16kV	H, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-20.
PG	480V Load Centers and MCCs	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-20.
PK	125VDC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-20.
PL	Local Instrument Panels	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-20.

Table C-20-2 Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-20			
System	**System Name**	**PFSSD Function***	**Comments**
PN	120VAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-20.
QB	Standby AC Lighting	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-20.
QD	Emergency Lighting	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-20.
RL	Control Room MCB	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-20.
RP	Miscellaneous Control Panels	R, M, H, P, S	Power to lockout relays 86XRP1, 86XRP2 and 86XRP3 could be affected. This will not impact PFSSD.
SA	ESFAS	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-20.
SB	Reactor Protection System	R, S	RPS Channel 2 could be affected. RPS Channels 1, 3 and 4 are unaffected.
SC	Reactor Instrumentation	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-20.
SE	Ex-Core Neutron Monitoring	R, P	Source range monitor SENE0032B could be affected. Source range monitoring remains available using SENI0031B, SENI0060A/B and SENI0061A/B.
SY	Switchyard	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-20.
UU	Supervisory System	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-20.

3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD

This section describes operator actions that may need to be performed inside or outside the control room to achieve and maintain hot standby if a fire occurs in area C-20. This section also describes cold shutdown repairs that may need to be made to achieve and maintain cold shutdown conditions. Operator actions are proceduralized in OFN KC-016.

3.1 ACTIONS OUTSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

Operator Manual Actions (OMAs) are those actions outside the main control room required to achieve and maintain hot standby. OMAs are identified in E-1F9900 and were determined from thermal hydraulic analysis WCNOC-CP-002. Applicable E-1F9900 OMAs are annotated herein. All other actions outside the control room are desirable for plant control in support of hot standby but not required to achieve and maintain hot standby.

3.1.1 Steam Generator ARVs

If damage occurs to cables associated with ABPV0002, local control station ABFHC0002, located in room 1509, can be used to close ARV ABPV0002.

3.2 ACTIONS INSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

None

3.3 ACTIONS TO ACHIEVE AND MAINTAIN COLD SHUTDOWN

None

4.0 CONCLUSION

Redundant post-fire safe shutdown capability is unaffected by a fire in area C-20.

5.0 DETAILED ANALYSIS

This section describes the detailed component-by-component and cable-by-cable analysis for a fire in area C-20.

5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA C-20

There are no PFSSD components located in fire area C-20. This fire area only contains cables associated with PFSSD equipment located in other areas.

5.2 PFSSD CABLE EVALUATION

Table C-20-3 lists all the PFSSD cables (S. in E-15000) located in fire area C-20. The applicable evaluation section is also listed in Table C-20-3.

Table C-20-3

5.2.1 Auxiliary Feedwater and Steam Generator Atmospheric Relief Valves

The PFSSD design requires the use of one auxiliary feedwater pump (AFP) supplying water to at least two steam generators. Atmospheric relief valves on the two steam generators being fed need to be controlled and atmospheric relief valves on the remaining two steam generators need to be closed. The Train A motor driven auxiliary feedwater pump (MDAFP) is aligned to supply steam generators B and C. The Train B MDAFP is aligned to supply steam generators A and D. The turbine driven auxiliary feedwater pump (TDAFP) is normally aligned to supply all four steam generators.

The normal source of water to the AFPs is the condensate storage tank (CST). The emergency supply is from the essential service water (ESW) system. For commercial concerns, the CST is the preferred source and contains sufficient volume to supply the entire auxiliary feedwater (AFW) demand to achieve cold shutdown.

Cables associated with ABHV0005, ABHV0006, FCHV0312 and FCFV0313 are run in area C-20. Damage to these cables could either cause all four valves to spuriously open at the same time, causing uncontrolled blowdown through the TDAFP, or prevent operation of one or more valve, preventing operation of the TDAFP. Uncontrolled cooldown is mitigated by FCFV0313 tripping on high speed. The Train A and Train B MDAFPs are available to supply feedwater to all four steam generators.

A number of cables associated with steam generator B ARV ABPV0002 are run in this area. Damage to these cables could cause the ARV to spuriously open and could prevent control from the control room. If this occurs, operators may need to control or close ABPV0002 using local controller ABFHC0002 in room 1509.

Cable 12RLK01AA supplies power to RL005/RL006 from switch NK4206. The PFSSD components on RL005/RL006 supplied by NK4206 are ABHV0005 and ABHV0006. Loss of power will fail the valves open, which is desired for operation of the turbine driven auxiliary feedwater pump (TDAFP).

Cable 12RPY09AA supplies 120 VAC power from NN0208 to BOP instrument rack RP053DA. Damage to this cable will affect the following PFSSD components:

- ALPY0038A - ESFAS LOW SUCTION PRESSURE SIGNAL CONVERTER
- ALPT0038 - ESFAS LOW SUCTION PRESSURE TRANSMITTER
- ABPIC0002A - STM GEN B ATM STEAM DUMP PRESSURE CONTROLLER
- ABHS0002 - ABPV0002 HANDSWITCH
- ALPI0026A - TDAFW PUMP PAL02 SUCTION PRESSURE

Low suction pressure (LSP) on 2 out of 3 AFW pressure transmitters (ALPT0037, ALPT0038 and ALPT0039) coincident with an auxiliary feedwater actuation signal (AFAS) will swap the AFW supply to ESW. Loss of power to ALPT0038 and ALPY0038A will satisfy 1/3 LSP logic, placing the LSP signal logic in a 1 out of 2 configuration. Therefore, low suction pressure or loss of power on another pressure transmitter will provide the permissive to swap if an AFAS is present.

Loss of power to ABPIC0002A and ABHS0002 could prevent operation of steam generator B ARV ABPV0002 from the control room. If this occurs, operators may need to control or close ABPV0002 using local controller ABFHC0002 in room 1509.

Loss of power to ALPI0026A will provide false indication of TDAFP suction pressure. In addition, other cables (12ALI07KD, 12ALI07KE and 12ALI07KF) associated with pressure transmitter ALPT0026 are located in this area. Damage to these cables will prevent indication of TDAFP suction pressure. The transmitter does not initiate any automatic functions and the TDAFP is not credited for a fire in this area. Train A and Train B MDAFP suction pressure indicators are unaffected.

Cable 12RPY09BA supplies 120 VAC power to RP147A. The only PFSSD component controlled by RP147A is ABPV0002. Therefore, loss of power to RP147A could prevent operation of ABPV0002.

Panel SA036C monitors pressure transmitter signals on ALPT0038 and provides AFAS outputs. Power cables 12SAK21CA and 12SAY21CA associated with SA036C are run in this area. Damage to these cables could result in a loss of power to the panel but will not prevent automatic operation of low suction pressure (LSP) swapover since the remaining 2 channels are available. AFAS is not credited for PFSSD but is analyzed for potential adverse impacts.

Based on the above discussion, the TDAFP may be affected but both MDAFPs are available to provide feedwater to the steam generators. Steam generator B ARV ABPV0002 may need to be controlled or closed using local controller ABFHC0002. Uncontrolled blowdown through the TDAFP is mitigated by FCFV0312 automatically tripping on high speed.

Up to three ARVs can fail closed or open without impacting ability to achieve and maintain hot standby according to thermal hydraulic analysis WCNOC-CP-002. With at least one ARV unaffected, no E-1F9900 OMA is required to address ARV closure or control. Reference Attachment 4, MSO Evaluation Scenario ID PWROG 23.

5.2.2 Load Shedder / Emergency Load Sequencer

The load shedder and emergency load sequencers are included in the PFSSD design to evaluate the impact of spurious operation or mal-operation. The load shedder/emergency load sequencer operates upon presence of the following conditions:

1. An undervoltage (UV) on a safeguards bus,
2. A safety injection signal (SIS) or a containment spray actuation signal (CSAS), or
3. An undervoltage on a safeguards bus with a SIS or CSAS.

Eight inputs (four undervoltage (UV) inputs and four degraded voltage inputs) on each safeguards bus (NB01 and NB02) monitor voltage conditions on that bus. An undervoltage condition on two of four UV relays on each bus will actuate the load shedder/sequencer and send a signal to start the associated diesel generator. In addition, degraded voltage sensed by two of four degraded voltage potential transformers (PTs) will, after a time delay, provide a signal to open the offsite feeder breakers on the associated bus.

The outputs from each safeguards bus (NB01 and NB02) are divided into 4 separation groups; 1, 2, 3 and 4 and routed to two control panels, NF039A and NF039B. The input section of each control panel also receives group 1, 2, 3 and 4 instrument power (120VAC). The inputs then pass through isolation devices, at which point all inputs to NF039A become separation group 1 and all inputs to NF039B become separation group 4. Interruption of either the inputs or the instrument power from one separation group would impact the associated input channel, but would not impact the other 3 input channels.

Cable 12NFY01CA supplies 120 VAC power to LSELS panel NF039A. Cable 12NFY01DA supplies 120 VAC power to LSELS panel NF039B. Panels NF039A and NF039B have four sources of Class 1E 120 VAC power, each from separate 120 VAC distribution switchboards, two on Train A and two on Train B. The LSELS system operates when a degraded voltage condition exists on 2 out of 4 sensors on a single 4,160 volt Class 1E bus. Loss of one source of AC power to each panel will have no adverse impact on PFSSD since 120 VAC power remains available from the remaining three sources.

Cables 12NFK01CA and 12NFK01DA are associated with separation group 2 UV relays on buses NB01 and NB02, respectively. Cables 12NFY01EA and 12NFY01FA are associated with separation group 2 degraded voltage PTs on buses NB01 and NB02, respectively. Cables associated with the remaining three UV relays and PTs from separation groups 1, 3 and 4 do not run in fire area C-20.

Automatic functioning of the bus NB01 and NB02 emergency load shedder / sequencer is unaffected by a fire in area C-20 because of the presence of circuits for only one of the four load shed/sequencer initiators. Therefore, a spurious start of the Train A and Train B diesel generators due to a false undervoltage condition on two of the four circuits is not credible.

Based on the above discussion, the Train A and Train B load shed/sequencers are available if a fire occurs in this area. Off-site power to both trains is unaffected based on Calculation XX-E-013, Appendix 2.

References: XX-E-013, E-15000, E-11005, E-13NF01, E-10NF, E-1F9411A, E-1F9411B, E-1F9412A, E-1F9412B, J-104-00347

5.2.3 Process Monitoring

Process monitoring is required to achieve and maintain safe shutdown. Some of the process instruments credited for safe shutdown could be affected by a fire in area C-20. These instruments, as well as the available redundant capability, are described in the following paragraphs.

Steam generator level indication is required to support the decay heat removal function. At least one level transmitter is required on each steam generator being used for heat removal. Cable 12AEI08GB, associated with steam generator B wide range level transmitter AELT0502, and 12SBS16AA, associated with steam generator B wide range level indicator AELI0502A, are run in fire area C-20. Narrow range level indication on steam generator B remains available. Cables for the remaining level transmitters are not run in fire area C-20. Therefore, level indication on all four steam generators is available.

RCS hot and cold leg temperature indication is required on at least one loop to verify sufficient flow through the steam generators to ensure RCS decay heat removal. The following table lists the RCS temperature elements credited for PFSSD.

RCS Hot and Cold Leg Temperature Elements Used for PFSSD	
COMPONENT	**FUNCTION**
BBTE0413A	RCS Hot Leg Temperature Element (WR) Loop 1
BBTE0413B	RCS Cold Leg Temperature Element (WR) Loop 1
BBTE0423A	RCS Hot Leg Temperature Element (WR) Loop 2
BBTE0423B	RCS Cold Leg Temperature Element (WR) Loop 2
BBTE0433A	RCS Hot Leg Temperature Element (WR) Loop 3
BBTE0433B	RCS Cold Leg Temperature Element (WR) Loop 3
BBTE0443A	RCS Hot Leg Temperature Element (WR) Loop 4
BBTE0443B	RCS Cold Leg Temperature Element (WR) Loop 4

Temperature elements BBTE0423B and BBTE0443A, as well as associated temperature indicators, could be affected by a fire in this area due to damage to cables 12BBI15HB, 12BBI15JB, 12SBS16BA and 12SBS16HA. The remaining temperature elements/indicators

are unaffected. Therefore, RCS hot and cold leg temperature indication remains available on loops 1 and 3.

Pressurizer level indication is required to be available to ensure sufficient make-up inventory is provided to compensate for RCS fluid shrinkage during cooldown and losses from the system. Pressurizer level indication is provided by level transmitters BBLT0459 and BBLT0460. Cables 12BBI16QB and 12SBS16GA for BBLT0460 are run in area C-20, so BBLI0460 may not be available. Circuits for BBLT0459/BBLI0459A do not run through fire area C-20 and are unaffected by a fire. Therefore, pressurizer level indication is available for a fire in area C-20 using BBLT0459/BBLI0459A.

Cable 12SBY09GA supplies 120 VAC power from NN0217 to RP148A. Panel SB148A receives signals from certain field transmitters (BBLT0460, BBTE0423, AELT0502 and BBTE0443) and sends the signals to the control room and the auxiliary shutdown panel (ASP). This ensures reliable diagnostic instrumentation is available at the ASP if a fire occurs in the control room. Loss of 120 VAC power to SB148A will prevent signals from these transmitters from reaching the control room and the ASP. However, redundant diagnostic instrumentation remains available in the control room. Therefore, loss of AC power will not impact PFSSD.

Based on the above discussion, process monitoring is available if a fire occurs in fire area C-20.

References: E-15000, XX-E-013, E-13AE08, E-13BB15, E-13BB16, E-13NN01, E-13SB09, E-13SB16, E-1F9201, E-1F9203, E-1F9301, M-12AE02, M-12BB01, M-12BB02

5.2.4 Relay Rack RP334

Cable 12RPK09BA supplies 125 VDC power from NK4201 to auxiliary relay rack RP334. The only relays in RP334 that are required for PFSSD are 86XRP1, 86XRP2 and 86XRP3. These are lockout relays used to isolate the control room if a fire occurs in the control room. Loss of DC power to the relays will prevent isolating the control room but will not cause a spurious control room isolation signal. Control room isolation is not required if a fire occurs in area C-20. Therefore, loss of DC power will not impact PFSSD.

References: XX-E-013, E-15000, E-13RP09, E-13RP15, E-093-00093

5.2.5 Reactor Protection System

The Reactor Protection System (RPS) monitors specified input parameters and initiates reactor protection features whenever those parameters are outside specified limits. Field installed transmitters continuously monitor various parameters and report the results to one of four process cabinets, one per channel. Signals are then sent from the process cabinets to both solid state protection cabinets, one on each train. The cabinets and associated channel are listed in the following table.

Process Cabinets	Solid State Protection Cabinets
Cabinet SB038 - Channel 1 Cabinet SB042 - Channel 2 Cabinet SB037 - Channel 3 Cabinet SB041 - Channel 4	Cabinet SB029A - Train A Input Cabinet Cabinet SB029B - Train A Logic Cabinet Cabinet SB029C - Train A Output Cabinet 1 Cabinet SB029D - Train A Output Cabinet 2 Cabinet SB032A - Train B Input Cabinet Cabinet SB032B - Train B Logic Cabinet Cabinet SB032C - Train B Output Cabinet 1 Cabinet SB032D - Train B Output Cabinet 2

The RPS is actuated upon 2/3 or 2/4 coincident logic, depending on the input parameter. This ensures that a loss of a single channel will not prevent the system from performing it's function.

Cables 12SBS01BD, 12SBS02BD and 12SBY09DA associated with reactor protection system channel 2 run through this area. These cables supply power from separation group 2 power supplies to panels SB029A, SB032A and SB042. Damage to these cables could cause a loss of RPS channel 2, but channels 1, 3 and 4 remain available. Therefore, the RPS is available if a fire occurs in this area.

References: XX-E-013, E-15000, E-13NN01, E-13SB01, E-13SB02, E-13SB03, E-13SB04, E-13SB05, E-13SB09, E-1F9431, E-1F9432, E-1F9433, J-10SA

5.2.6 Source Range Monitoring

PFSSD requires source range (SR) flux monitoring to be available to provide indication of cold shutdown reactivity conditions. Source range monitoring is provided by source range monitors SENE0031, SENE0032, SENY0060A & B, and SENY0061A & B.

Cable 12SES02AA supplies power to SE054B from NN0211. Panel SE054B is associated with source range neutron indicator SENI0032B. Loss of power to the panel will prevent SENI0032B from operating. Source range monitoring remains available using SENI0031B, SENI0060A/B and SENI0061A/B.

References: XX-E-013, E-15000, E-13SE02, E-1F9101

5.2.7 Class 1E 120 VAC Electrical Distribution System

The Class 1E 120 VAC electrical distribution system provides power to vital instrumentation and control loads for shutdown and normal operation. Under normal conditions, the system is supplied by inverters connected to the 125 VDC NK battery system. Swing inverters allow the primary inverters to be taken out of service for maintainance or repair without disrupting power to the associated vital AC bus. In the event of a loss of power to the inverters, a backup source of power is automatically lined up. The backup power source originates from the 480 VAC electrical distribution system (NG).

Cables 12NNK01LA and 12NNK01LB supply 125 VDC power from NK0203 to manual transfer switch NK80. Damage to these cables will disrupt the 125 VDC power supply from NK0203 to swing inverter NN16. 125 VDC power from NK0403 to swing inverter NN16 is unaffected.

Cables 12NNY01GA and 12NNY01GB supply 120 VAC power from swing inverter NN16 to bus NN02 through a manual transfer switch in inverter NN12. Damage to these cables will disrupt the 120 VAC power supply from swing inverter NN16 to NN02.

Inverters NN12 and NN14 and 120 VAC vital distribution buses NN02 and NN04 are located in a separate fire area and are unaffected by a fire in area C-20. The 125 VDC and 480 VAC power supply to inverters NN12 and NN14 are unaffected by a fire in area C-20.

Based on the above discussion, the Train A and Train B vital 120 VAC electrical distribution system is unaffected by a fire in this area.

5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA C-21 13

1.0 GENERAL AREA DESCRIPTION

Fire area C-21 is located on the 2032 elevation of the Control Building and includes the room listed in Table C-21-1.

Table C-21-1
Rooms Located in Fire Area C-21

ROOM #	DESCRIPTION
3501	Lower Cable Spreading Room

Fire area C-21 is protected with an automatic wet-pipe sprinkler system. In addition, automatic fire detection is installed throughout. The automatic suppression and detection system meets the requirements of 10CFR50, Appendix R, Section III.G.2. The area is separated from adjacent areas by minimum 3-hour fire resistant construction.

2.0 PRIMARY EQUIPMENT USED FOR PFSSD

Table C-21-2 lists each system credited for post-fire safe shutdown and provides a discussion regarding the availability of the system to perform its Post Fire Safe Shutdown (PFSSD) function if a severe fire occurs in this area. For a summary of the area analysis results, see Section 8.0 of the Fire Area Analysis Narrative section.

Table C-21-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-21

System	System Name	PFSSD Function*	Comments
AB	Main Steam	R, M, H, P, S	Steam generators A and C ARV control may be lost. Steam generator ARVs B and D are unaffected. Cooldown is assured using Aux Feedwater Pump B supplying steam generator D and the Turbine Driven Auxiliary Feedwater Pump supplying steam generator B. ABHS0080 may not be available to close the MSIVs and MSIV bypass valves. ABHS0079 is available to close the MSIVs and MSIV bypass valves. Steam line pressure transmitters ABPT0514, ABPT0524, ABPT0526, ABPT0534, ABPT0536 and ABPT0544 could be affected. In addition, steam line pressure instruments ABPI0514A, ABPI0524A, ABPI0526A, ABPI0534A, ABPI0536A and ABPI0544A in the main control room could be affected. Remaining steam line pressure transmitters and indicators are available.
AC	Main Turbine	R, H	A cable associated with turbine manual trip pushbuttons ACHS0002A and ACHS0002B could be damaged, which could prevent tripping the turbine from the control room. PFSSD is assured by isolating the MSIVs and MSIV bypass valves using ABHS0079.
AE	Main Feedwater	H, P	All PFSSD functions associated with the main feedwater system are satisfied. Steam generator A level indication is available using AELI0517 and AELI0519. Steam generator B level indication is available using AELI0502, AELI0527 and AELI0552. Steam generator C level indication is available using AELI0537 and AELI0553. Steam generator D level indication is available using AELI0504, AELI0547 and AELI0549. Isolate all four main feedwater isolation valves using hand switch AEHS0081.
AL	Aux. Feedwater System	H, P	All PFSSD functions associated with the auxiliary feedwater system are satisfied. Train B MDAFP is available to supply SGs A and D, however SG A ARV ABPV0001 could spuriously open and may need to be failed closed. The TDAFP is available to supply SGs B and C, however SG C ARV ABPV0003 could spuriously open and may need to be locally controlled or closed. Pressure transmitters/indicators ALPT0037/ALPI0037 and ALPT0038/ALPI0038A may be affected. Auxiliary feedwater suction pressure indication is available using pressure transmitter/indicator ALPT0039/ALPI0039A.
AP	Condensate Storage System	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-21.

Table C-21-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-21

System	System Name	PFSSD Function*	Comments
BB	Reactor Coolant System	R, M, H, P, S	Pressurizer PORV BBPCV0455A may open and block valve BBHV8000A may not close. If this occurs, Operators can close the PORV by placing BBHIS0455A in the CLOSE position. RCS pressure transmitter BBPT0405 could be affected. RCS pressure indication is available using BBPI0406. Pressurizer level transmitter BBLT0459 could be affected. Pressurizer level indication is available using BBLI0460A. Pressurizer pressure transmitters BBPT0455 and BBPT0457 could be affected. Pressurizer pressure transmitters BBPT0456 and BBPT0458 are unaffected. Pressurizer pressure indication is available using BBPI0456 and BBPI0458. Loss of inventory through the head vent valves is prevented by maintaining valve BBHV8002A closed and either BBHV8001B or BBHV8002B closed. Hand switch BGHIS8153A needs to be maintained in the close position to prevent an external hot short from opening valve BBHV8002A. RCS Loop 1 Wide Range Cold Leg Temperature Element BBTE413B and RCS Loop 4 Wide Range Hot Leg Temperature Element BBTE443A are available. RCP thermal barrier cooling could be affected due to spurious closure of BBHV0013, BBHV0014, BBHV0015 and BBHV0016. Reactor coolant pumps A and B may not stop using the control room hand switch. RCP seal injection remains available. Therefore, the inability to stop the RCPs will have no adverse impact on PFSSD. Pressurizer spray valves BBPCV0455B and BBPCV0455C could spuriously open. If this occurs, the valves can be closed by closing valve KAV0201 in fire area A-25.
BG	Chemical and Volume Control System	R, M, S	All PFSSD functions associated with the chemical and volume control system are satisfied. Train B Centrifugal Charging Pump (CCP) is available to provide charging flow from the RWST to the RCP seals through valve BGHV8357B. VCT level indicator BGLI0112 could be affected. Level indicator BGLI0185 is available to determine VCT level. Normal charging is isolated using BGHIS8105 to close valve BGHV8105. Cables for valve BGHV8106 could be damaged. Valves BGHV8153A and either BGHV8153B or BGHV8154B are maintained closed to isolate excess letdown. Letdown isolation valves BGLCV0459 and BGLCV0460 and letdown orifice isolation valves BGHV8149A, BGHV8149B, and BGHV8149C may need to be failed closed by closing valve KAV0201 in fire area A-25. RCP seal flow indication is available using BGFI0215B. RCP seal flow indicator BGFI0215A may be affected.
BM	Steam Generator Blowdown System	R, M, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-21.

Table C-21-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-21

System	System Name	PFSSD Function*	Comments
BN	Borated Refueling Water Storage System	R, M, H	The RWST is available to provide a suction source to Centrifugal Charging Pump B via valve BNLCV0112E.
EF	Essential Service Water System	H, S	All PFSSD functions associated with the essential service water system are satisfied. Train A ESW is unavailable due to damage to a number of associated components. Train B ESW is unaffected.
EG	Component Cooling Water System	S	All PFSSD functions associated with the component cooling water system are satisfied. A number of Train A CCW system components could be affected. The Train B CCW system is unaffected. CCW flow to the RCP thermal barriers could be affected as discussed in BB System comments above. CCW to RCP flow indicator EGFI0128 could be affected. CCW to RCP flow indicator EGFI0129 is unaffected. Valve EGHV0101 could be affected, preventing operation of Train A RHR. Valve EGHV0102 is unaffected.
EJ	Residual Heat Removal System	M, H, P	A number of Train A RHR system cables may be affected by a fire in this area. The Train B RHR system is available but a cold shutdown repair or containment entry may be required to open EJHV8701B.
EM	High Pressure Coolant Injection	R, M	All PFSSD functions associated with the high pressure coolant injection system are satisfied. BIT inlet valve EMHV8803A may be affected but valves EMHV8801B and EMHV8803B are available to ensure an available BIT flowpath using Train B CCP. The Train A SI Pump may spuriously start but the spurious actuation will not adversely impact PFSSD since the pump will be dead headed against RCS pressure. Therefore, no inventory will be lost from the RWST. In this condition, the pump could experience cavitation damage but this is a commercial concern, not a PFSSD concern. Operators can disconnect power to the pump by opening breaker NB0103, but this action is not required for PFSSD. SI test line valves EMHV8882 and EMHV8964 could be affected. The SI test line can be isolated by closing valve EMHV8871. A spurious SIS due to low pressurizer pressure or low steam line pressure can be terminated by entering EMG E-0 and taking the necessary actions.
EN	Containment Spray	R, M	Both containment spray pumps PEN01A and PEN01B could spuriously start and valves ENHV0006 and ENHV0012 could open, causing full flow containment spray. Pump PEN01B can be stopped by placing hand switch ENHIS0009 in pull-to-lock. Pump PEN01A can be stopped by opening breaker NB0102 in fire area C-9.

Table C-21-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-21

System	System Name	PFSSD Function*	Comments
EP	Safety Injection Accumulators	H	A containment entry may be required to close SI Accumulator injection valves EPHV8808A and EPHV8808C if these valves are unresponsive from the control room. The SI accumulators need to be isolated during cold shutdown, prior to the RCS reaching 1000 psig.
FB	Auxiliary Steam	R, H	Valve FBHV0081 could be affected. This component is not required if a fire occurs in fire area C-21.
FC	Auxiliary Turbines	R, H, P	Valve FCHV0003 and level switch FCLSH0003 could be affected. These components are not required if a fire occurs in fire area C-21. Valve FCFV0005 may be affected. The MSIVs can be closed using all-close hand switch ABHS0079.
GD	ESW Pump House HVAC	S	Train A ESW pump room ventilation system could be affected. Train B ESW pump room ventilation system is unaffected.
GF	AFW Pump Room Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-21.
GK	Control Room and Class 1E Switchgear Room Coolers	S	The PFSSD support function associated with this system is satisfied. Train A control room A/C unit SGK04A may be affected. Train B control room A/C unit SGK04B is unaffected. Train A Class 1E electrical equipment room A/C unit SGK05A may be affected. Train B Class 1E electrical equipment room A/C unit SGK05B is unaffected.
GL	Auxiliary Building HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-21.
GM	Emergency Diesel Generator Room HVAC	S	Train A EDG room ventilation could be affected. The Train B EDG room ventilation is unaffected.
GN	Containment Coolers	S	The PFSSD support function associated with this system is satisfied. Containment pressure transmitter GNPT0935 and GNPT0937 and pressure indicators GNPI0935 and GNPI0937 could be affected. Containment pressure transmitters GNPT0934 and GNPT0936 and indicators GNPI0934 and GNPI0936 are unaffected. Train A containment cooler fans SGN01A and SGN01C could be affected. Train B containment cooler fans SGN01B and SGN01D are unaffected.
JE	Diesel Fuel Oil	S	Low standpipe level switch JELSL0001C may be affected due to loss of power to RP053AC. This could prevent operation of the Train A diesel fuel oil transfer pump PJE01A on low standpipe level. The Train B diesel fuel oil transfer pump PJE01B is unaffected by a fire in this area.
KA	Instrument Air	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-21.

Table C-21-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-21

System	System Name	PFSSD Function*	Comments
KC	Fire Protection	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-21.
KH	Service Gas	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-21.
KJ	Standby Diesel Engine	S	Train A diesel engine may be affected by a fire in this area. Train B diesel engine is unaffected.
MA	Main Generation	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-21.
MR	Startup Transformer	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-21.
NB	4.16 kV System	S	Train A Class 1E 4.16 kV switchgear bus NB01 may be affected. Train B Class 1E 4.16 kV switchgear bus NB02 is unaffected.
NE	Standby Diesel Generator	S	Train A diesel generator may be affected by a fire in this area. Train B diesel generator is unaffected.
NF	Load Shed and Emergency Load Sequencing	S	The PFSSD function associated with the load shed/emergency load sequencing system is satisfied. Cables associated with two of the four undervoltage (UV) relays and degraded voltage potential transformers on Train A are run in fire area C-21. Cables associated with two of the four UV relays and degraded voltage potential transformers on Train B are run in fire area C-21. Emergency load shed/sequencer operates when 2/4 UV relays sense undervoltage on the bus. A spurious UV signal will cause the load shedder/sequencer to actuate and start the associated diesel generator. A true UV condition will actuate the two unaffected UV relays. Train B off-site power remains available.
NG	480V Load Centers and MCCs	S	Loss of power to NB01 will result in a loss of power to Train A 480 V load centers and MCCs. Redundant Train B 480 V load centers and MCCs are unaffected.
NK	125VDC	S	Train A class 1E 125 VDC power could be disrupted to control room panels RL001/RL002, RL005/RL006, RL017/RL018, RL019/RL020 and RL021/RL022. The normal source of power to NK01 and NK03, through the Train A 480 V distribution system, could be disrupted. 125 VDC battery sets NK011 and NK013 are unaffected. Train B class 1E 125 VDC power is unaffected.
NN	120VAC	S	The backup source of power to Train A Class 1E electrical distribution switchboards NN01 and NN03 could be affected. The normal source of power to NN01 and NN03 are unaffected due to the availability of 125 VDC battery sets NK011 and NK013. Train B Class 1E electrical distribution switchboards NN02 and NN04 are unaffected.

Table C-21-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-21

System	System Name	PFSSD Function*	Comments
PA	13.8kV	S	Breakers PA0105 and PA0106 could be affected by a fire in this area. Redundant capability is available.
PB	4.16kV	H, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-21.
PG	480V Load Centers and MCCs	S	Loss of all power on bus NB01 will result in Train A PG busses losing power. Off-site and on-site power to NB02 and Train B PG busses is unaffected. Breakers PG1101 and PG1901 could be affected. Redundant capability is available.
PK	125VDC	S	Battery charger PK21 could be affected. Battery charger PK22 is unaffected.
PL	Local Instrument Panels	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-21.
PN	120VAC	S	Power to non-class 1E 120 VAC switchboard PN07 may be affected. Non-class 1E 120 VAC switchboard PN08 is unaffected.
QB	Standby AC Lighting	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-21.
QD	Emergency Lighting	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-21.
RL	Control Room MCB	S	Separation groups 1 and 5 power supplies to a number of RL panels could be disrupted. Power is available from separation groups 4 and 6 power supplies to energize redundant Train B components.
RP	Miscellaneous Control Panels	R, M, H, P, S	Train A components and cables associated with this system could be affected. Train B components and cables associated with this system are unaffected. Power to panel RP043 could be affected. See SC system discussion for details. Power to panels RP053A and RP053D could be affected. Power to panels RP053B and RP147 is unaffected. Power to RP060 could be affected. RP060 is not required for PFSSD if a fire occurs in fire area C-21. 120 VAC control power to the automatic and manual start circuits in panel RP068 for Train A ESW pump room supply fan CGD01A could be affected. Train B ESW components are unaffected.
SA	ESFAS	S	Auxiliary feedwater low suction pressure (LSP) signal monitored by panel SA036A could be affected. Auxiliary feedwater LSP signals monitored by panels SA036B and SA036C are unaffected. Status panel input for GKHZ0029A/B, SGK04A and SGK05A could be affected. Status panel input for redundant Train B components is unaffected.

Table C-21-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-21

System	System Name	PFSSD Function*	Comments
SB	Reactor Protection System	R, S	RPS Channels 1 and 3 could be affected. RPS Channels 2 and 4 are unaffected. Train A reactor trip switchgear SB0102A could be affected such that a reactor trip occurs or a manual trip on Train A is prevented. Train B reactor trip switchgear cabinet SB102B is unaffected.
SC	Reactor Instrumentation	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-21.
SE	Ex-Core Neutron Monitoring	R, P	Source range monitor SENE0031 and SR monitor signal processor SENY0060B could be affected. Source range indication on SENI0032 could be affected. Source range monitoring remains available using SENY0061A/B and associated indicator.
SY	Switchyard	S	Cable 15SY134 could be damaged, causing a loss of one of the off-site power feeders (13-48) to NB01. Off-site power to NB02 is unaffected.
UU	Supervisory System	S	Cable 15UU003 could be damaged, causing a loss of one of the off-site power feeders (13-8) to NB01. Off-site power to NB02 is unaffected.

* R - Reactivity Control; M - Reactor Coolant Makeup; H - Decay Heat Removal; P - Process Monitoring; S - Support Function

3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD

This section describes operator actions that may need to be performed inside or outside the control room to achieve and maintain hot standby if a fire occurs in fire area C-21. This section also describes cold shutdown repairs that may need to be made to achieve and maintain cold shutdown conditions. Operator actions are proceduralized in OFN KC-016.

3.1 ACTIONS OUTSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

Operator Manual Actions (OMAs) are those actions outside the main control room required to achieve and maintain hot standby. OMAs are identified in E-1F9900 and were determined from thermal hydraulic analysis WCNOC-CP-002. Applicable E-1F9900 OMAs are annotated herein. All other actions outside the control room are desirable for plant control in support of hot standby but not required to achieve and maintain hot standby.

3.1.1 Steam Generator ARVs

It may be necessary to fail close ABPV0001 by isolating air and nitrogen to the valve using KAV1435 (air) and KAV1364 (Nitrogen) then venting air from the regulator. These valves are located in fire area A-23 and emergency lighting is available.

It may be necessary to close ABPV0003 using local controller ABFHC0003 in room 1509 (fire area A-23). Emergency lighting is provided, and access is available without traversing fire area C-21.

3.1.2 **Isolation of Letdown** (OMA, refer to E-1F9900)

A fire in area C-21 could prevent valves BGLCV0459, BGLCV0460, BGHV8149A, BGHV8149B, and BGHV8149C from being closed using their respective hand switches in the control room. If this occurs, isolate instrument air by closing valve KAV0201 in fire area A-25 to fail the valves closed.

3.1.3 **Containment Spray** (OMA, refer to E-1F9900)

Containment spray pump PEN01A could spuriously start and valve ENHV0006 could open, causing containment spray. The pump can be stopped by opening breaker NB0102 in fire area C-9.

3.1.4 **Normal Pressurizer Spray** (OMA, refer to E-1F9900)

Pressurizer spray valves BBPCV0455B and BBPCV0455C could spuriously open. If this occurs, the valves can be closed by closing valve KAV0201 in fire area A-25. Pressurizer pressure indication is available using BBPI0456 and BBPI0458 located on RL002.

3.2 ACTIONS INSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

3.2.1 Main Steam Isolation Valves and MSIV Bypass Valves

The capability to isolate the MSIVs and bypass valves using hand switch ABHS0080 may be affected. The MSIVs and bypass valves can be isolated using hand switch ABHS0079.

3.2.2 Main Feedwater Isolation Valves

The capability to isolate the MFIVs using hand switch AEHS0080 may be affected. Isolate the MFIVs using hand switch AEHS0081.

3.2.3 Safety Injection and Containment Spray

A spurious Safety Injection Signal (SIS) can be mitigated by consulting EMG E-0 and terminating the spurious SIS.

Containment spray pump PEN01B could spuriously start and valve ENHV0012 could open, causing containment spray. Pump PEN01B can be stopped by placing hand switch ENHIS0009 in pull-to-lock.

3.2.4 Auxiliary Feedwater

If steam generator A ARV ABPV0001 and steam generator C ARV ABPV0003 control is lost, use the Turbine Driven Auxiliary Feedwater Pump to supply steam generator B and the Train B Motor Driven Auxiliary Feedwater Pump to supply steam generator D.

3.2.5 Component Cooling Water

Train A CCW could be affected by a fire in this area. If this occurs, swap to Train B CCW using normal operating procedures if Train B CCW is not already running. Loss of CCW flow to the RCP thermal barriers can be diagnosed using flow indicator EGFI0129 on panel RL020.

3.2.6 Reactor Coolant Pump Seal Cooling

Thermal barrier cooling could be affected. RCP seal injection could temporarily be disrupted until the Train B CCP is lined up. The Train B CCP can be started and lined up to provide seal injection from the control room. RCP seal flow indication is available using BGFI0215B.

3.2.7 Pressurizer PORV/Block Valve

Pressurizer PORV BBPCV0455A could spuriously open and block valve BBHV8000A may not close. If this occurs, Operators can close the PORV by placing BBHIS0455A in the CLOSE position. Pressurizer pressure indication is available using BBPI0456 and BBPI0458 located on RL002.

3.3 ACTIONS TO ACHIEVE AND MAINTAIN COLD SHUTDOWN

3.3.1 RHR

Valve EJHV8701B may need to be manually opened or a cold shutdown repair made when aligning Train B RHR for shutdown cooling.

3.3.2 Safety Injection Accumulators

A containment entry may be required to close SI Accumulator injection valves EPHV8808A and EPHV8808C if these valves are unresponsive from the control room. The SI accumulators need to be isolated during cold shutdown, prior to the RCS reaching 1000 psig.

4.0 CONCLUSION

With some exceptions, redundant Post Fire Safe Shutdown capability exists if a severe fire occurs in fire area C-21. For those exceptions, feasible manual actions are available and are unaffected by the fire. Manual actions are documented in Section 3.0.

5.0 DETAILED ANALYSIS

This section describes the detailed component-by-component and cable-by-cable analysis for a fire in area C-21.

5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA C-21

PFSSD components (S. in E-15000) located in fire area C-21 are shown in Table C-21-3. An evaluation of each component and associated cables is provided in the sections that follow. The applicable evaluation section is listed in Table C-21-3.

Table C-21-3
PFSSD Components Located in Fire Area C-21

Room #	PFSSD Component	Component Description	Evaluation Section	Comments
3501	PN310	120 VAC Distribution Panel	5.1.1	Power to RP043 and RP047

5.1.1 120 VAC Distribution Panel PN310

120 VAC distribution panel PN310 supplies redundant power to NSSS control panels RP043 and RP047. 120 VAC distribution panel PN410 is a second source of power to RP043 and RP047.

Inverter PN03 supplies power to 120 VAC distribution panel PN310 (via cables 15PNY02AA and 15PNY02AB), which in turn supplies redundant 120 VAC power to NSSS control cabinets RP043 and RP047. Cable 15SCY12EA provides primary power to RP043 from breaker PN31001 and cable 15SCY12FA provides backup power to RP047 from breaker PN31002. For PFSSD, cabinet RP043 houses relays BGLCV0459X and BGLCV0460X, which are associated with letdown isolation valves BGLCV0459 and BGLCV0460, respectively. Cabinet RP047 includes controls for pressurizer PORVs and pressurizer spray.

Damage to cables 15PNY02AA and/or 15PNY02AB will disrupt power to panel PN310. Redundant power to RP043 and RP047 is available from 120 VAC distribution panel PN410. Therefore, loss of power to PN310 will not adversely impact PFSSD.

5.2.1 Steam Generator Atmospheric Relief Valves

PFSSD requires at least two steam generator atmospheric relief valves (ARV) be controlled and the other two closed. The ARVs are pneumatically operated using air from the compressed air system (KA) or nitrogen from the nitrogen accumulators. The valves open by pneumatic pressure and close by spring action. The valves are automatically controlled by a pressure transmitter input signal from a pressure transmitter installed on the outlet side of the steam generator. Alternatively, each valve can be controlled manually from the control room or the auxiliary shutdown panel by placing the pressure indicating controller (PIC) in manual.

As discussed in Section 5.2.7, a fire in area C-21 could damage cables and equipment associated with the Train A Motor Driven Auxiliary Feedwater Pump (MDAFP). The Turbine Driven Auxiliary Feedwater Pump (TDAFP) and the Train B MDAFP are available. The TDAFP can be lined up to feed steam generators B and C while the Train B MDAFP can be used to supply auxiliary feedwater to Steam Generators A and D.

Cables associated with steam generators A and C ARVs ABPV0001 and ABPV0003 are run in this area. Damage to these cables could prevent control or isolation of the associated ARV. ARV ABPV0001 can be failed closed by isolating air and nitrogen to the valve using KAV1435 (air) and KAV1364 (Nitrogen) then venting air from the regulator. These valves are located in fire area A-23 and emergency lighting is available. ARV ABPV0003 can be closed using local controller ABFHC0003, also located in fire area A-23.

Based on the above discussion, PFSSD can be achieved by controlling ARVs ABPV0002 and ABPV0004 and locally isolating ARVs ABPV0001 and ABPV0003. The TDAFP can be used to supply steam generator B and the Train B MDAFP can be used to supply steam generator D.

Up to three ARVs can fail closed or open without impacting ability to achieve and maintain hot standby according to thermal hydraulic analysis WCNOC-CP-002. With at least one ARV unaffected, no E-1F9900 OMA is required to address ARV closure or control. Reference Attachment 4, MSO Evaluation Scenario ID PWROG 23.

5.2.2 Safety Injection and Containment Spray

Calculation XX-E-013, Appendix 1 (PFSSD Support Section) provides a detailed discussion about the potential PFSSD impact of a spurious safety injection signal (SIS) and spurious containment spray actuation signal (CSAS). This section discusses the specific PFSSD impact if a fire occurs in this area.

Cables associated with containment pressure transmitters GNPT0935 and GNPT0937 and indicators GNPI0935 and GNPI0937 are run in fire area C-21. Consequently, a spurious CSAS due to false high containment pressure can occur if a fire occurs in fire area C-21. However, a spurious SIS due to high containment pressure cannot occur since only one of the three containment pressure SIS initiators have cables located in fire area C-21. Containment pressure indication is available using GNPI0934 and GNPI0936.

Cables associated with BBPT0455 and BBPT0457 are run in fire area C-21. Consequently, a fire in area C-21 can cause a spurious SIS due to false low pressurizer pressure.

Cables associated with steam line pressure transmitters ABPT0514, ABPT0524, ABPT0526, ABPT0534, ABPT0536 and ABPT0544 are run in fire area C-21. Consequently, the two out of

three logic for low steam line pressure initiation of SIS can be satisfied on steam generators B and C if a fire occurs in fire area C-21.

A spurious SIS starts the charging sequence which starts the CCPs and opens the BIT flowpath valves. For a fire in this area, Train B CCP is credited for PFSSD since a number of Train A PFSSD components could be lost. Train B BIT flowpath valves EMHV8801B and EMHV8803B are unaffected and would open on a SIS. The Train B RWST to CCP suction header valve BNLCV0112B is unaffected and would open on a SIS. Also, the Train B CCP mini flow valve BGHV8111 is unaffected and Train B CCW flow to the seal water heat exchanger is unaffected to ensure cooling of the recirc flow and RCP seal return. Train B CCW is also available for the CCP oil cooler. Therefore, the Train B charging pump will not be affected by a spurious SIS caused by a fire in this area.

A start of the credited CCW system (Train B) will not adversely impact the system. The Train B ESW system is unaffected and will start on a spurious SIS, providing necessary cooling water to the CCW heat exchanger.

A start of the AFW pumps will not adversely impact PFSSD. The Train B AFW pump and the TDAFP are credited for a fire in this area. Suction from the CST to the Train B AFW pump is unaffected. Suction from the Train B ESW system to the TDAFP is unaffected but if ALHV0036 spuriously closes suction would be lost to the TDAFP until operators open ALHV0033. The TDAFP does not auto start on a SIS, so damage to the TDAFP will not occur as a result of a spurious SIS. Discharge flow from the Train B AFW pump will either return to the CST or flow to the steam generators through the discharge control valves. Therefore, the Train B AFW pump and the TDAFP are unaffected by a spurious SIS caused by a fire in this area.

A spurious SIS will start both RHR pumps and open the containment sump to RHR pumps isolation valves with a coincident RWST low-low level signal. A spurious RWST low-low level signal is not credible for a fire in area C-21 as discussed in Section 5.2.18. Train A RHR pump minimum flow valve EJFCV0610 could be affected as discussed in Section 5.2.21 and CCW to the Train A RHR heat exchanger could be affected as discussed in Section 5.2.20. Therefore, the Train A RHR pump could be affected by a spurious pump start (due to a SIS) coincident with other component damage that causes the pump to overheat. The Train B RHR pump is unaffected because valve EJFCV0611 and Train B CCW is unaffected.

A spurious Containment Spray Actuation Signal (CSAS) due to spurious high containment pressure can be mitigated by placing CS pump control hand switches ENHIS0003 and ENHIS0009 in pull-to-lock. If Containment spray pump PEN01A does not stop because of control cable damage, the pump can be stopped by opening breaker NB0102 in fire area C-9. These switches are located on control room panel RL017.

Based on the above discussion, a fire in area C-21 could cause a spurious SIS due to low pressurizer pressure and low steam line pressure. A fire in C-21 could also cause a spurious CSAS due to high containment pressure. The spurious SIS and CSAS will not cause damage to credited hot standby or cold shutdown equipment.

5.2.3 Main Steam Isolation Bypass Valves

PFSSD requires the MSIVs and bypass valves be closed to prevent reactivity addition due to uncontrolled cooldown. The MSIVs and bypass valves are closed from the control room using hand switches ABHS0079 or ABHS0080. The bypass valves are normally closed.

Each of the four MSIV bypass valves (ABHV0012, ABHV0015, ABHV0018 and ABHV0021) has two redundant solenoids that control the position of the associated bypass valve. The bypass valves are normally closed with the solenoids de-energized. Both solenoids need to be energized to open the valve. One of the solenoids on each valve is on separation group 1 (Train A) and are controlled by hand switch ABHS0080. The other solenoids on each valve are on separation group 4 (Train B) and are controlled by hand switch ABHS0079.

Cable 11ABK23AE is associated with steam line isolation signal relay K627. Upon receipt of a steam line isolation signal, the relay contact opens and the bypass valves close. An open circuit in one of the two conductors will produce the same result as a steam line isolation signal, which is desired for PFSSD. A hot short between the conductors will bypass the contact and prevent a steam line isolation signal from closing the valves.

Cable 11ABK23AF is associated with handswitch ABHS0080 on the Train A MSIV bypass valve control circuit. An open circuit in one of the two conductors will de-energize the respective solenoid and close the bypass valves. A hot short between the conductors will bypass the handswitch contact and prevent closure of the valves using the handswitch.

Cable 11ABK23AG is associated with MSIV bypass valves ABHV0012, ABHV0015, ABHV0018 and ABHV0021. The bypass valves are normally closed, which is the desired PFSSD position. In order for the valves to spuriously open, both solenoids on the air line need to be energized. An external cable hot short on cable 11ABK23AG could energize the Train A solenoids but the Train B solenoids are unaffected by a fire in area C-21. In addition, hand switch ABHS0079 is available to ensure the bypass valves are closed. Therefore, a fire in area C-21 will not affect the ability to isolate the MSIV bypass valves.

Cable 11ABK26AB is associated with handswitch ABHS0080 on the Train A MSIV control circuit. An open circuit in one of the two conductors will prevent ABHS0080 from performing its function. A hot short between the conductors will close the MSIVs, which is the desired PFSSD position.

Redundant means are available to ensure the MSIV bypass valves are closed. Hand switch ABHS0079 is unaffected by the fire and can be used to ensure one of the two solenoids on each bypass valve are de-energized.

References: E-15000, XX-E-013, E-13AB23A, E-13AB23B, E-13AB26, E-13AB27, E-1F9101

5.2.4 Steam Generator Main Steam Isolation Valves (MSIVs)

PFSSD requires the MSIVs be closed to prevent reactivity addition due to uncontrolled cooldown. The MSIVs are closed from the control room using all close hand switches ABHS0079 or ABHS0080.

Each MSIV is designed to utilize system fluid (main steam) as the motive force to open and close. The valve actuation (open or close) is accomplished through positioning a series of six electric solenoid pilot valves to either direct the system fluid to the Upper Piston Chamber (UPC) and/or the Lower Piston Chamber (LPC), or vent either or both piston chambers. The six solenoid pilot valves are divided into two trains (3 per train) that are independently powered and controlled. Either train can independently perform the PFSSD function to close the valve and isolate main steam. This is done by actuating either all close hand switch ABHS0079 (separation group 4) or ABHS0080 (separation group 1) to de-energize the associated solenoid valves.

The following table identifies the solenoids and associated control cables for each hand switch.

MSIV	ABHS0079 (Sep Group 4)		ABHS0080 (Sep Group 1)	
	Solenoids	Cable	Solenoids	Cable
ABHV0011	MV2, MV4, MV6	14ABK28BH	MV1, MV3, MV5	11ABK29BH
ABHV0014	MV2, MV4, MV6	14ABK29AH	MV1, MV3, MV5	11ABK28AH
ABHV0017	MV2, MV4, MV6	14ABK28AH	MV1, MV3, MV5	11ABK29AH
ABHV0020	MV2, MV4, MV6	14ABK29BH	MV1, MV3, MV5	11ABK28BH

All 4 cables associated with the 12 separation group 1 solenoid valves are run in area C-21. Cable damage due to a fire will likely result in disruption of power to the solenoids, which will close the valves. The four separation group 4 cables associated with hand switch ABHS0079 are unaffected by a fire in area C-21. Therefore, hand switch ABHS0079 is available to close the four MSIVs.

Cable 11ABK30BB provides 125 VDC power to Train A main steam and feedwater isolation system (MSFIS) actuation cabinet SA075A from NK5119. Damage to this cable would disrupt power to the separation group 1 solenoids and close the MSIVs, which is the desired PFSSD position. In addition, the Train B MSFIS is unaffected by the fire and ABHS0079 is available to close the MSIVs.

Cables associated with isolation valves located downstream of the MSIVs are located in this area. These downstream isolation valves are used in the event the MSIVs cannot be closed. Valves ABHV0031, ABFV0023, ABLV0051, ABLV0053, FBHV0081 and FCHV0003 could be affected by a fire in this area. However, as stated in the previous paragraph, the MSIVs can be isolated using hand switch ABHS0079. Therefore, damage to cables associated with these downstream components will have no adverse impact on PFSSD.

Cable 15ACQ15BA is associated with main turbine master trip pushbuttons ACHS0002A and ACHS0002B. These pushbuttons are used for PFSSD to isolate the main turbine stop valves if the MSIVs cannot be closed. As stated previously, the MSIVs can be closed using ABHS0079. Therefore, damage to this cable will have no adverse impact on PFSSD.

Cable 15RLY01HA supplies 120VAC power to MCB RL023/RL024 miscellaneous circuits from PG19GCR217. Several loads are supplied by this power supply, but only eight are PFSSD components. These are ABLV0051, ABLV0053, ABFV0023, ABFV0025, ABFV0027, ABFV0029, FCHV0003, and ABHIS0032 which are components downstream of the Main Steam Isolation Valves (MSIVs). Loss of power to ABLV0051, ABLV0053, ABFV0023, ABFV0025, ABFV0027, ABFV0029 and FCHV0003 could fail the valves open. Loss of power to ABHIS0032 will cause a loss of hand switch indicator lights. However, a fire in area C-21

does not affect the ability to close the MSIVs and MSIV bypass valves using hand switch ABHS0079 in the main control room. Therefore, the MSIV downstream components can fail in an undesired position without any consequence on PFSSD.

Based on the above discussion, hand switch ABHS0079 is available to close the MSIVs in the event of a fire in area C-21.

References: E-15000, XX-E-013, E-13AB23A, E-13AB23B, E-13AB26, E-13AB27, E-13AB28, E-13AB29, E-13AB30, E-13AC15, E-13FB12, E-13RL01, E-13RL07, E-1F9101, E-1F9103, J-104-00295, J-104-00296, M-12AB02

5.2.5 Steam Generator Level and Pressure Indication

The decay heat removal function for PFSSD requires the use of two RCS loops and two Steam Generators. Steam generator (SG) level indication is required to support this function. The available success path if a fire occurs in area C-21 credits MDAFP B supplying SG D and the TDAFP supplying SG B. Therefore, level indication on SG B and SG D is required.

Diagnostic indication of steam line pressure is also required for PFSSD. Steam line pressure indication is used to determine if a steam generator ARV is stuck open, verification of heat removal per EMG ES-04, and verification of an actual SIS per EMG E-0. Section 5.2.2 discusses steam line pressure SIS initiation, whereas this section discusses availability of steam line pressure indication on the MCBs.

Cables associated with SG level transmitters AELT0501 (SG A WR), AELT0518 (SG A NR), AELT0551 (SG A NR), AELT0528 (SG B NR), AELT0529 (SG B NR), AELT0503 (SG C WR), AELT0538 (SG C NR), AELT0539 (SG C NR), AELT0548 (SG D NR) and AELT0554 (SG D NR) are run in area C-24. In addition, cables associated with level indicators associated with these level transmitters are run in this area. Damage to these cables due to a fire will prevent indication on the associated level indicators in the control room. Alternate level indication remains available on all four SGs using the following level indicators:

Steam Generator	Available Level Indication
A	AELI0517 (NR), AELI0519 (NR)
B	AELI0502 (WR), AELI0527 (NR), AELI0552 (NR)
C	AELI0537 (NR), AELI0553 (NR)
D	AELI0504 (WR), AELI0547 (NR), AELI0549 (NR)

As discussed in Section 5.2.2, cables associated with steam line pressure transmitters ABPT0514, ABPT0524, ABPT0526, ABPT0534, ABPT0536 and ABPT0544 are run in fire area C-21. In addition, cables associated with steam line pressure indicators on the MCB for these transmitters are run in this area. Consequently, steam line pressure indication in the MCR for these transmitters will not be available. Alternate steam line pressure indication remains available using the pressure indicators in the following table:

Steam Generator	Available Pressure Indication
A	ABPI0515A, ABPI0516A
B	ABPI0525A
C	ABPI0535A
D	ABPI0545A, ABPI0546A

Based on the above discussion, steam generator level indication and main steam line pressure indication is available on all four steam generators if a fire occurs in fire area C-21.

References: E-15000, XX-E-013, E-13AE08, E-13AE12, E-13SB08A, E-13SB08D, E-1F9203, M-12AE01, M-12AE02, M-761-00132, M-761-00133, M-761-00137

5.2.6 Steam Generator Main Feedwater Isolation Valves

PFSSD requires that either the main feedwater isolation valves (MFIVs) be closed or the main feedwater pumps be stopped to prevent overfilling the steam generators. Flow diversion from auxiliary feedwater (AFW) to the main feedwater system piping is prevented by check valves AEV0420, AEV0421, AEV0422 and AEV0423. Closure of the main feedwater isolation valves is not required to prevent AFW flow diversion.

Each MFIV is designed to utilize system fluid (feedwater) as the motive force to open and close. The valve actuation (open or close) is accomplished through positioning a series of six electric solenoid pilot valves to either direct the system fluid to the Upper Piston Chamber (UPC) and/or the Lower Piston Chamber (LPC), or vent either or both piston chambers. The six solenoid pilot valves are divided into two trains (3 per train) that are independently powered and controlled. Either train can independently perform the PFSSD function to close the valve and isolate main feedwater. This is done by actuating either all close hand switch AEHS0080 (separation group 1) or AEHS0081 (separation group 4) to de-energize the associated solenoid valves.

The following table identifies the solenoids and associated control cables for each hand switch.

MFIV	AEHS0080 (Sep Group 1)		AEHS0081 (Sep Group 4)	
	Solenoids	Cable	Solenoids	Cable
AEFV0039	MV1, MV3, MV5	11AEK16AH	MV2, MV4, MV6	14AEK17AH
AEFV0040	MV1, MV3, MV5	11AEK17AH	MV2, MV4, MV6	14AEK16AH
AEFV0041	MV1, MV3, MV5	11AEK16BH	MV2, MV4, MV6	14AEK17BH
AEFV0042	MV1, MV3, MV5	11AEK17BH	MV2, MV4, MV6	14AEK16BH

All 4 cables associated with the 12 separation group 1 solenoid valves are run in area C-21. Cable damage due to a fire will likely result in disruption of power to the solenoids, which will close the valves. The four separation group 4 cables associated with hand switch AEHS0081 are unaffected by a fire in area C-21. Therefore, hand switch AEHS0081 is available to close the four MFIVs.

Cable 11ABK30BB provides 125 VDC power to Train A main steam and feedwater isolation system (MSFIS) actuation cabinet SA075A from NK5119. Damage to this cable would disrupt power to the separation group 1 solenoids and close the MFIVs, which is the desired PFSSD position. In addition, the Train B MSFIS is unaffected by the fire and AEHS0081 is available to close the MFIVs.

Cable 11AEK14AB is a control cable associated with hand switch AEHS0080. An open circuit will prevent closing the MFIVs using this hand switch. A hot short will cause the valves to close, which is the desired PFSSD position. Hand switch AEHS0081 is unaffected by the fire.

Based on the above discussion, MFIV isolation is assured using hand switch AEHS0081.

References: E-15000, XX-E-013, E-13AB30, E-13AE14, E-13AE15, E-13AE16, E-13AE17, E-1F9201, J-104-00295, J-104-00296, M-12AE02

5.2.7 Auxiliary Feedwater

The PFSSD design requires the use of one auxiliary feedwater pump (AFP) supplying water to at least two steam generators. The turbine driven auxiliary feedwater pump (TDAFP) is normally aligned to supply all four steam generators. The Train A motor driven auxiliary feedwater pump (MDAFP) is aligned to supply steam generators B and C. The Train B MDAFP is aligned to supply steam generators A and D.

The normal source of water to the AFPs is the condensate storage tank (CST). The emergency supply is from the essential service water (ESW) system. For commercial concerns, the CST is the preferred source and contains sufficient volume to supply the entire AFW demand to achieve cold shutdown and is available if a fire occurs in this area.

Motor operated valves (MOVs) in the system allow operators to line up the auxiliary feedwater system as required to achieve and maintain safe shutdown. Damage to the MOV circuits due to a fire could prevent operators from lining up the system from the control room.

Several PFSSD cables associated with various components of the auxiliary feedwater system (AL) run through fire area C-21. These cables are identified in Table C-21-3. All cables are associated with Train A (separation group 1). There are no Train B (separation group 4) cables associated with the AFW system running through fire area C-21.

Damage to the Train A cables listed in Table C-21-3 could prevent operation of Train A MDAFP. However, Train B MDAFP and the TDAFP are unaffected by a fire in area C-21. The suction source to the Train B MDAFP is available from the CST and Train B ESW. The suction source to the TDAFP is available from Train B ESW only. The TDAFP is available to supply AFW to steam generators B and C but the capability of the TDAFP to supply steam generators A and D could be affected.

Condensate storage tank pressure transmitters ALPT0037, ALPT0038 and ALPT0039 are included in the PFSSD design because they initiate swap over to ESW upon 2/3 low CST pressure indications. Panels SA036A, SA036B and SA036C monitor pressure transmitter signals on ALPT0037, ALPT0039 and ALPT0038, respectively. A spurious low CST pressure due to fire damage to cables associated with two of these pressure transmitters could swap the water source to ESW. This is only a commercial concern and should be prevented if possible.

Cables 11ALI08AA and 11ALI08AC are instrument cables associated with ALPT0037. Cables associated with the remaining two pressure transmitters are not run in C-21. Therefore, swap over to ESW due to spurious low CST pressure is not feasible if a fire occurs in this area.

Cable 11SAK21AA supplies 125 VDC power to panel SA036A. Cable 11SAY21AA supplies 120 VAC power to panel SA036A. Damage to these cables could result in a loss of power to the panel and could prevent automatic operation of Train A low suction pressure (LSP) swap over. Power cables associated with LSP signals controlled by panels SA036B and SA036C are unaffected by a fire in this area.

Based on the above discussion, auxiliary feedwater is assured if a fire occurs in fire area C-21 using Train B MDAFP supplying auxiliary feedwater to steam generators A and D and the TDAFP supplying AFW to steam generators B and C. However, as discussed in Section 5.2.1, steam generators A and C ARVs could be affected. Therefore, the assured method to achieve PFSSD if a fire occurs in this area is the Train B MDAFP supplying steam generator D and the TDAFP supplying steam generator B.

References: E-15000, XX-E-013, E-13AL01A, E-13AL01B, E-13AL02A, E-13AL02B, E-13AL03A, E-13AL03B, E-13AL04A, E-13AL04B, E-13AL05A, E-13AL05B, E-13AL07A, E-13AL08, E-13AL09, E-13SA21, E-1F9202, E-1F9203, E-1F9204, E-1F9402A, E-1F9402B, J-10SA, M-12AL01

5.2.8 Pressurizer PORVs and Block Valves

PFSSD requires that either the pressurizer power operated relief valve (PORV) or its associated block valve be closed. Cables and components associated with PORV BBPCV0455A and associated block valve BBHV8000A are run through area C-21. Cables and components associated with PORV BBPCV0456A and associated block valve BBHV8000B are not located in fire area C-21.

The pressurizer PORVs are not considered high/low pressure interfaces. The valves are supplied power by an ungrounded 125 VDC system. Therefore, based on GL 86-10, consideration of multiple proper polarity hot shorts is not required. A single proper polarity hot short still needs to be considered.

In the event a fire causes BBPCV0455A to open and damages BBHV8000A cables, Operators can close BBPCV0455A by placing hand switch BBHIS0455A, located on RL021, in the close position. Pressurizer level and RCS pressure indication are available to diagnose a failed open PORV using BBLI0460A and BBPI0406, respectively. In addition, pressurizer pressure indication is available using BBPI0456 and BBPI0458.

Instrument cables 11BBI16KB and 13BBI16MB associated with pressurizer pressure transmitters BBPT0455 and BBPT0457 are run in fire area C-21. Damage to these cables could send a spurious high-pressure signal to the pressurizer master controller. As discussed in Calculation XX-E-013, Appendix 1, the Ovation pressurizer pressure control system uses 4-channel verification from all four pressurizer pressure transmitters to operate the pressurizer PORVs. Failure of a single channel will not cause the spurious operation of the PORVs since the system uses the 2nd highest input as the validated signal. Damage to two channels will not cause the PORVs to open because both channels would have to fail to the exact same value at the exact same time and therefore this failure mode is not credible, as discussed in XX-E-013.

Cable 15SBS06AD provides output from panel RP043 to solid state protection cabinet SB029D to energize relay K713 on high pressure in the pressurizer. High pressurizer pressure will close the K713 contact (drawing E-13BB40) and open pressurizer PORV BBPCV0455A. Low pressure in the pressurizer will open the K750 contact (drawing E-13BB40) and close the PORV. Therefore, damage to this cable could cause the spurious opening of the PORV. If damage is limited to this cable, the PORV can be closed by placing BBHIS0455A in the close position.

The PFSSD function of cable 15SBS08ED is to provide BBPT0455 pressurizer pressure input signals from SB038 (Protection Set I) to Ovation NSSS control cabinet 6 (RP047). The PFSSD function of cable 15SBS08GC is to provide BBPT0457 pressurizer pressure input signals from SB037 (Protection Set III) to Ovation NSSS control cabinet 6 (RP047). These cables carry a 0 to 10 VDC signal to the Ovation pressure control system. The operation of the Ovation pressure control system is described above and in Calculation XX-E-013. Due to the 4-channel validation logic of the Ovation controller, damage to these cables will not cause the spurious operation of the pressurizer PORVs, spray valves or heaters. Therefore, damage to cables 15SBS08ED and 15SBS08GC will not adversely impact PFSSD.

Cables 15SCR15RF and 15SCR15RG are Ethernet cables that provide data communication between panels RP047 and RP043. These cables support functionality of pressurizer PORV BBPCV0455A. Damage to these data cables will not result in spurious operation of the valve.

Based on the above discussion, pressurizer PORV BBPCV0455A could spuriously open due to damage to the PORV control cables and block valve BBHV8000A may not close due to cable damage. The PORV can be closed using hand switch BBHIS0455A in the main control room.

References: E-15000, XX-E-013, E-13BB16, E-13BB39, E-13BB40, E-13SB06, E-13SB08C, E-13SC03, E-13SC07, E-1F9201, E-1F9301, M-12BB02, M-744-00028, M-761-02018, M-761-02079, M-761-02127, M-761-02169, M-761A-00019, M-767-00186, OFN KC-016, CR 13079, DCP 12944, DCP 13324.

5.2.9 Reactor Coolant System (RCS) Pressure Indication

The PFSSD design requires RCS pressure indication to be available to ensure operators have adequate diagnostic indication of RCS pressure.

RCS pressure indication is provided in the control room using pressure indicators BBPI0405 or BBPI0406. Cable 11BBI15EB is an instrument cable that runs from pressure transmitter BBPT0405 to process protection cabinet SB038. Cable 11SBS08AC is an instrument cable that runs from SB038 to BBPI0405 on RL021. Damage to these cables will prevent pressure indication on BBPI0405.

Redundant RCS pressure transmitter BBPT0406 and pressure indicator BBPI0406 are unaffected by a fire in area C-21. Therefore, RCS pressure indication is available using BBPI0406.

References: E-15000, XX-E-013, E-13BB15, E-13BB16, E-13SB08D, E-1F9201, E-1F9205, M-12BB04, M-761-00133

5.2.10 RCS Hot and Cold Leg Temperature Elements

PFSSD requires RCS hot and cold leg temperature indication on at least one loop to verify flow through the steam generators. The temperature elements used for this purpose are listed in the table below.

RCS Hot and Cold Leg Temperature Elements/Indicators Used for PFSSD		
ELEMENT	**INDICATOR**	**FUNCTION**
BBTE0413A	BBTI0413A	RCS Hot Leg Temperature Element (WR) Loop 1
BBTE0413B	BBTI0413B	RCS Cold Leg Temperature Element (WR) Loop 1
BBTE0423A	BBTR0423	RCS Hot Leg Temperature Element (WR) Loop 2
BBTE0423B	BBTI0423B	RCS Cold Leg Temperature Element (WR) Loop 2
BBTE0433A	BBTR0433	RCS Hot Leg Temperature Element (WR) Loop 3
BBTE0433B	BBTR0433	RCS Cold Leg Temperature Element (WR) Loop 3
BBTE0443A	BBTR0443	RCS Hot Leg Temperature Element (WR) Loop 4
BBTE0443B	BBTR0443	RCS Cold Leg Temperature Element (WR) Loop 4

As identified in Table C-21-3, cables associated with RCS temperature elements BBTE0413A, BBTE0423A, BBTE0433B and BBTE0443B and RCS temperature indicators BBTI0413A and BBTI0423A are run in fire area C-21. A fire could damage these cables and cause temperature indication on the four temperature elements to be unavailable. Consequently, temperature indication on at least one leg on each loop could be lost, which is not in accordance with the PFSSD methodology at Wolf Creek.

Cable 15RLY01EA supplies 120 VAC power from PN0738 to RL021/RL022. The power splits at RL021/RL022 and supplies power to PFSSD component BBTR0423 as well as some non-PFSSD components. Loss of power to this temperature recorder will not adversely impact PFSSD since other methods are available to determine RCS temperature, as described below.

Procedure EMG ES-04, Attachment B Section B1 provides alternate indication in the control room that may be used to verify natural circulation flow. One of these methods verifies that steam generator pressure is stable or decreasing. Based on Sections 5.2.1 and 5.2.7, cooldown is assured using loops 2 and 4. Based on Section 5.2.5, SG B pressure transmitter ABPT0525 and SG D pressure transmitters ABPT0545 and ABPT0546 are unaffected by a fire in C-21. These pressure transmitters, along with their respective indicators in the control room, can be used, per EMG ES-04, to verify heat removal in loops 2 and 4.

The configuration is acceptable because, in the event of a fire in area C-21, cooldown can be performed using RCS loops 2 and 4. RCS wide range hot and cold leg temperature elements (BBTE0423B and BBTE0443A) as well as ABPT0525, ABPT0545 and ABPT0546 will provide indication of flow through the steam generators.

References: E-15000, XX-E-013, E-13BB15, E-13RL01, E-13RL06, E-13SB08D, E-1F9201, M-12AB01, M-12BB01, M-761-00133, EMG ES-04

5.2.11 Pressurizer Pressure and Level Indication

The PFSSD support function requires pressurizer pressure and level indication to be available. These indications are used to diagnose spurious actuations such as a failed open pressurizer PORV and failed open letdown valves causing a loss of RCS inventory.

Pressurizer pressure is provided by pressure transmitters BBPT0455, BBPT0456, BBPT0457 and BBPT0458. Signals from these transmitters are indicated in the control room on pressure indicators BBPI0455A, BBPI0456, BBPI0457 and BBPI0458, respectively. As discussed in Section 5.2.2, cables associated with BBPT0455 and BBPT0457 are run in fire area C-21. In addition, cable 15SBS08AA associated with BBPI0455A and cable 15SBS08CA associated with BBPI0457 are run in fire area C-21. Damage to these cables will prevent pressurizer pressure indication on these indicators. Cables associated with pressurizer pressure indicators BBPI0456 and BBPI0458 are unaffected by a fire in this area.

Pressurizer level is provided by level transmitters BBLT0459 and BBLT0460. Signals from these transmitters are indicated in the control room on level indicators BBLI0459A and BBLI0460A. Cable 11BBI16PB associated with BBLT0459 runs through area C-21. In addition, cable 11SBS08AA associated with BBLI0459A is run in area C-21. Damage to these cables could prevent pressurizer level indication on BBLI0459A. Cables associated with pressurizer level transmitter BBLT0460 and level indicator BBLI0460A are unaffected by a fire in area C-21.

Based on the above discussion, pressurizer pressure and level indication is available using BBPI0456, BBPI0458 and BBLI0460A if a fire occurs in this area.

References: E-15000, XX-E-013, E-13BB16, E-13SB08A, E-13SB08B, E-13SB08D, E-1F9301, J-200-00095, M-12BB02, M-761-00133, M-761-00137

5.2.12 Reactor Head Vent Valves

PFSSD requires that one of the two reactor vessel head vent valves on each flow path (2 flow paths total) be closed to prevent uncontrolled depressurization of the RCS. Either BBHV8001A or BBHV8002A and either BBHV8001B or BBHV8002B needs to be closed.

Cables associated with head vent valves BBHV8001A and BBHV8002A run through C-21. An external (+) 125 VDC hot short in these cables is the only failure that will spuriously open the valves. The cable associated with BBHV8001A runs in tray with other cables carrying the proper voltage and polarity, therefore BBHV8001A could spuriously open.

Cable 11BBK30CA, associated with BBHV8002A, runs in conduit throughout this area. Only one other cable (11BGK48CB) associated with excess letdown valve BGHV8153A runs in this conduit. A hot short between cables 11BBK30CA and 11BGK48CB will not cause BBHV8002A to open since 11BGK48CB does not have a normally energized proper polarity source conductor to cause the spurious operation. Hand switch BGHIS8153A is maintained in the close position (contacts open) which prevents energizing the source conductor.

Cables for the remaining two head vent valves are not run through area C-21. Therefore, the second flow path is isolated using either head vent valve BBHV8001B or BBHV8002B.

Based on the above discussion, the reactor head vent flow path will remain isolated throughout the event. Valve BBHV8002A will remain closed as long as BGHIS8153A is maintained in the close position and valves BBHV8001B and BBHV8002B are unaffected.

References: E-15000, XX-E-013, E-1F9301, E-13BB30, E-13BG48, M-12BB04

5.2.13 Centrifugal Charging System

At least one centrifugal charging pump (CCP) is required for PFSSD to provide RCP seal cooling, reactivity control and inventory control. These functions are accomplished using a CCP taking suction from the refueling water storage tank (RWST) and injecting through the RCP seals. RCP seal injection provides approximately 20 gpm makeup to the RCS and provides adequate boron concentration to maintain sub-critical reactivity conditions. If RCP seal injection is unavailable, reactivity and inventory control is provided by lining up the CCPs to the boron injection tank (BIT). The normal charging pump (NCP) is not credited and is assumed lost.

Cables 11BGB01AB and 11BGB01AE associated with breaker NB0104 control circuit for Train A charging pump motor DPBG05A run in this area. Damage to the cables could prevent operation of the Train A charging pump. Redundant Train B charging pump PBG05B is unaffected by a fire in this area.

Cables 11BGG11CC and 11BGG11CD associated with Train A CCP miniflow valve BGHV8110 run through area C-21. Redundant Train B cables for miniflow valve BGHV8111 are run in a different area and are unaffected by a fire in area C-21.

Cable 11BGG52AC, associated with Train A RCP seal injection flow throttling valve BGHV8357A, is run in fire area C-21. Damage to this cable will prevent operation of the valve from the control room. PFSSD requires RCP seal injection using an available centrifugal charging pump and flowing through the associated throttling valve. Cables associated with redundant Train B valve BGHV8357B are run in a separate fire area and are unaffected by a fire in area C-21.

Cable 11BGI51AA associated with RCP total seal flow transmitter BGFT0215A and cable 11SBS08AA associated with RCP total seal flow indicator BGFI0215A are run in this area. Damage to these cables could prevent operators from using BGFI0215A to diagnose a loss of RCP seal injection. Flow indicator BGFI0215B is unaffected by a fire in this area and can be used to inform operators if RCP seal injection has been lost.

Based on the above discussion, the Train A CCP could be affected but the Train B CCP is available if a fire occurs in area C-21. Loss of the operating charging pump can be diagnosed using BGFI0215B.

References: XX-E-013, E-15000, E-13BG01, E-13BG11B, E-13BG51, E-13BG52, E-13SB08D, E-1F9102, E-1F9302, E-1F9401A, M-12BG03

5.2.14 Charging Flow to Regenerative Heat Exchanger Isolation Valves

PFSSD requires charging flow to be directed to the RCP seals. To ensure adequate flow to RCP seals, flow diversion to the regenerative heat exchanger needs to be prevented. Valves BGHV8105 and BGHV8106 are included in the PFSSD design to accomplish this task. Manual valve BG8402B is also included to provide an alternate means of closing this flow path if either BGHV8105 or BGHV8106 are unavailable and is also used during alternate safe shutdown per OFN RP-017.

Cables associated with BGHV8106 are run in fire area C-21 and could be damaged by a fire, preventing valve BGHV8106 from being closed from the control room. Cables associated with redundant valve BGHV8105 do not run in fire area C-21. Consequently, valve BGHV8105 can be isolated from the control room if a fire occurs in fire area C-21.

References: E-15000, XX-E-013, E-13BG11A, E-1F9102, E-1F9302, M-12BG03

5.2.15 Volume Control Tank (VCT)

Power and control cables associated with VCT valve BGLCV0112B run through fire area C-21. Cables for redundant VCT valve BGLCV0112C are run in a separate fire area and are unaffected by a fire in area C-21. The PFSSD position of these valves is at least one closed. Therefore, PFSSD can be accomplished by isolation of BGLCV0112C.

A hot short could cause inadvertent closure of BGLCV0112B. If this occurs prior to establishing suction from the RWST, damage to the operating charging pump could occur due to loss of suction. The assumptions in calculation XX-E-013 state that systems and components are in their normal operating position or status prior to the fire. The Normal Charging Pump (NCP) is the normally operated pump and is assumed to be operating at the time of the fire. Inadvertent closure of valve BGLCV0112B with no suction from the RWST would result in damage to the NCP but the centrifugal charging pumps would remain unaffected. As stated in 5.2.13, the Train A CCP may be unavailable but the Train B CCP is unaffected by the fire.

As discussed in Section 5.2.2, a spurious SIS could occur as a result of a fire in this area, causing automatic start of the CCPs and swap over to the RWST. RWST to CCP B suction valve BNLCV0112E is unaffected by a fire in area C-21 and would open, as designed, upon receipt of a SIS. Therefore, if valve BGLCV0112B were to spuriously close coincident with a SIS, the suction source to CCP B would be available.

Cables 11BGI51CA and 11SBS08AA associated with VCT level transmitter BGLT0112 runs through area C-21. Damage to cable 11BGI51CA could cause a false low-low VCT level signal and initiate refueling water sequence, which is the desired PFSSD lineup. Damage to cables 11BGI51CA or 11SBS08AA could prevent VCT level indication on BGLI0112 in the control room. Cables associated with BGLT0185 are unaffected by the fire and BGLI0185 will provide reliable level indication in the control room.

Based on the above discussion, a fire in area C-21 that affects components associated with the VCT will not adversely impact the ability to achieve and maintain PFSSD.

References: XX-E-013, E-15000, E-13BG12, E-13BG12A, E-13BG51, E-13BN01, E-13SB08D, E-1F9102, E-1F9302, M-12BG03

5.2.16 Excess Letdown Isolation Valves

PFSSD requires the excess letdown path be isolated to prevent uncontrolled depressurization of the RCS. To accomplish this, either normally closed valve BGHV8153A or BGHV8154A must be maintained closed and either normally closed valve BGHV8153B or BGHV8154B must be maintained closed. Cables associated with valves BGHV8153A and BGHV8154A are run in fire area C-21.

Cable 11BGK48DB is run in cable tray through area C-21. A hot short in this cable will energize the solenoid and open valve BGHV8154A. The cable tray carries other cables that have the proper voltage and polarity such that a cable-to-cable hot short is possible. Therefore, valve BGHV8154A could spuriously open if a fire occurs in fire area C-21.

Cable 11BGK48CB is run in conduit through area C-21. This conduit carries one other cable (11BBK30CA) which is a control cable for head vent valve BBHV8002A and is normally de-energized. Therefore, the possibility of an inter-cable hot short that would cause valve BGHV8153A to open is not credible.

A hot short in cable 11BGK48CB is not sufficient to cause the valve to open because this failure mode would not energize the control solenoid.

Circuits for BGHV8153B and BGHV8154B do not run through fire area C-21 and are unaffected by a fire in this area. Therefore, these valves remain closed.

Based on this discussion, there is reasonable assurance that cable damage, along with any combination of cable failures, will not cause valve BGHV8153A to spuriously open in the event of a fire in area C-21. Therefore, both excess letdown flow paths will remain isolated.

References: E-15000, XX-E-013, E-1F9301, E-13BG48, M-12BG01

5.2.17 Refueling Water Storage Tank (RWST) to Charging Pumps Suction Isolation Valves

Cables associated with RWST to CCP A valve BNLCV0112D run through fire area C-21. As stated earlier, the Train A CCP may not be available if a fire occurs in fire area C-21. Therefore, the Train B CCP is used, taking suction from the RWST. Cables associated with valve BNLCV0112E are unaffected by a fire in area C-21. Therefore, BNLCV0112E can be opened from the control room to provide the necessary suction from the RWST to Train B CCP.

References: E-15000, XX-E-013, E-13BN01, E-1F9102, E-1F9302, M-12BN01

5.2.18 Refueling Water Storage Tank (RWST) and Containment Sump Isolation Valves

To prevent drain down of the RWST into the containment sump, PFSSD requires that either valve BNHV8812A or valve EJHV8811A and valve BNHV8812B or valve EJHV8811B be closed during hot standby. For cold shutdown, the operating train containment sump valve (EJHV8811A or EJHV8811B) must be maintained closed to prevent flow diversion from the RCS to the containment sump. Valves BNHV8812A and BNHV8812B are normally open and valves EJHV8811A and EJHV8811B are normally closed.

A control cable (11BNG03AC) for valve BNHV8812A runs through fire area C-21. Damage to this cable could prevent closing this valve from the control room or could cause the valve to spuriously close. In addition, cable damage could prevent the valve from automatically closing when valve EJHV8811A reaches full open position.

A control cable (11EJG06AC) associated with valve EJHV8811A runs through fire area C-21. Damage to this cable will not result in valve EJHV8811A opening as long as valve BNHV8812A remains open. If valve BNHV8812A is fully closed, it will provide a permissive for valve EJHV8811A to open. If valve EJHV8811A opens due to damage to cable 11EJG06AC, drain down will not occur since valve BNHV8812A is closed.

The instrument cable for RWST level transmitter BNLT0930 and level indicators BNLI0930 and BNLI0932 run through area C-21. Cables for the remaining three RWST level transmitters and two level indicators are unaffected. Damage to the cables associated with BNLI0930 and BNLI0932 will not cause a spurious low RWST level. Since only one RWST level transmitter cable is run in this area, a spurious low RWST level signal is not credible.

Based on the above discussion, drain down of the RWST to the containment sump is not credible if a fire occurs in area C-21.

5.2.19 Essential Service Water System

One train of Essential Service Water (ESW) is required to be operable to ensure adequate cooling for essential equipment. A number of cables associated with Train A ESW components are run in this area. Therefore, Train A ESW cannot be relied on for PFSSD if a fire occurs in this area. Cables associated with Train B ESW are run in a different fire area. Therefore, Train B ESW is available if a fire occurs in fire area C-21.

Valve EFHV0023 is a normally open isolation valve on the service water system feed to the Train A Essential Service Water System. Either this valve or valve EFHV0025 is required to be closed when operating the Train A ESW system for PFSSD. Power and control cables associated with EFHV0023 are run in this area. Damage to these cables could prevent closing EFHV0023 from the control room. Redundant valve EFHV0025 is unaffected by a fire in area C-21 and can be closed from the control room to isolate this flowpath. In addition, check valve EFV0470 is installed in this line and will prevent flow diversion in the unlikely event valve EFHV0025 cannot be closed.

Valve EFHV0024 is a normally open isolation valve on the service water system feed to the Train B Essential Service Water System. Either this valve or valve EFHV0026 is required to be closed when operating the Train B ESW system for PFSSD. Power and control cables associated with EFHV0024 are run in this area. Damage to these cables could prevent closing EFHV0024 from the control room. Redundant valve EFHV0026 is unaffected by a fire in area C-21 and can be closed from the control room to isolate this flowpath. In addition, check valve EFV0471 is installed in this line and will prevent flow diversion in the unlikely event valve EFHV0026 cannot be closed.

Valve EFHV0041 is a normally open isolation valve on the return line from the Train A Essential Service Water System to the service water system. Either this valve or valve EFHV0039 is required to be closed when operating the Train A ESW system for PFSSD. Power and control cables associated with EFHV0041 are run in this area. Damage to these cables could prevent closing EFHV0041 from the control room. Redundant valve EFHV0039 is unaffected by a fire in area C-21 and can be closed from the control room to isolate this flowpath.

Valve EFHV0042 is a normally open isolation valve on the return line from the Train B Essential Service Water System to the service water system. Either this valve or valve EFHV0040 is required to be closed when operating the Train B ESW system for PFSSD. Power and control cables associated with EFHV0042 are run in this area. Damage to these cables could prevent closing EFHV0042 from the control room. Redundant valve EFHV0040 is unaffected by a fire in area C-21 and can be closed from the control room to isolate this flowpath.

Valve EFHV0037 is the Train A return isolation valve from ESW to the Ultimate Heat Sink. This valve is required to be open when operating the Train A ESW system for PFSSD. A cable (11EFG06AC) associated with this valve is run in this area and damage could cause the valve to spuriously close. Circuits for redundant Train B valve EFHV0038 are not run in area C-21 and will be unaffected by the fire.

Cable 11GDI04AA provides ESW A room temperature from temperature element GDTE0001 to temperature controller GDTC0001. Cables 11GDI04AB and 11GDI04AC provide signals from GDTC0001 to outside air intake damper GDTZ0001A and recirculation damper GDTZ0001B, respectively, to change position based on room temperature. Damage to these cables could prevent operation of the dampers. Temperature controls for Train B ESW pump room are unaffected by a fire in area C-21.

Cable 11GDG01AC is associated with the indicator lights on Train A ESW pump room supply fan CGD01A hand switch GDHIS0001B. Damage to this cable could prevent operation of the fan. Cables for Train B ESW pump room supply fan CGD01B are unaffected by a fire in this area.

Cable 11RPY10BA supplies 120 VAC control power to the automatic and manual start circuits in panel RP068 from NG01ACR1 for Train A ESW pump room supply fan CGD01A. Cables 11GDY01AA, 11GDY01AB and 11GDY01AC are associated with the Train A ESW pump room supply fan CGD01A control circuit. Damage to these cables could prevent operation of the unit, which could prevent continuous operation of the Train A ESW pump. If this occurs, the Train B ESW pump room supply fan is unaffected by the fire.

PFSSD is assured for a fire in area C-21 using Train B ESW pump PEF01B and associated components.

References: E-15000, XX-E-013, E-093-00052, E-093-00053, E-13EF02, E-13EF03, E-13EF04, E-13EF05, E-13EF06, E-13EF07, E-13EF08, E-13EF09, E-13RP10, E-13EF11, E-K3EF08, E-K3GD01, E-K3GD04, E-1F9402A, E-1F9402B, E-1F9403, E-1F9424A, E-1F9443, E-K3EF01, J-201-00139, M-12EF01, M-12EF02, M-K2EF01, M-K2GD01

5.2.20 Component Cooling Water

For PFSSD, the component cooling water (CCW) system is used to provide cooling to the centrifugal charging pump (CCP) oil cooler, the RHR heat exchanger and the RHR pump seal cooler. In addition, the CCW system provides cooling to the RCP thermal barriers and is credited as a backup to RCP seal injection for maintaining seal cooling. Cables associated with Train A CCW pumps PEG01A and PEG01C are run in this area. Damage to these cables could prevent operation of the Train A CCW system.

Cables associated with a number of valves in the Train A CCW system are run in fire area C-21. These cables and associated valves are listed in Table C-21-3. Cables associated with valves in the Train B CCW system do not run in fire area C-21 and are unaffected by a fire in this area.

Valves BBHV0013, BBHV0014, BBHV0015, BBHV0016, EGHV0058, EGHV0061, EGHV0126 and EGHV0132 provide isolation capability for CCW flow to/from the RCP thermal barriers. Cables associated with these components are located in area C-21. If the valves fail to the open position, CCW would continue to flow to the RCP components, including the thermal barrier. This continued flow of water will not adversely impact PFSSD. If the valves fail to the closed position, CCW flow to the thermal barrier could be lost. This is acceptable since RCP seal injection is available.

Flow transmitters BBFT0017, BBFT0018, BBFT0019 and BBFT0020 are associated with valves BBHV0013, BBHV0014, BBHV0015 and BBHV0016, respectively. The flow transmitters monitor flow in the CCW piping and shut the valves on high CCW flow. Cables associated with these flow transmitters are run in this area. Damage to these cables could cause a spurious high CCW flow signal and close the valves. Damage to the valve cables could prevent re-opening the valves.

Cable 11EGI19AA is associated with CCW to RCP flow indicator EGFI0128. Cable 11EGI19AB is associated with CCW to RCP flow transmitter EGFT0128. Damage to these cables could prevent operators from diagnosing a loss of CCW flow to the RCP thermal barriers using flow indicator EGFI0128. CCW to RCP flow indicator EGFI0129 is unaffected by a fire in area C-21 and can be used to diagnose a loss of CCW flow to the RCP thermal barriers.

Based on the above discussion, a fire in area C-21 could affect CCW flow to/from the RCP thermal barriers. The Train B CCW system is available to supply cooling to the remaining Train B PFSSD components. Loss of CCW flow to the RCP thermal barriers can be diagnosed using flow indicator EGFI0129. RCP seal injection is unaffected.

References: E-15000, XX-E-013, E-13BB03, E-13BB28, E-13EG01A, E-13EG01B, E-13EG05A, E-13EG05B, E-13EG07, E-13EG09, E-13EG09A, E-13EG13, E-13EG16, E-13EG17A, E-13EG18, E-13EG19, E-1F9303, E-1F9401A, M-12EG01, M-12EG02, M-12EG03

5.2.21 Residual Heat Removal System

PFSSD requires one train of residual heat removal (RHR) to be available for shutdown cooling. The RHR system is not used for hot standby.

A number of cables associated with the RHR system run in fire area C-21. These cables are discussed in the following paragraphs. The PFSSD impact on the RHR system due to a spurious SIS is discussed in Section 5.2.2. This Section discusses fire damage to RHR system cables and components absent a spurious SIS.

Valve EGHV0101 is the Train A CCW to RHR Heat Exchanger control valve. Valve EGHV0102 is the Train B CCW to RHR Heat Exchanger control valve. PFSSD requires that the valve on the operating train of CCW be closed until shutdown cooling mode is entered, at which time the valve on the operating train of RHR needs to be open. Cables 11EGG07AC and 11EGG07AD are control cables associated with valve EGHV0101. Damage to either cable could cause the spurious opening of the valve and could prevent operation when lining up for shutdown cooling. Valve EGHV0102 is unaffected by a fire in this area.

Cables 11EJB01AB and 11EJB01AC are control cables associated with Train A RHR pump feeder breaker NB00101. Damage to these cables could prevent operation of the pump from the control room or could cause the pump to spuriously operate. If the pump fails to operate, the Train B RHR pump is available. If the pump spuriously operates with no suction source, it will likely become damaged and the Train B RHR system will be used.

Cable 11EJG04AC is a control cable associated with normally closed valve EJHV8804A. This valve is required to remain closed when aligning Train A RHR for cold shutdown. For hot standby, the valve can be in any position. Damage to this cable could cause the valve to open which would cause flow diversion from Train A RHR to the charging header. Train B valve EJHV8804B is unaffected by a fire in area C-21.

Cables associated with normally closed valves EJHV8701A (Train A) and EJHV8701B (Train B) run in fire area C-21. These valves are required to be open when aligning the respective RHR Train for cold shutdown. Cable damage could prevent opening the associated valve from the control room. Therefore, a fire in area C-21 may require a cold shutdown repair to be made within 72 hours per 10CFR50, Appendix R or a containment entry to manually open EJHV8701B when using RHR Train B.

Cable 11EJG08AC, associated with Train A RHR pump mini-flow valve EJFCV0610, runs in fire area C-21. The mini-flow valve protects the Train A RHR pump during low-flow in the system. Damage to the cable could prevent operation of the valve. Cables associated with Train B RHR mini-flow valve EJFCV0611 do not run in fire area C-21. Therefore, the Train B RHR pump mini-flow valve is unaffected by a fire in area C-21.

The RHR pump discharge to RCS cold leg isolation valve (EJHV8809A or EJHV8809B) needs to be open on the operating train. Damage to cables 11EJG09CC and 11EJG09CD would

likely result in valve EJHV8809A remaining in its as-is normally open position, which is the preferred PFSSD position. However, two proper intra-cable hot shorts in cable 11EJG09CD or one intra-cable hot short in cable 11EJG09CD combined with a short to ground on conductor 31 would spuriously close the valve.

Cable 15EJI12AA is an instrument AC power cable associated with Train A RHR flow control valve EJHCV0606. Cable 15RLY01DA supplies 120 VAC power to RL017/RL018 from PN0736, where the power splits and feeds EJHCV0606 via cable 15EJI12AA. Damage to these cables would cause a loss of power to the valve controller which will fail the valve open, which is the desired position if using Train A RHR. The Train B RHR flow control valve EJHCV0607 is unaffected by a fire in this area.

Based on the above discussion, a number of Train A RHR components could be affected by a fire in area C-21 but Train B RHR is unaffected. A cold shutdown repair or containment entry may be required to open valve EJHV8701B when going to cold shutdown.

References: E-15000, XX-E-013, E-13EJ01, E-13EJ04A, E-13EJ04B, E-13EJ05A, E-13EJ05B, E-13EJ08, E-13EJ09A, E-13EJ12, E-13RL01, E-13RL04, E-1F9205, E-1F9301, E-1F9401A, M-12EJ01, CR 25002

5.2.22 Safety Injection Pumps

The PFSSD strategy is to prevent operation of the Safety Injection (SI) pumps to ensure an adequate supply of borated water in the RWST. One cable (11EMB01AB) associated with Train A SI pump is run in fire area C-21. Damage to this cable could cause the spurious start of the pump and could prevent stopping the pump from the control room.

If the Train A SI pump spuriously starts with the reactor at normal pressure, PFSSD will be assured. The pump will not discharge into the RCS due to the pressure differential between the RCS (approximately 2,235 psig) and the SI pump shutoff pressure (approximately 1,565 psig). In addition, the set point of the discharge relief valve (EM8853A) to the Recycle Holdup Tank is 1,825 psig. Therefore, no inventory will be lost from the RWST if the SI pumps spuriously start. With the SI pump operating at zero flow, damage to the pump could occur, which is a commercial concern only since the SI pump is not credited in the PFSSD analysis. If necessary, the pump can be stopped by opening breaker NB0103, but this action is not required for PFSSD.

Based on the above discussion, spurious operation of the Train A SI pump will not adversely impact PFSSD.

References: E-15000, XX-E-013, E-13EM01, E-1F9102, E-1F9302, M-12EM01, M-721-00096, WCRE-01

5.2.23 Boron Injection Tank Flowpath

The Boron Injection Tank (BIT) flowpath is credited for reactivity control and reactor coolant makeup. For reactivity control, the BIT flowpath is credited as an alternate source of boration in the event RCP seal injection is unavailable. Based on Calculation XX-E-013, RCP seal injection will provide sufficient boration to achieve and maintain cold shutdown reactivity conditions. Therefore, the BIT flowpath is not required for reactivity control if RCP seal injection is available. Since RCP seal injection is limited to 5 gpm per seal or 20 gpm total injection to the RCS, an additional RCS charging flowpath is required for adequate RCS makeup during plant transition from hot standby to cold shutdown. The BIT injection path was selected as the additional RCS charging flowpath.

A fire in area C-21 uses CCP B, since circuits and support systems for CCP A may be affected by the fire. Also, based on the discussion in 5.2.37, a fire in area C-21 has the possibility to cause a momentary loss of inventory through the letdown flow path until the letdown isolation valves close automatically or are failed closed.

Train A BIT inlet valve EMHV8803A may be affected by a fire in this area. Cables 11EMG02AC and 11EMG02AD, associated with EMHV8803A, are run in this area. Damage to these cables could prevent opening the valve and could prevent a flowpath from Train A CCP to the RCS via the BIT. Redundant Train B valve EMHV8801B is unaffected by a fire in this area so the Train B CCP flowpath to the RCS via the BIT is available.

The SIS test line is required to be isolated when charging through the BIT to prevent inventory loss. Either valve EMHV8964 or EMHV8871 is required to remain closed to prevent flow diversion through the SIS test line. Alternatively, both valves EMHV8843 and EMHV8882 can be closed to prevent flow. Cables associated with EMHV8964 and EMHV8882 are run in this area and the valves could open if damaged by a fire. Redundant valve EMHV8871 is unaffected by the fire and is available to ensure the SIS test line remains isolated.

Breaker PK6116 supplies power to a number of 125VDC loads on RL017/RL018 via cable 15RLK01DA. The only PFSSD load supplied by PK6116 is the control solenoid for valve EMHV8882. Valve EMHV8882 is the boron injection downstream test line and is required to be closed for PFSSD. De-energizing the control solenoid closes EMHV8882. Therefore, loss of power to the solenoid due to damage to cable 15RLK01DA will not impact PFSSD.

Based on the above discussion, charging through the BIT is unaffected by a fire in this area using Train B CCP and valves EMHV8801B and EMHV8803B. The SI test line can be isolated using valve EMHV8871.

References: E-15000, XX-E-013, E-13EM02, E-13EM02A, E-13EM02B, E-13EM02C, E-13EM05A, E-13EM12, E-13RL01, E-1F9302, M-12EM01, M-12EM02

5.2.24 Containment Spray Pumps

Spurious start of the containment spray (CS) pumps may complicate PFSSD due to the possible depletion of inventory in the RWST. Therefore, a spurious start of the CS pumps should be avoided or mitigated. A control cable (11ENB01AB) associated with Train A CS pump PEN01A runs through area C-21 and could cause a spurious start of the pump. The cable damage could prevent stopping the pump from the control room.

Normally closed valve ENHV0006 could open due to a spurious containment spray actuation signal. Also, a control cable associated with this valve runs in fire area C-21 and a hot short could cause the valve to open. If this occurs, water would flow from the containment spray nozzles, depleting inventory in the RWST.

Train B CS pump PEN01B could also start due to a spurious CSAS and valve ENHV0012 could open, causing containment spray on the Train B system. Cables associated with PEN01B are not run in this area so the pump can be stopped by placing main control room hand switch ENHIS0009 in pull-to-lock.

The total flow in the containment spray system with both pumps operating is 6,330 gpm (M-10EN). As stated above, the Train B pump can be stopped from the control room, after which the flow from containment spray will be 3,165 gpm. Based on calculation XX-E-013, Appendix 1, a maximum of 214,260 gallons of water can be lost from the RWST to maintain sufficient volume to achieve cold shutdown.

As stated previously, level indication in the RWST is available, so operators have the ability to diagnose a reducing RWST inventory. Assuming the Train B CS pump is stopped from the control room within 5 minutes, the time available to mitigate containment spray is:

6,330 gpm x 5 minutes = 31,650 gallons lost in first 5 minutes

214,260 gallons – 31,650 gallons = 182,610 gallons remaining after 5 minutes

182,610 gallons / 3,165 gpm = 57.7 minutes

57.7 min + 5 minutes = **62.7 minutes available**

A fire in this area could also result in the inability to isolate letdown, as discussed in Section 5.2.37. The maximum inventory loss through letdown is 195 gpm through all three orifice valves. If a multiple spurious operation scenario exists where containment spray spuriously operates concurrent with failed open letdown valves, the available time to mitigate this condition is as follows:

6,330 gpm + 195 gpm = 6,525 gpm lost for the first 5 minutes

6,525 gpm x 5 min = 32,625 gallons lost in first 5 minutes

214,260 gallons – 32,625 gallons = 181,635 gallons remaining after 5 minutes

Letdown is isolated in 50 minutes, at which time the 195 gpm flow goes to zero. The volume reduction from the RWST 45 minutes after the first containment spray pump is stopped is:

(3,165 gpm + 195 gpm) x 45 minutes = 151,200 gallons lost

181,635 gallons – 151,200 gallons = 30,435 gallons remaining after 50 minutes

30,435 gallons / 3,165 gpm = 9.6 minutes

50.0 min + 9.6 minutes = **59.6 minutes available**

Based on the above discussion, there is 59.6 minutes available to mitigate containment spray and failed open letdown, assuming one containment spray pump is stopped from the control room within 5 minutes and letdown is isolated within 50 minutes. Pump PEN01B can be stopped from the control room using ENHIS0009. Pump PEN01A can be stopped by opening breaker NB0102 in fire area C-9. This is an OMA. Refer to E-1F9900 for details. Reference Attachment 4, MSO Evaluation Scenario ID PWROG 16.

5.2.25 Safety Injection Accumulator Isolation Valves

PFSSD requires isolation of the SI accumulators prior to reducing RCS pressure below the injection pressure to avoid unnecessary accumulator discharge. This is accomplished by closing valves EPHV8808A, EPHV8808B, EPHV8808C and EPHV8808D. These valves are normally open with the MCC breaker administratively locked in the open position. Cables for valves EPHV8808A and EPHV8808C are run in fire area C-21.

Since the breakers for these valves are normally open, damage to these cables will not cause the valves to spuriously change position. However, damage to the cables will prevent closing the associated valve from the control room after power is restored.

The SI accumulators need to be isolated during cold shutdown, prior to the RCS reaching 1000 psig. If necessary, a containment entry can be made to manually close the valves.

References: E-15000, XX-E-013, M-12EP01, E-13EP02A, E-1F9201, CKL EP-120

5.2.26 Control Room Air Conditioning

Cables associated with Train A control room A/C unit SGK04A are run in this area. Damage to these cables could prevent operation of this unit. Cables associated with Train B control room A/C unit SGK04B are run in a separate area. Therefore, the Train B control room A/C unit is unaffected by a fire in this area.

Power and control cables associated with Train A Control Room A/C unit supply and return dampers GKHZ0029A and GKHZ0029B are run in area C-21. Damage to these cables could prevent operation of the associated dampers. Circuits for Train B Control Room A/C unit dampers do not run in area C-21.

Based on the above discussion, Control Room environmental conditions will be unaffected by a fire in area C-21.

References: XX-E-013, E-15000, E-13GK02A, E-13GK02B, E-13SA19, E-1F9442, M-12GK01

5.2.27 Class 1E Electrical Equipment Room A/C Unit

Power and control cables associated with Train A class 1E Electrical Equipment room A/C unit SGK05A are run in fire area C-21. A fire could damage these circuits and prevent operation of the unit. Circuits for Train B class 1E Electrical Equipment A/C unit SGK05B do not run in fire area C-21. Therefore, the Train B class 1E Electrical Equipment A/C unit is unaffected by a fire in this area.

Cable 11SAZ19KA associated with SGK05A is run in fire area C-21. Damage to this cable could prevent operation of SGK05A. Cables associated with SGK05B are unaffected by a fire in area C-21.

Cable 15GKK31CB is associated with the fire isolation signal on SGK05A. Damage to this cable could cause the unit to stop and prevent a re-start. Fire isolation signal cables associated with Train B class 1E A/C unit SGK05B are unaffected.

Based on the above discussion, Train B class 1E electrical equipment room cooling is available and is unaffected by a fire in area C-21.

References: XX-E-013, E-15000, E-13GK13, E-13GK31, E-13SA19, E-1F9444, M-12GK03, M-622.1A-00002

5.2.28 Standby Diesel Generation

Cables associated with the Train A diesel generator are run in this area. Also, cables associated with the Train A diesel generator room supply fan and exhaust damper run in this area. Damage to these cables could prevent operation of the Train A diesel generator and support systems.

Calculation XX-E-013 documents a loss of off-site power evaluation that identifies the fire areas in and around the plant in which a fire could cause a loss of off-site and on-site power. Per XX-E-013 and Section 5.2.30 of this evaluation, a fire in area C-21 could cause a loss of

off-site power on Train A. Train B off-site power and Train B diesel generator are unaffected by a fire in this area. Therefore, loss of the Train A diesel generator and off-site power to Train A will have no adverse impact on PFSSD.

References: XX-E-013, E-15000, E-13GM01, E-13GM04, E-13JE01, E-13KJ01A, E-13KJ06, E-13NE01, E-13NE10, E-1F9411A, E-1F9412A, E-1F9423, M-12GM01

5.2.29 Containment Coolers

PFSSD requires containment cooling to maintain the containment environment within EQ limits. Cables associated with Train A containment coolers are run in fire area C-21. Damage to these cables could prevent operation of the Train A containment coolers if a fire occurs in this area. Circuits for the Train B containment coolers are run in a separate fire area and are unaffected by a fire in area C-21.

As discussed earlier, Train B ESW is available if a fire occurs in fire area C-21. Therefore, the Train B containment coolers will have the necessary service water flow to ensure proper operation.

References: E-15000, XX-E-013, E-13GN02, E-13GN02A, E-1F9441, M-12GN01

5.2.30 Class 1E 4.16 kV ESF Switchgear Bus

Several cables associated with class 1E 4.16 kV switchgear bus NB01 are located in this area. Damage to these cables could prevent operation of Train A equipment powered by NB01. Cables associated with class 1E 4.16 kV switchgear bus NB02 are located in a different fire area and are unaffected by a fire in area C-21.

Cable 15RLK01CA supplies 125 VDC power to panel RL013/RL014 from PK6115. The PFSSD function of RL013/RL014 is to allow isolation of off-site power to NB01 and NB02 in the event of a fire in areas C-9 and C-10, respectively. RL013/RL014 is not required for PFSSD if a fire occurs in fire area C-21. Therefore, damage to this cable will not adversely impact the ability to achieve and maintain PFSSD in the event of a fire in area C-21.

Cable 15RPK09RA supplies 125 VDC power to panel RP060 from PK5113. The PFSSD function of RP060 is to isolate off-site power to NB01 and NB02 in the event of a fire in areas C-9 and C-10, respectively. RP060 is not required for PFSSD if a fire occurs in fire area C-21. Therefore, damage to this cable will not adversely impact the ability to achieve and maintain PFSSD in the event of a fire in area C-21.

Cable 15SY134 is associated with 13.8 kV off-site feeder breaker 13-48. Breaker 13-48 is one of two redundant off-site power feeders to bus NB01. Cable 15UU003 is associated with 13.8 kV off-site feeder breaker 13-8. Breaker 13-8 is the other redundant off-site power feeder for NB01. Damage to these cables could isolate the off-site power feed to NB01. Train B class 1E 4.16 kV bus NB02 is unaffected by a fire in area C-21. Therefore, damage to these cables will have no adverse impact on PFSSD.

Based on the above discussion, loss of power to NB01 and associated loads will not adversely impact PFSSD due to the availability of NB02 to supply redundant Train B PFSSD equipment.

References: XX-E-013, E-15000, E-13NB01, E-13NB02, E-13NB03, E-13NB10, E-13NB12, E-13NB13, E-13NG01A, E-13RL01, E-13RP09, E-1F9423, E-1F9425, E-1F9426, E-1000-SY12, E-1000-UU00, E-1005-SY01, E-1005-SY07

5.2.31 Train A 480 VAC Load Centers

Cables associated with 480 VAC load centers NG01, NG03 and motor control center (MCC) NG05E are run in area C-21. Damage to these cables could de-energize the load centers and MCCs, preventing operation of the associated Train A equipment.

Cables 11PKK10AA and 11PKK10AB are associated with the 125 VDC control circuit for NG0102, which supplies 480 VAC power to battery charger PK021. Damage to these cables could prevent closing NG0102 and supplying power to PK021. Battery charger PK022 is unaffected by a fire in this area.

Train B 480 VAC load centers NG02, NG04 and MCC NG06E are unaffected by a fire in this area and are available to supply power to redundant Train B equipment. Therefore, a fire in area C-21 will not impact the ability to supply power to required Train B 480 VAC equipment.

References: XX-E-013, E-15000, E-13NG10, E-13NG11, E-13PK10, E-1F9423, E-1F9424A, E-1F9424B, E-1F9424C, E-1F9424D, E-K3NG10

5.2.32 Class 1E 125 VDC Power to Main Control Boards

Several cables that supply class 1E 125 VDC power to the main control boards are run in fire area C-21. The cables run from the power supply to the control panel where the power is split to supply specific loads. The cables, power supply, control panel and affected PFSSD components are summarized in the following table.

CABLE	POWER SUPPLY	CONTROL PANEL	PFSSD EQUIPMENT	POSITION ON LOSS OF POWER	REQUIRED PFSSD POSITION
11RLK01AA	NK4119	RL001/002	BGHV8153A BGHV8154A	Closed Closed	Closed Closed
11RLK01CA	NK4112	RL017/018	EMHV8964	Closed	Closed
11RLK01DA	NK4113	RL019/020	EGTV0029 GMHZ0009	Closed Open	Closed Open
11RLK01EA	NK5109	RL021/022	BBHV8001A BBHV8002A	Closed Closed	Closed Closed

Based on the above table, the PFSSD equipment fails to the desired position upon loss of power. Therefore, damage to the cables will not adversely impact PFSSD.

References: E-15000, XX-E-013, E-13BB30, E-13BG48, E-13EG16, E-13EM12, E-13GM04, E-13RL01, E-13RL02, E-13RL03, E-13RL04, E-13RL05, E-13RL06, E-1F9301, E-1F9302, E-1F9401A, E-1F9422A, E-1F9444, M-12BB04, M-12BG01, M-12EG02, M-12EM01, M-12GM01

5.2.33 BOP Instrument Racks

BOP instrument racks RP053A, RP053B, RP053D and RP147 are credited in the PFSSD analysis. The following table identifies the PFSSD components served by each instrument rack.

Instrument Rack	PFSSD Components
RP053A (RP053AA, RP053AB, RP053AC)	ALHV0009, ALHV0011 ALPY0037A, EGFT0128, EGPSL0077, GDTSL0001, JELSL0001C
RP053B (RP053BA, RP053BB, RP053BC)	ALHV0007, ALPY0039A, EGFT0129, EGPSL0078, GDTSL0011, JELSL0021C
RP053D (RP053DA, RP053DB)	ALPY0038A
RP147 (RP147A, RP147B)	ALHV0005

Cables 11RPY09CA and 11RPY09DA supply 120 VAC power to Train A BOP instrument rack RP053A. Damage to these cables could cause a loss of function of panel RP053A and associated PFSSD components.

Cable 13RPY09AA supplies 120 VAC power to Train A BOP instrument rack RP053DB. Damage to this cable could cause a loss of function of panel RP053D and ALPY0038A.

Pressure converters ALPY0037A and ALPY0038A are associated with ESFAS low auxiliary feedwater suction pressure. Loss of these devices due to a fire could prevent an automatic swap over from the CST to the ESW system. The CST contains sufficient volume for PFSSD, and pressure indication is available in the control room using ALPT0039. Therefore, loss of these pressure converters will not adversely impact PFSSD.

Instrument racks RP053B and RP147B are unaffected by the fire. Therefore, loss of PFSSD components associated with RP053A and RP053D will not adversely impact PFSSD.

References: E-15000, XX-E-013, E-13AL08, E-13AL09, E-13EG13, E-13JE01, E-13NN01, E-13RP09, E-1F9101, E-1F9202, E-1F9204, E-1F9401B, E-1F9411A, E-1F9411B, E-1F9424D, E-1F9443, E-K3GD04, M-12AL01, M-12EG01, M-12JE01, M-K2GD01, E-K3GD01A

5.2.34 Reactor Protection System

The Reactor Protection System (RPS) monitors specified input parameters and initiates reactor protection features whenever those parameters are outside specified limits. Field installed transmitters continuously monitor various parameters and report the results to one of four process cabinets, one per channel. Signals are then sent from the process cabinets to both solid state protection cabinets, one on each train. The cabinets and associated channel are listed in the following table.

Process Cabinets	Solid State Protection Cabinets
Cabinet SB038 - Channel 1 Cabinet SB042 - Channel 2 Cabinet SB037 - Channel 3 Cabinet SB041 - Channel 4	Cabinet SB029A - Train A Input Cabinet Cabinet SB029B - Train A Logic Cabinet Cabinet SB029C - Train A Output Cabinet 1 Cabinet SB029D - Train A Output Cabinet 2

Process Cabinets	Solid State Protection Cabinets
	Cabinet SB032A - Train B Input Cabinet Cabinet SB032B - Train B Logic Cabinet Cabinet SB032C - Train B Output Cabinet 1 Cabinet SB032D - Train B Output Cabinet 2

The RPS is actuated upon 2/3 or 2/4 coincident logic, depending on the input parameter. This ensures that a loss of a single channel will not prevent the system from performing its function.

A number of cables associated with reactor protection system channels 1 and 3 run through this area. Some of these cables supply power from separation group 1 and 3 power supplies to the various panels. Other cables provide channel 1 and 3 signals from process cabinets SB037 and SB038 to solid state protection cabinets SB029A and SB032A. Cables associated with field installed transmitters associated with the RPS are discussed in other sections.

Cables 11SBS12AA and 11SBS12AC are associated with separation group 1 reactor trip circuits. Damage to these cables due to hot shorts could cause a spurious plant trip. Open circuits could prevent a manual trip on Train A but the Train B reactor trip circuits are unaffected by the fire.

Damage to cables associated with the RPS that run in this area could cause a loss of RPS channels 1 and 3, but channels 2 and 4 remain available. Spurious RPS actuation due to cable damage will not adversely impact PFSSD. These spurious actuations can either be mitigated as discussed in other sections (i.e., spurious SIS and CSAS), or the spurious actuation places the plant in a safe condition as designed. Therefore, damage to these cables will not adversely impact the ability to achieve and maintain safe shutdown.

References: XX-E-013, E-15000, E-11NK01, E-11NK02, E-13NN01, E-13SB01, E-13SB02, E-13SB05, E-13SB08A, E-13SB08D, E-13SB09, E-13SB10, E-13SB12A, E-1F9101, E-1F9102, E-1F9431, E-1F9432, E-1F9433, J-10SA, M-761-00132, M-761-00136, M-761-000167

5.2.35 Source Range Monitoring

PFSSD requires source range (SR) flux monitoring to be available. Source range monitoring is provided by source range monitors SENE0031, SENE0032, SENY0060A & B, and SENY0061A & B.

Cable 11SES01AA is a power cable associated with panel SE054A, which is associated with SR monitor SENE0031. Cables 11SES01BB and 11SES01BC are control cables associated with SE054A. Cable 11SES07BB is an instrument cable associated with SENY0060B. Cable 15SES05AA is an instrument cable that runs from SE054A to RL003 and provides control room indication for SENE0031. Cable 15SES05BA is an instrument cable that runs from SE054B to RL003 and provides control room indication for SENE0032.

Damage to these cables could prevent operation of the associated source range monitor or prevent source range indication in the control room. Source Range monitoring remains available for a fire in area C-21 using SENY0061A/B.

For a more detailed evaluation on Source Range monitoring, see Calculation XX-E-013.

References: E-15000, XX-E-013, E-13NN01, E-13SE01, E-13SE05, E-13SE07, E-1F9101, E-1F9421

5.2.36 Load Shedder / Emergency Load Sequencer

The load shedder and emergency load sequencers are included in the PFSSD design to evaluate the impact of spurious operation or mal-operation. The load shedder/emergency load sequencer operates upon presence of the following conditions:

1. An undervoltage (UV) on a safeguards bus,
2. A safety injection signal (SIS) or a containment spray actuation signal (CSAS), or
3. An undervoltage on a safeguards bus with a SIS or CSAS.

Eight inputs (four undervoltage (UV) inputs and four degraded voltage inputs) on each safeguards bus (NB01 and NB02) monitor voltage conditions on that bus. An undervoltage condition on two of four UV relays on each bus will actuate the load shedder/sequencer and send a signal to start the associated diesel generator. In addition, degraded voltage sensed by two of four degraded voltage potential transformers (PTs) will, after a time delay, provide a signal to open the offsite feeder breakers on the associated bus.

Cables 11NFK01CA, 11NFK01DA, 13NFK01CA and 13NFK01DA associated with two of the four undervoltage relays on each bus run in area C-21. Also, cables 11NFY01EA, 11NFY01FA, 13NFY01GA and 13NFY01HA associated with two of the four degraded voltage PTs on each bus are run in fire area C-21. Cables associated with the remaining two UV relays and PTs do not run in fire area C-21. Therefore, automatic functioning of the bus NB01 and NB02 emergency load shed/sequencer is unaffected by a fire in area C-21 due to the availability of at least two UV relay inputs.

A spurious actuation of the load shedder/sequencer due to damage to cables associated with two of the four UV relays will not adversely impact the ability to achieve and maintain safe shutdown. The load shedder will shed all safety related and non-safety related loads from the bus and start the diesel generator. Safety-related loads will then be sequenced back onto the bus in a pre-determined order. In addition, based on Section 5.2.2, a spurious SIS and CSAS could occur, causing the LOCA sequencer to actuate. Section 5.2.2 discusses mitigation of a spurious SIS and CSAS.

Based on Calculation XX-E-013, Appendix 2, an actual loss of off-site power could occur on Train A while Train B off-site power remains available. In the event of a spurious undervoltage signal that causes the load shedder/sequencer to actuate, operators can re-align Train B off-site power from the control room, if necessary, to energize required PFSSD loads.

Separation groups 1 and 3 power supply cables for load shedder/sequencer logic and input cabinets NF039A, NF039B and NF039C run in fire area C-21. Damage to these cables could cause a loss of Train A DC and AC power to the panels. Redundant Train B DC and AC power is available from separation groups 2 and 4 power supplies.

Based on the above discussion, damage to cables associated with the load shedder/sequencer will not adversely impact the ability to achieve and maintain safe shutdown.

References: XX-E-013, E-15000, E-11NB01, E-11NB02, E-12NF01, E-13NF01, E-10NF, E-1F9411A, E-1F9411B, E-1F9412A, E-1F9412B, E-1F9402A, E-1F9402B, E-1F9403, E-1F9425, E-1F9426

5.2.37 Letdown Isolation Valves

Valves BGLCV0459 and BGLCV0460 are isolation valves installed in series on the inlet side of the regenerative heat exchanger. PFSSD requires that either of these valves be closed.

Cables 15BGK10AA, 15BGK10AC and 15BGK10AD are power/control cables for the BGLCV0459 solenoid valve (BGHY0459). Air supplied by an open (energized) solenoid valve will open valve BGLCV0459. A closed (de-energized) solenoid valve will cause loss of air pressure and closure of valve BGLCV0459.

Cables 15BGK10BA, 15BGK10BC and 15BGK10BD are power/control cables for the BGLCV0460 solenoid valve (BGHY0460). Air supplied by an open (energized) solenoid valve will open valve BGLCV0460. A closed (de-energized) solenoid valve will cause loss of air pressure and closure of valve BGLCV0460.

Either BGLCV0459 or BGLCV0460 must be closed or letdown orifice isolation valves BGHV8149A, BGHV8149B, and BGHV8149C must be closed. The cables for BGLCV0459 or BGLCV0460 are run in a common enclosure in cable trays. A hot short on the cables could cause the valves to open. A hot short on cables 15BGK10AA and 15BGK10BA prevents closing BGLCV0459 and BGLCV0460 from the control room. Other cables run in the cable trays have the proper voltage for hot shorts which can bypass MCB hand switches for BGLCV0459 and BGLCV0460. BGLCV0459 and BGLCV0460 constitute a high/low pressure interface. Therefore, multiple simultaneous hot shorts must be considered.

Letdown orifice isolation valves BGHV8149A, BGHV8149B, and BGHV8149C are listed as PFSSD components because of the interlock between these valves and BGLCV0459 and BGLCV0460. The interlock prevents closure of the letdown valves when any one or more orifice isolation valves are open. Cables associated with all three letdown orifice isolation valves are located in this fire area. Damage to these cables could prevent closure of the valves from the control room. Therefore, a fire in area C-21 could prevent closure of all three letdown orifice isolation valves (BGHV8149A, BGHV8149B, and BGHV8149C) as well as the two letdown isolation valves (BGLCV0459 and BGLCV0460) using their respective hand switches in the control room.

Cable 15RLK01AA supplies 125 VDC power from breaker PK5117 to several non-safety related components on panel RL001/RL002. Some of these components are credited for PFSSD. These components are BGLCV0459, BGLCV0460, BGHV8149A, BGHV8149B and BGHV8149C. Damage to this cable will de-energize power to these valves, failing them closed which is the desired PFSSD position. If letdown is needed during cold shutdown, the excess letdown flowpath can be used or a cold shutdown repair made to restore normal letdown. Therefore, damage to this cable will not adversely impact PFSSD.

See Section 5.1.1 for discussion of power to relays BGLCV0459X and BGLCV0460X.

Section III.G.2 separation requirements for BGLCV0459 and BGLCV0460 are not satisfied (redundant cables are routed in common raceway). However, BGLCV0459 and BGLCV0460 can be closed by locally closing KAV0201 in fire area A-25. Based on WCNOC-CP-002, letdown flow needs to be isolated within 50 minutes if a fire occurs in this area. E-1F9900 documents the feasibility and reliability that this action can be completed within 50 minutes. The OMA was approved by the NRC in License Amendment 191. Reference Attachment 4, MSO Evaluation Scenario ID PWROG 6.

References: E-15000, XX-E-013, E-13BG10, E-13BG35, E-13SC12, E-1F9301, M-12BG01, WCNOC-CP-002, E-1F9900, License Amendment 191, DCP 13324

5.2.38 Reactor Coolant Pumps

The reactor coolant pumps are not credited in the PFSSD analysis. However, the capability to stop the pumps from the control room in the event of a loss of all seal cooling is credited. Westinghouse Technical Bulletin TB-04-22, Rev. 1 recommends that if all seal cooling is lost (RCP seal injection and thermal barrier heat exchanger flow), operators need to stop the pumps before a seal LOCA occurs.

Three control cables associated with reactor coolant pumps A and B are run in fire area C-21. Damage to these cables in the event of a fire could prevent operators from stopping the A and B RCPs from the control room. However, a fire in C-21 will not cause a loss of all seal cooling since RCP seal injection remains available.

Based on the above discussion, the inability to trip the A and B RCPs from the control room will have no adverse impact on PFSSD. The pumps can continue to operate, providing forced flow circulation. If the pumps spuriously stop, natural circulation cooldown can be used.

References: E-15000, XX-E-013, E-13BB01, Westinghouse TB-04-22 Rev. 1

5.2.39 Normal Pressurizer Spray

The normal pressurizer spray valves are included in the PFSSD design because spurious operation of pressurizer sprays can cause a decrease in pressure which can lead to boiling in the core. The pressurizer spray valves are part of the pressurizer pressure control system.

The pressurizer normal spray valves (BBPCV0455B and BBPCV0455C) operate off a signal from the Ovation pressurizer pressure control system. The operation of the pressure control system is discussed in Calculation XX-E-013.

Instrument cables 11BBI16KB and 13BBI16MB associated with pressurizer pressure transmitters BBPT0455 and BBPT0457 are run in fire area C-21. Damage to these cables could send a spurious high-pressure signal to the pressurizer pressure control system. As discussed in Calculation XX-E-013, Appendix 1, the Ovation pressurizer pressure control system uses 4-channel verification from all four pressurizer pressure transmitters to operate the pressurizer PORVs. Failure of a single channel will not cause the spurious operation of the PORVs since the system uses the 2nd highest input as the validated signal. Damage to two channels will not cause the PORVs to open because both channels would have to fail to the exact same value at the exact same time and therefore this failure mode is not credible, as discussed in XX-E-013.

Cable 15BBI19AA associated with pressurizer spray valve BBPCV0455B, and cable 15BBI19BA associated with pressurizer spray valve BBPCV0455C are run in this area. Damage to these cables could cause the spurious opening of the spray valves.

Cables 15SCR15RF and 15SCR15RG are Ethernet cables that provide data communication between panels RP047 and RP043. These cables support functionality of pressurizer spray valves. Damage to these data cables will not result in spurious operation of the valves.

As discussed in Section 5.2.38, RCPs A and B may not stop using the hand switches in the control room. The C and D RCPs can be stopped from the control room. As stated in XX-E-013, with the D RCP stopped, the spray flow would be reduced. Therefore, operators could stop the D RCP to reduce the spray flow but the flow may not be completely eliminated.

The pressurizer spray valves are electro/pneumatic operated and loss of air pressure will close the valves. The air supply comes from the compressed air system. Closing valve KAV0201 will remove air from the pressurizer spray valves and close the valves. As discussed in

Section 5.2.40, valve KAFV0029 may not close from the control room. Based on WCNOC-CP-002, spray flow needs to be stopped within 50 minutes. E-1F9900 documents the feasibility and reliability that this action can be completed within 50 minutes. The OMA was approved by the NRC in License Amendment 191. Reference Attachment 4, MSO Evaluation Scenario ID PWROG 36.

Based on the above discussion, the pressurizer spray valves could spuriously open if a fire occurs in this area but the valves can be closed by closing KAV0201 to isolate air to containment. Pressurizer pressure indication is available using BBPI0456 and BBPI0458 located on RL002.

References: E-15000, XX-E-013, E-13BB19, E-13SC03, M-12KA01, M-761-02128, M-761-02129, WCNOC-CP-002, E-1F9900, License Amendment 191, DCP 13324

5.2.40 Containment Air Supply

Valve KAFV0029 is an isolation valve on the containment compressed air supply line. This valve is credited for PFSSD in the event of a fire in certain areas to isolate air to letdown isolation valves BGLCV0459 and BGLCV0460 and pressurizer spray valves BBPCV0455B and BBPCV0455C to fail the valves closed. Valve KAFV0029 is a diverse means of closing these valves if the fire prevents closing the valves using their respective control room hand switches.

Cables 11KAK02AA and 11KAK02AB are control cables associated with valve KAFV0029. Damage to these cables could prevent closure of the valve from the control room or could cause the valve to spuriously close. If the valve spuriously closes, PFSSD will not be affected as documented in E-1F9900.

As discussed in Sections 5.2.37 and 5.2.39, a fire in area C-21 may require closure of the air supply to containment to achieve PFSSD. Letdown isolation valves BGLCV0459 and BGLCV0460 could be affected by a fire in this area and may not close using their control room hand switches. In addition, pressurizer spray valves BBPCV0455B and BBPCV0455C could spuriously open in the event of a fire in this area and the valves may not close using their hand switches in the control room.

Based on the above discussion, damage to cables 11KAK02AA and/or 11KAK02AB could prevent isolation of the air supply to containment from the control room to close BGLCV0459, BGLCV0460, BBPCV0455B and BBPCV0455C. However, valve KAV0201 can be used to isolate air to containment if necessary. Therefore, damage to these cables will have no adverse impact on the ability to achieve and maintain safe shutdown following a fire in this area.

References: E-15000, XX-E-013, E-13KA02, E-1F9900

5.2.41 Steam Generator Feedwater Pumps

Main feedwater pump steam supply valves FCFV0005 and FCFV0105 are credited in the PFSSD analysis to trip the main feedwater pumps if the main steam isolation valves (MSIVs) are affected by a fire. Closing the MSIVs stops steam flow to the feedwater pumps' turbines and stops the feedwater pumps. The steam generator feedwater pumps are tripped in the event of a fire to prevent overfilling the steam generators.

Non-Class 1E 120 VAC Inverter PN09 and distribution panel PN09A provide power to FCFV0005 trip relays in panel FC169C. Cable 15FCQ29AE runs from control room hand switches FCHS0018A and FCHS0018B to panel FC169A. This cable provides the signal to close FCFV0005 when both hand switches are simultaneously depressed. Cable 15FCY35AA provides the primary source of 120 VAC power from distribution panel PN09A to panel FC169A, which distributes power to the trip relays in panel FC169C. The alternate source of power to panel FC169A is not credited for PFSSD and is assumed lost.

A fire in area C-21 could damage cables 15FCQ29AE and 15FCY35AA. If this occurs, operators in the control room would not be able to close valve FCFV0005 to stop steam flow to steam generator feedwater pump PAE01A.

A fire in area C-21 will not affect the ability to close the MSIVs from the control room. All-close hand switch ABHS0079 is unaffected and can be used to close the MSIVs from the control room.

Based on the above discussion, valve FCFV0005 may not close if a fire occurs in this area. However, the MSIVs can be closed using hand switch ABHS0079 in the main control room. Therefore, the configuration is acceptable.

References: E-15000, XX-E-013, E-13FC29A, E-13FC35, E-13RP10, E-1F9103, E-1F9421

5.2.42 Load Center Feeder Breakers PA0105 and PA0106 and MCC Feeder Breakers PG1101 and PG1901

Load center feeder breakers PA0105 and PA0106 are credited for PFSSD because they supply power to credited non-safety related loads. Cables 15PGA10AC, associated with PA0105, and 15PGA10BC associated with PA0106, run in this area. Cable 15PGG13AA associated with PG1101 is run in this area. Cable 15PGG13DA associated with PG1901 is run in this area. A fire induced short circuit in these cables will trip the associated breaker.

Breakers PA0105 and PG1101 supply power to the following PFSSD components:

- PG11JFR2 – Main Steam Supply to 2nd Stage Reheat Valve ABHV0031
- PG11KBR3 – Auxiliary Steam System Control Valve FBHV0081

PG11JFR2 and PG11KBR3 supply power to components downstream of the MSIVs. The MSIVs are unaffected by a fire in this area and can be closed from the control room using hand switch ABHS0079. Therefore, the MSIV downstream components are not required if a fire occurs in this area.

Based on the above discussion, loss of breakers PA0105 or PG1101 will not adversely affect PFSSD if a fire occurs in this area.

Breakers PA0106 and PG1901 supply power to the following PFSSD components:

- PG19GCR217 – MCB Misc. Power Circuits RL023
- PG19GFR3 – Instr. Bus Transformer Alt. Feed XPN07D

PFSSD components supplied power from PG19GCR217 are associated with MSIV downstream components. The MSIVs are unaffected by a fire in this area and can be closed from the control room. Therefore, the MSIV downstream components are not required if a fire occurs in this area.

PG19GFR3 is credited as one source of power to 120 VAC distribution switchboard PN07. The redundant source of power from NG01BEF4 could also be affected by a fire in this area. Distribution switchboard PN08 is unaffected by a fire in this area and is available to supply 120 VAC to redundant PFSSD equipment.

Based on the above discussion, loss of breakers PA0106 or PG1901 will not adversely affect PFSSD if a fire occurs in this area.

5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA C-22 13
5.2 PFSSD CABLE EVALUATION 16

1.0 GENERAL AREA DESCRIPTION

Fire area C-22 is located on the 2073 elevation of the Control Building and includes the rooms listed in Table C-22-1.

Table C-22-1
Rooms Located in Fire Area C-22

ROOM #	DESCRIPTION
3801	Upper Cable Spreading Room

Fire area C-22 is protected with an automatic wet-pipe sprinkler system. In addition, automatic fire detection is installed throughout. The automatic suppression and detection system meets the requirements of 10CFR50, Appendix R, Section III.G.2. The area is separated from adjacent areas by minimum 3-hour fire resistant construction.

2.0 PRIMARY EQUIPMENT USED FOR PFSSD

Table C-22-2 lists each system credited for post-fire safe shutdown and provides a discussion regarding the availability of the system to perform its Post Fire Safe Shutdown (PFSSD) function if a severe fire occurs in this area. For a summary of the area analysis results, see Section 8.0 of the Fire Area Analysis Narrative section.

Table C-22-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-22

System	System Name	PFSSD Function*	Comments
AB	Main Steam	R, M, H, P, S	Steam generators B and D ARV control from the main control room may be lost. Steam generator ARVs A and C are unaffected. Cooldown is assured using motor driven auxiliary feedwater pump A supplying steam generator C. Steam generator B ARV control can be achieved using ABPIC0002B at the auxiliary shutdown panel (RP118B). Steam generator D ARV can be closed using ABPIC0004B at the auxiliary shutdown panel (RP118B). Steam line pressure transmitters ABPT0516 and ABPT0546 could be affected. In addition, steam line pressure indicators ABPI0515A, ABPI0516A, ABPI0525A, ABPI0535A, ABPI0545A and ABPI0546A could be affected. Remaining steam line pressure transmitters and indicators are available. ABHS0079 may not be available to close the MSIVs and MSIV bypass valves. ABHS0080 is available to close the MSIVs and MSIV bypass valves. A number of main steam valves located downstream of the MSIVs could open. This will have no adverse impact on PFSSD since the MSIVs and bypass valves can be isolated. Main steam to TDAFP valves ABHV0005 and ABHV0006 could close, preventing operation of the TDAFP. See AL discussion for auxiliary feedwater availability.
AC	Main Turbine	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-22.
AE	Main Feedwater	H, P	All PFSSD functions associated with the main feedwater system are satisfied. Steam generator A level indication is available using AELI0501, AELI0518 and AELI0551. Steam generator B level indication is available using AELI0528 and AELI0529. Steam generator C level indication is available using AELI0503, AELI0538 and AELI0539. Steam generator D level indication is available using AELI0548 and AELI0554. Isolate all four main feedwater isolation valves using hand switch AEHS0080. The motor driven main feedwater pump PAE02 and the Train B turbine driven main feedwater pump PAE01B could spuriously start or fail to stop due to damage to associated control cables. The pumps themselves are not considered PFSSD related since they are not required to support PFSSD. Spurious start of the pumps will have no adverse impact on PFSSD since the main feedwater isolation valves can be isolated.
AL	Aux. Feedwater System	H, P	All PFSSD functions associated with the auxiliary feedwater system are satisfied. The Train B MDAFP and the TDAFP are affected. The Train A MDAFP is available to supply SGs B and C, however, as stated in the AB system discussion, SG B ARV ABPV0002 may need to be controlled at the auxiliary shutdown panel (RP118B). Pressure transmitters ALPT0038 and ALPT0039 may be affected, causing a spurious swap over to ESW. This is acceptable since ESW is the safety related auxiliary feedwater source. Auxiliary feedwater suction pressure indication is available using pressure indicator ALPI0037A.
AP	Condensate Storage System	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-22.

Table C-22-2 Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-22			
System	**System Name**	**PFSSD Function***	**Comments**
BB	Reactor Coolant System	R, M, H, P, S	All PFSSD functions associated with the reactor coolant system are satisfied. All four seal water injection valves will remain open. When transferring to RHR, valve BBPV8702A may need to be manually opened, or a cold shutdown repair performed, to provide a suction source from the RCS to RHR pump A. Pressurizer PORV BBPCV0456A may open and block valve BBHV8000B may not close. If this occurs, Operators can close the PORV by placing BBHIS0456A in the CLOSE position. RCS pressure indication is available using BBPI0405. Reactor vessel head vent valve BBHV8002B could spuriously open. The remaining head vent valves are unaffected and will remain closed to isolate the head vent flow path. RCS loops 3 and 4 temperature recorders BBTR0433 and BBTR0443 could be affected. Temperature recorders and indicators on loops 1 and 2 are unaffected. Pressurizer pressure transmitter BBPT0458 could be affected. Pressurizer pressure indicators BBPI0456 and BBPI0458 could also be affected. Pressurizer pressure indicators BBPI0455A and BBPI0457 are unaffected. Pressurizer level indication is available using BBLI0459A. Pressurizer level indicator BBLI0460A could be affected. Pressurizer pressure selector switch BBPS0455F could be affected. This will not adversely impact PFSSD. Reactor coolant pumps C and D may not stop using the control room hand switch. RCP seal injection remains available to provide cooling to the RCP seals.
BG	Chemical and Volume Control System	R, M, S	All PFSSD functions associated with the chemical and volume control system are satisfied. Train A Centrifugal Charging Pump (CCP) is available to provide charging flow from the RWST to the RCP seals and the BIT injection flowpath. Train B CCP miniflow valve BGHV8111 may be affected. Train A CCP miniflow valve BGHV8110 is unaffected. Train B CCP to RCP seal injection valve BGHV8357B may be affected. Train A CCP to RCP seal injection valve BGHV8357A is unaffected. Normal charging isolation valve BGHV8105 may be affected. Redundant isolation valve BGHV8106 is unaffected. VCT isolation valve BGLCV0112C may be affected but redundant valve BGLCV0112B can be isolated using BGHIS0112B. VCT level transmitter BGLT0185 may be affected. VCT level transmitter BGLT0112 is unaffected. Excess letdown valve BGHV8154B could spuriously open. Redundant valve BGHV8153B is unaffected. RCP seal flow indication is available using BGFI0215A. RCP seal flow indicator BGFI0215B may be affected.

Table C-22-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-22

System	System Name	PFSSD Function*	Comments
BM	Steam Generator Blowdown System	R, M, H	All PFSSD functions associated with the steam generator blow down system are satisfied. Steam generator blow down is isolated by closing valves BMHV0001, BMHV0002, BMHV0003 and BMHV0004 using BMHIS0001C, BMHIS0002C, BMHIS0003C and BMHIS0004C, located on the BM157 panel in the radwaste control room.
BN	Borated Refueling Water Storage System	R, M, H	The RWST is available to provide a suction source to Centrifugal Charging Pump A via valve BNLCV0112D. RWST level indication is available using BNLI0930 and BNLI0932.
EF	Essential Service Water System	H, S	All PFSSD functions associated with the Essential Service Water (ESW) system are satisfied. A number of components associated with Train B ESW may be affected. Train A ESW is available.
EG	Component Cooling Water System	S	All PFSSD functions associated with the Component Cooling Water (CCW) system are satisfied. Train B CCW may be affected. Train A CCW is available. CCW flow to the RCP thermal barrier could be temporarily disrupted due to closure of valves EGHV0062 and EGHV0071. Valves EGHV0132 and EGHV0126 can be opened from the control room to restore CCW flow to the thermal barriers. RCP seal injection is unaffected. CCW to RCP flow indicator EGFI0129 could be affected. CCW to RCP flow indicator EGFI0128 is unaffected. Valve EGHV0102 could be affected, preventing operation of Train B RHR. Valve EGHV0101 is unaffected.
EJ	Residual Heat Removal System	M, H, P	All PFSSD functions associated with Residual Heat Removal (RHR) system are satisfied. The Train B RHR pump may be affected but the Train A RHR pump is available. RHR pump B mini-flow valve EJFCV0611 is affected but RHR pump A mini-flow valve EJFCV0610 is available. Loss of RCS inventory through the RHR flow path is prevented by maintaining valves EJHV8701A and EJHV8701B closed. Valve EJHV8701A can be opened from the control room when transitioning to RHR for cold shutdown. RHR Train B to SI Pump B isolation valve EJHV8804B could spuriously open. RHR Train A to CVCS valve EJHV8804A is unaffected. Train B RHR pump discharge to RCS cold leg isolation valve EJHV8809B is affected. Train A RHR pump discharge to RCS cold leg isolation valve EJHV8809A is unaffected. Valve EJHV8840 could spuriously open. This will not affect hot standby but the valve will need to be closed prior to shutdown cooling. RHR Train B flow control valve EJHCV0607 could be affected. RHR Train A flow control valve EJHCV0606 is unaffected.

Table C-22-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-22

System	System Name	PFSSD Function*	Comments
EM	High Pressure Coolant Injection	R, M	Train B safety injection pump PEM01B could spuriously start. Injection will not occur with the reactor at normal pressure. The pump can be stopped by opening breaker NB0202, but this action is not required for PFSSD. Charging flow from CCP A to the RCS is available through the BIT by opening valves EMHV8803A and EMHV8801A. Prevent flow diversion through the SIS test line when charging through the BIT by maintaining valve EMHV8964 closed.
EN	Containment Spray	R, M	Containment spray pump PEN01B could spuriously start and valve ENHV0012 could open, causing containment spray. Pump PEN01B can be stopped by opening breaker NB0203 in area C-10. Containment spray pump PEN01A is unaffected.
EP	Safety Injection Accumulators	H	The PFSSD Decay Heat Removal function associated with the Safety Injection Accumulators is satisfied. Accumulator injection lines can be isolated by closing valves EPHV8808A, EPHV8808B, EPHV8808C and EPHV8808D. It may be necessary to make a containment entry to manually close EPHV8808B and EPHV8808D prior to the RCS reaching 1000 psig.
FB	Auxiliary Steam	R, H	All PFSSD functions associated with the auxiliary steam system are satisfied. Valve FBHV0080 could spuriously open. This will have no adverse impact on PFSSD since the main steam isolation valves can be isolated.
FC	Auxiliary Turbines	R, H, P	Turbine driven auxiliary feedwater pump (TDAFP) trip and throttle valve FCHV0312 may be affected. In addition, TDAFP electrical control panel FC219 could be affected. As stated in the AL system discussion, the Train A MDAFP is available. Turbine driven auxiliary feedwater pump steam trap valve FCFV0310 may not close. Uncontrolled blow down through this 1-inch line will not cause unacceptable RCS cooldown and will not impact PFSSD. Main feedwater pump turbine KFC01B and low point drain valve FCHV0103 could be affected. This will have no adverse impact on PFSSD since the main steam isolation valves can be isolated. Valve FCFV0105 may be affected. The MSIVs can be closed using all-close hand switch ABHS0080.
GD	ESW Pump House HVAC	S	The PFSSD function associated with ESW pump house HVAC is satisfied. The Train B ESW pump room ventilation system could be affected. The Train A ESW pump room ventilation system is unaffected.
GF	AFW Pump Room Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-22.

Table C-22-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-22

System	System Name	PFSSD Function*	Comments
GK	Control Room and Class 1E Switchgear Room Coolers	S	The PFSSD function associated with the Control Room and Class 1E Switchgear Room Coolers is satisfied. Train B control room A/C unit SGK04B could be affected. Train A control room A/C unit SGK04A is unaffected. Train B control room A/C dampers GKHZ0040A and GKHZ0040B could be affected. Train A control room A/C dampers are unaffected. Train B class 1E electrical equipment room A/C unit SGK05B could be affected. Train A Class 1E electrical equipment room A/C unit SGK05A is unaffected.
GL	Auxiliary Building HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-22.
GM	Emergency Diesel Generator Room HVAC	S	The PFSSD function associated with the emergency diesel generator room HVAC system is satisfied. The Train B emergency diesel generator exhaust damper GMHZ0019 could be affected. The Train A diesel generator room HVAC system is unaffected.
GN	Containment Coolers	S	The PFSSD function associated with the containment coolers is satisfied. Train B containment coolers SGN01B and SGN01D could be affected. Train A containment coolers SGN01A and SGN01C are available. Containment pressure transmitter GNPT0934 could be affected. Containment pressure indication on GNPI0934 and GNPI0936 could be affected. Containment pressure indicators GNPI0935 and GNPI0937 are unaffected.
JE	Diesel Fuel Oil	S	The PFSSD function associated with the Diesel Fuel Oil System is satisfied. The Train B emergency fuel oil transfer pump PJE01B may be affected. The Train A emergency fuel oil transfer pump PJE01A is unaffected. The Train B emergency diesel generator day tank level transmitter JELT0021 may be affected. The Train A day tank level transmitter is unaffected.
KA	Instrument Air	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-22.
KC	Fire Protection	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-22.
KH	Service Gas	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-22.
KJ	Standby Diesel Engine	S	The PFSSD function associated with the Standby Diesel System is satisfied. The Train B diesel engine may be affected. The Train A diesel engine is unaffected.
MA	Main Generation	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-22.
MR	Startup Transformer	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-22.

Table C-22-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-22

System	System Name	PFSSD Function*	Comments
NB	4.16 kV System	S	The PFSSD function associated with the class 1E 4.16 kV system is satisfied. A loss of off-site and on-site power to NB02 may occur. Breaker 13-8, which supplies power to NB01, could spuriously open. Breaker 13-48 is available to supply off-site power to NB01. On-site power to NB01 is unaffected.
NE	Standby Diesel Generator	S	The PFSSD function associated with the standby diesel system is satisfied. The Train B standby diesel generator could be affected. The Train A standby diesel generator is unaffected.
NF	Load Shed and Emergency Load Sequencing	S	The PFSSD function associated with the load shed/emergency load sequencing system is satisfied. Cables associated with two of the four undervoltage (UV) relays and degraded voltage potential transformers on Trains A and B are run in fire area C-22. Emergency load shed/sequencer operates when 2/4 UV relays sense undervoltage on the bus. A spurious UV signal will cause the load shedder/sequencer to actuate and start the associated diesel generator. A true UV condition will actuate the two unaffected UV relays. Train A off-site power remains available.
NG	480V Load Centers and MCCs	S	The PFSSD function associated with the class 1E 480 volt load centers is satisfied. A loss of off-site and on-site power to Train B 480 VAC Class 1E load centers and MCCs could occur. Off-site and on-site power to Train A 480 VAC Class 1E load centers and MCCs is available.
NK	125VDC	S	Train B class 1E 125 VDC power could be disrupted to control room panels RL001/RL002, RL005/RL006, RL017/RL018, RL019/RL020, RL021/RL022 and RL023/RL024. Train A class 1E 125 VDC power is unaffected. The normal source of power to NK02 and NK04, through the Train B 480 V distribution system, could be disrupted. 125 VDC battery sets NK012 and NK014 are unaffected. Train B class 1E 125 VDC power could be disrupted to RPS output panel SB032D. 125 VDC power is available to Train A RPS output panel SB029D.
NN	120VAC	S	The backup source of power to Train B Class 1E electrical distribution switchboards NN02 and NN04 could be affected. The normal source of power to NN02 and NN04 is unaffected due to the availability of 125 VDC battery sets NK012 and NK014. Train A Class 1E electrical distribution switchboards NN01 and NN03 are unaffected.
PA	13.8kV	S	NB02 feeder breaker PA0201 could be affected. One source of off-site power to NB01 is unaffected. Breakers PA0206 and PA0207 could be affected by a fire in this area. Redundant capability is available.
PB	4.16kV	H, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-22.
PG	480V Load Centers and MCCs	S	Power from PG20GBR217 to RL023 could be affected. Power from PG19GCR217 to RL023 is unaffected. Power to load centers PG12 and PG20 could be lost. Redundant capability remains available.

Table C-22-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-22

System	System Name	PFSSD Function*	Comments
PK	125VDC	S	The PFSSD function associated with the non-class 1E 125 VDC system is satisfied. Battery charger PK22 may be affected. Battery set PK12 will maintain 125 VDC power to PK02. Also, Train A non-class 1E 125 VDC system is unaffected.
PL	Local Instrument Panels	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-22.
PN	120VAC	S	Power from PN0833 to RL017/RL018 may be affected. Power from PN0835 to RL021/RL022 may be affected. Power from PN0736 and PN0738 to RL017/RL018 and RL021/RL022 is unaffected.
QB	Standby AC Lighting	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-22.
QD	Emergency Lighting	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-22.
RL	Control Room MCB	S	The PFSSD function associated with the control room panels is satisfied. Train B Class 1E 125 VDC power to RL001/RL002, RL005/RL006, RL017/RL018, RL019/RL020, RL021/RL022 and RL023/RL024 could be disrupted. The components either fail in the desired PFSSD position or the redundant Train A component is available. Train A Class 1E 125 VDC power is unaffected. Non class 1E (separation group 6) 120 VAC power to panels RL017/RL018, RL021/RL022 and RL023/RL024 could be affected. Non class 1E (separation group 5) 120 VAC power to panels RL017/RL018, RL021/RL022 and RL023/RL024 is unaffected.
RP	Miscellaneous Control Panels	R, M, H, P, S	Power to BOP instrument racks RP053B and RP053D could be disrupted. BOP instrument racks RP053A and RP147B are unaffected. Train B 120 VAC control power to RP068 could be affected. Train A 120 VAC control power to RP068 is unaffected. Power to Group 2 Process Control Rack RP047 could be affected. This will not affect PFSSD as discussed in Section 5.2.16.
SA	ESFAS	S	ESFAS panels SA036B and SA036C could be affected, preventing CST low suction pressure swap over to ESW. This will not adversely impact PFSSD since the CST contains sufficient volume to achieve cold shutdown. Status panel inputs for ABHV0005, ABHV0006, GKHZ0040A/B, SGK04B and SGK05B could be affected. This will not adversely impact PFSSD.
SB	Reactor Protection System	R, S	All PFSSD functions associated with the reactor protection system are satisfied. Train B reactor trip switchgear SB102B could be affected. Train A reactor trip switchgear SB102A is unaffected. Reactor protection system channels 2 and 4 could be affected but channels 1 and 3 remain available.

Table C-22-2 Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-22			
System	**System Name**	**PFSSD Function***	**Comments**
SC	Reactor Instrumentation	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-22.
SE	Ex-Core Neutron Monitoring	R, P	All PFSSD functions associated with the ex-core neutron monitoring system are satisfied. The source range recorder for source range monitor SENY0061B could be affected. Source range monitoring remains available using SENE0031, SENE0032 and SENY0060A/B
SY	Switchyard	S	Hand switch 1HSSY0018 could be affected, causing switchyard breaker 13-8 to open. Breaker 13-8 is one source of off-site power to NB01. The second source of power is from breaker 13-48, which is unaffected by a fire in this area.
UU	Supervisory System	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-22.

* R - Reactivity Control; M - Reactor Coolant Makeup; H - Decay Heat Removal; P - Process Monitoring; S - Support Function

3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD

This section describes operator actions that may need to be performed inside or outside the control room to achieve and maintain hot standby if a fire occurs in area C-22. This section also describes cold shutdown repairs that may need to be made to achieve and maintain cold shutdown conditions. Operator actions are proceduralized in OFN KC-016.

3.1 ACTIONS OUTSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

Operator Manual Actions (OMAs) are those actions outside the main control room required to achieve and maintain hot standby. OMAs are identified in E-1F9900 and were determined from thermal hydraulic analysis WCNOC-CP-002. Applicable E-1F9900 OMAs are annotated herein. All other actions outside the control room are desirable for plant control in support of hot standby but not required to achieve and maintain hot standby.

3.1.1 Steam Generator ARVs

Steam generator B and D ARVs ABPV0002 and ABPV0004 control could be lost. If this occurs, the ARVs can be controlled or closed using associated PICs at the auxiliary shutdown panel (RP118B).

3.1.2 Steam Generator Blowdown Isolation

Blowdown may not be isolable using BMHIS0001A, BMHIS0002A, BMHIS0003A and BMHIS0004A. Therefore, it may be necessary to isolate blow down using BMHIS0001C, BMHIS0002C, BMHIS0003C and BMHIS0004C located on BM157 in the Radwaste Control room.

3.1.3 Containment Spray Pump (OMA, refer to E-1F9900)

Containment spray pump PEN01B could spuriously start and valve ENHV0012 could open, causing containment spray. The pump can be stopped by opening breaker NB0203 in area C-10. Access is available without traversing area C-22 and emergency lighting is provided.

3.2 ACTIONS INSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

3.2.1 Main Steam Isolation Valves and MSIV Bypass Valves

The capability to isolate the MSIVs and bypass valves using hand switch ABHS0079 may be affected. The MSIVs and bypass valves can be isolated using hand switch ABHS0080.

3.2.2 Main Feedwater Isolation Valves

The capability to isolate the MFIVs using hand switch AEHS0081 may be affected. Isolate the MFIVs using hand switch AEHS0080.

3.2.3 Thermal Barrier Cooling

CCW flow to the thermal barrier cooling coils could be lost due to the spurious closure of valves EGHV0062 and EGHV0071. If this occurs, operators could open bypass valves EGHV0126 and EGHV0132 to restore thermal barrier cooling. Otherwise, operators should close EGHV0061 using EGHIS0061 to prevent a steam bubble from damaging the CCW piping. CCW to RCP flow indicator EGFI0128 is available to diagnose a loss of CCW flow to the RCP thermal barriers.

3.2.4 Volume Control Tank

Valve BGLCV0112C may not close in response to a signal from the control room. Redundant valve BGLCV0112B can be isolated using BGHIS0112B on RL001.

3.2.5 Boron Injection Tank (BIT)

If necessary, to establish an alternate makeup and boration flowpath, the Train A CCP is available to charge through the BIT and valves EMHV8801A and EMHV8803A can be opened using EMHIS8801A and EMHIS8803A.

3.2.6 Component Cooling Water

Train B CCW could be affected by a fire in this area. If this occurs, swap to Train A CCW using normal operating procedures if Train A CCW is not already running.

3.2.7 Pressurizer PORV/Block Valve

Pressurizer PORV BBPCV0456A could spuriously open and block valve BBHV8000B may not close. If this occurs, Operators can close the PORV by placing BBHIS0456A in the CLOSE position.

3.3 ACTIONS TO ACHIEVE AND MAINTAIN COLD SHUTDOWN

3.3.1 RHR

A number of Train B RHR components, including the Train B RHR pump, may be affected by a fire in this area. Use Train A RHR for shutdown cooling. Valve BBPV8702A may need to be manually opened, or a cold shutdown repair performed, when aligning Train A RHR.

Valve EJHV8840 could spuriously open in the event of a fire in this area. This will not affect hot standby, however the valve will need to be locally closed prior to entering shutdown cooling mode.

3.3.2 Safety Injection Accumulators

It may be necessary to make a containment entry to close SI Accumulator injection valves EPHV8808B and EPHV8808D if these valves are unresponsive from the control room. Otherwise, nitrogen pressure can be relieved from the tanks to prevent injection. Valves EPHV8808A and EPHV8808C are unaffected.

4.0 CONCLUSION

With some exceptions, redundant Post Fire Safe Shutdown capability exists if a severe fire occurs in area C-22. For those exceptions, feasible manual actions are available and are unaffected by the fire. Manual actions are documented in Section 3.0.

5.0 DETAILED ANALYSIS

This section describes the detailed component-by-component and cable-by-cable analysis for a fire in area C-22.

5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA C-22

PFSSD components (S. in E-15000) located in fire area C-22 are shown in Table C-22-3. An evaluation of each component and associated cables is provided in the sections that follow. The applicable evaluation section is listed in Table C-22-3.

Table C-22-3
PFSSD Components Located in Fire Area C-22

Room #	PFSSD Component	Component Description	Evaluation Section	Comments
3801	PN410	120 VAC Distribution Panel	5.1.1	Power to RP043 and RP047

5.1.1 120 VAC Distribution Panel PN410

120 VAC distribution panel PN410 supplies redundant power to NSSS control panels RP043 and RP047. 120 VAC distribution panel PN310 is a second source of power to RP043 and RP047.

Inverter PN04 supplies power to 120 VAC distribution panel PN410 (via cables 16PNY02AA and 16PNY02AB), which in turn supplies redundant 120 VAC power to NSSS control cabinets RP043 and RP047. Cable 16SCY12EA provides backup power to RP043 from breaker PN41001 and cable 16SCY12FA provides primary power to RP047 from breaker PN41002. For PFSSD, cabinet RP043 houses relays BGLCV0459X and BGLCV0460X, which are associated with letdown isolation valves BGLCV0459 and BGLCV0460, respectively. Cabinet RP047 includes controls for pressurizer PORVs and pressurizer spray.

Damage to cables 16PNY02AA and/or 16PNY02AB will disrupt power to panel PN410. Redundant power to RP043 and RP047 is available from 120 VAC distribution panel PN310. Therefore, loss of power to PN410 will not adversely impact PFSSD.

5.2.1 Steam Generator Atmospheric Relief Valves

PFSSD requires at least two steam generator atmospheric relief valves (ARVs) be controlled and the other two closed. The ARVs are pneumatically operated using air from the compressed air system (KA) or nitrogen from the nitrogen accumulators. The valves open by pneumatic pressure and close by spring action. The valves are automatically controlled by a pressure transmitter installed on the outlet side of the steam generator. Alternatively, each valve can be controlled manually from the control room or the auxiliary shutdown panel by placing the pressure indicating controller (PIC) in manual.

Cables associated with Steam Generator Atmospheric Relief Valves ABPV0001 and ABPV0003 are not run in area C-22. Cables associated with Steam Generator Atmospheric Relief Valves ABPV0002 and ABPV0004 are run in area C-22. Damage to these cables could prevent controlling ARVs ABPV0002 and ABPV0004 from the control room. Because of the fail-close design of the valve, it is unlikely that spurious signals due to cable damage will cause the valves to open. However, in the unlikely event the valves open, they can be controlled or closed using the associated PIC at the auxiliary shutdown panel (RP118B).

As discussed in Section 5.2.2, a fire in this area could affect the Train B motor driven auxiliary feedwater pump (MDAFP) and the turbine driven auxiliary feedwater pump (TDAFP). Therefore, only the Train A MDAFP is available to feed steam generators B and C. As stated above, steam generator B ARV could be affected. Therefore, the only assured PFSSD flow path is the Train A MDAFP feeding steam generator C and controlling cooldown using ABPV0003.

Up to three ARVs can fail closed or open without impacting ability to achieve and maintain hot standby according to thermal hydraulic analysis WCNOC-CP-002. With at least one ARV unaffected, no E-1F9900 OMA is required to address ARV closure or control. Reference Attachment 4, MSO Evaluation Scenario ID PWROG 23.

Based on the above discussion and the results of Calculation WCNOC-CP-002, there is reasonable assurance that damage to the steam generator ARVs as described above will not adversely impact the ability to achieve and maintain safe shutdown if a fire occurs in area C-22.

References: E-15000, XX-E-013, E-1F9101, E-13AB20B, M-12AB01, Calculation WCNOC-CP-002

5.2.2 Auxiliary Feedwater

The PFSSD design requires the use of one auxiliary feedwater pump (AFP) supplying water to at least two steam generators. The turbine driven auxiliary feedwater pump (TDAFP) is normally aligned to supply all four steam generators. The Train A motor driven auxiliary feedwater pump (MDAFP) is aligned to supply steam generators B and C. The Train B MDAFP is aligned to supply steam generators A and D.

The normal source of water to the AFPs is the condensate storage tank (CST). The emergency supply is from the essential service water (ESW) system. For commercial concerns, the CST is the preferred source and contains sufficient volume to supply the entire AFW demand to achieve cold shutdown.

Motor operated valves (MOVs) in the system allow operators to line up the auxiliary feedwater system as required to achieve and maintain safe shutdown. Damage to the MOV circuits due to a fire could prevent operators from lining up the system from the control room.

As shown in Table C-22-3, several PFSSD cables associated with various components of the auxiliary feedwater (AL) system runs through fire area C-22. In addition, cables 12FCK23AA and 12FCK24AE, associated with TDAFP mechanical trip and throttle valve FCHV0312 and

TDAFP control panel FC219, are run in this area. Damage to these cables could prevent operation of the TDAFP and the Train B MDAFP. In addition, motor operated valves in the flowpath from the Train B MDAFP to steam generators A and D and from the TDAFP to steam generators B and C could spuriously close. Cables associated with the Train A MDAFP, as well as the suction and discharge valves, are unaffected by a fire in this area.

Cable 12RLK01AA supplies 125 VDC power from NK4206 to RL005/RL006, where it's split and supplies control power to TDAFP main steam supply valves ABHV0005 and ABHV0006, as well as other non-PFSSD components. Damage to this cable could cause a loss of control power to these valves. Loss of control power will cause the valves to fail open, which is the desired PFSSD position. However, damage to cables 12ABK01AD and 12ABK01BD could cause ABHV0005 and ABHV0006 to close, preventing operation of the TDAFP. In addition, damage to cables 12SAZ23AA and 12SAZ23BA could cause a loss of valve position status for valves ABHV0005 and ABHV0006.

Panels SA036A, SA036B and SA036C monitor pressure transmitter signals on ALPT0037, ALPT0039 and ALPT0038, respectively. Instrument cables associated with ALPT0038 and ALPT0039 are run in this area. Damage to these cables could cause a spurious low CST pressure signal and initiate swap over to the ESW system. This is only a commercial concern and should be prevented if possible.

Power cables associated with SA036B and SA036C are run in this area. Damage to these cables could result in a loss of power to the panels and could prevent automatic operation of low suction pressure (LSP) swap over. This is acceptable since the CST contains sufficient volume to achieve cold shutdown. In addition, operators can monitor CST level using pressure indicator ALPI0037A, which is unaffected by the fire.

Based on the above discussion, auxiliary feedwater is assured if a fire occurs in area C-22 using Train A MDAFP supplying auxiliary feedwater to steam generators B and C. However, steam generator B ARV could be affected, as discussed in Section 5.2.1.

References: E-15000, XX-E-013, E-13AB01, E-13AB01A, E-13AL01A, E-13AL01B, E-13AL02B, E-13AL03A, E-13AL03B, E-13AL04B, E-13AL05A, E-13AL05B, E-13AL07B, E-13AL08, E-13AL09, E-13RL01, E-13RL03, E-13SA21, E-13SA23, E-1F9101, E-1F9202, E-1F9203, E-1F9204, E-1F9402A, E-1F9402B, E-1F9422B, E-13FC23, E-13FC24, J-10SA, M-12AB02, M-12AL01, M-12FC02

5.2.3 Main Steam Isolation Valves Downstream Components

Cables for several main steam (AB) valves located downstream of the main steam isolation valves (MSIVs) are located in this area. These valves are used for PFSSD to isolate the main steam lines in the event the MSIVs or MSIV bypass valves fail to close. Damage to these cables could cause the associated component to fail open.

Cable 16RLY01GA supplies 120 VAC power to control room panel RL023/RL024. At RL023/RL024, the power is split and supplies power to FCHV0103, ABLV0050 and ABLV0052, as well as other non-PFSSD components. These components are required to be functional for PFSSD in the event the MSIVs and MSIV bypass valves cannot be isolated. Loss of power will cause the valves to remain open.

Cable 14ABY31BA is associated with steam dump control switch ABHS0064. Damage to this cable could actuate the steam dumps.

Cable 16FBG12BC is associated with main steam to auxiliary steam reboiler isolation valve FBHV0080. Damage to this cable could prevent closing the valve. Valve FBHV0080 is required to be isolated if the MSIVs and MSIV bypass valves cannot be isolated.

As discussed in Sections 5.2.9 and 5.2.10, the MSIVs and MSIV bypass valves can be isolated using hand switch ABHS0080 if a fire occurs in area C-22. Therefore, these downstream valves can fail open with no adverse impact on PFSSD.

References: E-15000, XX-E-013, E-13AB02B, E-13AB08, E-13AB11A, E-13AB11B, E-13AB11C, E-13AB18, E-13AB22, E-13AB31, E-13FB12, E-13FC08A, E-13RL01, E-13RL07, E-1F9103, E-1F9424E, M-12AB03, M-12FB01, M-12FC04

5.2.4 Load Shedder / Emergency Load Sequencer

The load shedder and emergency load sequencers are included in the PFSSD design to evaluate the impact of spurious operation or mal-operation. The load shedder/emergency load sequencer operates upon presence of the following conditions:

1. An undervoltage (UV) on a safeguards bus,
2. A safety injection signal (SIS) or a containment spray actuation signal (CSAS), or
3. An undervoltage on a safeguards bus with a SIS or CSAS.

Eight inputs (four undervoltage (UV) inputs and four degraded voltage inputs) on each safeguards bus (NB01 and NB02) monitor voltage conditions on that bus. An undervoltage condition on two of four UV relays on each bus will actuate the load shedder/sequencer and send a signal to start the associated diesel generator. In addition, degraded voltage sensed by two of four degraded voltage potential transformers (PTs) will, after a time delay, provide a signal to open the offsite feeder breakers on the associated bus.

Cables 12NFK01CA, 12NFK01DA, 14NFK01CA and 14NFK01DA associated with two of the four undervoltage relays on each bus run in area C-22. Also, cables 12NFY01EA, 14NFY01EA, 12NFY01FA and 14NFY01FA associated with two of the four degraded voltage PTs on each bus are run in fire area C-22. Cables associated with the remaining two UV relays and PTs do not run in fire area C-22. Therefore, automatic functioning of the bus NB01 and NB02 emergency load shed/sequencer is unaffected by a fire in area C-22 due to the availability of at least two UV relay inputs.

A spurious actuation of the load shedder/sequencer due to damage to cables associated with two of the four UV relays will not adversely impact the ability to achieve and maintain safe shutdown. The load shedder will shed all safety related and non-safety related loads from the bus and start the diesel generator. Safety-related loads will then be sequenced back onto the bus in a pre-determined order. Per Section 5.2.8, a spurious SIS and CSAS cannot occur, so the LOCA sequencer mode will not spuriously actuate. The LOCA sequencer mode will actuate in the event of an actual SIS or CSAS.

Based on Calculation XX-E-013, Appendix 2, an actual loss of off-site power could occur on Train B while Train A off-site power remains available. In the event of a spurious undervoltage signal that causes the load shedder/sequencer to actuate, operators can re-align Train A off-site power from the control room, if necessary, to energize required PFSSD loads.

Separation groups 2 and 4 power cables associated with NF039A, NF039B and NF039C are run in this area. Separation groups 1 and 3 power cables associated with these panels are unaffected. Therefore, power to the load shedder/sequencer panels is available.

Based on the above discussion, damage to cables associated with the load shedder/sequencer will not adversely impact the ability to achieve and maintain safe shutdown.

References: XX-E-013, E-15000, E-11005, E-12NF01, E-13NF01, E-10NF, E-1F9402A, E-1F9402B, E-1F9403, E-1F9411A, E-1F9411B, E-1F9412A, E-1F9412B, E-1F9425, E-1F9426

5.2.5 BOP Instrument Racks

BOP instrument racks RP053A, RP053B, RP053D and RP147 are credited in the PFSSD analysis. The following table identifies the PFSSD components served by each instrument rack.

Instrument Rack	PFSSD Components
RP053A (RP053AA, RP053AB, RP053AC)	ALHV0009, ALHV0011 ALPY0037A, EGFT0128, EGPSL0077, GDTSL0001, JELSL0001C
RP053B (RP053BA, RP053BB, RP053BC)	ALHV0007, ALPY0039A, EGFT0129, EGPSL0078, GDTSL0011, JELSL0021C
RP053D (RP053DA, RP053DB)	ALPY0038A
RP147 (RP147A, RP147B)	ALHV0005

Cable 12RPY09AA supplies 120 VAC power to BOP instrument rack RP053D. Damage to this cable could cause a loss of function of ALPY0038A.

Cables 14RPY09BA and 14RPY09CA supply 120 VAC power to BOP instrument rack RP053B. Damage to these cables could cause a loss of function of panel RP053B and associated PFSSD components.

Pressure converters ALPY0038A and ALPY0039A are associated with ESFAS low auxiliary feedwater suction pressure. Loss of these devices due to a fire could prevent an automatic swap over from the CST to the ESW system. The CST contains sufficient volume for PFSSD and pressure indication is available in the control room using ALPT0037. Therefore, loss of these pressure converters will not adversely impact PFSSD.

Instrument racks RP053A and RP147B are unaffected by the fire. Therefore, loss of PFSSD components associated with RP053B and RP053D will not adversely impact PFSSD.

References: E-15000, XX-E-013, E-13AL08, E-13AL09, E-13EG13, E-13JE01, E-13NN01, E-13RP09, E-1F9101, E-1F9202, E-1F9204, E-1F9401B, E-1F9411B, E-1F9411A, E-1F9424D, E-1F9443, E-K3GD01A, E-K3GD04, M-12AL01, M-12EG01, M-12JE01, M-K2GD01

5.2.6 Essential Service Water

Either the Train A or the Train B essential service water (ESW) system is required to be available to ensure PFSSD. The ESW system supplies water to the following PFSSD components on the associated train:

- CCP room cooler
- RHR pump room cooler
- Class 1E switchgear room A/C condenser
- diesel generator engine cooling
- control room A/C condenser
- auxiliary feedwater pump room cooler
- motor and turbine driven auxiliary feedwater pump suction (backup to CST)
- containment air coolers
- electrical penetration room cooler
- component cooling water pump room cooler
- component cooling water heat exchanger
- component cooling water system makeup

A number of components associated with Train B ESW system could be affected by a fire in this area. The Train B ESW pump and a number of Train B ESW control valves could spuriously operate or may not operate when required. The Train B ESW pump room supply fan and associated dampers may not operate. Therefore, the Train B ESW system cannot be relied on if a fire occurs in this area.

The service water system provides the normal source of water to the ESW piping. Service water supply to and return from the ESW piping is each controlled by two valves installed in series. One of the two valves on each leg is required to be closed for PFSSD to prevent flow diversion from the credited ESW system. As discussed in the previous paragraph, the Train B ESW system may not be available if a fire occurs in this area. One valve (EFHV0025) on the Train A service water to ESW piping supply line and one valve (EFHV0039) on the Train A ESW to service water return line may be affected by the fire and may not close on a signal from the control room. Redundant valves EFHV0023 and EFHV0041 are unaffected by the fire and will close on a signal from the control room. Therefore, the ESW/service water cross connects can be isolated if a fire occurs in this area. In addition, check valve EFV0470 is installed between valves EFHV0023 and EFHV0025 and will prevent flow diversion from Train A ESW to the service water system. Also, check valve EFV0471 is installed between valves EFHV0024 and EFHV0026 and will prevent flow diversion from Train B ESW to the service water system.

Cable 14RPY10BA supplies 120 VAC control power to the automatic and manual start circuits for the Train B ESW pump room supply fan CGD01B. The control power is supplied via this cable to control room panel RP068. If power is lost due to damage to this cable, then the Train B ESW pump room supply fan will not start either automatically, when the ESW pump starts, or manually from the control room. If this occurs, the Train A ESW pump room supply fan remains unaffected by the fire.

Cables 14GDY01BA, 14GDY01BB and 14GDY01BD are associated with Train B ESW pump room supply fan CGD01B. Damage to these cables could prevent operation of the supply fan. Train A ESW pump room supply fan CGD01A is unaffected by a fire in this area.

The Train A ESW system is unaffected by a fire in area C-22. Therefore, the Train A ESW system is available if a fire occurs in area C-22.

1F9402B, E-1F9403, E-1F9424B, E-1F9443, J-201-00133, M-12EF01, M-12EF02, M-K2EF01, M-K2GD01

5.2.7 Reactor Protection System

The Reactor Protection System (RPS) monitors specified input parameters and initiates reactor protection features whenever those parameters are outside specified limits. Field installed transmitters continuously monitor various parameters and report the results to one of four process cabinets, one per channel. Signals are then sent from the process cabinets to both solid state protection cabinets, one on each train. The cabinets and associated channel are listed in the following table:

Process Cabinets	Solid State Protection Cabinets
Cabinet SB038 - Channel 1 Cabinet SB042 - Channel 2 Cabinet SB037 - Channel 3 Cabinet SB041 - Channel 4	Cabinet SB029A - Train A Input Cabinet Cabinet SB029B - Train A Logic Cabinet Cabinet SB029C - Train A Output Cabinet 1 Cabinet SB029D - Train A Output Cabinet 2 Cabinet SB032A - Train B Input Cabinet Cabinet SB032B - Train B Logic Cabinet Cabinet SB032C - Train B Output Cabinet 1 Cabinet SB032D - Train B Output Cabinet 2

The RPS is actuated upon 2/3 or 2/4 coincident logic, depending on the input parameter. This ensures that a loss of a single channel will not prevent the system from performing its function. Loss of power to a single cabinet will render the channel or Train inoperative.

Cables associated with RPS channels 2 and 4 run through this area. These cables supply power from separation groups 2 and 4 power supplies to panels SB029A, SB032A, SB032D, SB041 and SB042. Power cables associated with RPS channels 1 and 3 are run in a separate fire area.

A number of instrumentation cables associated with reactor protection system channel 4 run through this area. These cables provide channel 4 signals from process cabinet SB041 to solid state protection cabinets SB029A and SB032A and from process cabinets SB041 and SB042 to main control board post-accident monitoring. Damage to these cables will not adversely impact PFSSD due to availability of channels 1, 2 and 3 diagnostic instrumentation.

Damage to cables associated with the RPS due to a fire in this area could cause a loss of RPS channels 2 and 4, but channels 1 and 3 remain available. Spurious RPS actuation due to cable damage will not adversely impact PFSSD. These spurious actuations can either be mitigated as discussed in other sections (i.e., spurious SIS and CSAS), or the spurious actuation places the plant in a safe condition as designed. Therefore, damage to these cables will not adversely impact the ability to achieve and maintain safe shutdown.

References: XX-E-013, E-15000, E-11NK02, E-13NN01, E-13SB01, E-13SB02, E-13SB05, E-13SB08A, E-13SB08D, E-13SB09, E-1F9102, E-1F9103, E-1F9203, E-1F9205, E-1F9421, E-1F9433, E-1F9431, E-1F9432, M-761-000167

5.2.8 Safety Injection and Containment Spray

A spurious safety injection signal (SIS) could cause the safety injection pumps to operate. A spurious containment spray actuation signal (CSAS) could cause the containment spray pumps to operate, depleting inventory in the RWST. These conditions are not desirable for PFSSD at Wolf Creek.

Safety injection (SI) is initiated automatically by any of the following conditions:

1. Two out of three high containment pressures monitored by pressure transmitters GNPT0934, GNPT0935 and GNPT0936.
2. Two out of four low pressurizer pressures monitored by pressure transmitters BBPT0455, BBPT0456, BBPT0457 and BBPT0458.
3. Two out of three low steam line pressures on any steam generator monitored by ABPT0514, ABPT0515 and ABPT0516 on SG A; ABPT0524, ABPT0525 and ABPT0526 on SG B; ABPT0534, ABPT0535 and ABPT0536 on SG C; and ABPT0544, ABPT0545 and ABPT0546 on SG D. Two out of three logic must be satisfied on a single steam generator line. Low pressure on a single pressure transmitter co-incident with low pressure on another pressure transmitter on a different steam generator line will not initiate SIS.

Containment spray (CS) is initiated automatically by two out of four high containment pressures monitored by pressure transmitters GNPT0934, GNPT0935, GNPT0936 and GNPT0937.

A cable associated with containment pressure transmitter GNPT0934 is run in area C-22. Cables associated with the remaining containment pressure transmitters are not run in area C-22. Therefore, a spurious CSAS cannot occur due to a fire in this area. Also, a spurious SIS due to high containment pressure cannot occur.

Cables associated with containment pressure indicators GNPI0934 and GNPI0936 are run in this area. Damage to these cables will prevent use of these indicators but will not initiate a spurious CSAS or SIS. Containment pressure indication remains available using GNPI0935 and GNPI0937.

A cable associated with pressurizer pressure transmitter BBPT0458 is run in area C-22. Cables associated with the remaining pressurizer pressure transmitters do not run in area C-22. Consequently, a fire in area C-22 cannot cause a spurious SIS due to low pressurizer pressure.

Cables associated with steam line pressure transmitters ABPT0516 and ABPT0546 are run in area C-22. Cables associated with the remaining steam line pressure transmitters do not run in area C-22. Consequently, a spurious two out of three logic for low steam line pressure initiation of SIS cannot be satisfied if a fire occurs in area C-22.

Based on the above discussion, a spurious SIS and CSAS cannot occur if a fire occurs in this area.

References: E-15000, XX-E-013, E-13AB21, E-13BB16, E-13GN05, E-1F9431, E-1F9432, E-1F9433, M-12AB01, M-12BB02, M-12GN01, M-761-02038, M-761-02091

5.2.9 Steam Generator Main Steam Isolation Bypass Valves

Each of the four MSIV bypass valves (ABHV0012, ABHV0015, ABHV0018 and ABHV0021) has two redundant solenoids that control the position of the associated bypass valve. The bypass valves are normally closed with the solenoids de-energized. Both solenoids need to be energized to open the valve. One of the solenoids on each valve is on separation group 1 (Train A) and are controlled by hand switch ABHS0080. The other solenoids on each valve are on separation group 4 (Train B) and are controlled by hand switch ABHS0079.

Cable 14ABK23FE is associated with steam line isolation signal relay K627. Upon receipt of a steam line isolation signal, the relay contact opens and the bypass valves close. An open circuit in one of the two conductors will produce the same result as a steam line isolation signal, which is desired for PFSSD. A hot short between the conductors will bypass the contact and prevent a steam line isolation signal from closing the valves.

Cable 14ABK23FF is associated with handswitch ABHS0079 on the Train B MSIV bypass valve control circuit. An open circuit in one of the two conductors will de-energize the respective solenoid and close the bypass valves. A hot short between the conductors will bypass the handswitch contact and prevent closure of the valves using the handswitch.

Cable 14ABK23FG is associated with reset switch ABHS0100 on the Train B MSIV bypass valve control circuit. An open circuit will have no impact on the ability to close the bypass valves. A hot short between the conductors will act as a reset signal and maintain the auxiliary relay energized, maintaining the four Train B bypass valve solenoids energized and therefore providing the Train B permissive to open the valves.

Redundant means are available to ensure the MSIV bypass valves are closed. Hand switch ABHS0080 is unaffected by the fire and can be used to ensure one of the two solenoids on each bypass valve are de-energized.

References: E-15000, XX-E-013, E-13AB23B, E-1F9101, M-12AB02

5.2.10 Steam Generator Main Steam Isolation Valves (MSIVs)

PFSSD requires the MSIVs be closed to prevent reactivity addition due to uncontrolled cooldown. The MSIVs are closed from the control room using all close hand switches ABHS0079 or ABHS0080.

Each MSIV is designed to utilize system fluid (main steam) as the motive force to open and close. The valve actuation (open or close) is accomplished through positioning a series of six electric solenoid pilot valves to either direct the system fluid to the Upper Piston Chamber (UPC) and/or the Lower Piston Chamber (LPC), or vent either or both piston chambers. The six solenoid pilot valves are divided into two trains (3 per train) that are independently powered and controlled. Either train can independently perform the PFSSD function to close the valve and isolate main steam. This is done by actuating either all close hand switch ABHS0079 (separation group 4) or ABHS0080 (separation group 1) to de-energize the associated solenoid valves.

The following table identifies the solenoids and associated control cables for each hand switch.

MSIV	ABHS0079 (Sep Group 4)		ABHS0080 (Sep Group 1)	
	Solenoids	Cable	Solenoids	Cable
ABHV0011	MV2, MV4, MV6	14ABK28BH	MV1, MV3, MV5	11ABK29BH
ABHV0014	MV2, MV4, MV6	14ABK29AH	MV1, MV3, MV5	11ABK28AH
ABHV0017	MV2, MV4, MV6	14ABK28AH	MV1, MV3, MV5	11ABK29AH
ABHV0020	MV2, MV4, MV6	14ABK29BH	MV1, MV3, MV5	11ABK28BH

All 4 cables associated with the 12 separation group 4 solenoid valves are run in area C-22. Cable damage due to a fire will likely result in disruption of power to the solenoids, which will close the valves. The four separation group 1 cables associated with hand switch ABHS0080 are unaffected by a fire in area C-22. Therefore, hand switch ABHS0080 is available to close the four MSIVs.

Cable 14ABK30BB provides 125 VDC power to Train B main steam and feedwater isolation actuation system (MSFIS) cabinet SA075B from NK5423. Damage to this cable would disrupt power to the separation group 4 solenoids and close the MSIVs, which is the desired PFSSD position. In addition, the Train A MSFIS is unaffected by the fire and ABHS0080 is available to close the MSIVs.

Based on the above discussion, hand switch ABHS0080 is available to close the MSIVs in the event of a fire in area C-22.

References: E-15000, XX-E-013, E-13AB27, E-13AB28, E-13AB29, E-13AB30, E-1F9101, M-12AB02

5.2.11 Steam Generator Level and Pressure Indication

The decay heat removal function for PFSSD requires the use of two RCS loops and two Steam Generators. Steam generator (SG) level indication is required to support this function. A fire in area C-22 uses MDAFP A to supply SGs B and C. Therefore, level indication on steam generators B and C is required.

Diagnostic indication of steam line pressure is also required for PFSSD. Steamline pressure indication is used to determine if a steam generator ARV is stuck open, verification of heat removal per EMG ES-04, and verification of an actual SIS per EMG E-0. Section 5.2.8 discusses steam line pressure SIS initiation, whereas this section discusses availability of steam line pressure indication on the MCBs.

Cables associated with level transmitters AELT0517 (SG A NR), AELT0527 (SG B NR), AELT0537 (SG C NR) and AELT0547 (SG D NR) run in this area. In addition, cables associated with level indicators AELI0502 (SG B WR), AELI0504 (SG D WR), AELI0517 (SG A NR), AELI0519 (SG A NR), AELI0527 (SG B NR), AELI0537 (SG C NR), AELI0547 (SG D NR), AELI0549 (SG D NR), AELI0552 (SG B NR) and AELI0553 (SG C NR) run in this area. Consequently, steam generator level indication on these level indicators could be affected. Alternate level indication remains available on all four SGs using the following level indicators:

Steam Generator	Available Level Indication
A	AELI0501 (WR), AELI0518 (NR), AELI0551 (NR)
B	AELI0528 (NR), AELI0529 (NR)
C	AELI0503 (WR), AELI0538 (NR), AELI0539 (NR)
D	AELI0548 (NR), AELI0554 (NR)

Circuits associated with steam generator level indication at the auxiliary shutdown panel (RP118B) are run in area C-22. Damage to these circuits will affect AELI0504A (SG D Wide Range Level Indicator at RP118B), AELI0517X (SG A Narrow Range Level Indicator at RP118B) and AELI0537X (SG C Narrow Range Level Indicator at RP118B). Damage to these circuits will not impact the redundant level indicators in the main control room.

As discussed in Section 5.2.8, cables associated with steam line pressure transmitters ABPT0516 and ABPT0546 are run in fire area C-22. In addition, cables associated with steam line pressure indicators ABPI0515A, ABPI0516A, ABPI0525A, ABPI0535A, ABPI0545A and ABPI0546A are run in this area. Consequently, steam line pressure indication in the MCR for

these transmitters and indicators will not be available. Alternate steam line pressure indication remains available using the pressure indicators in the following table:

Steam Generator	Available Pressure Indication
A	ABPI0514A
B	ABPI0524A, ABPI0526A
C	ABPI0534A, ABPI0536A
D	ABPI0544A

Based on the above discussion, steam generator level indication and main steam line pressure indication is available on all four steam generators if a fire occurs in fire area C-22.

References: E-15000, XX-E-013, E-13AE08, E-13SB08D, E-13SB16, E-1F9203, M-12AE02, M-761-00135

5.2.12 Steam Generator Main Feedwater Isolation Valves

PFSSD requires that either the main feedwater isolation valves (MFIVs) be closed or the main feedwater pumps be stopped to prevent overfilling the steam generators. Flow diversion from auxiliary feedwater (AFW) to the main feedwater system piping is prevented by check valves AEV0420, AEV0421, AEV0422 and AEV0423. Closure of the main feedwater isolation valves is not required to prevent AFW flow diversion.

Each MFIV is designed to utilize system fluid (feedwater) as the motive force to open and close. The valve actuation (open or close) is accomplished through positioning a series of six electric solenoid pilot valves to either direct the system fluid to the Upper Piston Chamber (UPC) and/or the Lower Piston Chamber (LPC), or vent either or both piston chambers. The six solenoid pilot valves are divided into two trains (3 per train) that are independently powered and controlled. Either train can independently perform the PFSSD function to close the valve and isolate main feedwater. This is done by actuating either all close hand switch AEHS0080 (separation group 1) or AEHS0081 (separation group 4) to de-energize the associated solenoid valves.

The following table identifies the solenoids and associated control cables for each hand switch.

MFIV	AEHS0080 (Sep Group 1)		AEHS0081 (Sep Group 4)	
	Solenoids	Cable	Solenoids	Cable
AEFV0039	MV1, MV3, MV5	11AEK16AH	MV2, MV4, MV6	14AEK17AH
AEFV0040	MV1, MV3, MV5	11AEK17AH	MV2, MV4, MV6	14AEK16AH
AEFV0041	MV1, MV3, MV5	11AEK16BH	MV2, MV4, MV6	14AEK17BH
AEFV0042	MV1, MV3, MV5	11AEK17BH	MV2, MV4, MV6	14AEK16BH

All 4 cables associated with the 12 separation group 4 solenoid valves are run in area C-22. Cable damage due to a fire will likely result in disruption of power to the solenoids, which will close the valves. The four separation group 4 cables associated with hand switch AEHS0080 are unaffected by a fire in area C-22. Therefore, hand switch AEHS0080 is available to close the four MFIVs.

Cable 14AEK15AB is a control cable associated with hand switch AEHS0081. An open circuit will prevent closing the MFIVs using this hand switch. A hot short will cause the valves to close, which is the desired PFSSD position. Hand switch AEHS0080 is unaffected by the fire.

Cable 14ABK30BB provides 125 VDC power to Train B main steam and feedwater isolation actuation system (MSFIS) cabinet SA075B from NK5423. Damage to this cable would disrupt

power to the separation group 4 solenoids and close the MFIVs, which is the desired PFSSD position. In addition, the Train A MSFIS is unaffected by the fire and AEHS0080 is available to close the MFIVs.

Based on the above discussion, MFIV isolation is assured using hand switch AEHS0080.

References: E-15000, XX-E-013, E-13AB30, E-13AE14, E-13AE15, E-13AE16, E-13AE17, E-1F9201, J-104-00295, J-104-00296, M-12AE02, M-630-00044

5.2.13 Reactor Coolant Pump (RCP) Seal Injection

PFSSD requires RCP seal injection to provide a boron injection path, provide makeup to the RCS to maintain hot standby inventory and prevent damage to the RCP seals. The Component Cooling Water (CCW) system is an alternative means of cooling the RCP seals.

A fire in area C-22 could damage power and control cables associated with all four RCP seal injection valves (BBHV8351A, BBHV8351B, BBHV8351C and BBHV8351D). The seal injection valves are normally open and de-energized with the circuit breaker maintained in the OFF position. The valves are not high/low pressure interface valves so three-phase hot shorts do not have to be considered and, consequently, damage to the power cables will not cause the valves to spuriously close. Damage to the control cables will not cause the valves to close because the power and control circuits are de-energized. Therefore, a fire in this area will not cause the seal injection valves to close.

Cable 14BGG52BC is associated with CCP B to RCP seal injection valve BGHV8357B. Redundant Train A CCP to RCP seal injection valve BGHV8357A is unaffected.

Cable 14BGI51BA is associated with RCP seal total flow transmitter BGFT0215B. Cable 14SBS08DA is associated with RCP seal total flow indicator BGFI0215B. Damage to these cables could cause a loss of seal flow indication on BGFI0215B. RCP seal total flow indicator BGFI0215A is unaffected by a fire in area C-22 and can be used to diagnose a loss of the operating charging pump.

Based on the above discussion, RCP seal injection is available. RCP seal total flow indicator BGFI0215A can be used to diagnose a loss of the operating charging pump.

References: E-15000, XX-E-013, E-13BB04, E-13BG51, E-13BG52, E-13SB08D, E-1F9102, E-1F9302, E-1F9303, M-12BB03, M-12BG03

5.2.14 Component Cooling Water

The component cooling water system is required for PFSSD to provide cooling water to the CCP oil coolers, seal water heat exchanger, RHR heat exchanger, RHR pump seal cooler and RCP thermal barriers (to maintain RCP seal cooling in the event RCP seal injection is lost). In addition, the CCW system provides cooling to the RCP thermal barriers and is credited as a backup to RCP seal injection for maintaining seal cooling.

Cables associated with components on the Train B CCW system run through area C-22. Damage to these cables due to a fire could prevent operation of the associated equipment and prevent operation of Train B CCW. Cables associated with redundant Train A CCW are run in a different fire area and are unaffected by the fire.

To ensure an operable flow path, either valves EGHV0071 or EGHV0126 must be open and either EGHV0058 or EGHV0127 must be open. In addition, either valves EGHV0062 or EGHV0132 must be open and either EGHV0061 or EGHV0133 must be open. Also, valve EGHV0015 needs to be open when operating the Train A CCW system to ensure a return flow path to the suction side of the CCW pumps.

Cables associated with valves EGHV0062, EGHV0071, EGHV0127 and EGHV0133 run through area C-22. If the fire affects cables associated with EGHV0062 and EGHV0071, the valves may spuriously close. This can be mitigated by opening valves EGHV0132 and EGHV0126 using associated hand switches EGHIS0132 and EGHIS0126 on RL020.

Cable 14EGI19BA is associated with CCW to RCP flow indicator EGFI0129. Cable 14EGI19BB is associated with CCW to RCP flow transmitter EGFT0129. Damage to these cables could prevent operation of EGFI0129. CCW to RCP flow indicator EGFI0128 is unaffected and can be used to diagnose a loss of CCW flow to the thermal barriers. Cable 14EGG05BC associated with EGHV0016 and cable 14EGG05DC associated with EGHV0054 are run in this area. If Train B CCW is operating at the time of the fire, these valves will be open. If it is necessary to swap to Train A CCW, these valves will need to be closed to prevent flow diversion to Train B CCW and potential loss of suction to the Train A CCW pumps. If the fire damages these cables, the valves may not respond to a close signal and one or both of these valves may remain open when operating the Train A CCW system.

Calculation M-EG-24 determines the amount of inventory lost from one train of CCW to the other train given a single failure of EGHV0015, EGHV0016, EGHV0053 or EGHV0054. The calculation also evaluates the impact on CCW pump NPSH given these failures. Based on the results of the calculation, there is no adverse impact on NPSH if a single failure occurs. In the case where both valves remain open, PFSSD is assured because, if EGHV0054 is open, check valve EGV0061 will prevent flow diversion from Train A to Train B CCW.

Based on the above discussion, Train A CCW is available to provide cooling to essential PFSSD components as well as provide cooling to the RCP thermal barriers. Flow indicator EGFI0128 is available to diagnose a loss of CCW flow to the RCP thermal barriers.

References: E-15000, XX-E-013, E-13EG01C, E-13EG01D, E-13EG05A, E-13EG05B, E-13EG07, E-13EG07A, E-13EG09, E-13EG10, E-13EG13, E-13EG15, E-13EG16, E-13EG18, E-13EG18A, E-13EG19, E-1F9303, E-1F9401A, E-1F9401B, M-12EG01, M-12EG02, M-12EG03, Calculation M-EG-24

5.2.15 Residual Heat Removal (RHR)

PFSSD requires one train of residual heat removal (RHR) to be available for shutdown cooling. The RHR system is not used for hot standby.

Hot shutdown requires isolation of the RCS to RHR flow path by maintaining either BBPV8702A or EJHV8701A closed and either BBPV8702B or EJHV8701B closed. Cold shutdown requires RHR taking suction from the RCS. RHR pump suction from the RCS is controlled by valves BBPV8702A and EJHV8701A (Train A) and BBPV8702B and EJHV8701B (Train B). The PFSSD strategy credits Train A RHR to achieve cold shutdown if a fire occurs in area C-22.

Control cables associated with RHR pump B (PEJ01B) could be damaged, causing a spurious pump start or preventing the pump from being started. Cables associated with RHR pump A are unaffected by a fire in area C-22.

Cables 14BBG12AF and 14BBG12AG are control cables associated with BBPV8702A. An inter-cable (cable-to-cable) hot short between cables 14BBG12AF and 14BBG12AG will bypass the control room hand switch and provide the permissive to open BBPV8702A. Valve EJHV8701A will remain closed since cables associated with this valve are not run through area C-22. Furthermore, BBPV8702A and EJHV8701A are administratively maintained closed with the breaker locked open. The 3-phase power cables associated with both valves are not run in this area, so a 3-phase hot short is not credible.

Cables 14BBG12BF and 14BBG12BG are control cables associated with BBPV8702B. An inter-cable (cable-to-cable) hot short between cables 14BBG12BF and 14BBG12BG will

bypass the control room hand switch and provide the permissive to open BBPV8702B. Valve EJHV8701B will remain closed since cables associated with this valve are not run through area C-22. Furthermore, BBPV8702B and EJHV8701B are administratively maintained closed with the breaker locked open. The 3-phase power cables associated with both valves are not run in this area, so a 3-phase hot short is not credible.

An open circuit in cable 14BBG12AF could prevent remote opening of valve BBPV8702A when transitioning to RHR Train A. If this occurs, a cold shutdown repair or a containment entry will be necessary to open the valve. Valve EJHV8701B can be controlled from the control room.

Valve EGHV0101 is the Train A CCW to RHR Heat Exchanger control valve. Valve EGHV0102 is the Train B CCW to RHR Heat Exchanger control valve. These valves are normally closed during power operation. PFSSD requires that the valve on the operating train of CCW be closed until shutdown cooling mode is entered, at which time the valve on the operating train of RHR needs to be open. Cables 14EGG07BC and 14EGG07BD are control cables associated with valve EGHV0102. Damage to either cable could cause the spurious opening of the valve and could prevent operation when lining up for shutdown cooling. Valve EGHV0101 is unaffected by a fire in this area.

When RHR pumps are operating, the associated mini-flow valve (EJFCV0610 or EJFCV0611) needs to be controlled. The mini-flow valves prevent RHR pump overheating by re-circulating water from the discharge side of the RHR heat exchanger to the suction side of the RHR pump. The mini-flow valve opens when the flow indicator measures low flow and closes on high flow. Damage to cable 14EJG08BC could prevent mini-flow valve EJFCV0611 from operating properly. If the Train B RHR pump spuriously starts and EJFCV0611 fails to operate, the pump could be damaged. This is a commercial concern only since Train A RHR pump and mini-flow valve EJFCV0610 are unaffected by a fire in this area.

The RHR heat exchanger discharge control valve on the operating train (EJHCV0606 (Train A) or EJHCV0607 (Train B)) needs to be available. Cable 16EJI12BA, which is associated with EJHCV0607, runs through area C-22. Cable 16RLY01DA provides 120 VAC power to RL017/RL018 (EJHY0607) from PN0833. Damage to these cables could result in the loss of control of valve EJHCV0607. Valve EJHCV0606 is unaffected by a fire in this area.

RHR pump A discharge to CVCS control valve EJHV8804A needs to be closed when operating the Train A RHR system. RHR pump B discharge to SI Pump B control valve EJHV8804B needs to be closed when operating the Train B RHR system. Damage to cable 14EJG04BC could cause valve EJHV8804B to spuriously open. Cables associated with EJHV8804A do not run in area C-22.

Cables associated with Train B RHR pump discharge to RCS cold leg isolation valve EJHV8809B run in area C-22. Damage to these cables could prevent operating the valve from the control room. Cables associated with Train A RHR pump discharge to RCS cold leg isolation valve EJHV8809A do not run in area C-22. Consequently, valve EJHV8809A is unaffected by a fire in area C-22.

The cold shutdown mode of PFSSD requires isolation of hot leg recirculation. Valve EJHV8840 is used to isolate RHR flow to the RCS hot leg loops 2 and 3. This valve is normally closed and is required to be closed for cold shutdown. During hot standby, the valve can be in any position. Cables associated with valve EJHV8840 run through area C-22. Damage to cables 14EJG09AC and 14EJG09AD would likely result in valve EJHV8840 remaining in its as-is normally closed position, which is the preferred PFSSD position. However, two proper intra-cable hot shorts in cable 14EJG09AD or one intra-cable hot short in cable 14EJG09AD combined with a short to ground on conductor U1 would spuriously open the valve.

As stated above, the position valve EJHV8840 (open or closed) will not affect hot standby. The valve needs to be closed for cold shutdown. The valve has been modified to address NRC IN

92-18 and can be closed manually prior to entering shutdown cooling mode. The torque and limit switches are not bypassed by postulated damage to these cables.

Based on the above discussion, the Train B RHR system could be affected by a fire in this area but the Train A RHR system is available. Valve EJHV8840 may need to be manually closed when transitioning to shutdown cooling mode of operation.

References: E-15000, XX-E-013, E-13BB12A, E-13BB12B, E-13EG07A, E-13EJ01, E-13EJ04B, E-13EJ08, E-13EJ09C, E-13EJ12, E-13RL01, E-13RL04, E-1F9205, E-1F9301, E-1F9401A, E-1F9421, M-12BB01, M-12EJ01

5.2.16 Pressurizer Power Operated Relief Valves and Associated Block Valves

PFSSD requires that either the pressurizer power operated relief valve (PORV) or its associated block valve be closed. Cables and components associated with PORV BBPCV0456A and associated block valve BBHV8000B are run through area C-22. Cables and components associated with PORV BBPCV0455A and associated block valve BBHV8000A are not located in area C-22.

The pressurizer PORVs are not considered high/low pressure interfaces. The valves are supplied power by an ungrounded 125 VDC system. Therefore, based on GL 86-10, consideration of multiple proper polarity hot shorts is not required. A single proper polarity hot short still needs to be considered. Damage to the BBPCV0456A control cables in this area could cause the spurious opening of the valve.

In the event a fire causes BBPCV0456A to open and damages BBHV8000B cables, Operators can close BBPCV0456A by placing hand switch BBHIS0456A, located on RL021, in the close position. Pressurizer level and RCS pressure indication are available to diagnose a failed open PORV using BBLI0459A and BBPI0405, respectively. In addition, pressurizer pressure indication is available using BBPI0455A and BBPI0457.

An instrument cable (14BBI16NB) associated with pressurizer pressure transmitter BBPT0458 is run in fire area C-22. Damage to this cable could send a spurious high-pressure signal to the pressure control system but will not open pressurizer PORVs BBPCV0455A or BBPCV0456A. As discussed in Calculation XX-E-013, Appendix 1, the Ovation pressurizer pressure control system uses 4-channel verification from all four pressurizer pressure transmitters to operate the pressurizer PORVs. Failure of a single channel will not cause the spurious operation of the PORVs since the system uses the 2nd highest input as the validated signal.

Cable 16SBS06BD provides output from panel RP047 to solid state protection cabinet SB032D to energize relay K713 on high pressure in the pressurizer. High pressurizer pressure will close the K713 contact (drawing E-13BB40) and open pressurizer PORV BBPCV0456A. Low pressure in the pressurizer will open the K750 contact (drawing E-13BB40) and close the PORV. Therefore, damage to this cable could cause the spurious opening of the PORV. If damage is limited to this cable, the PORV can be closed by placing BBHIS0456A in the close position.

The PFSSD function of cable 16SBS08FD is to provide BBPT0456 pressurizer pressure input signals from SB042 (Protection Set II) to Ovation NSSS control cabinet 6 (RP047). The PFSSD function of cable 16SBS08HC is to provide BBPT0458 pressurizer pressure input signals from SB041 (Protection Set IV) to Ovation NSSS control cabinet 6 (RP047). These cables carry a 0 to 10 VDC signal to the Ovation pressure control system. The operation of the Ovation pressure control system is described above and in Calculation XX-E-013. Due to the 4-channel validation logic of the Ovation controller, damage to these cables will not cause the spurious operation of the pressurizer PORVs, spray valves or heaters.

Based on the above discussion, pressurizer PORV BBPCV0456A could spuriously open due to damage to the PORV control cables or due to a spurious high pressurizer pressure signal and block valve BBHV8000B may not close due to cable damage. The PORV can be closed using hand switch BBHIS0456A in the main control room.

References: XX-E-013, E-15000, E-13BB16, E-13BB39, E-13BB40, E-13SB06, E-13SB08C, E-1F9201, E-1F9301, E-1F9421, J-200-00095, M-12BB02, M-744-00028, M-761-02048, M-761-02102, OFN KC-016, CR 13079, DCP 12944

5.2.17 Reactor Coolant System (RCS) Pressure Indication

The PFSSD design requires RCS pressure indication to be available to ensure operators have adequate diagnostic indication of RCS pressure.

RCS pressure indication is provided in the control room using pressure indicators BBPI0405 or BBPI0406. Cable 14BBI16BB is an instrument cable associated with BBPI0406 that runs from process protection cabinet SB148B to RL002. Damage to this cable could prevent RCS pressure indication on BBPI0406.

Redundant RCS pressure transmitter BBPT0405 and pressure indicator BBPI0405 are unaffected by a fire in area C-22. Therefore, RCS pressure indication is available using BBPI0405.

References: XX-E-013, E-15000, E-13BB16, E-1F9201, E-1F9205, M-12BB04

5.2.18 Reactor Head Vent Valves

PFSSD requires that one of the two reactor vessel head vent valves on each flow path (2 flow paths total) be closed to prevent uncontrolled depressurization of the RCS. Either BBHV8001A or BBHV8002A and either BBHV8001B or BBHV8002B needs to be closed.

A cable (14BBK30DA) associated with one of the four head vent valves (BBHV8002B) runs through area C-22. Cables for remaining head vent valves BBHV8001A, BBHV8002A and BBHV8001B are not run through C-22 and are unaffected by the fire. Therefore, at least one valve on each flow path can be controlled and spurious opening of BBHV8002B will have no adverse impact on PFSSD.

References: E-15000, XX-E-013, E-13BB30, E-1F9301, M-12BB04

5.2.19 Centrifugal Charging Pumps

At least one centrifugal charging pump (CCP) is required for PFSSD to provide RCP seal cooling, reactivity control and inventory control. These functions are accomplished using a CCP taking suction from the refuelling water storage tank (RWST) and injecting through the RCP seals. RCP seal injection provides approximately 20 gpm makeup to the RCS and provides adequate boron concentration to maintain sub-critical reactivity conditions. If RCP seal injection is unavailable, reactivity and inventory control is provided by lining up the CCPs to the boron injection tank (BIT). The normal charging pump (NCP) is not credited and is assumed lost.

Control cables associated with Train B Centrifugal Charging Pump (CCP) PBG05B run through area C-22. Damage to these cables could prevent operation of the pump. Redundant Train A CCP cables are run in a separate fire area and are unaffected by a fire.

Control cables associated with Train B charging pump miniflow valve BGHV8111 run through area C-22. Redundant Train A cables for miniflow valve BGHV8110 are run in a different area and are unaffected by a fire in area C-22.

Cables associated with RWST to charging pump B control valve BNLCV0112E are run in this area. Damage to these cables could prevent opening or cause spurious closure of the valve. Redundant valve BNLCV0112D is unaffected by a fire in area C-22.

Based on the above discussion, the Train A CCP is available if a fire occurs in area C-22.

References: XX-E-013, E-15000, E-13BG01A, E-13BG11C, E-13BN01A, E-1F9102, E-1F9302, E-1F9401A, M-12BG03, M-12BN01

5.2.20 Charging Flow to Regenerative Heat Exchanger Isolation Valves

PFSSD requires charging flow to be directed to the RCS through the RCP seals. To ensure adequate flow to the RCP seals, flow diversion to the regenerative heat exchanger needs to be prevented. Valves BGHV8105 and BGHV8106 are included in the PFSSD equipment list to accomplish this task. Manual valve BG8402B is also included to provide an alternate means of closing this flow path during alternate safe shutdown using OFN RP-017.

A control cable associated with BGHV8105 is run in area C-22 and could be damaged by a fire, preventing valve BGHV8105 from being closed from the control room. Cables associated with valve BGHV8106, and its hand switch (BGHIS8106), are unaffected by a fire in area C-22. Therefore, valve BGHV8106 is available to isolate flow to the regenerative heat exchanger.

References: E-15000, XX-E-013, E-13BG11A, E-1F9102, E-1F9302, M-12BG03

5.2.21 Volume Control Tank (VCT) Discharge Valves

PFSSD requires isolation of the Volume Control Tank (VCT) discharge to charging pumps suction using either valve BGLCV0112B or BGLCV0112C. Cables associated with BGLCV0112C are run in area C-22. Damage to these cables could prevent closing this valve from the control room. Cables associated with BGLCV0112B are unaffected by a fire in this area.

Cable 14BGI51DA is an instrumentation cable for VCT level transmitter BGLT0185. Damage to this cable could send a false VCT low-low level signal and close relay K647 on the close circuit for valve BGLCV0112C. This would fail the valve closed if all other permissives are met, which is the desired PFSSD position. Therefore, damage to this cable will have no adverse impact on the ability to isolate the VCT discharge flow path.

Based on the above discussion, valve BGLCV0112B can be isolated using BGHIS0112B in the main control room.

References: E-15000, XX-E-013, E-13BG12A, E-13BG51, E-1F9102, E-1F9302, M-12BG03

5.2.22 Excess Letdown

The excess letdown flowpath is required to be isolated to prevent uncontrolled depressurization of the RCS. Therefore, either normally closed valve BGHV8153A or BGHV8154A must be maintained closed and either normally closed valve BGHV8153B or BGHV8154B must be maintained closed.

One cable associated with BGHV8154B runs through fire area C-22. Therefore, the remaining valves are unaffected by a fire in area C-22 and will remain closed.

References: E-15000, XX-E-013, E-1F9301, E-13BG48, M-12BG01

5.2.23 Steam Generator Blowdown to Blowdown Flash Tank Isolation Valves

The reactivity control function requires the steam generator blow down to blow down flash tank valves (BMHV0001, BMHV0002, BMHV0003, and BMHV0004) be closed to prevent reactivity addition from uncontrolled cooldown. Cables associated with these valves are run in area C-22. An open circuit in these cables will fail the valves closed, which is the desired PFSSD position. A hot short on these cables could prevent the valves from being closed using hand switches BMHIS0001A, BMHIS0002A, BMHIS0003A and BMHIS0004A in the main control room.

Redundant means for closing valves BMHV0001, BMHV0002, BMHV0003 and BMHV0004 are available and are unaffected by a fire in area C-22. This redundant means uses BMHIS0001C, BMHIS0002C, BMHIS0003C and BMHIS0004C, located on the BM157 panel in the radwaste control room. Access is available without traversing area C-22.

Although the configuration is not in literal compliance with 10CFR50, Appendix R, feasible manual actions are available and are unaffected by the fire.

Thermal hydraulic analysis WCNOC-CP-002 shows insignificant impact on SG inventory even with all four blowdown valves open. Therefore, no E-1F9900 OMA is required to close blowdown valves to achieve and maintain hot standby. Reference Attachment 4, MSO Evaluation Scenario ID PWROG 34.

References: E-15000, XX-E-013, E-13BM06A, E-1F9101, M-12BM01

5.2.24 Refueling Water Storage Tank (RWST) and Containment Sump Isolation Valves

To prevent drain down of the RWST into the containment sump, PFSSD requires that either valve BNHV8812A or valve EJHV8811A and valve BNHV8812B or valve EJHV8811B be closed during hot standby. For cold shutdown, the operating train containment sump valve (EJHV8811A or EJHV8811B) must be maintained closed to prevent flow diversion from the RCS to the containment sump. Valves BNHV8812A and BNHV8812B are normally open and valves EJHV8811A and EJHV8811B are normally closed.

Cable 14BNG03BC, associated with valve BNHV8812B, runs through area C-22. Damage to this cable could prevent closing this valve from the control room or could cause the valve to spuriously close. In addition, cable damage could prevent the valve from automatically closing when valve EJHV8811B reaches full open position.

A control cable (14EJG06BC) associated with valve EJHV8811B runs through fire area C-22. Damage to this cable will not result in valve EJHV8811B opening as long as valve BNHV8812B remains open. If valve BNHV8812B is fully closed, it will provide a permissive for valve EJHV8811B to open. If valve EJHV8811B opens due to damage to cable 14EJG06BC, drain down will not occur since valve BNHV8812B is closed.

Cable 14BNI07FA, associated with RWST level transmitter BNLT0933, is run in area C-22.
Cable 14SBS08AB, associated with RWST level indicator BNLI0931, is run in area C-22.
Cable 14SBS08DB, associated with RWST level indicator BNLI0933, is run in area C-22.
Circuits for the remaining RWST level transmitters and indicators are not run in area C-22.
Therefore, RWST level indication is available using level indicators BNLI0930 and BNLI0932.

Based on the above discussion, drain down of the RWST to the containment sump is not credible if a fire occurs in area C-22.

References: E-15000, XX-E-013, E-13BN03A, E-13EJ06B, E-13BN07, E-1F9102, E-1F9204, E-1F9205, M-12BN01, M-12EJ01, M-10BN, M-761-02039, M-761-02092

5.2.25 RCS Hot and Cold Leg Temperature Indication

PFSSD requires RCS hot and cold leg temperature indication on at least one loop to verify flow through the steam generators. The temperature elements and control room indicators used for this purpose are listed in the following table.

RCS Hot and Cold Leg Temperature Elements/Indicators Used for PFSSD		
ELEMENT	**INDICATOR**	**FUNCTION**
BBTE0413A	BBTI0413A	RCS Hot Leg Temperature Element (WR) Loop 1
BBTE0413B	BBTI0413B	RCS Cold Leg Temperature Element (WR) Loop 1
BBTE0423A	BBTR0423	RCS Hot Leg Temperature Element (WR) Loop 2
BBTE0423B	BBTI0423B	RCS Cold Leg Temperature Element (WR) Loop 2
BBTE0433A	BBTR0433	RCS Hot Leg Temperature Element (WR) Loop 3
BBTE0433B	BBTR0433	RCS Cold Leg Temperature Element (WR) Loop 3
BBTE0443A	BBTR0443	RCS Hot Leg Temperature Element (WR) Loop 4
BBTE0443B	BBTR0443	RCS Cold Leg Temperature Element (WR) Loop 4

Cable 14SBS08AC, associated with RCS temperature indicators BBTI0413B and BBTI0423B, is run in fire area C-22. A fire could damage this cable and cause temperature indication on the two temperature elements to be unavailable. Consequently, RCS loops 1 and 2 cold leg temperature indication could be lost.

Cable 16RLY01EA supplies 120 VAC power to control room panel RL021/RL022. At RL021/RL022, the power is split and supplies power to BBTR0433 and BBTR0443, as well as other non-PFSSD components. Damage to this cable could disrupt power to BBTR0433 and BBTR0443. Consequently, RCS loops 3 and 4 temperature indication could be lost.

Procedure EMG ES-04, Attachment B Section B1 provides alternate indication in the control room that may be used to verify natural circulation flow. One of these methods verifies that steam generator pressure is stable or decreasing. Based on Sections 5.2.1 and 5.2.2, cooldown is assured using loops 2 and 3, however SG B ARV could be affected. Based on Section 5.2.11, SG B pressure transmitters ABPT0524 and ABPT0526 and SG C pressure transmitters ABPT0534 and ABPT0536 are unaffected by a fire in C-22. These pressure transmitters, along with their respective indicators in the control room, can be used, per EMG ES-04, to verify heat removal in loops 2 and 3.

The configuration is acceptable because, in the event of a fire in area C-22, cooldown can be performed using RCS loops 2 and 3. RCS wide range hot leg temperature elements BBTE0413A and BBTE0423A as well as ABPT0524, ABPT0526, ABPT0534 and ABPT0536 will provide indication of flow through the steam generators.

References: E-15000, XX-E-013, E-13BB15, E-13RL01, E-13RL06, E-13SB08D, E-1F9201, E-1F9421, M-12BB01, M-761-00135, EMG-ES-04

5.2.26 Safety Injection (SI) Pumps

The preferred PFSSD condition of the SI pumps is off. Therefore, a spurious start of the SI pumps should be avoided or mitigated. A control cable (14EMB01BB) associated with the Train B SI pump PEM01B runs through area C-22 and could cause the spurious start of the pump and prevent stopping the pump from the control room.

If the Train B SI pump spuriously starts with the reactor at normal pressure, PFSSD will be assured. The pump will not discharge into the RCS due to the pressure differential between

the RCS (approximately 2,235 psig) and the SI pump shutoff pressure (approximately 1,565 psig). In addition, the set point of the discharge relief valve (EM8853B) to the Recycle Holdup Tank is 1,825 psig. Therefore, no inventory is lost from the RWST if the SI pumps spuriously start. With the SI pump operating with no flow, damage to the pump could occur, which is a commercial concern since the SI pump is not credited in the PFSSD analysis. If necessary, the pump can be stopped by opening breaker NB0202, but this action is not required for PFSSD.

Based on the above discussion, spurious operation of the Train B SI pump will not adversely impact PFSSD.

References: XX-E-013, E-15000, E-13EM01, E-1F9102, E-1F9302, M-12EM01, M-721-00096, WCRE-01

5.2.27 Boron Injection Tank Flowpath

The Boron Injection Tank (BIT) flowpath is credited for reactivity control and reactor coolant makeup. For reactivity control, the BIT flowpath is credited as an alternate source of boration in the event RCP seal injection is unavailable. Based on Calculation XX-E-013, RCP seal injection will provide sufficient boration to achieve and maintain cold shutdown reactivity conditions. Therefore, the BIT flowpath is not required for reactivity control if RCP seal injection is available. Since RCP seal injection is limited to 5 gpm per seal or 20 gpm total injection to the RCS, an additional RCS charging flowpath is required for adequate RCS makeup during plant transition from hot standby to cold shutdown. The BIT injection path was selected as the additional RCS charging flowpath.

As discussed in Section 5.2.13, RCP seal injection is available in the event of a fire in area C-22. In addition, the letdown and excess letdown flowpaths can be isolated if a fire occurs in this area. Therefore, boration and inventory control through the BIT is not required to ensure PFSSD.

Cables associated with Train B BIT inlet valve EMHV8803B are run in this area. Damage to these cables could prevent opening the valve from the control room. Cables associated with Train B BIT outlet valve EMHV8801B and redundant Train A valves EMHV8803A and EMHV8801A are unaffected by a fire in this area. Therefore, BIT injection is available using the Train A CCP and valves EMHV8803A and EMHV8801A.

To prevent CCP flow diversion through the SIS test line when charging through the BIT, valves EMHV8843 and EMHV8882 need to be closed. If either or both of these valves cannot be closed, then closing or maintaining closed either valve EMHV8871 or EMHV8964 will prevent flow in the SIS test line. Cables associated with EMHV8843 and EMHV8871 are run in this area. Damage to these cables could cause the valves to open. Cables associated with EMHV8964 do not run in area C-22. Therefore, valve EMHV8964 can be controlled to prevent flow through the SIS test line when charging through the BIT.

Based on the above discussion, the BIT flowpath is available to provide a charging flowpath using the Train A CCP.

References: E-15000, XX-E-013, E-13EM02, E-13EM02A, E-13EM02B, E-13EM02C, E-13EM04, E-13EM04A, E-1F9302, M-12EM01, M-12EM02

5.2.28 Containment Spray (CS) Pumps

Spurious start of the CS pumps may complicate PFSSD due to the possible depletion of inventory in the RWST. Therefore, a spurious start of the CS pumps should be avoided or mitigated. A control cable (14ENB01BB) associated with Train B CS pump PEN01B runs through area C-22 and could cause a spurious start of the pump. The cable damage could prevent stopping the pump from the control room.

Normally closed valve ENHV0012 could open due to damage to associated control cables. If this occurs coincident with a running Train B CS pump, water would flow from the containment spray nozzles, depleting inventory in the RWST.

The total flow in the containment spray system during injection phase with one pump operating is 3,165 gpm (M-10EN). Based on calculation XX-E-013, Appendix 1, a maximum of 214,260 gallons of water can be lost from the RWST to maintain sufficient volume to achieve cold shutdown.

As stated previously, level indication in the RWST is available, so operators have the ability to diagnose a reducing RWST inventory. The time available to mitigate containment spray is:

214,260 gallons / 3,165 gpm = 67.7 minutes

Based on the above discussion, there is 67 minutes available to mitigate containment spray. This is an OMA. Refer to E-1F9900 for details. Reference Attachment 4, MSO Evaluation Scenario ID PWROG 16.

References: XX-E-013, E-15000, E-13EN01, E-13EN03, E-1F9102, E-1F9302, E-1F9424B, E-1F9433, M-10EN, M-12EN01

5.2.29 Safety Injection Accumulator Isolation Valves

PFSSD requires isolation of the SI accumulators prior to reducing RCS pressure below the injection pressure to avoid unnecessary accumulator discharge. This is accomplished by closing valves EPHV8808A, EPHV8808B, EPHV8808C and EPHV8808D. These valves are normally open with the MCC breaker administratively locked in the open position. Cables for valves EPHV8808B and EPHV8808D are run in area C-22.

Since the breakers for these valves are normally open, damage to these cables will not cause the valves to spuriously change position. However, damage to the cables will prevent closing the associated valve from the control room after power is restored.

The SI accumulators need to be isolated during cold shutdown, prior to the RCS reaching 1000 psig. If necessary, a containment entry can be made to manually close the valves.

5.2.30 TDAFP Steam Trap Drain Valve

Valve FCFV0310 is an isolation valve on the 1-inch steam trap line associated with the TDAFP. Solenoid valve FCFY0310 controls the position of valve FCFV0310. PFSSD requires this valve to be closed to prevent uncontrolled loss of steam through this flow path.

Cable 14FCK21AA is a control cable associated with valve FCFV0310. Inter or intra-cable hot shorts could cause the valve to spuriously open. There are no energized 125 VDC cables in the same conduit as cable 14FCK21AA, so inter-cable hot shorts causing the valve to open are not possible. An intra-cable hot short from conductor 2 to conductor 1 will energize the solenoid and open the valve. This can be mitigated by depressing the close pushbutton on hand switch FCHIS0310. However, since this is a momentary contact switch, the operator would have to maintain the the button in the depressed position.

Uncontrolled blowdown through this 1-inch line is bounded by the main steam line break analysis and loss of steam through this line will not result in uncontrolled cooldown. Therefore, if the valve remains open, PFSSD is assured.

References: E-15000, XX-E-013, E-13FC21, E-1F9202, M-12FC02

5.2.31 Control Room Air Conditioning

Control room air conditioning is required to be available to satisfy the PFSSD support function. Two redundant and independent air conditioning units (SGK04A and SGK04B) are provided to satisfy this function. At least one unit is required to be available for PFSSD.

Cables 14GKG02BC, 14GKG02BD, 14GKG02BE and 14GKG02BF are control cables associated with control room A/C unit SGK04B. Damage to these cables due to a fire could prevent operation of Train B Control Room A/C unit.

Cable 14SAZ20EA is a control cable associated with status panel SA066B indication of Train B control room A/C dampers GKHZ0040A and GKHZ0040B. Cable 14SAZ20GA is a control cable that provides status panel SA066B indication of Train B control room A/C unit SGK04B. Damage to these cables could prevent operation of the associated components.

Cable 14SAZ20NA is a control cable associated with status panel SA066B indication of Train B control room A/C unit isolation hand switch GKHS0040 position. A short to ground on this cable would blow the control power fuse for SGK04B and prevent operation of the unit.

Cable 14GKY02BA, associated with control room A/C unit SGK04B supply and return dampers GKHZ0040A and GKHZ0040B, is run in this area. Damage to this cable could prevent operation of the dampers. Circuits for Train A control room A/C unit SGK04A do not run through area C-22 and are unaffected by a fire. Therefore, control room air conditioning is available using SGK04A. Status panel indication of Train A control room A/C components is unaffected.

References: XX-E-013, E-15000, E-13GK02C, E-13GK02D, E-13SA20, E-1F9442, M-12GK01, M-622.1A-00007

5.2.32 Class 1E Electrical Equipment Room Air Conditioning

The PFSSD support function requires Class 1E electrical equipment air conditioning on the operating train of equipment. Class 1E electrical equipment air conditioning is provided by units SGK05A (Train A) and SGK05B (Train B).

Cables associated with Train B Class 1E electrical equipment room A/C unit SGK05B are run in area C-22. Damage to these cables could prevent operation of the unit.

Cable 14SAZ20HA provides a control power signal from panel GK196C to status panel SA066B to monitor SGK05B control power. Damage to this cable could prevent operation of SGK05B.

Cable 14SAZ20PA is a control cable associated with status panel SA066B indication of Train B Class 1E A/C unit isolation hand switch GKHS0103 position. A short to ground on this cable would blow the control power fuse for SGK05B and prevent operation of the unit.

Cables associated with Train A Class 1E electrical equipment room A/C unit SGK05A are unaffected by a fire in this area. Therefore, room cooling for Train A Class 1E electrical equipment remains available.

References: XX-E-013, E-15000, E-13GK13A, E-13SA20, E-1F9444, M-12GK03, M-622.1A-00002

5.2.33 Standby Diesel Generation

Cables associated with the Train B diesel generator are run in this area. Also, cables associated with the Train B diesel generator room exhaust damper GMHZ0019 run in this area. Damage to these cables could prevent operation of the Train B diesel generator.

A fire in area C-22 could cause a loss of several Train B components, however, Train A components are available and are unaffected by the fire. Based on calculation XX-E-013, off-site power is available on Train A if a fire occurs in area C-22. Therefore, neither diesel generator is required if a fire occurs in this area and mal-operation of the Train B diesel generator will have no adverse impact on safe shutdown.

References: XX-E-013, E-15000, E-12KJ01, E-13GM01A, E-13GM04A, E-13JE01, E-13JE04, E-13KJ03A, E-13KJ07, E-13NE11, E-13NE13, E-1F9411A, E-1F9411B, E-1F9412A, E-1F9412B, E-1F9444, M-12GM01, M-12JE01

5.2.34 Containment Coolers

PFSSD requires containment cooling to maintain the containment environment within EQ limits. Cables associated with Train B containment coolers are run in area C-22. Damage to these cables could prevent operation of the Train B containment coolers. Circuits associated with Train A containment coolers are run in a separate fire area and are unaffected by a fire in area C-22.

As discussed earlier, Train A ESW is available if a fire occurs in area C-22. Therefore, the Train A containment coolers will have the necessary service water flow to ensure proper operation.

References: E-15000, XX-E-013, E-13GN02A, E-1F9441, M-12GN01

5.2.35 Class 1E 4.16 kV ESF Switchgear Bus NB01 and NB02

Bus NB02 supplies power to Train B Engineered Safety Features (ESF) components. A fire in area C-22 could damage cables associated with NB02, including cable 16NBA11AB which is associated with XNB02 feeder breaker PA0201 and disrupt power to all Train B ESF components.

Control cables associated with bus NB02 Synchro-scope and associated switches are run in area C-22. Damage to these cables could prevent some of the monitoring functions for NB02 but would not cause a loss of the NB02 bus.

Cable 16SY001 is associated with switch 1HSSY0018, which controls switchyard breaker 13-8. Damage to this cable could cause the breaker to open, causing a loss of one source of power to XNB01. Switchyard breaker 13-48 is unaffected by a fire in area C-22 and will remain available to provide off-site power to NB01.

Redundant Train A ESF components, supplied by NB01, are unaffected by a fire in area C-22. Therefore, loss of power to Train B components due to a fire in area C-22 will not impact the ability to achieve and maintain safe shutdown.

References: XX-E-013, E-15000, E-1000-SY00, E-1005-SY01, E-13NB04, E-13NB05, E-13NB06, E-13NB14, E-13NB15, E-13NB11, E-1F9423, E-1F9426, KD-7496

5.2.36 Train B 480 Volt Class 1E Load Centers

Cables associated with Train B 480 VAC Class 1E load centers NG02, NG04 and motor control center (MCC) NG06E are run in area C-22. In addition, as stated in other sections, loss of power to these load centers could occur due to loss of Train B off-site and on-site power. Therefore, Train B load centers and associated equipment may not be available if a fire occurs in this area.

Cable 14PKK11AA is associated with 480 VAC breaker NG0409. NG0409 supplies 480 VAC power to Train B 125 VDC battery charger PK22, which energizes the PK02 bus. Damage to this cable could disable power to the battery charger but will not de-energize PK02 due to the installed batteries. Battery set PK12 will maintain 125 VDC power to PK02. In addition, NG0102 is unaffected and will continue to supply power to Train A 125 VDC battery charger PK21.

Redundant Train A components, supplied by NG01, NG03 and NG05E are unaffected by a fire in area C-22. Therefore, loss of power to Train B 480 VAC Class 1E load centers NG02, NG04 and MCC NG06E will not impact the ability to achieve and maintain safe shutdown.

References: XX-E-013, E-15000, E-11NG02, E-13NG10A, E-13NG11A, E-13NG11B, E-13PK11, E-K3NG10A, E-1F9411B, E-1F9412B, E-1F9422C, E-1F9423, E-1F9424A, E-1F9424B, E-1F9424C, E-1F9424D

5.2.37 Class 1E 125 VDC Distribution System

Power cables associated with the Class 1E 125 VDC electrical distribution system are run in area C-22. These cables supply 125 VDC power to various PFSSD loads. The cables and supplied PFSSD equipment are summarized in the following table.

CABLE	POWER SUPPLY	CONTROL PANEL	PFSSD COMPONENTS
14RLK01AA	NK04407	RL001/002	BGHV8153B, BGHV8154B
14RLK01BA	NK04409	RL005/006	FCFY0310
14RLK01CA	NK04412	RL017/018	EMHV8843, EMHV8871
14RLK01DA	NK04413	RL019/020	EGTV0030, GMHZ0019
14RLK01EA	NK04414	RL021/022	BBHV8001B, BBHV8002B
14RLK01FA	NK04411	RL023/024	BMHV0001, BMHV0002, BMHV0003, BMHV0004

Damage to these cables could cause a loss of power to the associated components. This is acceptable for PFSSD since the components fail in the desired PFSSD position upon loss of power, or the redundant Train A component is available to perform the PFSSD function.

References: XX-E-013, E-15000, E-13BB30, E-13BG48, E-13BM06A, E-13EG16, E-13EM04, E-13EM04A, E-13FC21, E-13GM04A, E-13RL01, E-13RL02, E-13RL03, E-13RL04, E-13RL05, E-13RL06, E-13RL07, E-1F9101, E-1F9202, E-1F9301, E-1F9302, E-1F9401A, E-1F9422B, E-1F9444, M-12BB04, M-12BG01, M-12BM01, M-12EG02, M-12EM01, M-12EM02, M-12FC02

5.2.38 Reactor Trip Switchgear

The reactor trip switchgear is required to ensure the ability to manually trip the reactor. The reactor is tripped using either hand switch SBHS0001 or SBHS0042 in the main control room. Each hand switch has contacts associated with Train A reactor trip switchgear SB102A and Train B reactor trip switchgear SB102B.

Cables 14SBS12BA and 14SBS12BC, associated with separation group 4 trip circuits, are run in area C-22. A hot short in these cables could cause a spurious reactor trip, which is the desired PFSSD condition. An open circuit will prevent a manual reactor trip on Train B reactor trip switchgear SB102B.

Cables associated with separation group 1 trip circuits are unaffected by a fire in area C-22. Therefore, operation of either hand switch SBHS0001 or SBHS0042 will cause a reactor trip on redundant Train A reactor trip switchgear SB102A.

References: XX-E-013, E-15000, E-13SB12A, E-1F9101

5.2.39 Source Range Monitoring

PFSSD requires source range (SR) flux monitoring to be available. Source range monitoring is provided by source range monitors SENE0031, SENE0032, SENY0060A & B, and SENY0061A & B.

Cable 14SES07BC is an instrumentation cable associated with SR monitor signal processor SENY0061B. This cable runs from SENY0061B to the source range recorder on RL020. Damage to this cable could prevent operation of the recorder. Source Range monitoring remains available for a fire in area C-22 using SENE0031, SENE0032, SENY0060A/B and SENY0061A.

For a more detailed evaluation on Source Range monitoring, see Calculation XX-E-013, Attachment 3.

References: E-15000, XX-E-013, E-13SE07, E-1F9101

5.2.40 Steam Generator Feedwater Pumps

Main feedwater pump steam supply valves FCFV0005 and FCFV0105 are credited in the PFSSD analysis to trip the main feedwater pumps if the main steam isolation valves (MSIVs) are affected by a fire. Closing the MSIVs stops steam flow to the feedwater pumps' turbines and stops the feedwater pumps. The steam generator feedwater pumps are tripped in the event of a fire to prevent overfilling the steam generators.

Non-Class 1E 120 VAC Inverter PN10 and distribution panel PN10A provide power to FCFV0105 trip relays in panel FC170C. Cable 16FCQ29AE runs from control room hand switches FCHS0118A and FCHS0118B to panel FC170A. This cable provides the signal to close FCFV0105 when both hand switches are simultaneously depressed.

A fire in area C-22 could damage cable 16FCQ29AE. If this occurs, operators in the control room may not be able to close valve FCFV0105 to stop steam flow to steam generator feedwater pump PAE01B.

A fire in area C-22 will not affect the ability to close the MSIVs from the control room. All-close hand switch ABHS0080 is unaffected and can be used to close the MSIVs from the control room.

Based on the above discussion, valve FCFV0105 may not close if a fire occurs in this area. However, the MSIVs can be closed using hand switch ABHS0080 in the main control room. Therefore, the configuration is acceptable.

Cable 16AEB20AD is associated with motor driven feedwater pump PAE02. Damage to this cable could cause a spurious start of the associated pump or prevent the pump from stopping. As discussed in Section 5.2.12, the main feedwater isolation valves (MFIVs) can be isolated if a fire occurs in this area. With the MFIVs closed, spurious operation of pump PAE02 will have no adverse impact on PFSSD.

References: E-15000, XX-E-013, E-13AE20, E-13FC29B, E-13FC35, E-13RP10, E-1F9103, E-1F9201, E-1F9421, M-12FC04

5.2.41 Reactor Coolant Pumps

The reactor coolant pumps are not credited in the PFSSD analysis. However, the capability to stop the pumps from the control room in the event of a loss of all seal cooling is credited. Westinghouse Technical Bulletin TB-04-22, Rev. 1 recommends that if all seal cooling is lost (RCP seal injection and thermal barrier heat exchanger flow), operators need to stop the pumps before a seal LOCA occurs.

Three control cables associated with reactor coolant pumps C and D are run in fire area C-22. Damage to these cables in the event of a fire could prevent operators from stopping the C and D RCPs from the control room. However, a fire in C-22 will not cause a loss of all seal cooling since RCP seal injection and thermal barrier cooling remain available.

Based on the above discussion, the inability to trip the C and D RCPs from the control room will have no adverse impact on PFSSD. The pumps can continue to operate, providing forced flow circulation. If the pumps spuriously stop, natural circulation cooldown can be used.

References: E-15000, XX-E-013, E-13BB01, Westinghouse TB-04-22 Rev. 1

5.2.42 Pressurizer Pressure and Level Indication

The PFSSD support function requires pressurizer pressure and level indication to be available. These indications are used to diagnose spurious actuations such as a failed open pressurizer PORV and failed open letdown valves causing a loss of RCS inventory.

Pressurizer pressure is provided by pressure transmitters BBPT0455, BBPT0456, BBPT0457 and BBPT0458. Signals from these transmitters are indicated in the control room on pressure indicators BBPI0455A, BBPI0456, BBPI0457 and BBPI0458, respectively. As discussed in Section 5.2.8, a cable associated with BBPT0458 is run in fire area C-22. In addition, cable 16SBS08BA associated with BBPI0456 and cable 16SBS08DA associated with BBPI0458 are run in fire area C-22. Damage to these cables will prevent pressurizer pressure indication on these indicators. Cables associated with pressurizer pressure indicators BBPI0455A and BBPI0457 are unaffected by a fire in this area.

Pressurizer level is provided by level transmitters BBLT0459 and BBLT0460. Signals from these transmitters are indicated in the control room on level indicators BBLI0459A and BBLI0460A. Cable 14SBS08AA associated with BBLI0460A is run in area C-22. Damage to this cable could prevent pressurizer level indication on BBLI0460A. Cables associated with pressurizer level indicator BBLI0459A are unaffected by a fire in area C-22.

Based on the above discussion, pressurizer pressure and level indication is available using BBPI0455A, BBPI0457 and BBLI0459A if a fire occurs in this area.

References: E-15000, XX-E-013, E-13BB16, E-13SB08A, E-13SB08B, E-13SB08D, E-1F9301, J-200-00095, M-12BB02, M-761-00135, M-761-00139

5.2.43 Load Center Feeder Breakers PA0206 and PA0207 and Load Centers PG12 and PG20 Incoming Feeder Breakers PG1201 and PG2001

Load center feeder breakers PA0206, PA0207 PG1201 and PG2001 are credited for PFSSD because they supply power to credited non-safety related loads. Cables associated with these breakers run in this area. PFSSD impact due to damage to these cables is discussed below.

Cable 16PGA10CC is a control cable associated with breaker PA0206 and runs in fire area C-22. An intra-cable hot short in this cable will trip PA0206. Cable 16PGG13AA is a control cable associated with breaker PG1201 and runs in fire area C-22. Damage to this cable could trip PG1201. Breakers PA0206 and PG1201 supply power to the following PFSSD components:

- PG12KAF4 – Main Steam Supply to 2nd Stage Reheat Valve ABHV0032
- PG12KAF5 – Main Steam Supply to Steam Seals Valve ABHV0046
- PG12KEF3 – Auxiliary Steam System Control Valve FBHV0080

PG12KAF4, PG12KAF5 and PG12KEF3 supply power to components downstream of the MSIVs. The MSIVs are unaffected by a fire in this area and can be closed from the control room using hand switch ABHS0079. Therefore, the MSIV downstream components are not required if a fire occurs in this area.

Cable 16PGA11AB, associated with PA0207, runs in this area. A fire induced short circuit in this cable will trip the breaker. Cable 16PGG13DA, associated with PG2001, runs in this area. Damage to this cable will trip the breaker.

Breakers PA0207 and PG2001 supply power to the following PFSSD components:

- PG20GBR217 – MCB Misc. Power Circuits RL023
- PG20GER5 – Instr. Bus Transformer Alt. Feed XPN08D

PFSSD components powered from PG20GBR217 are associated with MSIV downstream components. The MSIVs are unaffected by a fire in this area and can be closed from the control room. Therefore, the MSIV downstream components are not required if a fire occurs in this area.

PG20GER5 is credited as one source of power to PN08. The redundant source of power from NG02BBF1 could also be affected by a fire in this area as discussed in Section 5.2.36. Redundant components powered from inverter PN07 are unaffected by a fire in this area.

Based on the above discussion, loss of breakers PA0206, PA0207, PG1201 and PG2001 will have no adverse impact on PFSSD.

References: XX-E-013, E-15000, E-11PG20, E-11PG21, E-11PK02, E-13PG10, E-13PG11, E-13PG13, E-13RL07, E-1F9421, E-1F9422C, E-1F9424E, KD-7496, DCP 13324

5.2.44 Normal Pressurizer Spray

The normal pressurizer spray valves are included in the PFSSD design because spurious operation of pressurizer sprays can cause a decrease in pressure which can lead to boiling in the core. The pressurizer spray valves are part of the pressurizer pressure control system.

The pressurizer normal spray valves (BBPCV0455B and BBPCV0455C) operate off a signal from the Ovation pressurizer pressure control system. The operation of the pressure control system is discussed in Calculation XX-E-013.

Instrument cables 14BBI16NB and 16SBS08HC associated with pressurizer pressure transmitter BBPT0458 are run in fire area C-22. Instrument cable 16SBS08FD associated with pressurizer pressure transmitter BBPT0456 is run in fire area C-22. Damage to these cables could send spurious high-pressure signals to the pressure control system. The operation of the Ovation pressure control system is described in Calculation XX-E-013. Due to the 4-channel validation logic of the Ovation controller, damage to these cables will not cause the spurious operation of the pressurizer PORVs, spray valves or heaters.

Based on the above discussion, the pressurizer spray valves will not spuriously open if a fire occurs in this area.

5.0 DETAILED ANALYSIS 14
5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA C-23 14
5.2 PFSSD CABLE EVALUATION 14

1.0 GENERAL AREA DESCRIPTION

Fire area C-23 is located on the 2026 elevation of the Control Building and includes the rooms listed in Table C-23-1.

Table C-23-1
Rooms Located in Fire Area C-23

ROOM #	DESCRIPTION
3505	South Electrical Chase - 2026 Elevation

Fire area C-23 is protected by an automatic wet-pipe sprinkler system. In addition, automatic fire detection is installed throughout. The automatic suppression and detection system meets the requirements of 10CFR50, Appendix R, Section III.G.2.c.

2.0 PRIMARY EQUIPMENT USED FOR PFSSD

Table C-23-2 lists each system credited for post-fire safe shutdown and provides a discussion regarding the availability of the system to perform its Post Fire Safe Shutdown (PFSSD) function if a severe fire occurs in this area. For a summary of the area analysis results, see Section 8.0 of the Fire Area Analysis Narrative section.

Table C-23-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-23

System	System Name	PFSSD Function*	Comments
AB	Main Steam	R, M, H, P, S	Cables associated with S/G D ARV ABPV0004 may be damaged, preventing control of this valve from the control room. The ARV can be isolated by closing valves KAV1429 and KAV1365 to isolate air and nitrogen to the ARV. The capability to isolate the MSIVs and bypass valves using hand switch ABHS0079 may be affected. The MSIVs and bypass valves can be isolated using hand switch ABHS0080. Three main steam valves located downstream of the MSIVs could open. This will have no adverse impact on PFSSD since the MSIVs and bypass valves can be isolated.
AC	Main Turbine	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-23.
AE	Main Feedwater	H, P	All PFSSD functions associated with the main feedwater system are satisfied. Steam generator (SG) level indication is available on SG B using wide range level transmitter AELT0502 and narrow range level transmitters AELT0528, AELT0529 and AELT0552. Steam generator level indication is available on SG C using wide range level transmitter AELT0503 and narrow range level transmitters AELT0538, AELT0539 and AELT0553. The capability to isolate the MFIVs using hand switch AEHS0081 may be affected. Isolate the MFIVs using hand switch AEHS0080.
AL	Aux. Feedwater System	H, P	Train B motor driven auxiliary feedwater pump (MDAFP) may be affected. The turbine driven auxiliary feedwater pump (TDAFP) is available to take suction from either the CST or the Train A ESW system and supply steam generators A, C and D. The Train A MDAFP is available to take suction from either the CST or the Train A ESW system and supply steam generators B and C. Steam generator D flow transmitter ALFT0001 may be affected. Steam generator A flow transmitter ALFT0007, steam generator B flow transmitter ALFT0009 and steam generator C flow transmitter ALFT0011 are unaffected.
AP	Condensate Storage System	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-23.

Table C-23-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-23

System	System Name	PFSSD Function*	Comments
BB	Reactor Coolant System	R, M, H, P, S	All PFSSD functions associated with the reactor coolant system are satisfied. When transferring to RHR, valve BBPV8702A may need to be manually opened or a cold shutdown repair performed to provide a suction source from the RCS to RHR pump A. Pressurizer PORV BBPCV0456A may open and block valve BBHV8000B may not close. If this occurs, Operators can close the PORV by placing BBHIS0456A in the CLOSE position. RCS pressure indicator BBPI0406 may not function. RCS pressure indicator BBPI0405 is unaffected. Reactor vessel head vent valve BBHV8002B could spuriously open. The remaining head vent valves are unaffected and will remain closed to isolate the head vent flow path. RCS temperature recorders BBTR0433 and BBTR0443 on loops 3 and 4 could lose power. Temperature indication on loops 1 and 2 remains available. Pressurizer pressure transmitter BBPT0458 and indicator BBPI0458 could be affected. The remaining three pressurizer pressure transmitters and indicators are unaffected. Reactor coolant pumps C and D may not stop using the control room hand switch. RCP seal injection and thermal barrier cooling remain available. Therefore, the inability to stop the RCPs will have no adverse impact on PFSSD.
BG	Chemical and Volume Control System	R, M, S	All PFSSD functions associated with the chemical and volume control system are satisfied. Train A Centrifugal Charging Pump (CCP) is available to provide charging flow from the RWST to the RCP seals and the BIT injection flowpath. Train B CCP miniflow valve BGHV8111 may be affected. Train A CCP miniflow valve BGHV8110 is unaffected. VCT isolation valve BGLCV0112C may be affected but redundant valve BGLCV0112B can be isolated using BGHIS0112B. CCP B to RCP seal injection valve BGHV8357B could be affected. Redundant Train A CCP to RCP seal injection valve BGHV8357A is unaffected. Excess letdown valve BGHV8154B could spuriously open. Redundant valve BGHV8153B is unaffected. RCP seal flow indication is available using BGFI0215A. RCP seal flow indicator BGFI0215B may be affected.
BM	Steam Generator Blowdown System	R, M, H	All PFSSD functions associated with the steam generator blowdown system are satisfied. Steam generator blowdown is isolated by closing valves BMHV0001, BMHV0002, BMHV0003 and BMHV0004 using BMHIS0001C, BMHIS0002C, BMHIS0003C and BMHIS0004C, located on the BM157 panel in the radwaste control room.

Table C-23-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-23

System	System Name	PFSSD Function*	Comments
BN	Borated Refueling Water Storage System	R, M, H	All PFSSD functions associated with the borated refueling water storage system are satisfied. The RWST is available to provide a suction source to Centrifugal Charging Pump A via valve BNLCV0112D. RWST level transmitter BNLT0933 may be affected. RWST level transmitters BNLT0930, BNLT0931 and BNLT0932 are unaffected.
EF	Essential Service Water System	H, S	All PFSSD functions associated with the Essential Service Water (ESW) system are satisfied. A number of components associated with Train B ESW may be affected. Train A ESW is available.
EG	Component Cooling Water System	S	All PFSSD functions associated with the Component Cooling Water (CCW) system are satisfied. Train B CCW may be affected. Train A CCW is available. CCW flow to the RCP thermal barrier could be temporarily disrupted due to closure of valve EGHV0062. Valve EGHV0132 can be opened from the control room to restore CCW flow to the thermal barriers. RCP seal injection is unaffected. CCW to RCP flow indicator EGFI0129 could be affected. CCW to RCP flow indicator EGFI0128 is unaffected. Valve EGHV0102 could be affected, preventing operation of Train B RHR. Valve EGHV0101 is unaffected.
EJ	Residual Heat Removal System	M, H, P	All PFSSD functions associated with Residual Heat Removal (RHR) system are satisfied. The Train B RHR pump may be affected but the Train A RHR pump is available. Loss of RCS inventory through the RHR flow path is prevented by maintaining valves EJHV8701A and EJHV8701B closed. Valve EJHV8701A can be opened from the control room when transitioning to RHR for cold shutdown. RHR pump B mini-flow valve EJFCV0611 is affected but RHR pump A mini-flow valve EJFCV0610 is available. RHR Train B to SI Pump B isolation valve EJHV8804B could spuriously open. RHR Train A to CVCS valve EJHV8804A is unaffected. Train B RHR pump discharge to RCS cold leg isolation valve EJHV8809B is affected. Train A RHR pump discharge to RCS cold leg isolation valve EJHV8809A is unaffected. Valve EJHV8840 could spuriously open in the event of a fire in this area. This will not affect hot standby, however the valve will need to be locally closed prior to entering shutdown cooling mode. RHR Train B flow control valve EJHCV0607 could be affected. RHR Train A flow control valve EJHCV0606 is unaffected.

Table C-23-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-23

System	System Name	PFSSD Function*	Comments
EM	High Pressure Coolant Injection	R, M	Train B safety injection pump PEM01B could spuriously start. Injection will not occur with the reactor at normal pressure. The pump can be stopped by opening breaker NB0202, but this action is not required for PFSSD. Since RCP seal injection is available, charging through the BIT is not required for hot standby. For cold shutdown, both BIT flowpaths are available. Prevent flow diversion through the SIS test line when charging through the BIT by maintaining valve EMHV8964 closed.
EN	Containment Spray	R, M	Containment spray pump PEN01B could spuriously start and valve ENHV0012 could open, causing containment spray. Pump PEN01B can be stopped by opening breaker NB0203 in area C-10. Containment spray pump PEN01A is unaffected.
EP	Safety Injection Accumulators	H	Accumulator injection lines can be isolated by closing valves EPHV8808A, EPHV8808B, EPHV8808C and EPHV8808D. It may be necessary to make a containment entry to manually close EPHV8808B and EPHV8808D prior to the RCS reaching 1000 psig.
FB	Auxiliary Steam	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-23.
FC	Auxiliary Turbines	R, H, P	Valve FCFV0105 may be affected. The MSIVs can be closed using all-close hand switch ABHS0080.
GD	ESW Pump House HVAC	S	The PFSSD function associated with ESW pump house HVAC is satisfied. The Train B ESW pump room ventilation system could be affected. The Train A ESW pump room ventilation system is unaffected.
GF	AFW Pump Room Coolers	S	The PFSSD function associated with the Auxiliary Feedwater Pump Room Coolers is satisfied. Train B motor driven auxiliary feedwater pump room cooler SGF02B may be affected. Train A motor driven auxiliary feedwater pump room cooler SGF02A is unaffected.
GK	Control Room and Class 1E Switchgear Room Coolers	S	The PFSSD function associated with the Control Room and Class 1E Switchgear Room Coolers is satisfied. Train B control room A/C unit SGK04B may be affected. Train A control room A/C unit SGK04A is unaffected. Both Train A and Train B class 1E electrical equipment room A/C units (SGK05A and SGK05B) may be affected. If SGK05A spuriously shuts down or cannot be started, the spurious fire isolation signal can be bypassed by placing hand switch GKHS0101 in bypass position and the unit can be started using GKHIS0100. Hand switches GKHIS0100 and GKHS0101 are located on panel RP068 in the main control room.
GL	Auxiliary Building HVAC	S	The PFSSD function associated with the Auxiliary Building HVAC system is satisfied. Train B CCW pump room cooler SGL11B may be affected. Train A CCW pump room cooler SGL11A is unaffected.

Table C-23-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-23

System	System Name	PFSSD Function*	Comments
GM	Emergency Diesel Generator Room HVAC	S	The PFSSD function associated with the emergency diesel generator room HVAC system is satisfied. The Train B emergency diesel generator exhaust damper GMHZ0019 could be affected. The Train A diesel generator room HVAC system is unaffected.
GN	Containment Coolers	S	The PFSSD function associated with the containment coolers is satisfied. Train B containment coolers SGN01B and SGN01D could be affected. Train A containment coolers SGN01A and SGN01C are available.
JE	Diesel Fuel Oil	S	The PFSSD function associated with the Diesel Fuel Oil System is satisfied. The Train B emergency fuel oil transfer pump PJE01B may be affected. The Train A emergency fuel oil transfer pump PJE01A is unaffected. The Train B emergency diesel generator day tank level transmitter JELT0021 may be affected. The Train A day tank level transmitter is unaffected.
KA	Instrument Air	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-23.
KC	Fire Protection	S	Cables associated with Halon protection in class 1E electrical equipment switchboard rooms 3408 and 3414 could be damaged by a fire in area C-23, causing Halon release in these rooms and subsequent shutdown of SGK05A. This will not adversely impact PFSSD (See GK discussion).
KH	Service Gas	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-23.
KJ	Standby Diesel Engine	S	The PFSSD function associated with the Standby Diesel System is satisfied. The Train B diesel engine may be affected. The Train A diesel engine is unaffected.
MA	Main Generation	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-23.
MR	Startup Transformer	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-23.
NB	4.16 kV System	S	The PFSSD function associated with the class 1E 4.16 kV system is satisfied. A loss of off-site and on-site power to NB02 may occur. A loss of off-site power to NB01 may occur. On-site power to NB01 is unaffected.
NE	Standby Diesel Generator	S	The PFSSD function associated with the standby diesel generator system is satisfied. The Train B standby diesel generator could be affected. The Train A standby diesel generator is unaffected.

Table C-23-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-23

System	System Name	PFSSD Function*	Comments
NF	Load Shed and Emergency Load Sequencing	S	The PFSSD function associated with the load shed/emergency load sequencing system is satisfied. Cables associated with one of the four undervoltage (UV) relays and degraded voltage potential transformers on Trains A and B are run in fire area C-23. Emergency load shed/sequencer operates when 2/4 UV relays sense undervoltage on the bus. Therefore, automatic operation of the load shed/sequencer is unaffected.
NG	480V Load Centers and MCCs	S	The PFSSD function associated with the class 1E 480 volt load centers is satisfied. A loss of off-site and on-site power to Train B 480 VAC Class 1E load centers and MCCs could occur. A loss of off-site power to Train A 480 VAC Class 1E load centers and MCCs could occur. On-site power to Train A 480 VAC Class 1E load centers and MCCs is available.
NK	125VDC	S	Train B class 1E 125 VDC power could be disrupted to control room panels RL001/RL002, RL005/RL006, RL017/RL018, RL019/RL020, RL021/RL022 and RL023/RL024. Train A class 1E 125 VDC power is unaffected. The normal source of power to NK02 and NK04, through the Train B 480 V distribution system, could be disrupted due to loss of off-site and on-site power to Train B. 125 VDC battery sets NK012 and NK014 are unaffected. Train B class 1E 125 VDC power could be disrupted to RPS output panel SB032D. 125 VDC power is available to Train A RPS output panel SB029D.
NN	120VAC	S	The backup source of power to Train B Class 1E electrical distribution switchboards NN02 and NN04 could be affected due to loss of Train B on-site and off-site power to NB02. The normal source of power to NN02 and NN04 is unaffected due to the availability of 125 VDC battery sets NK012 and NK014. The normal and backup sources of power to Train A Class 1E electrical distribution switchboards NN01 and NN03 are unaffected.
PA	13.8kV	S	Breaker PA0207 could be affected by a fire in this area. Redundant capability is available.
PB	4.16kV	H, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-23.
PG	480V Load Centers and MCCs	S	Power from PG20GBR217 to RL023 could be affected, preventing closure of some components located downstream of the MSIVs. As discussed in the AB system summary, the MSIVs can be closed using ABHS0080 in the control room. Therefore, loss of power from PG20GBR217 to RL023 will have no adverse impact on PFSSD. Load Center PG20 could lose power. Redundant capability is available.
PK	125VDC	S	The PFSSD function associated with the non-class 1E 125 VDC system is satisfied. Battery charger PK22 may be affected. Battery set PK12 will maintain 125 VDC power to PK02. Also, Train A non-class 1E 125 VDC system is unaffected.

Table C-23-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-23

System	System Name	PFSSD Function*	Comments
PL	Local Instrument Panels	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-23.
PN	120VAC	S	Power from PN0833 to RL017/RL018 may be affected. Power from PN0835 to RL021/RL022 may be affected. Power from PN0736 and PN0738 through Train A EDG and NG01B to RL017/RL018 and RL021/RL022 is unaffected.
QB	Standby AC Lighting	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-23.
QD	Emergency Lighting	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-23.
RL	Control Room MCB	S	The PFSSD function associated with the control room panels is satisfied. Train B Class 1E 125 VDC power to RL001/RL002, RL005/RL006, RL017/RL018, RL019/RL020, RL021/RL022 and RL023/RL024 could be disrupted. The components either fail in the desired PFSSD position or the redundant Train A component is available. Train A Class 1E 125 VDC power is unaffected. Non class 1E (separation group 6) 120 VAC power to panels RL017/RL018, RL021/RL022 and RL023/RL024 could be affected. Non class 1E (separation group 5) 120 VAC power to panels RL017/RL018, RL021/RL022 and RL023/RL024 is unaffected.
RP	Miscellaneous Control Panels	R, M, H, P, S	Power to BOP instrument rack RP053B could be disrupted. BOP instrument racks RP053A, RP053D and RP147 are unaffected. Train B 120 VAC control power to panel RP068 could be affected. Train A 120 VAC control power to panel RP068 is unaffected. Control room lockout relays 86XRP5, 86XRP6 and 86XRP7 could be affected, preventing operation of Train B auxiliary feedwater. Train A auxiliary feedwater and the turbine driven auxiliary feedwater pumps remain available. Power to Group 2 Process Control Rack RP047 could be affected. This will not affect PFSSD as discussed in Section 5.2.12.
SA	ESFAS	S	125 VDC and 120 VAC power to panel SA036B could be lost, resulting in a loss of Channel 4 Engineered Safety Features Actuation System (ESFAS). ESFAS Channels 1 and 2 are unaffected. Status panel input for SGK05B could be affected. This will not adversely impact PFSSD.

Table C-23-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-23

System	System Name	PFSSD Function*	Comments
SB	Reactor Protection System	R, S	All PFSSD functions associated with the reactor protection system are satisfied. A loss of power to input channel 4 in SB029A and SB032A could occur. Input channels 1, 2 and 3 remain available. Train B output cabinet SB032D could lose power. Train A output cabinets are unaffected. Train B reactor trip switchgear SB102B could be affected. Train A reactor trip switchgear SB102A is unaffected. Channel 4 process protection panel SB041 could lose power. Process protection channels 1, 2 and 3 remain available. A number of process monitoring instruments at the ASP could be affected. Redundant process monitoring instruments in the main control room are unaffected.
SC	Reactor Instrumentation	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-23.
SE	Ex-Core Neutron Monitoring	R, P	All PFSSD functions associated with the ex-core neutron monitoring system are satisfied. SR monitor signal processor SENY0061B and SR monitor amplifier SENY0061A could be affected. Source range monitoring remains available using SENE0031, SENE0032 and SENY0060A/B
SY	Switchyard	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-23.
UU	Supervisory System	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-23.

* R - Reactivity Control; M - Reactor Coolant Makeup; H - Decay Heat Removal; P - Process Monitoring; S - Support Function

3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD

This section describes operator actions that may need to be performed inside or outside the control room to achieve and maintain hot standby if a fire occurs in area C-23. This section also describes cold shutdown repairs that may need to be made to achieve and maintain cold shutdown conditions. Operator actions are proceduralized in OFN KC-016.

3.1 ACTIONS OUTSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

Operator Manual Actions (OMAs) are those actions outside the main control room required to achieve and maintain hot standby. OMAs are identified in E-1F9900 and were determined from thermal hydraulic analysis WCNOC-CP-002. Applicable E-1F9900 OMAs are annotated herein. All other actions outside the control room are desirable for plant control in support of hot standby but not required to achieve and maintain hot standby.

3.1.1 Steam Generator Atmospheric Relief Valves

Cables associated with S/G ARV ABPV0004 may be damaged, preventing control of this valve from the control room. The ARV can be isolated by closing valve KAV1429 and nitrogen is isolated by closing valve KAV1365. The air and nitrogen supply valves are located in fire area A-23 and access is available without having to traverse area C-23.

3.1.2 Steam Generator Blowdown Isolation

Blowdown may not be isolable using BMHIS0001A, BMHIS0002A, BMHIS0003A and BMHIS0004A. Therefore, it may be necessary to isolate blowdown using BMHIS0001C, BMHIS0002C, BMHIS0003C and BMHIS0004C located on BM157 in the Radwaste Control room.

3.1.3 **Containment Spray Pump** (OMA, refer to E-1F9900)

Containment spray pump PEN01B could spuriously start and valve ENHV0012 could open, causing containment spray. The pump can be stopped by opening breaker NB0203 in area C-10. Access is available without traversing area C-23 and emergency lighting is provided. Operators have 67 minutes to mitigate containment spray.

3.2 ACTIONS INSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

3.2.1 Main Steam Isolation Valves and MSIV Bypass Valves

The capability to isolate the MSIVs and bypass valves using hand switch ABHS0079 may be affected. The MSIVs and bypass valves can be isolated using hand switch ABHS0080.

3.2.2 Main Feedwater Isolation Valves

The capability to isolate the MFIVs using hand switch AEHS0081 may be affected. Isolate the MFIVs using hand switch AEHS0080.

3.2.3 Volume Control Tank

Valve BGLCV0112C may not close in response to a signal from the control room. Redundant valve BGLCV0112B can be isolated using BGHIS0112B on RL001.

3.2.4 Class 1E A/C Unit SGK05A

Class 1E electrical equipment room A/C unit SGK05A may be affected due to damage to cables associated with the fire detection system. If SGK05A spuriously shuts down or cannot

be started, the spurious fire isolation signal can be bypassed by placing hand switch GKHS0101 in bypass position and the unit can be started using GKHIS0100. Hand switches GKHIS0100 and GKHS0101 are located on panel RP068 in the main control room.

3.2.5 Component Cooling Water

Train B CCW could be affected by a fire in this area. If this occurs, swap to Train A CCW using normal operating procedures if Train A CCW is not already running.

3.2.6 Reactor Coolant Pump Seal Injection

The normal charging pump is not analyzed and is assumed lost. To ensure an uninterrupted seal injection flow, operators should start Train A CCP and open BGHV8357A using BGHIS8357B. RCP seal flow indication is available using BGFI0215A.

3.2.7 Thermal Barrier Cooling

CCW flow to the thermal barrier cooling coils could be interrupted due to the spurious closure of valve EGHV0062. If this occurs, operators should open bypass valve EGHV0132 using EGHIS0132 to restore thermal barrier cooling. CCW to RCP flow indicator EGFI0128 is unaffected and can be used to diagnose a loss of thermal barrier cooling.

3.2.8 Pressurizer PORV/Block Valve

Pressurizer PORV BBPCV0456A could spuriously open and block valve BBHV8000B may not close. If this occurs, Operators can close the PORV by placing BBHIS0456A in the CLOSE position. Pressurizer pressure indication is available using BBPI0455A, BBPI0456 and BBPI0457 located on RL002.

3.3 ACTIONS TO ACHIEVE AND MAINTAIN COLD SHUTDOWN

3.3.1 RHR

A number of Train B RHR components, including the Train B RHR pump, may be affected by a fire in this area. Use Train A RHR for shutdown cooling. Valve BBPV8702A may need to be manually opened, or a cold shutdown repair performed, when aligning Train A RHR.

Valve EJHV8840 could spuriously open in the event of a fire in this area. This will not affect hot standby, however the valve will need to be locally closed prior to entering shutdown cooling mode.

3.3.2 Safety Injection Accumulators

It may be necessary to make a containment entry to close SI Accumulator injection valves EPHV8808B and EPHV8808D if these valves are unresponsive from the control room. Otherwise, nitrogen pressure can be relieved from the tanks to prevent injection. Valves EPHV8808A and EPHV8808C are unaffected.

4.0 CONCLUSION

With some exceptions, redundant Post Fire Safe Shutdown capability exists if a severe fire occurs in area C-23. For those exceptions, feasible manual actions are available and are unaffected by the fire. Manual actions are documented in Section 3.0.

5.0 DETAILED ANALYSIS

This section describes the detailed component-by-component and cable-by-cable analysis for a fire in area C-23.

5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA C-23

There are no PFSSD components located in area C-23. This fire area only contains cables associated with PFSSD equipment located in other areas.

5.2 PFSSD CABLE EVALUATION

Table C-23-3 lists all the PFSSD cables (S. in E-15000) located in fire area C-23. The applicable evaluation section is also listed in Table C-23-3.

Table C-23-3
PFSSD Cables Located in Fire Area C-23

Cable #	Location	Primary PFSSD Equipment	Cable Function (P) Power (C) Control (I) Instrumentation	Evaluation Section	Comments
14ABI20HE	3505	ABPY0004	I	5.2.1	SG D Atmospheric Relief Valve I/P Converter

5.2.1 Steam Generator Atmospheric Relief Valves

PFSSD requires at least two steam generator atmospheric relief valves (ARVs) be controlled and the other two closed. The ARVs are pneumatically operated using air from the compressed air system (KA) or nitrogen from the nitrogen accumulators. The valves open by pneumatic pressure and close by spring action. The valves are automatically controlled by a pressure transmitter installed on the outlet side of the steam generator. Alternatively, each valve can be controlled manually from the control room or the auxiliary shutdown panel by placing the pressure indicating controller (PIC) in manual.

As discussed in Section 5.2.8, a fire in this area could affect the Train B motor driven auxiliary feedwater pump (MDAFP) and the turbine driven auxiliary feedwater pump (TDAFP). Therefore, only the Train A MDAFP is available to feed steam generators B and C. Consequently, steam generator ARVs ABPV0001 and ABPV0004 need to be isolated and steam generator ARVs ABPV0002 and ABPV0003 need to be controlled.

Several cables associated with steam generator ARV ABPV0004 are run in area C-23, as identified in Table C-23-3. Damage to these cables could prevent isolating ABPV0004 from the control room. If this occurs, an operator can close it by isolating air and nitrogen supply valves KAV1429 and KAV1365, respectively in fire area A-23. Cables for the remaining ARVs are not run in area C-23 and, therefore, the PFSSD function for controlling two steam generators is satisfied.

Based on the above discussion, steam generator atmospheric relief valve control can be achieved by one local operator action outside the control room.

Up to three ARVs can fail closed or open without impacting ability to achieve and maintain hot standby according to thermal hydraulic analysis WCNOC-CP-002. With at least one ARV unaffected, no E-1F9900 OMA is required to address ARV closure or control. Reference Attachment 4, MSO Evaluation Scenario ID PWROG 23.

References: E-15000, XX-E-013, E-13AB20B, E-1F9101, J-14KA81, M-12AB01, M-12KA05

5.2.2 Safety Injection and Containment Spray

A spurious safety injection signal (SIS) could cause the safety injection pumps to operate. A spurious containment spray actuation signal (CSAS) could cause the containment spray pumps to operate, depleting inventory in the RWST. These conditions are not desirable for PFSSD at Wolf Creek.

Safety injection (SI) is initiated automatically by any of the following conditions:

1. Two out of three high containment pressures monitored by pressure transmitters GNPT0934, GNPT0935 and GNPT0936.
2. Two out of four low pressurizer pressures monitored by pressure transmitters BBPT0455, BBPT0456, BBPT0457 and BBPT0458.
3. Two out of three low steam line pressures on any steam generator monitored by ABPT0514, ABPT0515 and ABPT0516 on SG A; ABPT0524, ABPT0525 and ABPT0526 on SG B; ABPT0534, ABPT0535 and ABPT0536 on SG C; and ABPT0544, ABPT0545 and ABPT0546 on SG D. Two out of three logic must be satisfied on a single steam generator line. Low pressure on a single pressure transmitter co-incident with low pressure on another pressure transmitter on a different steam generator line will not initiate SIS.

Containment spray (CS) is initiated automatically by two out of four high containment pressures monitored by pressure transmitters GNPT0934, GNPT0935, GNPT0936 and GNPT0937.

A cable (14BBI16NB) associated with pressurizer pressure transmitter BBPT0458 is run in area C-23. Cables associated with the remaining pressurizer pressure transmitters do not run in area C-23. Consequently, a fire in area C-23 cannot cause a spurious SIS due to low pressurizer pressure.

Based on the above discussion, a spurious SIS and CSAS cannot occur if a fire occurs in this area.

References: E-15000, XX-E-013, E-13AB21, E-13BB16, E-13GN05, E-1F9431, E-1F9432, E-1F9433, M-12AB01, M-12BB02, M-12GN01

5.2.3 Main Steam Isolation Valves Downstream Components

The main steam isolation valves downstream components are used for PFSSD to isolate the main steam lines in the event the MSIVs or MSIV bypass valves fail to close.

Cable 16RLY01GA supplies 120 VAC power from PG20GBR217 to control room panel RL023/RL024. At RL023/RL024, the power is split and supplies power to FCHV0103, ABLV0050 and ABLV0052, as well as other non-PFSSD components. These components are required to be functional for PFSSD in the event the MSIVs and MSIV bypass valves cannot be isolated. Loss of power will cause the valves to remain open.

As discussed in Sections 5.2.4 and 5.2.5, the MSIVs and the MSIV bypass valves can be isolated using hand switch ABHS0080 if a fire occurs in area C-23. Therefore, these downstream valves can fail open with no adverse impact on PFSSD.

References: E-15000, XX-E-013, E-13RL01, E-13RL07, E-1F9103, E-1F9424E, M-12AB03

5.2.4 Steam Generator Main Steam Isolation Bypass Valves

PFSSD requires that the bypass valves for the main steam isolation valves be closed to prevent reactivity addition due to uncontrolled cooldown. The bypass valves are closed from the control room using all close hand switches ABHS0079 (Train B) or ABHS0080 (Train A).

Each of the four MSIV bypass valves (ABHV0012, ABHV0015, ABHV0018 and ABHV0021) has two redundant solenoids that control the position of the associated valve. The bypass valves are normally closed with the solenoids de-energized. Both solenoids need to be energized to open the valve. One of the solenoids on each valve is on separation group 1 (Train A) and is controlled by hand switch ABHS0080. The other solenoids on each valve are on separation group 4 (Train B) and are controlled by hand switch ABHS0079.

Separation group 4 MSIV bypass solenoid valve cables (14ABK23FA, 14ABK23FB, 14ABK23FC, 14ABK23FD, 14ABK23FE, 14ABK23FF and 14ABK23FG) are run in this area. Damage to these cables could impact the ability to close the valves using hand switch ABHS0079. Redundant means are available to ensure the MSIV bypass valves are closed. Hand switch ABHS0080 is unaffected by the fire and can be used to close the bypass valves if they are open at the time of the fire.

Cable 14RPK09AA supplies 125 VDC power from NK4417 to auxiliary relay panel RP210. The PFSSD loads supplied by this cable are as follows:

- Relay 94XAB06
- Solenoid valve ABHY0012B
- Solenoid valve ABHY0015B
- Solenoid valve ABHY0018B
- Solenoid valve ABHY0021B

The solenoid valves listed above are associated with MSIV bypass valves ABHV0012, ABHV0015, ABHV0018 and ABHV0021. Damage to cable 14RPK09AA will cause a loss of power to the relay and solenoids and fail the valves closed, which is the desired PFSSD position. Therefore, damage to cable 14RPK09AA will not adversely impact PFSSD.

Based on the above discussion, the MSIV bypass valves can be isolated using hand switch ABHS0080 in the main control room.

References: E-15000, XX-E-013, E-13AB23B, E-13RP09, E-1F9101, E-1F9422B, E-093-00050, E-093-00051, M-12AB02

5.2.5 Steam Generator Main Steam Isolation Valves

PFSSD requires that the main steam isolation valves (MSIVs) be closed to prevent reactivity addition due to uncontrolled cooldown. The MSIVs are closed from the control room using all close hand switches ABHS0079 (Train B) or ABHS0080 (Train A).

Cable 14ABK30BB provides 125 VDC power from NK5423 to Train B main steam and feedwater isolation actuation system (MSFIS) cabinet SA075B. A loss of 125 VDC power to SA075B will cause a loss of power to the Train B solenoid valves on each MSIV and fail the MSIVs closed, which is the desired PFSSD position. In addition, the Train A MSFIS actuation cabinet SA075A is unaffected by a fire in area C-23 and ABHS0080 is available to close the MSIVs.

Based on the above discussion, the MSIVs would likely fail closed in the event a fire in area C-23 damages cable 14ABK30BB. Hand switch ABHS0080 is unaffected by a fire in this area and can be used from the control room to isolate the MSIVs.

References: E-15000, XX-E-013, E-13AB30, E-1F9101, M-12AB02

5.2.6 Steam Generator Level Indication

The decay heat removal function for PFSSD requires the use of two RCS loops and two Steam Generators. Steam generator (SG) level indication is required to support this function. A fire in area C-23 uses MDAFP A to supply SGs B and C. Therefore, level indication on steam generators B and C is required.

Cables 14AEI08PB and 14AEI08QB associated with SGs B and C level transmitters AELT0527 (SGB NR) and AELT0537 (SGC NR) run in this area. Damage to these cables could prevent accurate level indication on AELI0527 and AELI0537 in the main control room. Cables associated with the remaining level transmitters on steam generators B and C do not run in this area. Therefore, level indication will be available on steam generators B and C using the following level transmitters:

Steam Generator	Available Level Indication
B	AELI0502 (WR), AELI0528 (NR), AELI0529 (NR), AELI0552 (NR)
C	AELI0503 (WR), AELI0538 (NR), AELI0539 (NR), AELI0553 (NR)

Cables 14SBS16BA, 14SBS16XA and 14SBS16YA, associated with SGs B and D level indicators AELI0502A and AELI0504A at the auxiliary shutdown panel (ASP) are run in fire area C-23. The ASP is not credited if a fire occurs in this area so loss of indication at the ASP will have no adverse impact on PFSSD.

Cables 14AEI08LB, 14AEI08NB and 14AEI08RB associated with SGs A and D level transmitters AELT0504, AELT0517 and AELT0547 are run in this area. Since SGs A and D

are not credited for a fire in this area, damage to these cables will have no adverse impact on PFSSD.

Based on the above discussion, steam generator B and C level indication is assured if a fire occurs in area C-23.

References: E-15000, XX-E-013, E-13AE08, E-13SB16, E-1F9203, M-12AE02

5.2.7 Steam Generator Main Feedwater Isolation Valves

PFSSD requires that either the main feedwater isolation valves (MFIVs) be closed or the main feedwater pumps be stopped to prevent overfilling the steam generators. Flow diversion from auxiliary feedwater (AFW) to the main feedwater system piping is prevented by check valves AEV0420, AEV0421, AEV0422 and AEV0423. Closure of the main feedwater isolation valves is not required to prevent AFW flow diversion.

Cable 14ABK30BB provides 125 VDC power to Train B main steam and feedwater isolation actuation system (MSFIS) cabinet SA075B from NK5423. Damage to this cable would disrupt power to the separation group 4 solenoids and close the MFIVs, which is the desired PFSSD position. In addition, the Train A MSFIS is unaffected by the fire and AEHS0080 is available to close the MFIVs.

Based on the above discussion, the MFIVs would likely fail closed in the event a fire in area C-23 damages cable 14ABK30BB. Hand switch AEHS0080 is unaffected by a fire in this area and can be used from the control room to isolate the MFIVs.

References: E-15000, XX-E-013, E-13AB30, E-1F9201, M-12AE02

5.2.8 Auxiliary Feedwater

The PFSSD design requires the use of one auxiliary feedwater pump (AFP) supplying water to at least two steam generators. The turbine driven auxiliary feedwater pump (TDAFP) is normally aligned to supply all four steam generators. The Train A motor driven auxiliary feedwater pump (MDAFP) is aligned to supply steam generators B and C. The Train B MDAFP is aligned to supply steam generators A and D.

The normal source of water to the AFPs is the condensate storage tank (CST). The emergency supply is from the essential service water (ESW) system. For commercial concerns, the CST is the preferred source and contains sufficient volume to supply the entire AFW demand to achieve cold shutdown.

Motor operated valves (MOVs) in the system allow operators to line up the auxiliary feedwater system as required to achieve and maintain safe shutdown. Damage to the MOV circuits due to a fire could prevent operators from lining up the system from the control room.

Several PFSSD cables associated with various components of the auxiliary feedwater system (AL) run through fire area C-23. These cables are identified in Table C-23-3. Damage to these cables could prevent operation of the Train B MDAFP. In addition, motor operated valves in the flowpath from the Train B MDAFP to steam generator D and from the TDAFP to steam generator B could spuriously close. Cables associated with the TDAFP and the Train A MDAFP are unaffected by a fire in this area. The TDAFP is available to take suction from either the CST or the Train A ESW system and supply steam generators A, B and D. The Train A MDAFP is available to take suction from either the CST or the Train A ESW system and supply steam generators B and C.

Power cables associated with SA036B are run in this area. Damage to these cables could result in a loss of power to the panel but panels SA036A and SA036C remain available. Therefore, automatic operation of low suction pressure (LSP) swapover is available.

A cable associated with the Train B MDAFP room cooler motor (DSGF02B) is run in this area. Damage to this cable could prevent operation of the cooler motor. The Train A MDAFP room cooler motor (DSGF02A) is unaffected.

Based on the above discussion, auxiliary feedwater is assured if a fire occurs in area C-23 using Train A MDAFP supplying auxiliary feedwater to steam generators B and C and the TDAFP supplying auxiliary feedwater to steam generators A, C and D.

References: E-15000, XX-E-013, E-13AL01B, E-13AL02B, E-13AL03B, E-13AL04B, E-13AL05B, E-13AL07B, E-13AL09, E-13GF01, E-13SA21, E-1F9202, E-1F9203, E-1F9204, E-1F9402A, E-1F9402B, E-1F9444, J-10SA, M-12AL01, M-12GF01

5.2.9 Reactor Coolant Pump (RCP) Seal Injection

PFSSD requires RCP seal injection to provide a boron injection path, provide makeup to the RCS to maintain hot standby inventory and prevent damage to the RCP seals. The Component Cooling Water (CCW) system is an alternative means of cooling the RCP seals.

Power and control cables associated with seal injection valves BBHV8351A, BBHV8351B, BBHV8351C and BBHV8351D, are run in this area. The valves are normally open and de-energized and are required to remain open during a fire. The valves are not high/low pressure interface valves so three-phase hot shorts do not have to be considered and, consequently, damage to the power cables will not cause the valves to close. Damage to the control cable for each valve located in this area will not cause the valves to spuriously close since a hot short or open circuit in these cables will not bypass the control room hand switch. Furthermore, the valves are de-energized so cable damage could not cause the valves to close.

Cable 14BGG52BC is associated with Train B RCP seal injection flow throttling valve BGHV8357B. Damage to this cable could prevent the Train B centrifugal charging pump (CCP) from supplying water to the RCP seals. Train A seal injection flow throttling valve BGHV8357A is unaffected by a fire in this area.

Cable 14BGI51BA is associated with RCP seal total flow transmitter BGFT0215B. Damage to this cable could cause a loss of seal flow indication on BGFI0215B. RCP seal total flow indicator BGFI0215A is unaffected by a fire in area C-23 and can be used to diagnose a loss of RCP seal injection.

Based on the above discussion, RCP seal injection is available if a fire occurs in fire area C-23 using the Train A CCP. RCP seal total flow indicator BGFI0215A can be used to diagnose a loss of RCP seal injection in the event of a loss of the operating charging pump.

References: E-15000, XX-E-013, E-13BB04, E-13BG51, E-13BG52, E-1F9102, E-1F9302, E-1F9303, M-12BB03

5.2.10 Component Cooling Water

The component cooling water system is required for PFSSD to provide cooling water to the CCP oil coolers, seal water heat exchanger, RHR heat exchanger and RHR pump seal cooler. In addition, the CCW system provides cooling to the RCP thermal barriers and is credited as a backup to RCP seal injection for maintaining seal cooling.

Cables associated with components on the Train B CCW system run through area C-23. Damage to these cables due to a fire could prevent operation of the associated equipment and prevent operation of Train B CCW. Cables associated with redundant Train A CCW are run in a different fire area and are unaffected by the fire.

Cables associated with Train B CCW pump room cooler SGL11B run in area C-23. Damage to these cables could prevent operation of the unit. Cables associated with redundant Train A CCW and room cooler SGL11A are run in a different fire area and are unaffected by the fire.

As discussed in Section 5.2.9, RCP seal injection is unaffected by a fire in this area. Therefore, the CCW to thermal barrier cooling coil flow path is not required to ensure adequate seal cooling.

Cables associated with valves EGHV0062, EGHV0127 and EGHV0133 run through area C-23. If the fire affects cables associated with EGHV0062 the valve may spuriously close. If this occurs, operators can open bypass valve EGHV0132 from the control room if thermal barrier cooling is desired. This is not a time critical action since RCP seal injection is unaffected.

Based on the above discussion, Train A CCW is available to provide cooling to essential PFSSD components.

References: E-15000, XX-E-013, E-13EG01C, E-13EG01D, E-13EG10, E-13EG13, E-13EG16, E-13EG18, E-13EG18A, E-13GL06, E-1F9303, E-1F9401A, E-1F9401B, E-1F9444, M-12EG01, M-12EG02, M-12EG03, M-12GL02

5.2.11 Residual Heat Removal (RHR)

PFSSD requires one train of residual heat removal (RHR) to be available for shutdown cooling. The RHR system is not used for hot standby.

Hot shutdown requires isolation of the RCS to RHR flow path by maintaining either BBPV8702A or EJHV8701A closed and either BBPV8702B or EJHV8701B closed. Cold shutdown requires RHR taking suction from the RCS. RHR pump suction from the RCS is controlled by valves BBPV8702A and EJHV8701A (Train A) and BBPV8702B and EJHV8701B (Train B). The PFSSD methodology credits Train A RHR to achieve cold shutdown if a fire occurs in area C-23. At Wolf Creek, these valves are considered high/low pressure interface components for PFSSD analysis purposes.

A control cable associated with RHR pump B motor (DPEJ01B) could be damaged, causing a spurious pump start or preventing the pump from being started. Cables associated with RHR pump A are unaffected by a fire in area C-23.

Cables 14BBG12AF and 14BBG12AG are control cables associated with BBPV8702A. An inter-cable (cable-to-cable) hot short between cables 14BBG12AF and 14BBG12AG will bypass the control room hand switch and provide the permissive to open BBPV8702A. Valve EJHV8701A will remain closed since cables associated with this valve are not run through area C-23. Furthermore, BBPV8702A and EJHV8701A are administratively maintained closed with the breaker locked open. The 3-phase power cables associated with both valves are not run in this area, so a 3-phase hot short is not credible.

Cables 14BBG12BF and 14BBG12BG are control cables associated with BBPV8702B. An inter-cable (cable-to-cable) hot short between cables 14BBG12BF and 14BBG12BG will bypass the control room hand switch and provide the permissive to open BBPV8702B. Valve EJHV8701B will remain closed since cables associated with this valve are not run through area C-23. Furthermore, BBPV8702B and EJHV8701B are administratively maintained closed with the breaker locked open. The 3-phase power cables associated with both valves are not run in this area, so a 3-phase hot short is not credible.

An open circuit in cable 14BBG12AF could prevent remote opening of valve BBPV8702A when transitioning to RHR. If this occurs, a cold shutdown repair or a containment entry will be necessary to open the valve. Valve EJHV8701B can be controlled from the control room.

Valve EGHV0101 is the Train A CCW to RHR Heat Exchanger control valve. Valve EGHV0102 is the Train B CCW to RHR Heat Exchanger control valve. These valves are normally closed during power operation. PFSSD requires that the valve on the operating train of CCW be closed until shutdown cooling mode is entered, at which time the valve on the operating train of RHR needs to be open. As stated in Section 5.2.10, the Train B CCW system may not be available to supply cooling water to the Train B RHR heat exchanger. Cables 14EGG07BA and 14EGG07BB are associated with valve EGHV0102. Damage to the cables could prevent operation of EGHV0102 but would not cause the valve to spuriously open. Valve EGHV0101 is unaffected by a fire in this area.

When RHR pumps are operating, the associated mini-flow valve (EJFCV0610 or EJFCV0611) needs to be controlled. The mini-flow valves prevent RHR pump overheating by re-circulating water from the discharge side of the RHR heat exchanger to the suction side of the RHR pump. The mini-flow valve opens when the flow indicator measures low flow and closes on high flow. Damage to cable 14EJG08BC could prevent mini-flow valve EJFCV0611 from operating properly. If the Train B RHR pump spuriously starts and EJFCV0611 fails to operate, the pump could be damaged. This is a commercial concern only since Train A RHR pump and mini-flow valve EJFCV0610 are unaffected by a fire in this area.

The RHR heat exchanger discharge control valve on the operating train (EJHCV0606 (Train A) or EJHCV0607 (Train B)) needs to be available. Cable 16EJI12BA, which is associated with EJHCV0607, runs through area C-23. Cable 16RLY01DA provides 120 VAC power to RL017/RL018 (EJHY0607) from PN0833. Damage to these cables could result in a loss of valve EJHCV0607. Valve EJHCV0606 is unaffected by a fire in this area.

RHR pump A discharge to CVCS control valve EJHV8804A needs to be closed when operating the Train A RHR system. RHR pump B discharge to SI Pump B control valve EJHV8804B needs to be closed when operating the Train B RHR system. Damage to cable 14EJG04BC could cause valve EJHV8804B to spuriously open. The Train A RHR system is credited for a fire in this area so spurious opening of EJHV8804B will have no adverse impact on PFSSD. Cables associated with EJHV8804A do not run in area C-23.

Cables associated with Train B RHR pump discharge to RCS cold leg isolation valve EJHV8809B run in area C-23. Damage to these cables could prevent operating the valve from the control room. Cables associated with Train A RHR pump discharge to RCS cold leg isolation valve EJHV8809A do not run in area C-23. Consequently, valve EJHV8809A is unaffected by a fire in area C-23.

The cold shutdown mode of PFSSD requires isolation of hot leg recirculation. Valve EJHV8840 is used to isolate RHR flow to the RCS hot leg loops 2 and 3. This valve is normally closed and is required to be closed for cold shutdown. During hot standby, the valve can be in any position. Cables associated with valve EJHV8840 run through area C-23. Damage to cables 14EJG09AC and 14EJG09AD would likely result in valve EJHV8840 remaining in its as-is normally closed position, which is the preferred PFSSD position. However, two proper intra-cable hot shorts in cable 14EJG09AD or one intra-cable hot short in cable 14EJG09AD combined with a short to ground on conductor U1 would spuriously open the valve.

As stated above, the position of valve EJHV8840 (open or closed) will not affect hot standby. The valve needs to be closed for cold shutdown. The valve has been modified to address NRC IN 92-18 and can be closed manually prior to entering shutdown cooling mode. The torque and limit switches are not bypassed by postulated damage to these cables.

Based on the above discussion, the Train B RHR system could be affected by a fire in this area but the Train A RHR system is available. Valve BBPV8702A may need to be manually opened and valve EJHV8840 may need to be manually closed when transitioning to Train A RHR for shutdown cooling.

References: E-15000, XX-E-013, E-13BB12A, E-13BB12B, E-13EG07A, E-13EJ01, E-13EJ04B, E-13EJ08A, E-13EJ09C, E-13EJ12, E-13RL01, E-13RL04, E-1F9205, E-1F9301, E-1F9401A, E-1F9421, M-12BB01, M-12EJ01

5.2.12 Pressurizer Power Operated Relief Valves and Associated Block Valves

PFSSD requires that either the pressurizer power operated relief valve (PORV) or its associated block valve be closed. Cables and components associated with PORV BBPCV0456A and associated block valve BBHV8000B are run through area C-23. Cables and components associated with PORV BBPCV0455A and associated block valve BBHV8000A are not located in area C-23.

The pressurizer PORVs are not considered high/low pressure interfaces. The valves are supplied power by an ungrounded 125 VDC system. Therefore, based on GL 86-10, consideration of multiple proper polarity hot shorts is not required. A single proper polarity hot short still needs to be considered.

In the event a fire causes BBPCV0456A to open and damages BBHV8000B cables, Operators can close BBPCV0456A by placing hand switch BBHIS0456A, located on RL021, in the close position. Pressurizer level and RCS pressure indication are available to diagnose a failed open PORV using BBLI0459A, BBLI0460A and BBPI0405. In addition, pressurizer pressure indication is available using BBPI0455A, BBPI0456 and BBPI0457.

An instrument cable (14BBI16NB) associated with pressurizer pressure transmitter BBPT0458 is run in fire area C-23. Damage to this cable could send a spurious high-pressure signal to the Ovation pressure control system. However, as discussed in Calculation XX-E-013, Appendix 1, damage to a single pressure channel will not cause the spurious operation of the pressurizer PORVs.

Based on the above discussion, pressurizer PORV BBPCV0456A could spuriously open due to damage to the PORV control cables and block valve BBHV8000B may not close due to cable damage. The PORV can be closed using hand switch BBHIS0456A in the main control room.

References: XX-E-013, E-15000, E-13BB16, E-13BB39, E-13BB40, E-1F9301, E-1F9421, M-12BB02, CR 13079, DCP 12944, DCP 13324

5.2.13 Reactor Coolant System (RCS) Pressure Indication

The PFSSD design requires RCS pressure indication to be available. RCS pressure indication is provided in the control room using BBPI0405 or BBPI0406. Cable 14BBI16BA and 14BBI16BB associated with pressure transmitter BBPT0406 are located in fire area C-23. Damage to these cables could prevent RCS pressure indication on BBPI0406.

Cables associated with redundant RCS pressure transmitter BBPT0405 are unaffected by a fire in this area. Therefore, RCS pressure indication is available using BBPI0405.

References: E-15000, XX-E-013, E-13BB16, E-1F9201, E-1F9205, M-12BB04

5.2.14 Reactor Head Vent Valves

PFSSD requires that one of the two reactor vessel head vent valves on each flow path (2 flow paths total) be closed to prevent uncontrolled depressurization of the RCS. Either BBHV8001A or BBHV8002A and either BBHV8001B or BBHV8002B needs to be closed.

A cable (14BBK30DA) associated with one of the four head vent valves (BBHV8002B) runs through area C-23. Cables for remaining head vent valves BBHV8001A, BBHV8002A and BBHV8001B are not run through C-23 and are unaffected by the fire. Therefore, at least one valve on each flow path can be controlled and spurious opening of BBHV8002B will have no adverse impact on PFSSD.

References: E-15000, XX-E-013, E-13BB30, E-1F9301, M-12BB04

5.2.15 Centrifugal Charging Pumps

At least one centrifugal charging pump (CCP) is required for PFSSD to provide RCP seal cooling, reactivity control and inventory control. These functions are accomplished using a CCP taking suction from the refuelling water storage tank (RWST) and injecting through the RCP seals. RCP seal injection provides approximately 20 gpm makeup to the RCS and provides adequate boron concentration to maintain sub-critical reactivity conditions. If RCP seal injection is unavailable, reactivity and inventory control is provided by lining up the CCPs to the boron injection tank (BIT). The normal charging pump (NCP) is not credited and is assumed lost.

A control cable associated with Train B CCP motor DPBG05B runs through area C-23. Damage to this cable could prevent operation of the pump. Redundant Train A CCP cables are run in a separate fire area and are unaffected by a fire.

Two control cables associated with Train B CCP miniflow valve BGHV8111 are run through area C-23. Cables for Train A miniflow valve BGHV8110 are run in a different area and are unaffected by a fire in area C-23.

Cables associated with RWST to CCP B control valve BNLCV0112E are run in this area. Damage to these cables could prevent opening or cause spurious closure of the valve. Redundant valve BNLCV0112D is unaffected by a fire in area C-23.

Based on the above discussion, the Train A CCP is available if a fire occurs in area C-23.

References: XX-E-013, E-15000, E-13BG01A, E-13BG11C, E-13BN01A, E-1F9102, E-1F9302, E-1F9401A, M-12BG03, M-12BN01

5.2.16 Non-Class 1E 120 VAC Electrical Distribution System

The PFSSD function of the non-Class 1E 120 VAC electrical distribution system is to supply 120 VAC power to Main Control Boards (MCBs) RL017/RL018 and RL021/RL022. The power is split at the MCB to supply PFSSD components.

The PFSSD components that depend on 120 VAC power from RL017/RL018 are Residual Heat Removal (RHR) discharge valves EJHCV0606 (Train A) and EJHCV0607 (Train B). Non-class 1E switchboard panel PN07 supplies power from switch PN0736 to solenoid valve EJHY0606. Solenoid valve EJHY0606 controls the position of EJHCV0606 using hand controller EJHIC0606. Non-class 1E switchboard panel PN08 supplies power from switch PN0833 to solenoid valve EJHY0607. Solenoid valve EJHY0607 controls the position of EJHCV0607 using hand controller EJHIC0607.

The PFSSD components that depend on 120 VAC power from RL021/RL022 are temperature recorders BBTR0423, BBTR0433 and BBTR0443. Non-class 1E switchboard panel PN07 supplies power from switch PN0738 to temperature recorder BBTR0423. Non-class 1E switchboard panel PN08 supplies power from switch PN0835 to temperature recorders BBTR0433 and BBTR0443.

Cable 14PNG01AE supplies 480 VAC power from NG002BBF1 to 480/120V transformer XPN08A. Damage to this cable will result in a loss of power to the transformer and loss of 120 VAC feed to PN08 from this power source.

Cable 16PNY01AR provides an alternate power feed to switchboard PN08 from PG20GER5. Damage to this cable will result in a loss of the alternate power feed to PN08.

A loss of power to PN08 will result in a loss of power to EJHY0607, which will fail valve EJHCV0607 open and will prevent control of the valve from the control room. Loss of power to PN08 will also result in a loss of loops 3 and 4 temperature recorders BBTR0433 and BBTR0443, respectively.

Non-Class 1E 120 VAC power to panel PN07 is unaffected by a fire in this area. Train A RHR valve EJHCV0606 is unaffected by a fire in area C-23, so Train A RHR can be used for shutdown cooling. Also, operators can use available temperature indication on loops 1 and 2 if a loss of loops 3 and 4 temperature indication occurs.

Based on the above discussion, a fire in this area could result in a loss of power to PN08 but PN07 is unaffected.

References: XX-E-013, E-15000, E-13PN01, E-13RL01, E-13RL04, E-13RL06, E-1F9201, E-1F9205, E-1F9421, E-1F9424E

5.2.17 Volume Control Tank (VCT) Discharge Valves

PFSSD requires isolation of the Volume Control Tank (VCT) discharge to charging pumps suction by closing either valve BGLCV0112B or BGLCV0112C.

Power and control cables associated with BGLCV0112C are run in area C-23. Damage to these cables could prevent closing this valve from the control room or could cause the valve to spuriously close prior to lining up the RWST. If the valve closes prior to lining up the RWST, damage to the operating charging pump could occur. The assumptions in calculation XX-E-013 state that systems and components are in their normal operating position or status prior to the fire. The Normal Charging Pump (NCP) is the normally operated pump and is assumed to be operating at the time of the fire. Inadvertent closure of valve BGLCV0112C with no suction from the RWST would result in damage to the NCP but the centrifugal charging pumps would remain unaffected. As stated in 5.2.15, the Train B CCP may be unavailable but the Train A CCP is unaffected by the fire.

Cables associated with BGLCV0112B are unaffected by a fire in this area. Therefore, BGLCV0112B can be isolated from the control room after the RWST has been lined up.

References: E-15000, XX-E-013, E-13BG12A, E-13BN01A, E-1F9102, E-1F9302, M-12BG03, M-12BN01

5.2.18 Excess Letdown

The excess letdown flowpath is required to be isolated to prevent uncontrolled depressurization of the RCS. Therefore, either normally closed valve BGHV8153A or BGHV8154A must be maintained closed and either normally closed valve BGHV8153B or BGHV8154B must be maintained closed.

One cable associated with BGHV8154B runs through fire area C-23. The remaining valves are unaffected and will remain closed if a fire occurs in area C-23.

References: E-15000, XX-E-013, E-1F9301, E-13BG48, M-12BG01

5.2.19 Steam Generator Blowdown to Blowdown Flash Tank Isolation Valves

The reactivity control function requires the steam generator blowdown to blowdown flash tank valves (BMHV0001, BMHV0002, BMHV0003, and BMHV0004) be closed to prevent reactivity addition from uncontrolled cooldown. Cables associated with these valves are run in area C-23. An open circuit in these cables will fail the valves closed, which is the desired PFSSD position. A hot short on these cables could prevent the valves from being closed using hand switches BMHIS0001A, BMHIS0002A, BMHIS0003A and BMHIS0004A in the main control room.

Redundant capability exists for closing valves BMHV0001, BMHV0002, BMHV0003 and BMHV0004. The redundant means uses BMHIS0001C, BMHIS0002C, BMHIS0003C and BMHIS0004C, located on the BM157 panel in the radwaste control room. Access is available without traversing area C-23.

Although the configuration is not in literal compliance with 10CFR50, Appendix R, feasible manual actions are available and are unaffected by the fire.

Thermal hydraulic analysis WCNOC-CP-002 shows insignificant impact on SG inventory even with all four blowdown valves open. Therefore, no E-1F9900 OMA is required to close blowdown valves to achieve and maintain hot standby. Reference Attachment 4, MSO Evaluation Scenario ID PWROG 34.

References: E-15000, XX-E-013, E-13BM06A, E-1F9101, M-12BM01

5.2.20 Refueling Water Storage Tank (RWST) and Containment Sump Isolation Valves

The RWST is credited in the PFSSD analysis as the primary source of borated water to achieve cold shutdown. The Wolf Creek Technical Specifications ensure the minimum quantity and boron concentration is maintained to achieve cold shutdown.

To prevent draindown of the RWST into the containment sump, PFSSD requires that either valve BNHV8812A or valve EJHV8811A and valve BNHV8812B or valve EJHV8811B be closed during hot standby. For cold shutdown, the operating train containment sump valve (EJHV8811A or EJHV8811B) must be maintained closed to prevent flow diversion from the RCS to the containment sump. Valves BNHV8812A and BNHV8812B are normally open and valves EJHV8811A and EJHV8811B are normally closed.

Cable 14BNG03BC, associated with valve BNHV8812B, run through area C-23. Damage to this cable could prevent closure of the valve from the control room and could prevent automatic closure when valve EJHV8811B is fully open.

Cable 14EJG06BC, associated with EJHV8811B, runs through area C-23. Damage to this cable will not cause the valve to spuriously open.
The RWST level transmitters and associated circuits are included in the PFSSD analysis because of the automatic functions they perform. A low-low level in the RWST on 2 out of 4 RWST level transmitters, coincident with a safety injection signal, will provide a permissive for containment sump isolation valves EJHV8811A and EJHV8811B to open. This could cause the RWST to drain to the containment sump if the associated RWST to RHR valve does not close. Cable 14BNI07FA, associated with RWST level transmitter BNLT0933, is run in area C-23. Circuits for the remaining three RWST level transmitters are not run in area C-23. Therefore, a spurious low-low RWST level signal will not occur.

Based on the above discussion, RWST inventory is unaffected by a fire in area C-23.

References: E-15000, XX-E-013, E-13BN03A, E-13EJ06B, E-13BN07, E-1F9102, E-1F9204, E-1F9205, M-12BN01, M-12EJ01

5.2.21 Essential Service Water

Either the Train A or the Train B essential service water (ESW) system is required to be available to ensure PFSSD. The ESW system supplies water to the following PFSSD components on the associated train:

- CCP room cooler
- RHR pump room cooler
- Class 1E switchgear room A/C condenser
- diesel generator engine cooling
- control room A/C condenser
- auxiliary feedwater pump room cooler
- motor and turbine driven auxiliary feedwater pump suction (backup to CST)
- containment air coolers
- electrical penetration room cooler
- component cooling water pump room cooler
- component cooling water heat exchanger
- component cooling water system makeup

A number of components associated with Train B ESW system could be affected by a fire in this area. The Train B ESW pump and a number of Train B ESW control valves could spuriously operate or may not operate when required. The Train B ESW pump room supply fan and associated dampers may not operate. Therefore, the Train B ESW system cannot be relied on if a fire occurs in this area.

The service water system provides the normal source of water to the ESW piping. Service water supply to and return from the ESW piping is each controlled by two valves installed in series. One of the two valves on each leg is required to be closed for PFSSD to prevent flow diversion from the credited ESW system. As discussed in the previous paragraph, the Train B ESW system may not be available if a fire occurs in this area. One valve (EFHV0025) on the Train A service water to ESW piping supply line and one valve (EFHV0039) on the Train A ESW to service water return line may be affected by the fire and may not close on a signal from the control room. Redundant valves EFHV0023 and EFHV0041 are unaffected by the fire and will close on a signal from the control room. Therefore, the ESW/service water cross connects can be isolated if a fire occurs in this area. In addition, check valve EFV0470 is installed between valves EFHV0023 and EFHV0025 and will prevent flow diversion from Train A ESW to the service water system. Also, check valve EFV0471 is installed between valves

EFHV0024 and EFHV0026 and will prevent flow diversion from Train B ESW to the service water system.

Cable 14RPY10BA supplies 120 VAC control power to the automatic and manual start circuits for the Train B ESW pump room supply fan CGD01B. The control power is supplied via this cable to control room panel RP068. If power is lost due to damage to this cable, then the Train B ESW pump room supply fan will not start either automatically, when the ESW pump starts, or manually from the control room. If this occurs, the Train A ESW pump room supply fan remains unaffected by the fire.

Cables 14GDY01BA, 14GDY01BB and 14GDY01BD are associated with Train B ESW pump room supply fan CGD01B. Damage to these cables could prevent operation of the supply fan. Train A ESW pump room supply fan CGD01A is unaffected by a fire in this area.

The Train A ESW system is unaffected by a fire in area C-23 and ESW remains available in the event of a fire in this area.

References: E-15000, XX-E-013, E-13EF02, E-13EF02A, E-13EF03, E-13EF06A, E-13EF07A, E-13EF08A, E-13EF09A, E-13EF11, E-13RP10, E-K3EF01A, E-K3EF08, E-K3GD01A, E-K3GD04, E-K3GD04A, J-201-00133, E-1F9402A, E-1F9402B, E-1F9403, E-1F9424B, E-1F9443, M-12EF01, M-12EF02, M-K2EF01, M-K2GD01

5.2.22 Safety Injection (SI) Pumps

The preferred PFSSD condition of the SI pumps is off. Therefore, a spurious start of the SI pumps should be avoided or mitigated. A control cable (14EMB01BB) associated with Train B SI pump PEM01B runs through area C-23 and could cause a spurious start of the pump and prevent stopping the pump from the control room.

If the Train B SI pump spuriously starts with the reactor at normal pressure, PFSSD will be assured. The pump will not discharge into the RCS due to the pressure differential between the RCS (approximately 2,235 psig) and the SI pump shutoff pressure (approximately 1,565 psig). In addition, the setpoint of the discharge relief valve (EM8853B) to the Recycle Holdup Tank is 1,825 psig. Therefore, no inventory is lost from the RWST if the SI pumps spuriously start. With the SI pump operating with no flow, damage to the pump could occur, which is a commercial concern since the SI pump is not credited in the PFSSD analysis. If necessary, the pump can be stopped by opening breaker NB0202, but this action is not required for PFSSD.

Based on the above discussion, spurious operation of the Train B SI pump will not adversely impact PFSSD.

References: XX-E-013, E-15000, E-13EM01, E-1F9102, E-1F9302, M-12EM01, M-721-00096, WCRE-01

5.2.23 Boron Injection Tank Flowpath

The Boron Injection Tank (BIT) flowpath is credited for reactivity control and reactor coolant makeup. For reactivity control, the BIT flowpath is credited as an alternate source of boration in the event RCP seal injection is unavailable. Based on Calculation XX-E-013, RCP seal injection will provide sufficient boration to achieve and maintain cold shutdown reactivity conditions. Therefore, the BIT flowpath is not required for reactivity control if RCP seal injection is available. Since RCP seal injection is limited to 5 gpm per seal or 20 gpm total injection to the RCS, an additional RCS charging flowpath is required for adequate RCS makeup during plant transition from hot standby to cold shutdown. The BIT injection path was selected as the additional RCS charging flowpath.

As discussed in Section 5.2.9, RCP seal injection is available. Therefore, the BIT flowpath is not required for inventory control and boration during hot standby. The BIT flowpath is still necessary for cold shutdown. Cables associated with BIT inlet and outlet valves are not run in this area. Therefore, BIT injection can be lined up from the control room.

To prevent CCP flow diversion through the SIS test line when charging through the BIT, valves EMHV8843 and EMHV8882 need to be closed. If either or both of these valves cannot be closed, then closing or maintaining closed either valve EMHV8871 or EMHV8964 will prevent flow in the SIS test line. Cables associated with EMHV8843 and EMHV8871 are run in this area. Damage to these cables could cause the valves to open. Cables associated with EMHV8964 do not run in area C-23. Therefore, valve EMHV8964 can be controlled to prevent flow through the SIS test line when charging through the BIT.

Based on the above discussion, the BIT flowpath is not required for hot standby due to the availability of RCP seal injection. The BIT flowpath is available for cold shutdown.

References: E-15000, XX-E-013, E-13EM02A, E-13EM02B, E-13EM04, E-13EM04A, E-1F9302, M-12EM01, M-12EM02

5.2.24 Containment Spray (CS) Pumps

Spurious start of the CS pumps may complicate PFSSD due to the possible depletion of inventory in the RWST. Therefore, a spurious start of the CS pumps should be avoided or mitigated. A control cable (14ENB01BB) associated with Train B CS pump PEN01B runs through area C-23 and could cause a spurious start of the pump. The cable damage could prevent stopping the pump from the control room.

Normally closed valve ENHV0012 could open due to damage to associated control cables. If this occurs coincident with a running Train B CS pump, water would flow from the containment spray nozzles, depleting inventory in the RWST.

The total flow in the containment spray system during injection phase with one pump operating is 3,165 gpm (M-10EN). Based on calculation XX-E-013, Appendix 1, a maximum of 214,260 gallons of water can be lost from the RWST to maintain sufficient volume to achieve cold shutdown.

As stated previously, level indication in the RWST is available, so operators would quickly diagnose a reducing RWST inventory. The time available to mitigate containment spray is:

214,260 gallons / 3,165 gpm = 67 minutes

Based on the above discussion, there is 67 minutes available to mitigate containment spray. Pump PEN01B can be stopped by opening breaker NB0203 in area C-10. This is an OMA. Refer to E-1F9900 for details. Reference Attachment 4, MSO Evaluation Scenario ID PWROG 16.

References: XX-E-013, E-15000, E-13EN01, E-13EN03, E-1F9433, M-10EN, M-12EN01

5.2.25 Safety Injection Accumulator Isolation Valves

PFSSD requires isolation of the SI accumulators prior to reducing RCS pressure below the injection pressure to avoid unnecessary accumulator discharge. This is accomplished by closing valves EPHV8808A, EPHV8808B, EPHV8808C and EPHV8808D. These valves are normally open with the MCC breaker administratively locked in the open position.

Cables for valves EPHV8808B and EPHV8808D are run in area C-23. Since the breakers for these valves are normally open, damage to these cables will not cause the valves to spuriously change position. However, damage to the cables will prevent closing the associated valve from the control room after power is restored.

The SI accumulators need to be isolated during cold shutdown, prior to the RCS reaching 1000 psig. If necessary, a containment entry can be made to manually close the valves.

5.2.26 RCS Hot and Cold Leg Temperature Indication

PFSSD requires RCS hot and cold leg temperature indication on at least one loop to verify flow through the steam generators. The temperature elements and control room indicators used for this purpose are listed in the following table.

RCS Hot and Cold Leg Temperature Elements/Indicators Used for PFSSD		
ELEMENT	**INDICATOR**	**FUNCTION**
BBTE0413A	BBTI0413A	RCS Hot Leg Temperature Element (WR) Loop 1
BBTE0413B	BBTI0413B	RCS Cold Leg Temperature Element (WR) Loop 1
BBTE0423A	BBTR0423	RCS Hot Leg Temperature Element (WR) Loop 2
BBTE0423B	BBTI0423B	RCS Cold Leg Temperature Element (WR) Loop 2
BBTE0433A	BBTR0433	RCS Hot Leg Temperature Element (WR) Loop 3
BBTE0433B	BBTR0433	RCS Cold Leg Temperature Element (WR) Loop 3
BBTE0443A	BBTR0443	RCS Hot Leg Temperature Element (WR) Loop 4
BBTE0443B	BBTR0433	RCS Cold Leg Temperature Element (WR) Loop 4

Cable 16RLY01EA supplies 120 VAC power to control room panel RL021/RL022. At RL021/RL022, the power is split and supplies power to BBTR0433 and BBTR0443, as well as other non-PFSSD components. Damage to this cable could disrupt power to BBTR0433 and BBTR0443. Consequently, loops 3 and 4 RCS temperature indication could be lost. However, RCS temperature indication on loops 1 and 2 remains available. Therefore, the PFSSD function is satisfied.

References: E-15000, XX-E-013, E-13BB15, E-13RL01, E-13RL06, E-1F9201, E-1F9421, M-12BB01

5.2.27 Control Room Air Conditioning

PFSSD requires control room air conditioning to be available to maintain a tenable control room environment. Cable 14GKG02BA supplies 480 VAC power to panel GK199C. Panel GK199C is the power and control panel for Train B control room A/C unit SGK04B. Damage to this cable will prevent operation of SGK04B.

Cables associated with control room A/C unit SGK04B supply and return dampers GKHZ0040A and GKHZ0040B are run in this area. Damage to these cables could prevent operation of the dampers.

The Train A control room A/C unit is unaffected by a fire in this area. Therefore, control room air conditioning is available if a fire occurs in area C-23.

References: XX-E-013, E-15000, E-13GK02A, E-13GK02C, E-13GK02D, E-1F9442, M-12GK01

5.2.28 Class 1E Electrical Equipment Room Air Conditioning

Class 1E electrical equipment room air conditioning is required to satisfy the PFSSD support function of maintaining cooling within the Class 1E electrical equipment rooms.

Cables 14GKG13BG, 14GKG13BK and 14GKG13BM associated with Train B Class 1E electrical equipment room A/C unit SGK05B are run in area C-23. Damage to these cables could prevent operation of the unit.

Cable 14SAZ20HA provides a control power signal from panel GK196C to status panel SA066B to monitor SGK05B control power. Damage to this cable could prevent operation of SGK05B.

Power and control cables associated with Train A Class 1E electrical equipment room A/C unit SGK05A are unaffected by a fire in this area. However, cables associated with the fire detection alarm panel that initiates shutdown of SGK05A are run in fire area C-23. Cables 16KCQ21EA, 16KCQ21FA and 16KCQ21JA run from the main fire alarm panel (KC275) to Halon releasing panel KC230, located on the 2016 elevation of the control building in fire area C-35. Panel KC275 monitors smoke detectors in Halon protected switchboard rooms that are conditioned by SGK05A. Upon receipt of the proper detection sequence at KC275, a normally open auxiliary relay contact in KC275 closes and sends a short circuit signal over cables 16KCQ21FA or 16KCQ21JA to KC230. The short circuit signal received at KC230 initiates actuation of Halon in the affected room and shuts down SGK05A. If the cables are damaged in a fire and short circuit, Halon will be released into the Train A Class 1E electrical equipment rooms and class 1E A/C unit SGK05A will shut down.

Cable 16GKK31DB, associated with relay 95XGK08 runs in area C-23. If this cable is damaged, it could cause a spurious shutdown of both SGK05B.

If SGK05A spuriously shuts down or cannot be started, the spurious fire isolation signal can be bypassed by placing hand switch GKHS0101 in bypass position and the unit can be started using GKHIS0100. Hand switches GKHIS0100 and GKHS0101 are located on panel RP068 in the main control room.

References: XX-E-013, E-15000, E-13GK13, E-13GK13A, E-13GK31, E-13KC21, E-13SA20, E-1F9444, M-12GK03, M-655-00009, M-658-00042, M-658-00043, M-658-00044, M-622.1A-00002

5.2.29 Standby Diesel Generation

The PFSSD methodology requires at least one source of power to be available on the credited train. The standby diesel generators are credited whenever the fire could cause a loss of off-site power.

Several cables associated with the Train B diesel generator are run in this area. Also, cables associated with the Train B diesel generator room exhaust damper GMHZ0019 run in this area. Damage to these cables could prevent operation of the Train B diesel generator.

A fire in area C-23 credits Train A since the fire could cause a loss of several Train B components. Based on calculation XX-E-013, off-site power may not be available on both trains if a fire occurs in this area. The Train A emergency diesel generator is unaffected.

Based on the above discussion, only the Train A emergency diesel generator is available if a fire occurs in this area.

References: XX-E-013, E-15000, E-12KJ01, E-13GM01A, E-13GM04A, E-13JE01, E-13JE01A, E-13JE04, E-13KJ03A, E-13KJ07, E-13NE11, E-13NE13, E-1F9411A, E-1F9411B, E-1F9412A, E-1F9412B, E-1F9444, M-12GM01, M-12JE01

5.2.30 Containment Coolers

PFSSD requires containment cooling to maintain the containment environment within EQ limits. Cables associated with Train B containment coolers are run in area C-23. Damage to these cables could prevent operation of the Train B containment coolers. Circuits associated with Train A containment coolers are run in a separate fire area and are unaffected by a fire in area C-23.

As discussed earlier, Train A ESW is available if a fire occurs in area C-23. Therefore, the Train A containment coolers will have the necessary service water flow to ensure proper operation.

References: E-15000, XX-E-013, E-13GN02A, E-1F9441, M-12GN01

5.2.31 Class 1E 4.16 kV Offsite Power

Bus NB02 supplies power to Train B Engineered Safety Features (ESF) components. Cables associated with offsite power feeder breakers NB0209 and NB0212 are run in this area. In addition, cables associated with NB02 breaker control power are run in this area. Damage to these cables due to a fire could cause a loss of offsite power to NB02 and could prevent operation of the PFSSD equipment supplied by NB02. As stated in Section 5.2.15, the Train B emergency diesel generator may not be available if a fire occurs in this area.

Cables associated with transformers XNB01 and XNB02 lockout and phase differential relays are run in fire area C-23. Damage to these cables could cause a loss of offsite power on both trains.

Control cables associated with bus NB02 Synchro-scope and associated switches are run in area C-23. Damage to these cables could prevent some of the monitoring functions for NB02 but would not cause a loss of the NB02 bus.

As stated in Section 5.2.29, Train A emergency diesel generator is available and can be lined up to NB01 to provide power to Train A PFSSD loads. Therefore, a loss of offsite power on both trains due to a fire in area C-23 will not impact the ability to achieve and maintain safe shutdown. For a more detailed evaluation of offsite power availability, refer to Calculation XX-E-013.

References: XX-E-013, E-15000, E-1F9425, E-1F9426, E-13NB03, E-13NB04, E-13NB05, E-13NB06, E-13NB10, E-13NB11, E-13NB14, E-13NB15, E-1F9102, E-1F9423, E-1F9425, E-1F9426

5.2.32 Load Shedder / Emergency Load Sequencer

The load shedder and emergency load sequencers are included in the PFSSD design to evaluate the impact of spurious operation or mal-operation. The load shedder/emergency load sequencer operates upon presence of the following conditions:

1. An undervoltage (UV) on a safeguards bus,
2. A safety injection signal (SIS) or a containment spray actuation signal (CSAS), or
3. An undervoltage on a safeguards bus with a SIS or CSAS.

Eight inputs (four undervoltage (UV) inputs and four degraded voltage inputs) on each safeguards bus (NB01 and NB02) monitor voltage conditions on that bus. An undervoltage condition on two of four UV relays on each bus will actuate the load shedder/sequencer and send a signal to start the associated diesel generator. In addition, degraded voltage sensed by two of four degraded voltage potential transformers (PTs) will, after a time delay, provide a signal to open the offsite feeder breakers on the associated bus.

Cables 14NFK01CA and 14NFK01DA for one of the four UV relays on each bus are run in fire area C-23. Also, cables 14NFY01EA and 14NFY01FA associated with one of the four degraded voltage PTs on each bus are run in fire area C-23. Cables associated with the remaining three UV relays and PTs do not run in fire area C-23. Therefore, automatic functioning of the bus NB01 and NB02 emergency load shedder / sequencer is unaffected by a fire in area C-23 and a spurious start of the associated diesel generator due to a false undervoltage condition on two of the four circuits is not credible.

Cable 14NFK01AA is a DC power cable that runs from NK5412 to NF039C. Damage to this cable could prevent an auto start of the Train B emergency diesel generator upon degraded voltage on 2/4 Train B undervoltage relays or 2/4 input of Train B degraded voltage PTs.

Separation group 4 power cables 14NFY01GA and 14NFY01HA associated with NF039A, NF039B and NF039C are run in this area. Separation groups 1, 2 and 3 power cables associated with these panels are unaffected. Therefore, power to the load shedder/sequencer panels is available.

Based on the above discussion, the Train A and B load shedder/sequencers are available if a fire occurs in this area but the Train B emergency diesel generator may be affected.

References: XX-E-013, E-15000, E-11NB01, E-11NB02, E-12NF01, E-13NF01, E-10NF, E-1F9411A, E-1F9411B, E-1F9412A, E-1F9412B, E-1F9402A, E-1F9402B, E-1F9403, E-1F9425, E-1F9426

5.2.33 Train B 480 Volt Class 1E Load Centers

Train B 480 Volt Class 1E Load Centers are required for PFSSD to ensure power is available to supply PFSSD loads.

Cables associated with Train B 480 VAC Class 1E load centers NG02, NG04 and motor control center (MCC) NG06E are run in area C-23. In addition, as stated in other sections, loss of power to these load centers could occur due to loss of Train B off-site and on-site power. Therefore, Train B load centers and associated equipment may not be available if a fire occurs in this area.

Cable 14PKK11AA is associated with 480 VAC breaker NG0409. NG0409 supplies 480 VAC power to Train B 125 VDC battery charger PK22, which energizes the PK02 bus. Damage to this cable could disable power to the battery charger but will not de-energize PK02 due to the installed batteries. Battery set PK12 will maintain 125 VDC power to PK02. In addition, NG0102 is unaffected and will continue to supply power to Train A 125 VDC battery charger PK21.

Redundant Train A components, supplied by NG01, NG03 and NG05E are unaffected by a fire in area C-23. Therefore, loss of power to Train B 480 VAC Class 1E load centers NG02, NG04 and MCC NG06E will not impact the ability to achieve and maintain safe shutdown.

References: XX-E-013, E-15000, E-11NG02, E-13NG01A, E-13NG10A, E-13NG11A, E-13NG11B, E-13PK11, E-K3NG10A, E-1F9411B, E-1F9412B, E-1F9422C, E-1F9423, E-1F9424A. E-1F9424B, E-1F9424C, E-1F9424D

5.2.34 Class 1E 125 VDC Distribution System

The Class 1E 125 VDC electrical distribution system is required to supply power and control to required PFSSD equipment. The Class 1E 125 VDC system is supplied by the Class 1E 480 VAC system which is inverted to 125 VDC. In addition, backup batteries are installed to ensure continued uninterrupted power to the Class 1E 125 VDC buses. As stated previously, Train B Class 1E 480 VAC power could be affected by a fire in this area. However, the battery sets are unaffected and will supply 125 VDC power to the Train B components for approximately 4 hours. The Train A Class 1E 125 VDC system is unaffected.

Power cables associated with the Class 1E 125 VDC electrical distribution system are run in area C-23. These cables supply 125 VDC power to various PFSSD loads. The cables and supplied PFSSD equipment are summarized in the following table.

CABLE	NK BREAKER	CONTROL PANEL	PFSSD Components
14RLK01AA	NK04407	RL001/002	BGHV8153B, BGHV8154B
14RLK01BA	NK04409	RL005/006	FCFY0310
14RLK01CA	NK04412	RL017/018	EMHV8843, EMHV8871
14RLK01DA	NK04413	RL019/020	EGTV0030, GMHY0019
14RLK01EA	NK04414	RL021/022	BBHV8001B, BBHV8002B
14RLK01FA	NK04411	RL023/024	BMHV0001, BMHV0002, BMHV0003, BMHV0004

Damage to these cables could cause a loss of power to the associated components.

Valves BGHV8153B and BGHV8154B are isolation valves on the inlet side of the excess letdown heat exchanger. Loss of power to these valves will fail them closed, which is the desired PFSSD position.

Solenoid valve FCFY0310 is for TDAFP steam trap isolation valve FCFV0310. Loss of power to this solenoid valve will fail FCFV0310 closed, which is the desired PFSSD position.

Valves EMHV8843 and EMHV8871 are SI test line isolation valves on the BIT injection flow path. Loss of power to these valves will fail them closed, which is the desired PFSSD position.

Valve EGTV0030 is the Train B CCW temperature control valve. Loss of power to this valve will fail the valve closed and will provide the maximum cooling to the Train B components. This will not adversely impact PFSSD. In addition, Train A CCW is unaffected by the fire.

Solenoid valve GMHY0019 is for Train B emergency diesel generator exhaust damper actuator GMHZ0019. Loss of power to GMHY0019 will fail the exhaust damper open, which is the desired PFSSD position.

Valves BBHV8001B and BBHV8002B are reactor head vent isolation valves. Loss of power to these valves will fail them closed, which is the desired PFSSD position.

Valves BMHV0001, BMHV0002, BMHV0003 and BMHV0004 are steam generator blowdown valves. Loss of power to these valves will fail them closed, which is the desired PFSSD position.

Based on the above discussion, loss of power to the Train B Class 1E 125 VDC system as well as the components listed will have no adverse impact on PFSSD since the components fail in the desired PFSSD position and/or Train A Class 1E 125 VDC system is available.

References: XX-E-013, E-15000, E-13BB30, E-13BG48, E-13BM06A, E-13EG16, E-13EM04, E-13EM04A, E-13FC21, E-13GM04A, E-13RL01, E-13RL02, E-13RL03, E-13RL04, E-13RL05, E-13RL06, E-13RL07, E-1F9101, E-1F9202, E-1F9301, E-1F9302, E-1F9401A, E-1F9422B, E-1F9444, M-12BB04, M-12BG01, M-12BM01, M-12EG02, M-12EM01, M-12EM02, M-12FC02, M-12GM01

5.2.35 BOP Instrument Racks

BOP instrument racks RP053A, RP053B, RP053D and RP147 are credited in the PFSSD analysis. The following table identifies the PFSSD components served by each instrument rack.

Instrument Rack	PFSSD Components
RP053A (RP053AA, RP053AB, RP053AC)	ALHV0009, ALHV0011 ALPY0037A, EGFT0128, EGPSL0077, GDTSL0001, JELSL0001C
RP053B (RP053BA, RP053BB, RP053BC)	ALHV0007, ALPY0039A, EGFT0129, EGPSL0078, GDTSL0011, JELSL0021C
RP053D (RP053DA, RP053DB)	ALPY0038A
RP147 (RP147A, RP147B)	ALHV0005

Cables 14RPY09BA and 14RPY09CA supply 120 VAC power to BOP instrument rack RP053B. Damage to these cables could cause a loss of function of panel RP053B and associated PFSSD components.

A loss of PFSSD components controlled by RP053B will not adversely impact PFSSD as discussed below. A loss of valve ALHV0007 will prevent the Train B MDAFP from feeding steam generator A, however the TDAFP is available to feed steam generator A. ALPY0039A is associated with pressure transmitter ALPT0039 which is part of the 2/3 ESFAS Low Suction Pressure (LSP) signal logic. A LSP signal on 2 out of 3 pressure transmitters swaps the AFW source from CST to ESW. The remaining two pressure transmitters are unaffected so loss of ALPY0039A will have no adverse impact on PFSSD.

EGFT0129 is a flow transmitter on the CCW to RCP line and provides operators with the total CCW flow to the RCPs, including the thermal barriers. Flow transmitter EGFT0128 is unaffected and can be used by operators to determine if CCW is flowing to the thermal barriers.

EGPSL0078 is associated with the Train B CCW pump. A low-pressure signal on EGPT0078 will start the second CCW pump on Train B. Since Train A CCW is credited for a fire in this area, loss of this component will have no adverse impact on PFSSD.

GDTSL0011 is the low temperature switch for the Train B ESW pump room supply fan. Loss of this component will have no adverse impact since Train A ESW is unaffected by a fire in this area.

JELSL0021C is the level switch for Train B EDG day tank. Loss of this component will have no adverse impact since Train A EDG is unaffected by the fire.

Based on the above discussion, a loss of power to RP053B will have no adverse impact on PFSSD.

References: E-15000, XX-E-013, E-13AL08, E-13AL09, E-13EG13, E-13EG19, E-13JE01, E-13NN01, E-13RP09, E-1F9101, E-1F9202, E-1F9204, E-1F9401B, E-1F9411B, E-1F9411A, E-1F9424D, E-1F9443, E-K3GD01A, E-K3GD04, M-12AL01, M-12EG01, M-12JE01, M-K2GD01

5.2.36 Control Room Lockout Relays

Control room lockout relays are used in the event of a fire in the control room to isolate certain PFSSD components from the effects of a control room fire. This is done to ensure the equipment remains functional from the auxiliary shutdown panel.

Cables associated with control room lockout relays 86XRP5, 86XRP6 and 86XRP7 are run in area C-23. Equipment controlled by the relays is identified in the table below.

Panel RP335 PFSSD Relays	
Relay #	**Description**
86XRP5	Train B MDAFP from CST and ESW Supply Valves (ALHV0034 and ALHV0030)
86XRP6	ESW to TDAFP Supply Valve (ALHV0033)
86XRP7	Train B MDAFP (PAL01B)

Damage to these cables could prevent operation of associated equipment. This equipment is associated with the Train B auxiliary feedwater system. Train A auxiliary feedwater equipment is available and unaffected by a fire in this area.

Based on the above discussion, damage to cables associated with control room lockout relays 86XRP5, 86XRP6 and 86XRP7 will have no adverse impact on PFSSD.

References: XX-E-013, E-15000, E-13AL01B, E-13AL02B, E-13AL04B, E-13RP12, E-13RP14, E-13RP15, E-093-00095, E-093-00096, E-1F9202, E-1F9204

5.2.37 Reactor Protection System

The Reactor Protection System (RPS) monitors specified input parameters and initiates reactor protection features whenever those parameters are outside specified limits. Field installed transmitters continuously monitor various parameters and report the results to one of four process cabinets, one per channel. Signals are then sent from the process cabinets to both solid state protection cabinets, one on each train. The cabinets and associated channel are listed in the following table:

Process Cabinets	Solid State Protection Cabinets
Cabinet SB038 - Channel 1 Cabinet SB042 - Channel 2 Cabinet SB037 - Channel 3 Cabinet SB041 - Channel 4	Cabinet SB029A - Train A Input Cabinet Cabinet SB029B - Train A Logic Cabinet Cabinet SB029C - Train A Output Cabinet 1 Cabinet SB029D - Train A Output Cabinet 2 Cabinet SB032A - Train B Input Cabinet Cabinet SB032B - Train B Logic Cabinet Cabinet SB032C - Train B Output Cabinet 1 Cabinet SB032D - Train B Output Cabinet 2

The RPS is actuated upon 2/3 or 2/4 coincident logic, depending on the input parameter. This ensures that a loss of a single channel will not prevent the system from performing its function. Loss of power to a single cabinet will render the channel or Train inoperative.

Cables associated with RPS channel 4 run through this area. These cables supply power from separation group 4 power supplies to panels SB029A, SB032A, SB032D and SB041. Power cables associated with RPS channels 1, 2 and 3 are run in a separate fire area.

Based on the above discussion, the reactor protection system is available if a fire occurs in this area.

References: XX-E-013, E-15000, E-11NK02, E-13NN01, E-13SB01, E-13SB02, E-13SB05, E-13SB08A, E-13SB08D, E-13SB09, E-1F9102, E-1F9103, E-1F9203, E-1F9205, E-1F9421, E-1F9433, E-1F9431, E-1F9432, M-761-000167

5.2.38 Reactor Trip Switchgear

The reactor trip switchgear is required to ensure the ability to manually trip the reactor. The reactor is tripped using either hand switch SBHS0001 or SBHS0042 in the main control room. Each hand switch has contacts associated with Train A reactor trip switchgear SB102A and Train B reactor trip switchgear SB102B.

Cable 14SBS10BB supplies 125 VDC power to Train B reactor trip switchgear cabinet SB102B. Loss of 125 VDC power will prevent operation of the Train B reactor trip functions but redundant Train A reactor trip switchgear cabinet SB102A remains available. Therefore, loss of 125 VDC power will not impact PFSSD.

Cable 14SBS12BC, associated with separation group 4 trip circuits, is run in area C-23. A hot short in this cable could cause a spurious reactor trip, which is the desired PFSSD condition. An open circuit will prevent a manual reactor trip on Train B reactor trip switchgear SB102B.

Cables associated with separation group 1 trip circuits are unaffected by a fire in area C-23. Therefore, operation of either hand switch SBHS0001 or SBHS0042 will cause a reactor trip on redundant Train A reactor trip switchgear SB102A.

References: XX-E-013, E-15000, E-13SB12A, E-1F9101

5.2.39 Process Monitoring Instrumentation

Process instrumentation is required for PFSSD to provide operators with reliable diagnostic instrumentation of process variables. Circuits for a number of process instruments are run in area C-23. These circuits run from various process monitoring panels to the auxiliary shutdown panel (ASP) and provide indication at the ASP for control outside the control room.

Damage to these cables will not cause a loss of process monitoring capability in the main control room. Therefore, damage to these cables due to a fire in area C-23 will not adversely impact PFSSD.

References: XX-E-013, E-15000, E-13SB16, E-1F9201, E-1F9301, M-12BB01, M-12BB02, M-12BB04

5.2.40 Source Range Monitoring

PFSSD requires source range (SR) flux monitoring to be available to provide indication of cold shutdown reactivity conditions. Source range monitoring is provided by source range monitors SENE0031, SENE0032, SENY0060A & B, and SENY0061A & B.

Cable 14SES07BA is a power cable associated with SR monitor signal processor SENY0061B. Cable 14SES07CA is a power cable associated with SR monitor amplifier SENY0061A. Damage to these cables could prevent operation of the associated source range monitor.

Source Range monitoring remains available for a fire in area C-23 using SENE0031, SENE0032 and SENY0060A/B.

For a more detailed evaluation on Source Range monitoring, see Calculation XX-E-013, Attachment 3.

References: E-15000, XX-E-013, E-13SE07, E-1F9101

5.2.41 Reactor Coolant Pumps

The reactor coolant pumps are not credited in the PFSSD analysis. However, the capability to stop the pumps from the control room in the event of a loss of all seal cooling is credited. Westinghouse Technical Bulletin TB-04-22, Rev. 1 recommends that if all seal cooling is lost (RCP seal injection and thermal barrier heat exchanger flow), operators need to stop the pumps before a seal LOCA occurs.

One control cable associated with reactor coolant pumps C and D is run in fire area C-23. Damage to these cables in the event of a fire could prevent operators from stopping the C and D RCPs from the control room. However, a fire in C-23 will not cause a loss of all seal cooling since RCP seal injection and thermal barrier cooling remain available.

Based on the above discussion, the inability to trip the C and D RCPs from the control room will have no adverse impact on PFSSD. The pumps can continue to operate, providing forced flow circulation. If the pumps spuriously stop, natural circulation cooldown can be used.

5.2.42 Steam Generator Feedwater Pumps

Main feedwater pump steam supply valves FCFV0005 and FCFV0105 are credited in the PFSSD analysis to trip the main feedwater pumps if the main steam isolation valves (MSIVs) are affected by a fire. Closing the MSIVs stops steam flow to the feedwater pumps' turbines and stops the feedwater pumps. The steam generator feedwater pumps are tripped in the event of a fire to prevent overfilling the steam generators.

Non-Class 1E 120 VAC Inverter PN10 and distribution panel PN10A provide power to FCFV0105 trip relays in panel FC170C. Cable 16FCY35AA provides the primary source of 120 VAC power from distribution panel PN010A to panel FC170A. The alternate source of power to panel FC170A is not credited for PFSSD and is assumed lost.

A fire in area C-23 could damage cable 16FCY35AA. If this occurs, operators in the control room would not be able to close valve FCFV0105 to stop steam flow to steam generator feedwater pump PAE01B.

A fire in area C-23 will not affect the ability to close the MSIVs from the control room. All-close hand switch ABHS0080 is unaffected and can be used to close the MSIVs from the control room.

Based on the above discussion, valve FCFV0105 may not close if a fire occurs in this area. However, the MSIVs can be closed using hand switch ABHS0080 in the main control room. Therefore, the configuration is acceptable.

References: E-15000, XX-E-013, E-13FC35, E-1F9103, E-1F9421

5.2.43 Load Center Feeder Breakers PA0206, PA0207 and Load Center PG20 Incoming Feeder Breaker PG2001

Load center feeder breakers PA0206, PA0207 and PG2001 are credited for PFSSD because they supply power to credited non-safety related loads. Cables associated with these breakers run in this area. PFSSD impact due to damage to these cables is discussed below.

Cable 16PGA10CA is a control cable associated with breaker PA0206 and runs in fire area C-23. An intra-cable hot short in this cable will trip PA0206. Breaker PA0206 supplies power to the following PFSSD components:

- PG12KAF4 – Main Steam Supply to 2nd Stage Reheat Valve ABHV0032
- PG12KAF5 – Main Steam Supply to Steam Seals Valve ABHV0046
- PG12KEF3 – Auxiliary Steam System Control Valve FBHV0080

PG12KAF4, PG12KAF5 and PG12KEF3 supply power to components downstream of the MSIVs. The MSIVs are unaffected by a fire in this area and can be closed from the control room using hand switch ABHS0080. Therefore, the MSIV downstream components are not required if a fire occurs in this area.

Cable 16PGA11AC, associated with PA0207, runs in this area. A fire induced short circuit in this cable will trip the breaker. Cable 16PGG13DA, associated with PG2001, runs in this area. Damage to this cable will trip the breaker.

Breakers PA0207 and PG2001 supply power to the following PFSSD components:

- PG20GBR217 – MCB Misc. Power Circuits RL023
- PG20GER5 – Instr. Bus Transformer Alt. Feed XPN08D

PFSSD components powered from PG20GBR217 are associated with MSIV downstream components. The MSIVs are unaffected by a fire in this area and can be closed from the

control room. Therefore, the MSIV downstream components are not required if a fire occurs in this area.

PG20GER5 is credited as one source of power to PN08. The redundant source of power from NG02BBF1 could also be affected by a fire in this area as discussed in Section 5.2.36. Redundant components powered from inverter PN07 are unaffected by a fire in this area.

Based on the above discussion, loss of breakers PA0207 and PG2001 will have no adverse impact on PFSSD.

References: XX-E-013, E-15000, E-11PG20, E-11PG21, E-11PK02, E-13PG10, E-13PG11, E-13PG13, E-13RL07, E-1F9421, E-1F9422C, E-1F9424E, KD-7496, DCP 13324

5.2.44 120 VAC Distribution Panel PN410

120 VAC distribution panel PN410 supplies power to NSSS control panels RP043 and RP047.

Inverter PN04 supplies power to 120 VAC distribution panel PN410 (via cables 16PNY02AA and 16PNY02AB), which in turn supplies redundant 120 VAC power to NSSS control cabinets RP043 and RP047. For PFSSD, cabinet RP043 houses relays BGLCV0459X and BGLCV0460X, which are associated with letdown isolation valves BGLCV0459 and BGLCV0460, respectively. Cabinet RP047 includes controls for pressurizer PORVs and pressurizer spray.

Damage to cables 16PNY02AA and/or 16PNY02AB will disrupt power to panel PN410. Redundant power to RP043 and RP047 is available from 120 VAC distribution panel PN310. Therefore, loss of power to PN410 will not adversely impact PFSSD.

References: XX-E-013, E-15000, E-1F9421, DCP 13324

5.2.45 Normal Pressurizer Spray

The normal pressurizer spray valves are included in the PFSSD design because spurious operation of pressurizer sprays can cause a decrease in pressure which can lead to boiling in the core. The pressurizer spray valves are part of the pressurizer pressure control system.

The pressurizer normal spray valves (BBPCV0455B and BBPCV0455C) operate off a signal from the Ovation pressurizer pressure control system. The operation of the pressure control system is discussed in Calculation XX-E-013.

Cable 14BBI16NB associated with BBPT0458 is run in this area. Damage to this cable could cause a spurious high-pressure signal. As discussed in Calculation XX-E-013, Appendix 1, damage to a single pressure input channel will not cause the spurious operation of the pressurizer spray valves due to the Ovation 4-channel validation logic, which uses the 2nd highest signal as the validated signal and has built-in logic to detect and ignore a failed input.

Based on the above discussion, the pressurizer spray valves will not spuriously open if a fire occurs in this area.

4.0 CONCLUSION 12
5.0 DETAILED ANALYSIS 12
5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA C-24 12
5.2 PFSSD CABLE EVALUATION 13

1.0 GENERAL AREA DESCRIPTION

Fire area C-24 is located on the 2032 elevation of the Control Building and includes the rooms listed in Table C-24-1.

Table C-24-1
Rooms Located in Fire Area C-24

ROOM #	DESCRIPTION
3504	North Electrical Chase - 2032 Elevation

Fire area C-24 is protected with an automatic wet-pipe sprinkler system and automatic fire detection. The area is separated from adjacent areas by minimum 3-hour fire resistant construction.

2.0 PRIMARY EQUIPMENT USED FOR PFSSD

Table C-24-2 lists each system credited for post-fire safe shutdown and provides a discussion regarding the availability of the system to perform its Post Fire Safe Shutdown (PFSSD) function if a severe fire occurs in this area. For a summary of the area analysis results, see Section 8.0 of the Fire Area Analysis Narrative section.

Table C-24-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-24

System	System Name	PFSSD Function*	Comments
AB	Main Steam	R, M, H, P, S	Steam generator A ARV control may be lost. Steam generator ARVs B, C and D are unaffected. Cooldown is assured using Aux Feedwater Pump B supplying steam generator D and the Turbine Driven Auxiliary Feedwater Pump supplying steam generators B and C. ABHS0080 may not be available to close the MSIVs and MSIV bypass valves. ABHS0079 is available to close the MSIVs and MSIV bypass valves.
AC	Main Turbine	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-24.
AE	Main Feedwater	H, P	All PFSSD functions associated with the main feedwater system are satisfied. Steam generator (SG) level indication is available on SG A using narrow range level transmitters AELT0517, AELT0518 and AELT0519. Steam generator level indication is available on SG D using wide range level transmitter AELT0504 and narrow range level transmitters AELT0547, AELT0548 and AELT0549. Isolate all four main feedwater isolation valves using handswitch AEHS0081.
AL	Aux. Feedwater System	H, P	All PFSSD functions associated with the auxiliary feedwater system are satisfied. Train B MDAFP is available to supply SGs A and D, however SG A ARV ABPV0001 could spuriously open and may need to be failed closed. The TDAFP is available to supply SGs B and C. Pressure transmitter/indicator ALPT0037/ALPI0037 may be affected. Auxiliary feedwater suction pressure indication is available using pressure transmitters/indicators ALPT0038/ALPI0038A and ALPT0039/ALPI0039A.
AP	Condensate Storage System	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-24.

Table C-24-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-24

System	System Name	PFSSD Function*	Comments
BB	Reactor Coolant System	R, M, H, P, S	Pressurizer PORV BBPCV0455A may open and block valve BBHV8000A may not close. If this occurs, Operators can close the PORV by placing BBHIS0455A in the CLOSE position. RCS pressure transmitter BBPT0405 could be affected. RCS pressure indication is available using BBPI0406. Pressurizer level transmitter BBLT0459 could be affected. Pressurizer level indication is available using BBLI0460A. Pressurizer pressure transmitter BBPT0455 could be affected. Pressurizer pressure transmitters BBPT0456, BBPT0457 and BBPT0458 are unaffected. Therefore, pressurizer pressure indication is available using BBPI0456, BBPI0457 and BBPI0458. Reactor head vent valve BBHV8001A could spuriously open. Loss of inventory through the head vent valves is prevented by maintaining valve BBHV8002A closed and either BBHV8001B or BBHV8002B closed. RCS Loop 1 Wide Range Cold Leg Temperature Element BBTE413B and RCS Loop 4 Wide Range Hot Leg Temperature Element BBTE443A are available. RCP thermal barrier cooling could be affected due to spurious closure of BBHV0013, BBHV0014, BBHV0015 and BBHV0016. Reactor coolant pumps A and B may not stop using the control room hand switch. RCP seal injection remains available. Therefore, the inability to stop the RCPs will have no adverse impact on PFSSD. Pressurizer spray valves BBPCV0455B and BBPCV0455C could spuriously open. If this occurs, pressurizer spray can be stopped by closing KAFV0029 using KAHIS0029 in the main control room.
BG	Chemical and Volume Control System	R, M, S	All PFSSD functions associated with the chemical and volume control system are satisfied. Train B Centrifugal Charging Pump (CCP) is available to provide charging flow from the RWST to the RCP seals through valve BGHV8357B. VCT level indicator BGLI0112 could be affected. Level indicator BGLI0185 should be used to determine VCT level. Normal charging is isolated using BGHIS8105 to close valve BGHV8105. Cables for valve BGHV8106 could be damaged. Valve BGHV8153A and either BGHV8153B or BGHV8154B are maintained closed to isolate excess letdown. Letdown isolation valves BGLCV0459 and BGLCV0460 and letdown orifice isolation valves BGHV8149A, BGHV8149B, and BGHV8149C may need to be failed closed by closing valve KAFV0029 using KAHIS0029 in the main control room. RCP seal flow indication is available using BGFI0215B. RCP seal flow indicator BGFI0215A may be affected.

Table C-24-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-24

System	System Name	PFSSD Function*	Comments
BM	Steam Generator Blowdown System	R, M, H	All PFSSD functions associated with the steam generator blowdown system are satisfied. Steam generator blowdown is isolated by closing valves BMHV0001, BMHV0002, BMHV0003 and BMHV0004 using BMHIS0001A, BMHIS0002A, BMHIS0003A and BMHIS0004A, located on the RL024 panel in the main control room.
BN	Borated Refueling Water Storage System	R, M, H	The RWST is available to provide a suction source to Centrifugal Charging Pump B via valve BNLCV0112E. RWST level indication is available using BNLI0931, BNLI0932 and BNLI0933.
EF	Essential Service Water System	H, S	All PFSSD functions associated with the essential service water system are satisfied. Train A ESW is unavailable due to damage to a number of associated components. Train B ESW is unaffected.
EG	Component Cooling Water System	S	All PFSSD functions associated with the component cooling water system are satisfied. A number of Train A CCW system components could be affected. The Train B CCW system is unaffected. CCW flow to the RCP thermal barriers could be affected as discussed in BB System comments above. CCW to RCP flow indicator EGFI0128 could be affected. CCW to RCP flow indicator EGFI0129 is unaffected. Valve EGHV0101 could be affected, preventing operation of Train A RHR. Valve EGHV0102 is unaffected.
EJ	Residual Heat Removal System	M, H, P	A number of Train A RHR components may be affected. The Train B RHR pump is unaffected but valve EJHV8701B may need to be manually opened or a cold shutdown repair made when aligning Train B RHR for shutdown cooling. The Train A RHR system could be affected. The Train B RHR system is unaffected.
EM	High Pressure Coolant Injection	R, M	All PFSSD functions associated with the high-pressure coolant injection system are satisfied. BIT inlet valve EMHV8803A may be affected but valves EMHV8801A, EMHV8801B and EMHV8803B are available to ensure an available BIT flowpath using Train B CCP. The Train A SI Pump may spuriously start but the spurious actuation will not adversely impact PFSSD since the pump will be dead headed against RCS pressure. Therefore, no inventory will be lost from the RWST. In this condition, the pump could experience cavitation damage, but this is a commercial concern, not a PFSSD concern. Operators can disconnect power to the pump by opening breaker NB0103, but this action is not required for PFSSD. SI test line valves EMHV8882 and EMHV8964 could be affected. The SI test line can be isolated by closing valve EMHV8871.
EN	Containment Spray	R, M	Containment spray pump PEN01A could spuriously start and valve ENHV0006 could open, causing flow to the containment spray nozzles. Pump PEN01A can be stopped by opening breaker NB0102 in area C-9.

Table C-24-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-24

System	System Name	PFSSD Function*	Comments
EP	Safety Injection Accumulators	H	A containment entry may be required to close SI Accumulator injection valves EPHV8808A and EPHV8808C if these valves are unresponsive from the control room. The SI accumulators need to be isolated during cold shutdown, prior to the RCS reaching 1000 psig.
FB	Auxiliary Steam	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-24.
FC	Auxiliary Turbines	R, H, P	Valve FCFV0005 may be affected. The MSIVs can be closed using all-close hand switch ABHS0079.
GD	ESW Pump House HVAC	S	Train A ESW pump room ventilation system could be affected. Train B ESW pump room ventilation system is unaffected.
GF	AFW Pump Room Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-24.
GK	Control Room and Class 1E Switchgear Room Coolers	S	Train A control room A/C unit SGK04A may be affected. Train B control room A/C unit SGK04B is unaffected. Train A Class 1E electrical equipment room A/C unit SGK05A may be affected. Train B Class 1E electrical equipment room A/C unit SGK05B is unaffected.
GL	Auxiliary Building HVAC	S	Train A CCW pump room cooler SGL11A could be affected. Train B CCW pump room cooler SGL11B is unaffected.
GM	Emergency Diesel Generator Room HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-24.
GN	Containment Coolers	S	Containment pressure transmitter GNPT0937 could be affected. Containment pressure transmitters GNPT0934, GNPT0935 and GNPT0936 are unaffected. Train A containment cooler fans SGN01A and SGN01C could be affected. Train B containment cooler fans SGN01B and SGN01D are unaffected.
JE	Diesel Fuel Oil	S	Low standpipe level switch JELSL0001C may be affected due to loss of power to RP053AC. This could prevent operation of the Train A diesel fuel oil transfer pump PJE01A on low standpipe level. The Train B diesel fuel oil transfer pump PJE01B is unaffected by a fire in this area.
KA	Instrument Air	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-24.
KC	Fire Protection	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-24.
KH	Service Gas	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-24.
KJ	Standby Diesel Engine	S	Train A diesel engine may be affected by a fire in this area. Train B diesel engine is unaffected.

Table C-24-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-24

System	System Name	PFSSD Function*	Comments
MA	Main Generation	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-24.
MR	Startup Transformer	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-24.
NB	4.16 kV System	S	Train A Class 1E 4.16 kV switchgear bus NB01 may be affected. Train B Class 1E 4.16 kV switchgear bus NB02 is unaffected.
NE	Standby Diesel Generator	S	Train A diesel generator may be affected by a fire in this area. Train B diesel generator is unaffected.
NF	Load Shed and Emergency Load Sequencing	S	The PFSSD function associated with the load shed/emergency load sequencing system is satisfied. Cables associated with one of the four undervoltage relays and degraded voltage potential transformers on Train A are run in area C-24. Cables associated with one of the four undervoltage relays and degraded voltage potential transformers on Train B are run in area C-24. Emergency load shed/sequencer operates when 2/4 UV relays sense undervoltage on the bus. Therefore, Trains A and B Load Shed and Emergency Load Sequencing will be available.
NG	480V Load Centers and MCCs	S	Loss of power to NB01 will result in a loss of power to Train A 480 V load centers and MCCs. Redundant Train B 480 V load centers and MCCs are unaffected.
NK	125VDC	S	Train A class 1E 125 VDC power could be disrupted to control room panels RL001/RL002, RL005/RL006, RL017/RL018, RL019/RL020 and RL021/RL022. Train B class 1E 125 VDC power is unaffected.
NN	120VAC	S	Train A class 1E 120 VAC power could be disrupted to control room panels RP053AC, SA036A, SB029A, SB029D, SB032A, SB038, and SE054A. Train B class 1E 120 VAC power is unaffected.
PA	13.8kV	S	Breakers PA0105 and PA0106 could be affected by a fire in this area. Redundant capability is available.
PB	4.16kV	H, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-24.
PG	480V Load Centers and MCCs	S	Loss of all power on bus NB01 will result in Separation Group 5 PG busses losing power. Off-site and on-site power to NB02 and Separation Group 6 PG busses are unaffected. Breaker PG1901 could be affected. Redundant capability is available.
PK	125VDC	S	Battery charger PK21 could be affected. Battery charger PK22 is unaffected.
PL	Local Instrument Panels	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-24.

Table C-24-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-24

System	System Name	PFSSD Function*	Comments
PN	120VAC	S	Power to non-class 1E 120 VAC switchboard PN07 may be affected. Non-class 1E 120 VAC switchboard PN08 is unaffected.
QB	Standby AC Lighting	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-24.
QD	Emergency Lighting	S	The 125 VDC emergency lights in the control room could be affected. Self-contained battery powered lighting units are available to provide lighting in the control room.
RL	Control Room MCB	S	Train A class 1E 125 VDC power could be disrupted to control room panels RL001/RL002, RL005/RL006, RL017/RL018, RL019/RL020 and RL021/RL022. Train B class 1E 125 VDC power is unaffected. Separation group 5 non class 1E 125 VDC power could be disrupted to control room panels RL001/RL002, RL013/RL014 and RL017/RL018. Separation group 5 non class 1E 120 VAC power could be disrupted to control room panels RL017/RL018, RL021/RL022 and RL023/RL024. Separation group 6 non class 1E 125 VDC power and non-class 1E 120 VAC power remains available.
RP	Miscellaneous Control Panels	R, M, H, P, S	Train A components and cables associated with this system could be affected. Train B components and cables associated with this system are unaffected. Power to panel RP043 could be affected. See SC system discussion for details. 120 VAC power to panel RP053A could be affected. Power to panels RP053B, RP053D and RP147 is unaffected. The Train A PFSSD functions associated with panels RP060, RP068, RP211 and RP330 could be affected. Redundant capability exists and is unaffected by a fire in this area.
SA	ESFAS	S	Auxiliary feedwater low suction pressure (LSP) signal monitored by panel SA036A could be affected. Auxiliary feedwater LSP signals monitored by panels SA036B and SA036C are unaffected. Status indication of Train A class 1E electrical equipment room A/C unit SGK05A at status panel SA066A could be affected. Status indication of control room A/C unit SGK04A and associated dampers GKHZ0029A and GKHZ0029B could be affected. Status indication of redundant Train B components is unaffected.
SB	Reactor Protection System	R, S	A loss of power to input channel 1 in SB029A and SB032A could occur. Input channels 2, 3 and 4 remain available. Train A output cabinet 2 (SB029D) could lose power. Train A reactor trip switchgear SB0102A could be affected such that a reactor trip occurs or a manual trip on Train A is prevented. Train B output cabinets and Train B reactor trip switchgear cabinet are unaffected.
SC	Reactor Instrumentation	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-24.

Table C-24-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-24

System	System Name	PFSSD Function*	Comments
SE	Ex-Core Neutron Monitoring	R, P	Source range monitor SENE0031, SR monitor signal processor SENY0060B could be affected. Source range monitoring remains available using SENE0032 and SENY0061A/B.
SY	Switchyard	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-24.
UU	Supervisory System	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-24.

* R - Reactivity Control; M - Reactor Coolant Makeup; H - Decay Heat Removal; P - Process Monitoring; S - Support Function

3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD

This section describes operator actions that may need to be performed inside or outside the control room to achieve and maintain hot standby if a fire occurs in area C-24. This section also describes cold shutdown repairs that may need to be made to achieve and maintain cold shutdown conditions. Operator actions are proceduralized in OFN KC-016.

3.1 ACTIONS OUTSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

Operator Manual Actions (OMAs) are those actions outside the main control room required to achieve and maintain hot standby. OMAs are identified in E-1F9900 and were determined from thermal hydraulic analysis WCNOC-CP-002. Applicable E-1F9900 OMAs are annotated herein. All other actions outside the control room are desirable for plant control in support of hot standby but not required to achieve and maintain hot standby.

3.1.1 Steam Generator ARVs

It may be necessary to fail close ABPV0001 by isolating air and nitrogen to the valve using KAV1435 (air) and KAV1364 (Nitrogen) then venting air from the regulator. These valves are located in area A-23 and emergency lighting is available.

3.1.2 **Containment Spray** (OMA, refer to E-1F9900)

Containment spray pump PEN01A could spuriously start and valve ENHV0006 could open, causing containment spray. The pump can be stopped by opening breaker NB0102 in area C-9.

3.2 ACTIONS INSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

3.2.1 Main Steam Isolation Valves and MSIV Bypass Valves

The capability to isolate the MSIVs and bypass valves using handswitch ABHS0080 may be affected. The MSIVs and bypass valves can be isolated using handswitch ABHS0079.

3.2.2 Main Feedwater Isolation Valves

The capability to isolate the MFIVs using handswitch AEHS0080 may be affected. Isolate the MFIVs using handswitch AEHS0081.

3.2.3 Auxiliary Feedwater

If steam generator A ARV ABPV0001 control is lost, use the Turbine Driven Auxiliary Feedwater Pump (TDAFP) to supply steam generators B and C and control steam release using ARVs ABPV0002 and ABPV0003. Alternatively, the Train B Motor Driven Auxiliary Feedwater Pump (MDAFP) is available to supply steam generator D in conjunction with the TDAFP feeding either SG B or SG C.

3.2.4 Component Cooling Water

Train A CCW could be affected by a fire in this area. If this occurs, swap to Train B CCW using normal operating procedures if Train B CCW is not already running. Loss of CCW flow to the RCP thermal barriers can be diagnosed using flow indicator EGFI0129 on panel RL020.

3.2.5 Reactor Coolant Pump Seal Cooling

Thermal barrier cooling could be affected. RCP seal injection could temporarily be disrupted until the Train B CCP is lined up. The Train B CCP can be started and lined up from the control room. RCP seal flow indication is available using BGFI0215B.

3.2.6 Pressurizer PORV/Block Valve

Pressurizer PORV BBPCV0455A could spuriously open and block valve BBHV8000A may not close. If this occurs, Operators can close the PORV by placing BBHIS0455A in the CLOSE position. Pressurizer pressure indication is available using BBPI0456, BBPI0457 and BBPI0458 located on RL002.

3.2.7 Normal Pressurizer Spray

Pressurizer spray valves BBPCV0455B and BBPCV0455C could spuriously open. If this occurs, the spray can be stopped by isolating air to the valves. This can be accomplished by depressing the CLOSE push button on KAHIS0029 to close KAFV0029. KAHIS0029 is located on RL024. Pressurizer pressure indication is available using BBPI0456, BBPI0457 and BBPI0458.

3.2.8 Isolation of Letdown

A fire in area C-24 could prevent valves BGLCV0459, BGLCV0460, BGHV8149A, BGHV8149B, and BGHV8149C from being closed using their associated control room hand switches. If this occurs, the valves can be closed by isolating air to the valves. This can be accomplished by depressing the CLOSE push button on KAHIS0029 to close KAFV0029. KAHIS0029 is located on RL024. Pressurizer level indication is available using BBLI0460A.

3.3 ACTIONS TO ACHIEVE AND MAINTAIN COLD SHUTDOWN

3.3.1 Safety Injection Accumulators

A containment entry may be required to close SI Accumulator injection valves EPHV8808A and EPHV8808C if these valves are unresponsive from the control room. The SI accumulators need to be isolated during cold shutdown, prior to the RCS reaching 1000 psig.

3.3.2 Residual Heat Removal

Valve EJHV8701B may need to be manually opened or a cold shutdown repair made when aligning Train B RHR for shutdown cooling.

4.0 CONCLUSION

With some exceptions, redundant Post Fire Safe Shutdown capability exists if a severe fire occurs in area C-24. For those exceptions, feasible manual actions are available and are unaffected by the fire. Manual actions are documented in Section 3.0.

5.0 DETAILED ANALYSIS

This section describes the detailed component-by-component and cable-by-cable analysis for a fire in area C-24.

5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA C-24

There are no PFSSD components located in area C-24. This fire area only contains cables associated with PFSSD equipment located in other areas.

5.2 PFSSD CABLE EVALUATION

Table C-24-3 lists all the PFSSD cables (S. in E-15000) located in fire area C-24. The applicable evaluation section is also listed in Table C-24-3.

Table C-24-3
PFSSD Cables Located in Fire Area C-24

Cable #	Location	Primary PFSSD Equipment	Cable Function (P) Power (C) Control (I) Instrumentation	Evaluation Section	Comments

5.2.1 Steam Generator Atmospheric Relief Valves

PFSSD requires at least two steam generator atmospheric relief valves (ARV) be controlled and the other two closed. The ARVs are pneumatically operated using air from the compressed air system (KA) or nitrogen from the nitrogen accumulators. The valves open by pneumatic pressure and close by spring action. The valves are automatically controlled by a pressure transmitter input signal from a pressure transmitter installed on the outlet side of the steam generator. Alternatively, each valve can be controlled manually from the control room or the auxiliary shutdown panel by placing the pressure indicating controller (PIC) in manual.

As discussed in Section 5.2.7, a fire in area C-24 could damage cables and equipment associated with the Train A Motor Driven Auxiliary Feedwater Pump (MDAFP). The Turbine Driven Auxiliary Feedwater Pump (TDAFP) and the Train B MDAFP are available. The TDAFP can be lined up to feed steam generators B and C while the Train B MDAFP can be used to supply auxiliary feedwater to Steam Generators A and D.

Cables associated with steam generator A ARV ABPV0001 are run in this area. Damage to these cables could prevent control or isolation of the ARV. A single open ARV is bounded by the main steamline break analysis. If necessary, ABPV0001 can be failed closed by isolating air and nitrogen to the valve using KAV1435 (air) and KAV1364 (nitrogen) then venting air from the regulator. These valves are located in area A-23 and emergency lighting is available.

Steam generator ARVs ABPV0002, ABPV0003 and ABPV0004 are unaffected by a fire in this area and remain available to control steam release through steam generators B, C and D.

If ARV ABPV0001 control is lost, cooldown can be performed using the TDAFP, taking suction from the Train B ESW system and supplying steam generators B and C. Alternatively, the Train B MDAFP can be used to supply AFW to steam generator D and the TDAFP can be used to supply AFW to either steam generators B or C.

Up to three ARVs can fail closed or open without impacting ability to achieve and maintain hot standby according to thermal hydraulic analysis WCNOC-CP-002. With at least one ARV unaffected, no E-1F9900 OMA is required to address ARV closure or control. Reference Attachment 4, MSO Evaluation Scenario ID PWROG 23.

5.2.2 Safety Injection and Containment Spray

A spurious safety injection signal (SIS) could cause the safety injection pumps to operate. A spurious containment spray actuation signal (CSAS) could cause the containment spray pumps to operate, depleting inventory in the RWST. These conditions are not desirable for PFSSD at Wolf Creek.

Safety injection (SI) is initiated automatically by any of the following conditions:

1. Two out of three high containment pressures monitored by pressure transmitters GNPT0934, GNPT0935 and GNPT0936.
2. Two out of four low pressurizer pressures monitored by pressure transmitters BBPT0455, BBPT0456, BBPT0457 and BBPT0458.
3. Two out of three low steam line pressures on any steam generator monitored by ABPT0514, ABPT0515 and ABPT0516 on SG A; ABPT0524, ABPT0525 and ABPT0526 on SG B; ABPT0534, ABPT0535 and ABPT0536 on SG C; and ABPT0544, ABPT0545 and ABPT0546 on SG D. Two out of three logic must be satisfied on a single steam generator line. Low pressure on a single pressure transmitter co-incident with low pressure on another pressure transmitter on a different steam generator line will not initiate SIS.

Containment spray (CS) is initiated automatically by two out of four high containment pressures monitored by pressure transmitters GNPT0934, GNPT0935, GNPT0936 and GNPT0937.

Cables associated with ABPT0514, ABPT0524, ABPT0534, ABPT0544, BBPT0455 and GNPT0937 are run in area C-24. Cables associated with the remaining transmitters do not run in area C-24. Consequently, a spurious CSAS and SIS cannot occur if a fire occurs in area C-24.

5.2.3 Main Steam Isolation Bypass Valves

Each of the four MSIV bypass valves (ABHV0012, ABHV0015, ABHV0018 and ABHV0021) has two redundant solenoids that control the position of the associated bypass valve. The bypass valves are normally closed with the solenoids de-energized. Both solenoids need to be energized to open the valve. One of the solenoids on each valve is on separation group 1 (Train A) and is controlled by handswitch ABHS0080. The other solenoid on each valve is on separation group 4 (Train B) and is controlled by handswitch ABHS0079.

Cable 11ABK23AE is associated with steam line isolation signal relay K627. Upon receipt of a steam line isolation signal, the relay contact opens and the bypass valves close. An open circuit in one of the two conductors will produce the same result as a steam line isolation signal, which is desired for PFSSD. A hot short between the conductors will bypass the contact and prevent a steam line isolation signal from closing the valves.

Cable 11ABK23AF is associated with handswitch ABHS0080 on the Train A MSIV bypass valve control circuit. An open circuit in one of the two conductors will de-energize the respective solenoid and close the bypass valves. A hot short between the conductors will bypass the handswitch contact and prevent closure of the valves using the handswitch.

Cable 11ABK23AG is associated with MSIV bypass valves ABHV0012, ABHV0015, ABHV0018 and ABHV0021. The bypass valves are normally closed, which is the desired PFSSD position. In order for the valves to spuriously open, both solenoids on the air line need to be energized. An external cable hot short on cable 11ABK23AG could energize the Train A solenoids but the Train B solenoids are unaffected by a fire in area C-24. In addition, hand switch ABHS0079 is available to ensure the bypass valves are closed. Therefore, a fire in area C-24 will not affect the ability to isolate the MSIV bypass valves.

Redundant means are available to ensure the MSIV bypass valves are closed. Handswitch ABHS0079 is unaffected by the fire and can be used to ensure one of the two solenoids on each bypass valve is de-energized.

References: E-15000, XX-E-013, E-13AB23A, E-13AB23B, E-1F9101, M-12AB02

5.2.4 Steam Generator Main Steam Isolation Valves (MSIVs)

PFSSD requires the MSIVs be closed to prevent reactivity addition due to uncontrolled cooldown. The MSIVs are closed from the control room using all close hand switches ABHS0079 or ABHS0080.

Each MSIV is designed to utilize system fluid (main steam) as the motive force to open and close. The valve actuation (open or close) is accomplished through positioning a series of six electric solenoid pilot valves to either direct the system fluid to the Upper Piston Chamber (UPC) and/or the Lower Piston Chamber (LPC), or vent either or both piston chambers. The six solenoid pilot valves are divided into two trains (3 per train) that are independently powered and controlled. Either train can independently perform the PFSSD function to close the valve

and isolate main steam. This is done by actuating either all close hand switch ABHS0079 (separation group 4) or ABHS0080 (separation group 1) to de-energize the associated solenoid valves.

The following table identifies the solenoids and associated control cables for each hand switch.

MSIV	ABHS0079 (Sep Group 4)		ABHS0080 (Sep Group 1)	
	Solenoids	Cable	Solenoids	Cable
ABHV0011	MV2, MV4, MV6	14ABK28BH	MV1, MV3, MV5	11ABK29BH
ABHV0014	MV2, MV4, MV6	14ABK29AH	MV1, MV3, MV5	11ABK28AH
ABHV0017	MV2, MV4, MV6	14ABK28AH	MV1, MV3, MV5	11ABK29AH
ABHV0020	MV2, MV4, MV6	14ABK29BH	MV1, MV3, MV5	11ABK28BH

All 4 cables associated with the 12 separation group 1 solenoid valves are run in area C-24. Cable damage due to a fire will likely result in disruption of power to the solenoids, which will close the valves. The four separation group 4 cables associated with hand switch ABHS0079 are unaffected by a fire in area C-24. Therefore, hand switch ABHS0079 is available to close the four MSIVs.

Cable 11ABK30BB provides 125 VDC power to Train A main steam and feedwater isolation system (MSFIS) actuation cabinet SA075A from NK5119. Damage to this cable would disrupt power to the separation group 1 solenoids and close the MSIVs, which is the desired PFSSD position. In addition, the Train B MSFIS is unaffected by the fire and ABHS0079 is available to close the MSIVs.

Cable 15RLY01HA supplies 120 VAC power to MCB RL023/RL024 miscellaneous circuits from PG19GCR217. Several loads are supplied by this power supply, but only eight are PFSSD components. These are ABLV0051, ABLV0053, ABFV0023, ABFV0025, ABFV0027, ABFV0029, FCHV0003, and ABHIS0032 which are components downstream of the Main Steam Isolation Valves (MSIVs). Loss of power to ABLV0051, ABLV0053, ABFV0023, ABFV0025, ABFV0027, ABFV0029 and FCHV0003 could fail the valves open. Loss of power to ABHIS0032 will cause a loss of handswitch indicator lights. However, a fire in area C-24 does not affect the ability to close the MSIVs and MSIV bypass valves using handswitch ABHS0079 in the main control room. Therefore, the MSIV downstream components can fail in an undesired position without any consequence on PFSSD.

Based on the above discussion, hand switch ABHS0079 is available to close the MSIVs in the event of a fire in area C-24.

References: E-15000, XX-E-013, E-13AB23A, E-13AB23B, E-13AB26, E-13AB27, E-13AB28, E-13AB29, E-13AB30, E-13RL01, E-13RL07, E-1F9101, E-1F9103, J-104-00295, J-104-00296, M-12AB02

5.2.5 Steam Generator Level Indication

The decay heat removal function for PFSSD requires the use of two RCS loops and two Steam Generators. Steam generator (SG) level indication is required to support this function. A fire in area C-24 credits MDAFP B supplying SG D and the TDAFP supplying either SG B or C. As discussed in Section 5.2.1, steam generator A ARV ABPV0001 control could be lost.

Cables associated with SG level transmitters AELT0501 (SG A WR), AELT0551 (SG A NR), AELT0529 (SG B NR), AELT0539 (SG C NR) and AELT0554 (SG D NR) are run in area C-24. Damage to these cables due to a fire will prevent indication on the associated level indicators in the control room. Alternate level indication remains available on all four SGs using the following level indicators:

Steam Generator	Available Level Indication
A	AELI0517 (NR), AELI0518 (NR), AELI0519 (NR)
B	AELI0502 (WR), AELI0527 (NR), AELI0528 (NR), AELI0552 (NR)
C	AELI0503 (WR), AELI0537 (NR), AELI0538 (NR), AELI0553 (NR)
D	AELI0504 (WR), AELI0547 (NR), AELI0548 (NR), AELI0549 (NR)

Based on the above discussion, level indication on all four steam generators is assured if a fire occurs in area C-24.

References: E-15000, XX-E-013, E-1F9203, E-13AE08, E-13AE12, M-12AE02

5.2.6 Steam Generator Main Feedwater Isolation Valves

PFSSD requires that either the main feedwater isolation valves (MFIVs) be closed, or the main feedwater pumps be stopped to prevent overfilling the steam generators. Flow diversion from auxiliary feedwater (AFW) to the main feedwater system piping is prevented by check valves AEV0420, AEV0421, AEV0422 and AEV0423. Closure of the main feedwater isolation valves is not required to prevent AFW flow diversion.

Each MFIV is designed to utilize system fluid (feedwater) as the motive force to open and close. The valve actuation (open or close) is accomplished through positioning a series of six electric solenoid pilot valves to either direct the system fluid to the Upper Piston Chamber (UPC) and/or the Lower Piston Chamber (LPC), or vent either or both piston chambers. The six solenoid pilot valves are divided into two trains (3 per train) that are independently powered and controlled. Either train can independently perform the PFSSD function to close the valve and isolate main feedwater. This is done by actuating either all close hand switch AEHS0080 (separation group 1) or AEHS0081 (separation group 4) to de-energize the associated solenoid valves.

The following table identifies the solenoids and associated control cables for each hand switch.

MFIV	AEHS0080 (Sep Group 1)		AEHS0081 (Sep Group 4)	
	Solenoids	Cable	Solenoids	Cable
AEFV0039	MV1, MV3, MV5	11AEK16AH	MV2, MV4, MV6	14AEK17AH
AEFV0040	MV1, MV3, MV5	11AEK17AH	MV2, MV4, MV6	14AEK16AH
AEFV0041	MV1, MV3, MV5	11AEK16BH	MV2, MV4, MV6	14AEK17BH
AEFV0042	MV1, MV3, MV5	11AEK17BH	MV2, MV4, MV6	14AEK16BH

All 4 cables associated with the 12 separation group 1 solenoid valves are run in area C-24. Cable damage due to a fire will likely result in disruption of power to the solenoids, which will close the valves. The four separation group 4 cables associated with hand switch AEHS0081 are unaffected by a fire in area C-24. Therefore, hand switch AEHS0081 is available to close the four MFIVs.

Cable 11ABK30BB provides 125 VDC power to Train A main steam and feedwater isolation system (MSFIS) actuation cabinet SA075A from NK5119. Damage to this cable would disrupt power to the separation group 1 solenoids and close the MFIVs, which is the desired PFSSD position. In addition, the Train B MSFIS is unaffected by the fire and AEHS0081 is available to close the MFIVs.

Based on the above discussion, MFIV isolation is assured using hand switch AEHS0081.

References: E-15000, XX-E-013, E-13AB30, E-13AE14, E-13AE15, E-13AE16, E-13AE17, E-1F9201, J-104-00295, J-104-00296, M-12AE02, M-630-00044

5.2.7 Auxiliary Feedwater

The PFSSD design requires the use of one auxiliary feedwater pump (AFP) supplying water to at least two steam generators. The turbine driven auxiliary feedwater pump (TDAFP) is normally aligned to supply all four steam generators. The Train A motor driven auxiliary feedwater pump (MDAFP) is aligned to supply steam generators B and C. The Train B MDAFP is aligned to supply steam generators A and D.

The normal source of water to the AFPs is the condensate storage tank (CST). The emergency supply is from the essential service water (ESW) system. For commercial concerns, the CST is the preferred source and contains sufficient volume to supply the entire auxiliary feedwater (AFW) demand to achieve cold shutdown.

Motor operated valves (MOVs) in the system allow operators to line up the AFW system as required to achieve and maintain safe shutdown. Damage to the MOV circuits due to a fire could prevent operators from lining up the system from the control room.

Several PFSSD cables associated with various components of the AFW system (AL) run through fire area C-24. These cables are identified in Table C-24-3. All cables are associated with Train A (separation group 1). There are no Train B (separation group 4) cables associated with the AFW system running through area C-24.

Damage to the Train A cables listed in Table C-24-3 could prevent operation of Train A MDAFP. However, Train B MDAFP and the TDAFP are unaffected by a fire in area C-24. The suction source to the Train B MDAFP is available from the CST and Train B ESW. The suction source to the TDAFP is available from Train B ESW only. The TDAFP is available to supply AFW to steam generators B and C but the capability of the TDAFP to supply steam generators A and D could be affected.

Condensate storage tank pressure transmitters ALPT0037, ALPT0038 and ALPT0039 are included in the PFSSD design because they initiate swapover to ESW upon 2/3 low CST pressure indications. Panels SA036A, SA036B and SA036C monitor pressure transmitter signals on ALPT0037, ALPT0039 and ALPT0038, respectively. A spurious low CST pressure due to fire damage to cables associated with two of these pressure transmitters could swap the water source to ESW. This is only a commercial concern and should be prevented if possible.

Cable 11ALI08AA is an instrument cable associated with ALPT0037. Cables associated with the remaining two pressure transmitters are not run in C-24. Therefore, swapover to ESW due to spurious low CST pressure is not feasible if a fire occurs in this area.

Cable 11SAK21AA supplies 125 VDC power to panel SA036A from NK5110. Cable 11SAY21AA supplies 120 VAC power to panel SA036A from NN0103. Damage to these cables could result in a loss of power to the panel and could prevent automatic operation of Train A low suction pressure (LSP) swapover. Power cables associated with LSP signals controlled by panels SA036B and SA036C are unaffected by a fire in this area.

As discussed in Section 5.2.1, steam generator A ARV control could be lost. Therefore, it may be necessary to isolate steam generator A ARV and cooldown using steam generators B, C and/or D.

Based on the above discussion, auxiliary feedwater is assured if a fire occurs in area C-24 using Train B MDAFP supplying auxiliary feedwater to steam generator D and the TDAFP supplying AFW to steam generators B and C.

References: E-15000, XX-E-013, E-13AL01A, E-13AL01B, E-13AL02A, E-13AL02B, E-13AL03A, E-13AL03B, E-13AL04A, E-13AL04B, E-13AL05A, E-13AL05B, 13AL07A, E-13AL08, E-13AL09, E-13SA21, E-1F9202, E-1F9203, E-1F9204, E-1F9402A, E-1F9402B, J-10SA, M-12AL01

5.2.8 Pressurizer PORVs and Block Valves

PFSSD requires that either the pressurizer power operated relief valve (PORV) or its associated block valve be closed. Cables and components associated with PORV BBPCV0455A and associated block valve BBHV8000A are run through area C-24. Cables and components associated with PORV BBPCV0456A and associated block valve BBHV8000B are not located in area C-24.

The pressurizer PORVs are not considered high/low pressure interfaces. The valves are supplied power by an ungrounded 125 VDC system. Therefore, based on GL 86-10, consideration of multiple proper polarity hot shorts is not required. A single proper polarity hot short still needs to be considered.

In the event a fire causes BBPCV0455A to open and damages BBHV8000A cables, Operators can close BBPCV0455A by placing hand switch BBHIS0455A, located on RL021, in the close position. Pressurizer level and RCS pressure indication are available to diagnose a failed open PORV using BBLI0460A and BBPI0406, respectively. In addition, pressurizer pressure indication is available using BBPI0456, BBPI0457 and BBPI0458.

Instrument cable 11BBI16KB associated with pressurizer pressure transmitter BBPT0455 is run in fire area C-24. Damage to this cable could send a spurious high-pressure signal to the pressurizer master controller. However, as discussed in Calculation XX-E-013, Appendix 1, damage to a single pressure channel will not cause the spurious operation of the pressurizer PORVs.

Based on the above discussion, pressurizer PORV BBPCV0455A could spuriously open due to damage to the PORV control cables. The PORV can be closed using hand switch BBHIS0455A in the main control room.

References: E-15000, XX-E-013, E-13BB16, E-13BB39, E-13BB40, E-1F9201, E-1F9301, M-12BB02, CR 13079, DCP 12944, DCP 13324

5.2.9 Reactor Coolant System (RCS) Pressure Indication

The PFSSD design requires RCS pressure indication to be available. RCS pressure indication is provided in the control room using BBPT0405/BBPI0405 or BBPT0406/BBPI0406. Cable 11BBI15EB, associated with BBPT0405, runs through fire area C-24 and could be damaged by a fire.

Redundant RCS pressure transmitter BBPT0406 is unaffected by a fire in area C-24. Therefore, RCS pressure indication is available using BBPT0406/BBPI0406.

References: E-15000, XX-E-013, E-13BB15, E-13BB16, E-1F9201, E-1F9205, M-12BB04

5.2.10 RCS Hot and Cold Leg Temperature Elements

PFSSD requires RCS hot and cold leg temperature indication on at least one loop to verify flow through the steam generators. The temperature elements used for this purpose are listed in the following table.

As identified in Table C-24-3, cables associated with RCS temperature elements BBTE0413A, BBTE0423A, BBTE0433B and BBTE0443B are run in area C-24. A fire could damage these cables and prevent temperature indication on the four temperature elements. Consequently, temperature indication on at least one leg on each loop could be lost, which is not in accordance with the PFSSD methodology at Wolf Creek.

RCS Hot and Cold Leg Temperature Elements Used for PFSSD	
COMPONENT	**FUNCTION**
BBTE0413A	RCS Hot Leg Temperature Element (WR) Loop 1
BBTE0413B	RCS Cold Leg Temperature Element (WR) Loop 1
BBTE0423A	RCS Hot Leg Temperature Element (WR) Loop 2
BBTE0423B	RCS Cold Leg Temperature Element (WR) Loop 2
BBTE0433A	RCS Hot Leg Temperature Element (WR) Loop 3
BBTE0433B	RCS Cold Leg Temperature Element (WR) Loop 3
BBTE0443A	RCS Hot Leg Temperature Element (WR) Loop 4
BBTE0443B	RCS Cold Leg Temperature Element (WR) Loop 4

Cable 15RLY01EA supplies 120 VAC power from PN0738 to RL021/RL022. The power splits at RL021/RL022 and supplies power to PFSSD component BBTR0423 as well as some non-PFSSD components. This temperature recorder provides indication of RCS hot and cold leg temperature on loop 2.

Procedure EMG ES-04, Attachment B Section B1 provides alternate indication in the control room that may be used to verify natural circulation flow. One of these methods verifies that steam generator pressure is stable or decreasing. Based on Sections 5.2.1 and 5.2.7, cooldown can be performed using loops 2, 3 and 4. Based on Section 5.2.2, S/G B pressure instruments ABPT0525 and ABPT0526; S/G C pressure instruments ABPT0535 and ABPT0536; and S/G D pressure instruments ABPT0545 and ABPT0546 are unaffected by a fire in C-24. These pressure instruments, along with their respective indicators in the control room, can be used, per EMG ES-04, to verify heat removal in loops 2, 3 and 4.

The configuration is acceptable because, in the event of a fire in area C-24, cooldown can be performed using RCS loops 2, 3 and 4. The associated indicating devices for RCS wide range hot and cold leg temperature elements (BBTE0423B, BBTE0433A and BBTE0443A) as well as ABPT0525, ABPT0526, ABPT0535, ABPT0536, ABPT0545 and ABPT0546 will provide indication of flow through the steam generators.

References: E-15000, XX-E-013, E-13BB15, E-13RL01, E-13RL06, E-1F9201, M-12AB01, M-12BB01, EMG ES-04

5.2.11 Pressurizer Level Transmitters

PFSSD requires pressurizer level indication to be available. Level transmitters BBLT0459 and BBLT0460 provide pressurizer level indication. A cable associated with BBLT0459 runs through area C-24 and could be damaged, causing inoperability of BBLT0459 and its associated level indicator (BBLI0459A). Cables for BBLT0460/BBLI0460A do not run through fire area C-24.

Pressurizer level indication is available using BBLT0460/BBLI0460A if a fire occurs in area C-24.

References: E-15000, XX-E-013, E-13BB16, E-1F9301, M-12BB02

5.2.12 Reactor Head Vent Valves

PFSSD requires that one of the two reactor vessel head vent valves on each flow path (2 flow paths total) be closed to prevent uncontrolled depressurization of the RCS. Either BBHV8001A or BBHV8002A and either BBHV8001B or BBHV8002B needs to be closed.

A cable associated with head vent valve BBHV8001A runs through C-24. Cables for the remaining valves are unaffected. Therefore, the reactor head vent flow path will remain isolated throughout the event.

References: E-15000, XX-E-013, E-1F9301, E-13BB30, M-12BB04

5.2.13 Centrifugal Charging System

At least one centrifugal charging pump (CCP) is required for PFSSD to provide RCP seal cooling, reactivity control and inventory control. These functions are accomplished using a CCP taking suction from the refuelling water storage tank (RWST) and injecting through the RCP seals. RCP seal injection provides approximately 20 gpm makeup to the RCS and provides adequate boron concentration to maintain sub-critical reactivity conditions. If RCP seal injection is unavailable, reactivity and inventory control is provided by lining up the CCPs to the boron injection tank (BIT). The normal charging pump (NCP) is not credited and is assumed lost.

A control cable associated with Train A Centrifugal Charging Pump (CCP) runs through area C-24. Damage to this cable could prevent operation of the pump. Redundant Train B CCP cables are run in a separate fire area and are unaffected by a fire in this area.

Control cables associated with Train A CCP miniflow valve BGHV8110 are run through area C-24. Redundant Train B cables for miniflow valve BGHV8111 are run in a different area and are unaffected by a fire in area C-24.

Cable 11BGG52AC associated with Train A RCP seal injection flow throttling valve BGHV8357A is run in area C-24. Damage to this cable will prevent operation of the valve from the control room. PFSSD requires RCP seal injection using an available centrifugal charging pump and flowing through the associated throttling valve. Cables associated with redundant Train B valve BGHV8357B are run in a separate fire area and are unaffected by a fire in area C-24.

Cable 11BGI51AA is associated with RCP seal total flow transmitter BGFT0215A. Damage to this cable could prevent operation of the flow transmitter and could prevent operators from determining total RCP seal flow using flow indicator BGFI0215A. Flow indicator BGFI0215B is unaffected by a fire in area C-24 and can be used by operators to determine if seal flow is functioning.

Based on the above discussion, PFSSD is assured using Train B charging pump and aligning RCP seal injection flow through BGHV8357B. Operators can use flow indicator BGFI0215B to diagnose a loss of RCP seal injection in the event of a loss of the operating charging pump.

References: XX-E-013, E-15000, E-13BG01, E-13BG11B, E-13BG51, E-13BG52, E-1F9102, E-1F9302, E-1F9401A, M-12BG03

5.2.14 Charging Flow to Regenerative Heat Exchanger Isolation Valves

PFSSD requires charging flow to be directed to the RCP seals. To ensure adequate flow to RCP seals, flow diversion to the regenerative heat exchanger needs to be prevented. Valves BGHV8105 and BGHV8106 are included in the PFSSD design to perform this function. Manual valve BG8402B is also included to provide an alternate means of closing this flow path if either BGHV8105 or BGHV8106 are unavailable and is also used during alternate safe shutdown per OFN RP-017.

Cables associated with BGHV8106 are run in area C-24 and could be damaged by a fire, preventing valve BGHV8106 from being closed from the control room. Cables associated with redundant valve BGHV8105 do not run in area C-24. Consequently, valve BGHV8105 can be isolated from the control room if a fire occurs in area C-24.

References: E-15000, XX-E-013, E-13BG11A, E-1F9102, E-1F9302, M-12BG03

5.2.15 Volume Control Tank (VCT)

Power and control cables associated with VCT valve BGLCV0112B run through fire area C-24. Cables for redundant VCT valve BGLCV0112C are run in a separate fire area and are unaffected by a fire in area C-24. The PFSSD position of these valves is at least one closed. Therefore, PFSSD can be accomplished by isolation of BGLCV0112C.

A hot short could cause inadvertent closure of BGLCV0112B. If this occurs prior to establishing suction from the RWST, damage to the operating charging pump could occur due to loss of suction. The assumptions in calculation XX-E-013 state that systems and components are in their normal operating position or status prior to the fire. The Normal Charging Pump (NCP) is the normally operated pump and is assumed to be operating at the time of the fire. Inadvertent closure of valve BGLCV0112B with no suction from the RWST would result in damage to the NCP but the centrifugal charging pumps would remain unaffected. As stated in 5.2.13, the A Train CCP could be unavailable but the B Train CCP is unaffected by the fire.

A cable (11BGI51CA) associated with VCT level transmitter BGLT0112 runs through area C-24. A false low-low level signal associated with this level transmitter could initiate refueling water sequence, which is the desired PFSSD lineup. Damage to this cable could also cause a spurious VCT level indication on BGLI0112 in the control room. Cables associated with VCT level transmitter BGLT0185 are unaffected by the fire and BGLI0185 will provide reliable level indication in the control room.

Based on the above discussion, a fire in area C-24 that affects components associated with the VCT will not adversely impact the ability to achieve and maintain PFSSD.

References: XX-E-013, E-15000, E-13BG12, E-13BG12A, E-13BG51, E-13BN01, E-1F9102, E-1F9302, M-12BG03

5.2.16 Excess Letdown Isolation Valves

PFSSD requires the excess letdown path be isolated to prevent uncontrolled depressurization of the RCS. To accomplish this, either normally closed valve BGHV8153A or BGHV8154A must be maintained closed and either normally closed valve BGHV8153B or BGHV8154B must be maintained closed.

A cable associated with valve BGHV8154A is run in area C-24. Cables associated with remaining excess letdown valves are not run in area C-24. Therefore, excess letdown will remain isolated throughout the event.

References: E-15000, XX-E-013, E-13BG48, E-1F9301, M-12BG01

5.2.17 Refueling Water Storage Tank (RWST) to Charging Pumps Suction Isolation Valves

Cables associated with RWST to CCP A valve BNLCV0112D run through fire area C-24. As stated earlier, the Train A CCP may not be available if a fire occurs in area C-24. Therefore, the Train B CCP is used, taking suction from the RWST. Cables associated with valve BNLCV0112E are unaffected by a fire in area C-24. Therefore, BNLCV0112E can be opened from the control room to provide the necessary suction from the RWST to Train B CCP.

References: E-15000, XX-E-013, E-13BN01, E-1F9102, E-1F9302, M-12BN01

5.2.18 Refueling Water Storage Tank (RWST) and Containment Sump Isolation Valves

To prevent draindown of the RWST into the containment sump, PFSSD requires that either valve BNHV8812A or valve EJHV8811A and valve BNHV8812B or valve EJHV8811B be closed during hot standby. For cold shutdown, the operating train containment sump valve (EJHV8811A or EJHV8811B) must be maintained closed to prevent flow diversion from the RCS to the containment sump. Valves BNHV8812A and BNHV8812B are normally open and valves EJHV8811A and EJHV8811B are normally closed.

A control cable for valve BNHV8812A runs through fire area C-24. Damage to this cable could prevent closing this valve from the control room and could prevent the valve from automatically closing when valve EJHV8811A reaches full open position.

A control cable (11EJG06AC) associated with valve EJHV8811A runs through fire area C-24. Damage to this cable will not result in valve EJHV8811A opening as long as valve BNHV8812A remains open. If valve BNHV8812A is fully closed, it will provide a permissive for valve EJHV8811A to open. If valve EJHV8811A opens due to damage to cable 11EJG06AC, draindown will not occur since valve BNHV8812A is closed.

The instrument cable for RWST level transmitter BNLT0930 runs through area C-24. Cables for the remaining three RWST level transmitters are available. Therefore, RWST level indication is available using BNLI0931, BNLI0932 and BNLI0933.

Based on the above discussion, draindown of the RWST to the containment sump is not credible if a fire occurs in area C-24.

References: E-15000, XX-E-013, E-13BN03, E-13BN03A, E-13BN07, E-13EJ06A, E-13EJ06B, E-1F9102, E-1F9205, M-12BN01, M-12EJ01, M-10BN

5.2.19 Essential Service Water System

One train of Essential Service Water (ESW) is required to be operable to ensure adequate cooling for essential equipment. A number of cables associated with Train A ESW components are run in this area. Therefore, Train A ESW cannot be relied on for PFSSD if a fire occurs in this area. Cables associated with Train B ESW are run in a different fire area. Therefore, Train B ESW is available if a fire occurs in area C-24.

Valve EFHV0023 is a normally open isolation valve on the service water system feed to the Train A Essential Service Water System. Either this valve or valve EFHV0025 is required to be closed when operating the Train A ESW system for PFSSD. Power and control cables associated with EFHV0023 are run in this area. Damage to these cables could prevent closing EFHV0023 from the control room. Redundant valve EFHV0025 is unaffected by a fire in area C-24 and can be closed from the control room to isolate this flowpath. In addition, check valve EFV0470 is installed in this line and will prevent flow diversion in the unlikely event valve EFHV0025 cannot be closed.

Valve EFHV0024 is a normally open isolation valve on the service water system feed to the Train B Essential Service Water System. Either this valve or valve EFHV0026 is required to be closed when operating the Train B ESW system for PFSSD. Power and control cables associated with EFHV0024 are run in this area. Damage to these cables could prevent closing EFHV0024 from the control room. Redundant valve EFHV0026 is unaffected by a fire in area C-24 and can be closed from the control room to isolate this flowpath. In addition, check valve EFV0471 is installed in this line and will prevent flow diversion in the unlikely event valve EFHV0026 cannot be closed.

Valve EFHV0041 is a normally open isolation valve on the return line from the Train A Essential Service Water System to the service water system. Either this valve or valve EFHV0039 is required to be closed when operating the Train A ESW system for PFSSD. Power and control cables associated with EFHV0041 are run in this area. Damage to these cables could prevent closing EFHV0041 from the control room. Redundant valve EFHV0039 is unaffected by a fire in area C-24 and can be closed from the control room to isolate this flowpath.

Valve EFHV0042 is a normally open isolation valve on the return line from the Train B Essential Service Water System to the service water system. Either this valve or valve EFHV0040 is required to be closed when operating the Train B ESW system for PFSSD. Power and control cables associated with EFHV0042 are run in this area. Damage to these cables could prevent closing EFHV0042 from the control room. Redundant valve EFHV0040 is unaffected by a fire in area C-24 and can be closed from the control room to isolate this flowpath.

Valve EFHV0037 is the Train A return isolation valve from ESW to the Ultimate Heat Sink. This valve is required to be open when operating the Train A ESW system for PFSSD. A cable (11EFG06AC) associated with this valve is run in this area and damage could cause the valve to spuriously close. Circuits for redundant Train B valve EFHV0038 are not run in area C-24 and will be unaffected by the fire.

Cable 11GDI04AA provides ESW A room temperature from temperature element GDTE0001 to temperature controller GDTC0001. Cables 11GDI04AB and 11GDI04AC provide signals from GDTC0001 to outside air intake damper GDTZ0001A and recirculation damper GDTZ0001B, respectively, to change position based on room temperature. Damage to these cables could prevent operation of the dampers. Temperature controls for Train B ESW pump room are unaffected by a fire in area C-24.

Cable 11GDG01AC is associated with the indicator lights on Train A ESW pump room supply fan CGD01A hand switch GDHIS0001B. Damage to this cable could prevent operation of the

fan. Cables for Train B ESW pump room supply fan CGD01B are unaffected by a fire in this area.

Cable 11RPY10BA supplies 120 VAC control power to the automatic and manual start circuits in panel RP068 from NG01ACR1 for Train A ESW pump room supply fan CGD01A. Cables 11GDY01AA and 11GDY01AB are associated with the Train A ESW pump room supply fan CGD01A control circuit. Damage to these cables could prevent operation of the unit, which could prevent continuous operation of the Train A ESW pump. If this occurs, the Train B ESW pump room supply fan is unaffected by the fire.

PFSSD is assured for a fire in area C-24 using Train B ESW pump PEF01B and associated components.

References: E-15000, XX-E-013, E-093-00052, E-093-00053, E-13EF02, E-13EF03, E-13EF04, E-13EF05, E-13EF06, E-13EF07, E-13EF08, E-13EF09, E-13RP10, E-13EF11, E-K3EF08, E-K3GD01, E-K3GD04, E-1F9402A, E-1F9402B, E-1F9403, E-1F9424A, E-1F9443, E-K3EF01, J-201-00139, M-12EF01, M-12EF02, M-K2EF01, M-K2GD01

5.2.20 Component Cooling Water

For PFSSD, the component cooling water (CCW) system is used to provide cooling to the centrifugal charging pump (CCP) oil cooler, seal water heat exchanger, the RHR heat exchanger and the RHR pump seal cooler. In addition, the CCW system provides cooling to the RCP thermal barriers and is credited as a backup to RCP seal injection for maintaining seal cooling.

Cables associated with Train A CCW pumps PEG01A and PEG01C are run in this area. In addition, a cable associated with Train A CCW pump room cooler SGL11A is run in this area. Damage to these cables could prevent operation of the Train A CCW system.

Cables associated with a number of valves in the Train A CCW system are run in area C-24. These cables and associated valves are listed in Table C-24-3. Cables associated with valves in the Train B CCW system do not run in area C-24 and are unaffected by a fire in this area.

Valves BBHV0013, BBHV0014, BBHV0015, BBHV0016, EGHV0058, EGHV0061, EGHV0126 and EGHV0132 provide isolation capability for CCW flow to/from the RCP thermal barriers. Cables associated with these components are located in area C-24. If the valves fail to the open position, CCW would continue to flow to the RCP components, including the thermal barrier. This continued flow of water will not adversely impact PFSSD. If the valves fail to the closed position, CCW flow to the thermal barrier could be lost. This is acceptable since RCP seal injection is available.

Flow transmitters BBFT0017, BBFT0018, BBFT0019 and BBFT0020 are associated with valves BBHV0013, BBHV0014, BBHV0015 and BBHV0016, respectively. The flow transmitters monitor flow in the CCW piping and shut the valves on high CCW flow. Cables associated with these flow transmitters are run in this area. Damage to these cables could cause a spurious high CCW flow signal and close the valves. Damage to the valve cables could prevent re-opening the valves.

Cable 11EGI19AB is associated with CCW to RCP flow transmitter EGFT0128. Damage to this cable could prevent operators from diagnosing a loss of CCW flow to the RCP thermal barriers using flow indicator EGFI0128. CCW to RCP flow indicator EGFI0129 is unaffected by a fire in area C-18 and can be used to diagnose a loss of CCW flow to the RCP thermal barriers.

Based on the above discussion, a fire in area C-24 could affect CCW flow to/from the RCP thermal barriers. The Train B CCW system is available to supply cooling to the remaining

Train B PFSSD components. Loss of CCW flow to the RCP thermal barriers can be diagnosed using flow indicator EGFI0129. RCP seal injection is unaffected.

References: E-15000, XX-E-013, E-13BB03, E-13BB28, E-13EG01A, E-13EG01B, E-13EG05A, E-13EG05B, E-13EG09, E-13EG09A, E-13EG13, E-13EG16, E-13EG17A, E-13EG18, E-13EG19, E-13GL06, E-1F9303, E-1F9401A, E-1F9444, M-12EG01, M-12EG02, M-12EG03, M-12GL01

5.2.21 Residual Heat Removal System

PFSSD requires one train of residual heat removal (RHR) to be available for shutdown cooling. The RHR system is not used for hot standby. A number of cables associated with the RHR system run in area C-24. These cables are discussed in the following paragraphs.

Valve EGHV0101 is the Train A CCW to RHR Heat Exchanger control valve. Valve EGHV0102 is the Train B CCW to RHR Heat Exchanger control valve. These valves are normally closed during power operation. PFSSD requires that the valve on the operating train of CCW be closed until shutdown cooling mode is entered, at which time the valve on the operating train of RHR needs to be open. Cables 11EGG07AA, 11EGG07AB and 11EGG07AC are power and control cables associated with valve EGHV0101. Damage to cable 11EGG07AC could cause the spurious opening of the valve. Damage to all three cables could prevent operation when lining up for shutdown cooling. Valve EGHV0102 is unaffected by a fire in this area.

Cable 11EJB01AB is a control cable associated with Train A RHR pump feeder breaker NB00101. Damage to this cable could prevent operation of the pump from the control room or could cause the pump to spuriously operate. If the pump fails to operate, the Train B RHR pump is available. If the pump spuriously operates with no suction source, it will likely become damaged and the Train B RHR system will be used.

Cables 11EJG04AA, 11EJG04AB and 11EJG04AC are power and control cables associated with normally closed valve EJHV8804A. This valve is required to remain closed when aligning Train A RHR for cold shutdown. For hot standby, the valve can be in any position. Damage to these cables could cause the valve to open, which would cause flow diversion from Train A RHR to the charging pump suction header. Train B valve EJHV8804B is unaffected by a fire in area C-24.

Cables associated with normally closed valves EJHV8701A (Train A) and EJHV8701B (Train B) run in area C-24. These valves are required to be open when aligning the respective RHR Train for cold shutdown. Cable damage could prevent opening the associated valve from the control room. Therefore, a fire in area C-24 may require a cold shutdown repair to be made within 72 hours per 10CFR50, Appendix R or a containment entry to manually open EJHV8701B when using RHR Train B.

Cable 11EJG08AC, associated with Train A RHR pump mini-flow valve EJFCV0610, runs in area C-24. The mini-flow valve protects the Train A RHR pump during low-flow in the system. Damage to the cable could prevent operation of the valve. Cables associated with Train B RHR mini-flow valve EJFCV0611 do not run in area C-24. Therefore, the Train B RHR pump mini-flow valve is unaffected by a fire in area C-24.

The RHR pump discharge to RCS cold leg isolation valve (EJHV8809A or EJHV8809B) needs to be open on the operating train. Damage to cables 11EJG09CC and 11EJG09CD would likely result in valve EJHV8809A remaining in its as-is normally open position, which is the preferred PFSSD position. However, two proper intra-cable hot shorts in cable 11EJG09CD or one intra-cable hot short in cable 11EJG09CD combined with a short to ground on conductor 31 would spuriously close the valve.

Cable 15EJI12AA is an instrument AC power cable associated with Train A RHR flow control valve EJHCV0606. Cable 15RLY01DA supplies 120 VAC power from PN00736 to RL017/RL018 from PN0736, where the power splits and feeds EJHCV0606 via cable 15EJI12AA. Damage to these cables would cause a loss of power to the valve controller, failing the valve open, which is the desired position if using Train A RHR. Train B RHR flow control valve EJHCV0607 is unaffected by a fire in this area.

Based on the above discussion, a number of Train A RHR components could be affected by a fire in area C-24 but Train B RHR is unaffected.

5.2.22 Safety Injection Pumps

The PFSSD strategy is to prevent operation of the Safety Injection (SI) pumps to ensure an adequate supply of borated water in the RWST. One cable (11EMB01AB) associated with Train A SI pump is run in area C-24. Damage to this cable could cause the spurious start of the pump and could prevent stopping the pump from the control room.

If the Train A SI pump spuriously starts with the reactor at normal pressure, PFSSD will be assured. The pump will not discharge into the RCS due to the pressure differential between the RCS (approximately 2,235 psig) and the SI pump shutoff pressure (approximately 1,565 psig). In addition, the setpoint of the discharge relief valve (EM8853A) to the Recycle Holdup Tank is 1,825 psig. Therefore, no inventory will be lost from the RWST if the SI pumps spuriously start. With the SI pump operating at zero flow, damage to the pump could occur, which is a commercial concern only since the SI pump is not credited in the PFSSD analysis. If necessary, the pump can be stopped by opening breaker NB0103, but this action is not required for PFSSD.

Based on the above discussion, spurious operation of the Train A SI pump will not adversely impact PFSSD.

References: XX-E-013, E-15000, E-13EM01, E-1F9102, E-1F9302, M-12EM01, M-721-00096, WCRE-01

5.2.23 Boron Injection Tank Flow Path Valves

The Boron Injection Tank (BIT) flowpath is credited for reactivity control and reactor coolant makeup. For reactivity control, the BIT flowpath is credited as an alternate source of boration in the event RCP seal injection is unavailable. Based on Calculation XX-E-013, RCP seal injection will provide sufficient boration to achieve and maintain cold shutdown reactivity conditions. Therefore, the BIT flowpath is not required for reactivity control if RCP seal injection is available. Since RCP seal injection is limited to 5 gpm per seal or 20 gpm total injection to the RCS, an additional RCS charging flowpath is required for adequate RCS makeup during plant transition from hot standby to cold shutdown. The BIT injection path was selected as the additional RCS charging flowpath.

A fire in area C-24 uses CCP B, since circuits and support systems for CCP A may be affected by the fire. Also, based on the discussion in 5.2.37, a fire in area C-24 has the possibility to cause a momentary loss of inventory through the letdown flow path until the letdown isolation valves close automatically or are failed closed.

Train A BIT outlet valve EMHV8801A cable 11EMG02CF is run in this area. Cable 11EMG02CF is fire resistive and not susceptible to fire induced damage. Train A BIT inlet valve EMHV8803A may be affected by a fire in this area. Cable 11EMG02AC, associated with EMHV8803A, is run in this area. Damage to this cable could prevent opening the valve and

could prevent a flowpath from Train A CCP to the RCS via the BIT. Redundant Train B valve EMHV8803B is unaffected by a fire in this area so the Train B CCP flowpath to the RCS via the BIT is available.

The SIS test line is required to be isolated when charging through the BIT to prevent inventory loss. Either valve EMHV8964 or EMHV8871 is required to remain closed to prevent flow diversion through the SIS test line. Alternatively, both valves EMHV8843 and EMHV8882 can be closed to prevent flow. Cables associated with EMHV8964 and EMHV8882 are run in this area and the valves could open if damaged by a fire. Redundant valve EMHV8871 is unaffected by the fire and is available to ensure the SIS test line remains isolated.

Breaker PK6116 supplies power to a number of 125VDC loads on RL017/RL018 via cable 15RLK01DA. The only PFSSD load supplied by PK6116 is the control solenoid for valve EMHV8882. Valve EMHV8882 is the boron injection downstream test line and is required to be closed for PFSSD. De-energizing the control solenoid closes EMHV8882. Therefore, loss of power to the solenoid due to damage to cable 15RLK01DA will not impact PFSSD.

Based on the above discussion, charging through the BIT is unaffected by a fire in this area using Train B CCP and valves EMHV8801B and EMHV8803B. The SI test line can be isolated using valve EMHV8871.

References: E-15000, XX-E-013, E-13EM02, E-13EM02A, E-13EM02B, E-13EM02C, E-13EM05A, E-13EM12, E-13RL01, E-1F9302, M-12EM01, M-12EM02

5.2.24 Containment Spray Pumps

Spurious start of the containment spray (CS) pumps may complicate PFSSD due to the possible depletion of inventory in the RWST. Therefore, a spurious start of the CS pumps should be avoided or mitigated. A control cable (11ENB01AB) associated with Train A CS pump PEN01A runs through area C-24 and could cause a spurious start of the pump. The cable damage could prevent stopping the pump from the control room.

Normally closed valve ENHV0006 could open due to damage to associated control cables. If this occurs, water would flow from the containment spray nozzles, depleting inventory in the RWST.

The total flow in the containment spray system with one pump operating is 3,165 gpm (M-10EN). Based on calculation XX-E-013, Appendix 1, a maximum of 214,260 gallons of water can be lost from the RWST to maintain sufficient volume to achieve cold shutdown.

As stated previously, level indication in the RWST is available, so operators have the ability to diagnose a reducing RWST inventory. The time available to mitigate containment spray is:

214,260 gallons / 3,165 gpm = 67.7 minutes

A fire in this area could also result in the inability to isolate letdown, as discussed in Section 5.2.37. The maximum inventory loss through letdown is 195 gpm through all three orifice valves. If a multiple spurious operation scenario exists where containment spray spuriously operates concurrent with failed open letdown valves, the available time to mitigate this condition is as follows:

3,165 gpm + 195 gpm = 3,360 gpm

At this flowrate, the amount of time available to mitigate RWST inventory loss is:

214,260 gallons / 3,360 gpm = 63.7 minutes

Based on the above discussion, there is 63.7 minutes available to mitigate containment spray and failed open letdown, assuming letdown is isolated within 60 minutes. Pump PEN01A can be stopped by opening breaker NB0102 in fire area C-9. This is an OMA. Refer to E-1F9900 for details. Reference Attachment 4, MSO Evaluation Scenario ID PWROG 16.

References: XX-E-013, E-15000, E-13EN01, E-13EN03, E-1F9102, E-1F9302, E-1F9424A, E-1F9433, M-10EN, M-12EN01

5.2.25 Safety Injection Accumulator Isolation Valves

PFSSD requires isolation of the SI accumulators prior to reducing RCS pressure below the injection pressure to avoid unnecessary accumulator discharge. This is accomplished by closing valves EPHV8808A, EPHV8808B, EPHV8808C and EPHV8808D. These valves are normally open with the MCC breaker administratively locked in the open position. Cables for valves EPHV8808A and EPHV8808C are run in area C-24.

Since the breakers for these valves are normally open, damage to these cables will not cause the valves to spuriously change position. However, damage to the cables will prevent closing the associated valve from the control room after power is restored.

The SI accumulators need to be isolated during cold shutdown, prior to the RCS reaching 1000 psig. If necessary, a containment entry can be made to manually close the valves.

References: E-15000, XX-E-013, M-12EP01, E-13EP02A, E-1F9201, CKL EP-120

5.2.26 Control Room Air Conditioning

Cables associated with Train A control room A/C unit SGK04A are run in this area. In addition, cables associated with SGK04A supply and return dampers GKHZ0029B and GKHZ0029A, respectively, are run in this area. Damage to these cables could prevent operation of the unit.

Cables associated with Train B control room A/C unit SGK04B are run in a separate area. Therefore, the Train B control room A/C unit is unaffected by a fire in this area.

References: XX-E-013, E-15000, E-13GK02A, E-13GK02B, E-13GK02C, E-13SA19, E-1F9442, M-12GK01, M-622.1A-00007

5.2.27 Class 1E Electrical Equipment Room A/C Unit

Power and control cables associated with Train A class 1E Electrical Equipment room A/C unit SGK05A are run in area C-24. A fire could damage these circuits and prevent operation of the unit. Circuits for Train B class 1E Electrical Equipment A/C unit SGK05B do not run in area C-24. Therefore, the Train B class 1E Electrical Equipment A/C unit is unaffected by a fire in this area.

Cables 15GKK31CA and 15GKK31CB are associated with the fire isolation signal on SGK05A. Damage to these cables could cause the unit to stop and prevent a re-start. Cable 15RPK09NA is the power cable from PK5126 to separation group 5 relays in RP330. Damage to this cable could cause a loss of power to relay 95XGK07 and shut down SGK05A. Fire isolation signal cables associated with Train B class 1E A/C unit SGK05B are unaffected.

Cable 11SAZ19KA provides status indication of Train A class 1E electrical equipment room A/C unit SGK05A at status panel SA066A. Damage to this cable could blow the control power fuse and prevent operation of SGK05A.

Based on the above discussion, Train B class 1E electrical equipment room cooling is available and is unaffected by a fire in area C-24.

References: XX-E-013, E-15000, E-13GK13, E-13GK31, E-13RP09, E-13SA19, E-1F9444, M-12GK03, M-622.1A-00002

5.2.28 Standby Diesel Generation

Cables 11NEB10AA and 11NEB10AD associated with Train A diesel generator to NB01 feeder breaker NB0111 are run in this area. Damage to these cables could prevent line up to the Train A diesel generator to the NB01 bus.

Calculation XX-E-013 documents a loss of off-site power evaluation that identifies the fire areas in and around the plant in which a fire could cause a loss of off-site and on-site power. Per XX-E-013 and Section 5.2.30 of this evaluation, a fire in area C-24 could cause a loss of off-site power on Train A. Train B off-site power and Train B diesel generator are unaffected by a fire in this area. Therefore, loss of the Train A diesel generator and off-site power to Train A will have no adverse impact on PFSSD.

References: XX-E-013, E-15000, E-13NE10, E-1F9423

5.2.29 Containment Coolers

PFSSD requires containment cooling to maintain the containment environment within EQ limits. Cables associated with Train A containment coolers are run in area C-24. Damage to these cables could prevent operation of the Train A containment coolers if a fire occurs in this area. Circuits for the Train B containment coolers are run in a separate fire area and are unaffected by a fire in area C-24.

As discussed earlier, Train B ESW is available if a fire occurs in area C-24. Therefore, the Train B containment coolers will have the necessary service water flow to ensure proper operation.

References: E-15000, XX-E-013, E-13GN02, E-13GN02A, E-1F9441, M-12GN01

5.2.30 Class 1E 4.16 kV ESF Switchgear Bus

Several cables associated with class 1E 4.16 kV switchgear bus NB01 are located in this area. Damage to these cables could prevent operation of Train A equipment powered by NB01. Cables associated with class 1E 4.16 kV switchgear bus NB02 are located in a different fire area and are unaffected by a fire in area C-24.

Cable 15RLK01CA supplies 125 VDC power to panel RL013/RL014 from PK6115. The PFSSD function of RL013/RL014 is to allow isolation of off-site power to NB01 and NB02 in the event of a fire in areas C-9 and C-10, respectively. RL013/RL014 is not required for PFSSD if a fire occurs in area C-24. Therefore, damage to this cable will not adversely impact the ability to achieve and maintain PFSSD in the event of a fire in area C-24.

Cable 15RPK09RA supplies 125 VDC power to panel RP060 from PK5113. The PFSSD function of RP060 is to allow isolation of off-site power to NB01 and NB02 in the event of a fire in areas C-9 and C-10, respectively. RP060 is not required for PFSSD if a fire occurs in area C-24. Therefore, damage to this cable will not adversely impact the ability to achieve and maintain PFSSD in the event of a fire in area C-24.

References: XX-E-013, E-15000, E-13NB01, E-13NB02, E-13NB03, E-13NB10, E-13NB12, E-13NB13, E-13NG01A, E-13RL01, E-13RP09, E-1F9423, E-1F9425, E-1F9426

5.2.31 Train A 480 VAC Load Centers

Cables associated with 480 VAC load centers NG01, NG03 and NG05E are run in area C-24. Damage to these cables could de-energize the load centers and prevent operation of the associated Train A equipment.

Cables 11PKK10AA and 11PKK10AB are associated with the 125 VDC control circuit for breaker NG0102, which supplies 480 VAC power to battery charger PK021. Damage to these cables could prevent closing NG0102 and supplying power to PK021. Battery charger PK022 is unaffected by a fire in this area.

Train B 480 VAC load centers NG02, NG04 and NG06E are unaffected by a fire in this area and are available to supply power to redundant Train B equipment. Therefore, a fire in area C-24 will not impact the ability to supply power to required Train B 480 VAC equipment.

References: XX-E-013, E-15000, E-13NG01A, E-13NG10, E-13NG11, E-13PK10, E-1F9423, E-1F9424A, E-1F9424B, E-1F9424C, E-1F9424D, E-K3NG10

5.2.32 Class 1E 125 VDC Power to Main Control Boards

Several cables that supply class 1E 125 VDC power to the main control boards are run in area C-24. The cables run from the power supply to the control panel where the power is split to supply specific loads. The cables, power supply, control panel and affected PFSSD components are summarized in the following table.

CABLE	POWER SUPPLY	CONTROL PANEL	PFSSD EQUIPMENT	POSITION ON LOSS OF POWER	REQUIRED PFSSD POSITION
11RLK01AA	NK4119	RL001/002	BGHV8153A BGHV8154A	Closed Closed	Closed Closed
11RLK01CA	NK4112	RL017/018	EMHV8964	Closed	Closed
11RLK01DA	NK4113	RL019/020	EGTV0029 GMHZ0009	Closed Open	Closed Open
11RLK01EA	NK5109	RL021/022	BBHV8001A BBHV8002A	Closed Closed	Closed Closed

Based on the above table, the PFSSD equipment fails to the desired position upon loss of power. Therefore, damage to the cables will not adversely impact PFSSD.

References: E-15000, XX-E-013, E-13BB30, E-13BG48, E-13EG16, E-13EM12, E-13GM04, E-13RL01, E-13RL02, E-13RL03, E-13RL04, E-13RL05, E-13RL06, E-1F9301, E-1F9302, E-1F9401A, E-1F9422A, E-1F9444, M-12BB04, M-12BG01, M-12EG02, M-12EM01, M-12GM01

5.2.33 BOP Instrument Racks

BOP instrument racks RP053A, RP053B, RP053D and RP147 are credited in the PFSSD analysis. The following table identifies the PFSSD components served by each instrument rack.

Instrument Rack	PFSSD Components
RP053A (RP053AA, RP053AB, RP053AC)	ALHV0009 ALHV0011 ALPY037A EGFT0128 EGPSL0077 GDTSL0001 JELSL0001C
RP053B (RP053BA, RP053BB, RP053BC)	ALHV0007 ALPY0039A EGFT0129 EGPSL0078 GDTSL0011 JELSL0021C
RP053D (RP053DA, RP053DB)	ALPY0038A
RP147 (RP147A, RP147B)	ALHV0005

Cables 11RPY09CA and 11RPY09DA supply 120 VAC power to Train A BOP instrument rack RP053A. Damage to these cables could cause a loss of function of panel RP053A and associated PFSSD components.

Instrument racks RP053B, RP053D and RP147 are unaffected by the fire. Therefore, loss of PFSSD components associated with RP053A will not adversely impact PFSSD.

References: E-15000, XX-E-013, E-13AL08, E-13AL09, E-13EG13, E-13EG19, E-13JE01, E-13NN01, E-13RP09, E-1F9101, E-1F9202, E-1F9204, E-1F9401B, E-1F9411A, E-1F9411B, E-1F9424D, E-1F9443, E-K3GD04, M-12AL01, M-12EG01, M-12JE01, M-K2GD01, E-K3GD01A

5.2.34 Reactor Protection System

The Reactor Protection System (RPS) monitors specified input parameters and initiates reactor protection features whenever those parameters are outside specified limits. Field installed transmitters continuously monitor various parameters and report the results to one of four process cabinets, one per channel. Signals are then sent from the process cabinets to both solid state protection cabinets, one on each train. The cabinets and associated channel are listed in the following table.

Process Cabinets	Solid State Protection Cabinets
Cabinet SB038 - Channel 1 Cabinet SB042 - Channel 2 Cabinet SB037 - Channel 3 Cabinet SB041 - Channel 4	Cabinet SB029A - Train A Input Cabinet Cabinet SB029B - Train A Logic Cabinet Cabinet SB029C - Train A Output Cabinet 1 Cabinet SB029D - Train A Output Cabinet 2 Cabinet SB032A - Train B Input Cabinet Cabinet SB032B - Train B Logic Cabinet Cabinet SB032C - Train B Output Cabinet 1 Cabinet SB032D - Train B Output Cabinet 2

The RPS is actuated upon 2/3 or 2/4 coincident logic, depending on the input parameter. This ensures that a loss of a single channel will not prevent the system from performing its function.

Cables associated with RPS channel 1 run through this area. These cables supply power from separation group 1 power supplies to panels SB029A, SB029D, SB032A and SB038. Power cables associated with RPS channels 2, 3 and 4 are run in a separate fire area.

Cable 11SBS12AC is associated with reactor trip switchgear SB102A. Damage to this cable could cause a spurious reactor trip or could prevent an automatic or manual reactor trip on Train A. A tripped reactor is the desired PFSSD position. Train B reactor trip circuits are unaffected by a fire in this area so reactor trip can be accomplished on Train B.

Based on the above discussion, damage to RPS circuits due to a fire in area C-24 will not adversely impact the ability to achieve and maintain PFSSD.

References: XX-E-013, E-15000, E-11NK01, E-11NK02, E-13NN01, E-13SB01, E-13SB02, E-13SB05, E-13SB09, E-13SB12A, E-1F9101, E-1F9102, E-1F9431, E-1F9432, E-1F9433

5.2.35 Source Range Monitoring

PFSSD requires source range (SR) flux monitoring to be available. Source range monitoring is provided by source range monitors SENE0031, SENE0032, SENY0060A & B, and SENY0061A & B.

Cable 11SES01AA is a power cable associated with panel SE054A, which is associated with SR monitor SENE0031. Cable 11SES07BB is an instrument cable associated with SENY0060B. Damage to these cables could prevent operation of the associated source range monitor or prevent source range indication in the control room. Source Range monitoring remains available for a fire in area C-24 using SENE0032 and SENY0061A/B.

For a more detailed evaluation on Source Range monitoring, see Calculation XX-E-013.

References: E-15000, XX-E-013, E-13NN01, E-13SE01, E-13SE05, E-13SE07, E-1F9101, E-1F9421

5.2.36 Load Shedder / Emergency Load Sequencer

The load shedder and emergency load sequencers are included in the PFSSD design to evaluate the impact of spurious operation or mal-operation. The load shedder/emergency load sequencer operates upon presence of the following conditions:

1. An undervoltage (UV) on a safeguards bus,
2. A safety injection signal (SIS) or a containment spray actuation signal (CSAS), or
3. An undervoltage on a safeguards bus with a SIS or CSAS.

Eight inputs (four undervoltage (UV) inputs and four degraded voltage inputs) on each safeguards bus (NB01 and NB02) monitor voltage conditions on that bus. An undervoltage condition on two of four UV relays on each bus will actuate the load shedder/sequencer and send a signal to start the associated diesel generator. In addition, degraded voltage sensed by two of four degraded voltage potential transformers (PTs) will, after a time delay, provide a signal to open the offsite feeder breakers on the associated bus.

Cables 11NFK01CA and 11NFK01DA associated with one of the four undervoltage relays on each bus run in area C-24. Also, cables 11NFY01EA and 11NFY01FA associated with the degraded voltage PTs on each bus are run in fire area C-24. Cables associated with the remaining UV relays and PTs do not run in fire area C-24. Therefore, automatic functioning of

the bus NB01 and NB02 emergency load shed/sequencer is unaffected by a fire in area C-24 due to the availability of at least two UV relay inputs.

Separation group 1 power supply cables for load shedder/sequencer logic and input cabinets NF039A, NF039B and NF039C run in area C-24. Damage to these cables could cause a loss of Train A DC and AC power to the panels. Redundant Train B DC and AC power is available from separation groups 2 and 4 power supplies since separation groups 2 and 4 cables are located in a separate fire area.

Based on the above discussion, the load shedder/sequencer is not adversely affected by a fire in area C-24.

References: XX-E-013, E-15000, E-11NB01, E-11NB02, E-12NF01, E-13NF01, E-10NF, E-1F9411A, E-1F9411B, E-1F9412A, E-1F9412B, E-1F9402A, E-1F9402B, E-1F9403, E-1F9425, E-1F9426

5.2.37 Letdown Isolation Valves and Letdown Orifice Isolation Valves

Valves BGLCV0459 and BGLCV0460 are isolation valves installed in series on the inlet side of the regenerative heat exchanger. PFSSD requires that either of these valves or letdown orifice valves BGHV8149A, BGHV8149B, and BGHV8149C be closed.

Cables 15BGK10AA and 15BGK10AD are power/control cables for the BGLCV0459 solenoid valve (BGHY0459). Air supplied by an open (energized) solenoid valve will open valve BGLCV0459. A closed (de-energized) solenoid valve will cause loss of air pressure and closure of valve BGLCV0459.

Cables 15BGK10BA and 15BGK10BD are power/control cables for the BGLCV0460 solenoid valve (BGHY0460). Air supplied by an open (energized) solenoid valve will open valve BGLCV0460. A closed (de-energized) solenoid valve will cause loss of air pressure and closure of valve BGLCV0460.

Either BGLCV0459 or BGLCV0460 must be closed or letdown orifice isolation valves BGHV8149A, BGHV8149B, and BGHV8149C must be closed. The cables for BGLCV0459 or BGLCV0460 are routed in a common enclosure in cable trays. A hot short on the cables could cause the valves to open. A hot short on cables 15BGK10AA and 15BGK10BA prevents closing BGLCV0459 and BGLCV0460 from the control room. Other cables routed in the cable trays have the proper voltage for hot shorts which can bypass MCB handswitches for BGLCV0459 and BGLCV0460. BGLCV0459 and BGLCV0460 constitute a high/low pressure interface. Therefore, multiple simultaneous hot shorts must be considered.

Letdown orifice isolation valves BGHV8149A, BGHV8149B, and BGHV8149C are listed as PFSSD components because of the interlock between these valves and BGLCV0459 and BGLCV0460. The interlock prevents closure of the letdown valves when any one or more orifice isolation valves are open. Cables associated with all three letdown orifice isolation valves are located in this fire area. Damage to these cables could prevent closure of the valves from the control room. Therefore, a fire in area C-24 could prevent closure of all three letdown orifice isolation valves (BGHV8149A, BGHV8149B, and BGHV8149C) as well as the two letdown isolation valves (BGLCV0459 and BGLCV0460) using their respective hand switches in the control room.

Cable 15RLK01AA supplies 125 VDC power from breaker PK5117 to several non-safety related components on panel RL001/RL002. Some of these components are credited for PFSSD. These components are BGLCV0459, BGLCV0460, BGHV8149A, BGHV8149B and BGHV8149C. Damage to this cable will de-energize power to these valves, failing them closed which is the desired PFSSD position. If letdown is needed during cold shutdown, the excess letdown flowpath can be used or a cold shutdown repair made to restore normal letdown. Therefore, damage to this cable will not adversely impact PFSSD.

Valves BGLCV0459, BGLCV0460, BGHV8149A, BGHV8149B, and BGHV8149C are air operated and fail in the closed position. The valves are located in containment. Instrument air to containment is controlled by valve KAFV0029, which is unaffected by a fire in area C-24. Therefore, hand switch KAHIS0029 can be used to close the valve from the control room and isolate instrument air to containment. Pressurizer level indication is available using BBLI0460A.

Based on the above discussion, letdown valves BGLCV0459 and BGLCV0460 and letdown orifice valves BGHV8149A, BGHV8149B, and BGHV8149C can be closed from the control room if a fire occurs in area C-24.

References: E-15000, XX-E-013, E-13BG10, E-13BG35, E-13KA02, E-13SC12, E-1F9301, M-12BG01, M-12KA01

5.2.38 Steam Generator Blowdown to Blowdown Flash Tank Isolation Valves

Blowdown valves BMHV0001, BMHV0002, BMHV0003 and BMHV0004 are required to be closed for PFSSD. The valves are air operated, and each valve is controlled by three solenoid valves. All three solenoid valves are required to be energized to open the valve. If any one solenoid is de-energized, the associated valve will close or remain closed. Only two of the three solenoids for each valve are considered in the PFSSD analysis, so the third solenoid is assumed energized throughout the event.

Cable 15BMK16AA is the 125 VDC power feed to BM157. Damage to this cable could impact the ability to close the valves from BM157 in the Radwaste Control Room.

Cable 15RPK09EA supplies non-class 1E 125 VDC power to panel RP211 from PK5129. Loss of power to the relay panel will result in loss of power to relay 3XBM46. The function of this relay is to close valves BMHV0001, BMHV0002, BMHV0003, and BMHV0004 if a blowdown and sample process isolation signal is received. Under normal conditions the relay is de-energized, the auxiliary contacts are closed, and valves BMHV0001, BMHV0002, BMHV0003, and BMHV0004 are open. Damage to cable 15RPK09EA could result in the relay remaining de-energized which would prevent a blowdown and sample process isolation signal from closing the valves.

The normal means of closing the blowdown valves using panel RL024 mounted handswitches BMHIS0001A, BMHIS0002A, BMHIS003A and BMHIS0004A in the main control room is unaffected. Therefore, a fire in area C-24 will not prevent the closure of valves BMHV0001, BMHV0002, BMHV0003, and BMHV0004.

References: E-15000, XX-E-013, E-093-00028, E-13BM04, E-13BM06A, E-13BM06B, E-13BM06C, E-13BM06D, E-13BM16, E-13RP09, E-1F9101, E-1F9422A, E-1F9422C, M-12BM01

5.2.39 Non-Class 1E 120 VAC Electrical Distribution System

The PFSSD function of the non-Class 1E 120 VAC electrical distribution system is to supply 120 VAC power to Main Control Boards (MCBs) RL017/RL018 and RL021/RL022. The power is split at the MCB to supply specific PFSSD components. Power is supplied to respective loads from switchboards PN07 and PN08.

Cable 15PNY01AR provides an alternate power feed to switchboard PN07 from PG19GFR3. Damage to this cable will result in a loss of the alternate power feed to PN07. The primary source of power to PN07 from transformer XPN07A could also be affected due to the loss of NG01, as discussed in Section 5.2.31. Therefore, PN07 may not be available if a fire occurs in this area.

Switchboard PN08 is unaffected by a fire in this area. Loss of PN07 will have no adverse impact on PFSSD due to the availability of PN08.

References: XX-E-013, E-15000, E-13PN01, E-13PN01A, E-1F9201, E-1F9205, E-1F9421

5.2.40 Control Room Emergency Lights

Emergency lighting is provided in the control room to ensure adequate lighting during a station blackout and in the event a fire damages cables associated with the normal and standby lighting system. Emergency lights are supplied power from Class 1E 125 VDC breaker NK5120.

The control room has four sources of lighting; 1) Normal (QA); 2) Standby (QB); 3) Emergency (QD); and 4) Self-contained battery units. The normal lighting system is not evaluated in the PFSSD analysis and is assumed lost.

Cable 11QDK01AA is a 125 VDC power cable that runs from NK051A to the control room emergency lights. Damage to this cable will prevent operation of the emergency lights.

Self-contained Appendix R battery units are provided in the control room to provide minimum lighting for post-fire safe shutdown. Three units are provided in the front panel area, each with two light heads, to provide illumination on the main control boards. Two additional units are provided in the corridor area and two units are provided in the back panel area, each with two light heads. The Appendix R battery units are capable of providing minimum illumination for 8 hours, during which time action can be taken by maintenance to restore the normal or standby lighting system.

Based on the above discussion, sufficient lighting exists in the control room to achieve and maintain PFSSD.

References: E-15000, XX-E-013, E-093-00064, E-11NK01, E-13QD01, E-1F9422A, E-1L3604, E-1L8900

5.2.41 Reactor Coolant Pumps

The reactor coolant pumps are not credited in the PFSSD analysis. However, the capability to stop the pumps from the control room in the event of a loss of all seal cooling is credited. Westinghouse Technical Bulletin TB-04-22, Rev. 1 recommends that if all seal cooling is lost (RCP seal injection and thermal barrier heat exchanger flow), operators need to stop the pumps before a seal LOCA occurs.

One control cable associated with reactor coolant pumps A and B is run in fire area C-24. Damage to these cables in the event of a fire could prevent operators from stopping the A and B RCPs from the control room. However, a fire in C-24 will not cause a loss of all seal cooling since RCP seal injection remains available.

Based on the above discussion, the inability to trip the A and B RCPs from the control room will have no adverse impact on PFSSD. The pumps can continue to operate, providing forced flow circulation. If the pumps spuriously stop, natural circulation cooldown can be used.

References: E-15000, XX-E-013, E-13BB01, Westinghouse TB-04-22 Rev. 1

5.2.42 Normal Pressurizer Spray

The normal pressurizer spray valves are included in the PFSSD design because spurious operation of pressurizer sprays can cause a decrease in pressure which can lead to boiling in the core. The pressurizer spray valves are part of the pressurizer pressure control system.

The pressurizer normal spray valves (BBPCV0455B and BBPCV0455C) operate off a signal from the Ovation pressurizer pressure control system. The operation of the pressure control system is discussed in Calculation XX-E-013.

Cable 11BBI16KB associated with BBPT0455 is run in this area. Damage to this cable could cause a spurious high-pressure signal. As discussed in Calculation XX-E-013, Appendix 1, damage to a single pressure input channel will not cause the spurious operation of the pressurizer spray valves due to the Ovation 4-channel validation logic, which uses the 2nd highest signal as the validated signal and has built-in logic to detect and ignore a failed input.

Cable 15BBI19AA associated with pressurizer spray valve BBPCV0455B, and cable 15BBI19BA associated with pressurizer spray valve BBPCV0455C are run in this area. Damage to these cables could cause the spurious opening of the spray valves.

The pressurizer spray valves are electro/pneumatic operated and loss of air pressure will close the valves. The air supply comes from the compressed air system. Closing valve KAFV0029 using KAHIS0029 on RL024 will isolate compressed air to containment which will cause the pressurizer spray valves to close or prevent them from opening. Based on WCNOC-CP-002, spray flow needs to be stopped within 50 minutes. Since this is a control room action, this can be completed well within 50 minutes.

Based on the above discussion, the pressurizer spray valves could spuriously open if a fire occurs in this area. Pressurizer spray can be stopped by closing valve KAFV0029 from the main control room. Pressurizer pressure indication is available using BBPI0456, BBPI0457 and BBPI0458.

References: E-15000, XX-E-013, E-13BB19, E-13KA02, E-1F9304, M-744-00028, M-761A-00063, DCP 13324

5.2.43 Steam Generator Feedwater Pumps

Main feedwater pump steam supply valves FCFV0005 and FCFV0105 are credited in the PFSSD analysis to trip the main feedwater pumps if the main steam isolation valves (MSIVs) are affected by a fire. Closing the MSIVs stops steam flow to the feedwater pumps' turbines and stops the feedwater pumps. The steam generator feedwater pumps are tripped in the event of a fire to prevent overfilling the steam generators.

Non-Class 1E 120 VAC Inverter PN09 and distribution panel PN09A provide power to FCFV0005 trip relays in panel FC169C. Cable 15FCY35AA provides the primary source of 120 VAC power from distribution panel PN09A to panel FC169A, which distributes power to the trip relays in panel FC169C. The alternate source of power to panel FC169A is not credited for PFSSD and is assumed lost.

A fire in area C-24 could damage cable 15FCY35AA. If this occurs, operators in the control room would not be able to close valve FCFV0005 to stop steam flow to steam generator feedwater pump PAE01A.

A fire in area C-24 will not affect the ability to close the MSIVs from the control room. All-close hand switch ABHS0079 is unaffected and can be used to close the MSIVs from the control room.

Based on the above discussion, valve FCFV0005 may not close if a fire occurs in this area. However, the MSIVs can be closed using hand switch ABHS0079 in the main control room. Therefore, the configuration is acceptable.

References: E-15000, XX-E-013, E-13FC35, E-1F9103, E-1F9421

5.2.44 Load Center Feeder Breakers PA0105 and PA0106 and Load Center PG19 Incoming Feeder Breaker PG1901

Load center feeder breakers PA0105 and PA0106 are credited for PFSSD because they supply power to credited non-safety related loads. Cables 15PGA10AA, associated with PA0105, and 15PGA10BA and 15PGA10BB associated with PA0106, run in this area. Cables 15PGG13DA and 15PGG13DC associated with PG1901 are also run in this area. A fire induced short circuit in these cables will trip the associated breaker.

Breaker PA0105 supplies power to the following PFSSD components:

- PG11JFR2 – Main Steam Supply to 2nd Stage Reheat Valve ABHV0031
- PG11KBR3 – Auxiliary Steam System Control Valve FBHV0081

PG11JFR2 and PG11KBR3 supply power to components downstream of the MSIVs. The MSIVs are unaffected by a fire in this area and can be closed from the control room using hand switch ABHS0079. Therefore, the MSIV downstream components are not required if a fire occurs in this area.

Based on the above discussion, loss of breaker PA0105 will not adversely affect PFSSD if a fire occurs in this area.

Breakers PA0106 and PG1901 supply power to the following PFSSD components:

- PG19GCR217 – MCB Misc. Power Circuits RL023
- PG19GFR3 – Instr. Bus Transformer Alt. Feed XPN07D

PFSSD components supplied power from PG19GCR217 are associated with MSIV downstream components. The MSIVs are unaffected by a fire in this area and can be closed

from the control room. Therefore, the MSIV downstream components are not required if a fire occurs in this area.

PG19GFR3 is credited as the backup source of power to PN07. The primary source of power to PN07 is from NG01BEF4. As discussed in Section 5.2.31 the primary source of power to PN07 could also be affected. However, as discussed in Section 5.2.39, switchboard PN08 is available to supply power to redundant PFSSD loads.

Based on the above discussion, loss of breakers PA0105, PA0106 or PG1901 will not adversely affect PFSSD if a fire occurs in this area.

References: XX-E-013, E-15000, E-11PG20, E-11PG21, E-13PG10, E-1F9424E, KD-7496, DCP 13324

5.2.45 120 VAC Distribution Panel PN310

120 VAC distribution panel PN310 supplies power to NSSS control panels RP043 and RP047.

Inverter PN03 supplies power to 120 VAC distribution panel PN310 (via cables 15PNY02AA and 15PNY02AB), which in turn supplies redundant 120 VAC power to NSSS control cabinets RP043 and RP047. For PFSSD, cabinet RP043 houses relays BGLCV0459X and BGLCV0460X, which are associated with letdown isolation valves BGLCV0459 and BGLCV0460, respectively. Cabinet RP047 includes controls for pressurizer PORVs and pressurizer spray.

Damage to cables 15PNY02AA and/or 15PNY02AB will disrupt power to panel PN310. Redundant power to RP043 and RP047 is available from 120 VAC distribution panel PN410. Therefore, loss of power to PN310 will not adversely impact PFSSD.

1.0 GENERAL AREA DESCRIPTION

Fire area C-25 is located on the 2032 elevation of the Control Building and includes the room listed in Table C-25-1.

Table C-25-1
Rooms Located in Fire Area C-25

ROOM #	DESCRIPTION
C25	South Small Elec Chase 2032 Elevation

Fire area C-25 is protected with an automatic fire suppression and detection system. The area is bounded on all sides by minimum 3-hour fire rated construction.

2.0 PRIMARY EQUIPMENT USED FOR PFSSD

Table C-25-2 lists each system credited for post-fire safe shutdown and provides a discussion regarding the availability of the system to perform its Post Fire Safe Shutdown (PFSSD) function if a severe fire occurs in this area. For a summary of the area analysis results, see Section 8.0 of the Fire Area Analysis Narrative section.

Table C-25-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-25

System	System Name	PFSSD Function*	Comments
AB	Main Steam	R, M, H, P, S	It may be necessary to isolate SG B ARV using local control station ABFHC0002. Steam generators A, C and D ARVs are unaffected. Steam line pressure transmitters ABPT0515, ABPT0525, ABPT0535, ABPT0545 may be affected. The remaining steam line pressure transmitters are unaffected. Valves ABHV0005 and ABHV0006 could be affected, preventing operation of the turbine driven auxiliary feedwater pump. Both motor driven auxiliary feedwater pumps are available.
AC	Main Turbine	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-25.
AE	Main Feedwater	H, P	Steam generator B wide range water level transmitter AELT0502 may be affected. Remaining steam generator level transmitters are unaffected.
AL	Aux. Feedwater System	H, P	All PFSSD functions associated with the auxiliary feedwater system are satisfied. The turbine driven auxiliary feedwater pump (TDAFP) may not be available. The motor driven auxiliary feedwater pumps are unaffected.
AP	Condensate Storage System	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-25.
BB	Reactor Coolant System	R, M, H, P, S	Pressurizer level transmitter BBLT0460 may be affected. Redundant pressurizer level transmitter BBLT0459 is unaffected. RCS Temperature elements BBTE0413B, BBTE0423B, BBTE0433A and BBTE0443A, as well as associated temperature indicators, could be affected by a fire in this area. The remaining temperature elements/indicators are unaffected. Pressurizer pressure transmitter BBPT0456 may be affected. The remaining pressurizer pressure transmitters are unaffected. When transferring to RHR, valve BBPV8702A or BBPV8702B may need to be manually opened to provide a suction source from the RCS to RHR pump A or B. Pressurizer pressure indication is available using BBPI0455A, BBPI0457 or BBPI0458.
BG	Chemical and Volume Control System	R, M, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-25.
BM	Steam Generator Blowdown System	R, M, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-25.

Table C-25-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-25

System	System Name	PFSSD Function*	Comments
BN	Borated Refueling Water Storage System	R, M, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-25.
EF	Essential Service Water System	H, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-25.
EG	Component Cooling Water System	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-25.
EJ	Residual Heat Removal System	M, H, P	Both trains of RHR are available. However, as discussed in the BB system comments, it may be necessary to manually open BBPV8702A or BBPV8702B.
EM	High Pressure Coolant Injection	R, M	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-25.
EN	Containment Spray	R, M	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-25.
EP	Safety Injection Accumulators	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-25.
FB	Auxiliary Steam	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-25.
FC	Auxiliary Turbines	R, H, P	The TDAFP speed control valve FCFV0313 and trip and throttle valve FCHV0312 could be affected. The motor driven auxiliary feedwater pumps are available.
GD	ESW Pump House HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-25.
GF	AFW Pump Room Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-25.
GK	Control Room and Class 1E Switchgear Room Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-25.
GL	Auxiliary Building HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-25.

Table C-25-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-25

System	System Name	PFSSD Function*	Comments
GM	Emergency Diesel Generator Room HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-25.
GN	Containment Coolers	S	Containment pressure transmitter GNPT0936 may be affected. The remaining containment pressure transmitters are unaffected.
JE	Diesel Fuel Oil	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-25.
KA	Instrument Air	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-25.
KC	Fire Protection	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-25.
KH	Service Gas	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-25.
KJ	Standby Diesel Engine	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-25.
MA	Main Generation	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-25.
MR	Startup Transformer	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-25.
NB	4.16 kV System	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-25.
NE	Standby Diesel Generator	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-25.
NF	Load Shed and Emergency Load Sequencing	S	All PFSSD functions associated with load shed/emergency load sequencing system are satisfied. Separation group 2 power supply cables for load shedder/sequencer logic and input cabinets NF039A and NF039B could be affected. Redundant AC power is available from separation groups 1, 3 and 4 power supplies.
NG	480V Load Centers and MCCs	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-25.
NK	125VDC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-25.
NN	120VAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-25.
PA	13.8kV	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-25.
PB	4.16kV	H, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-25.

Table C-25-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-25

System	System Name	PFSSD Function*	Comments
PG	480V Load Centers and MCCs	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-25.

3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD

This section describes operator actions that may need to be performed inside or outside the control room to achieve and maintain hot standby if a fire occurs in area C-25. This section also describes cold shutdown repairs that may need to be made to achieve and maintain cold shutdown conditions. Operator actions are proceduralized in OFN KC-016.

3.1 ACTIONS OUTSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

Operator Manual Actions (OMAs) are those actions outside the main control room required to achieve and maintain hot standby. OMAs are identified in E-1F9900 and were determined from thermal hydraulic analysis WCNOC-CP-002. Applicable E-1F9900 OMAs are annotated herein. All other actions outside the control room are desirable for plant control in support of hot standby but not required to achieve and maintain hot standby.

3.1.1 Steam Generator ARVs

If damage occurs to cables associated with ABPV0002, local control station ABFHC0002, located in room 1509, can be used to close ARV ABPV0002.

3.2 ACTIONS INSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

None

3.3 ACTIONS TO ACHIEVE AND MAINTAIN COLD SHUTDOWN

3.3.1 Residual Heat Removal

It may be necessary to either perform a cold shutdown repair or manually open valve BBPV8702A or BBPV8702B when transitioning to RHR.

4.0 CONCLUSION

Redundant post-fire safe shutdown capability is unaffected by a fire in area C-25.

5.0 DETAILED ANALYSIS

This section describes the detailed component-by-component and cable-by-cable analysis for a fire in area C-25.

5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA C-25

There are no PFSSD components located in fire area C-25. This fire area only contains cables associated with PFSSD equipment located in other areas.

5.2 PFSSD CABLE EVALUATION

Table C-25-3 lists all the PFSSD cables (S. in E-15000) located in fire area C-25. The applicable evaluation section is also listed in Table C-25-3.

5.2.1 Auxiliary Feedwater and Steam Generator Atmospheric Relief Valves

The PFSSD design requires the use of one auxiliary feedwater pump (AFP) supplying water to at least two steam generators. Atmospheric relief valves on the two steam generators being fed need to be controlled and atmospheric relief valves on the remaining two steam generators need to be closed. The Train A motor driven auxiliary feedwater pump (MDAFP) is aligned to supply steam generators B and C. The Train B MDAFP is aligned to supply steam generators A and D. The turbine driven auxiliary feedwater pump (TDAFP) is normally aligned to supply all four steam generators.

The normal source of water to the AFPs is the condensate storage tank (CST). The emergency supply is from the essential service water (ESW) system. For commercial concerns, the CST is the preferred source and contains sufficient volume to supply the entire auxiliary feedwater (AFW) demand to achieve cold shutdown.

Cables associated with ABHV0005, ABHV0006, FCHV0312 and FCFV0313 are run in area C-25. Damage to these cables could either cause all four valves to spuriously open at the same time, causing uncontrolled blowdown through the TDAFP, or prevent operation of one or more valve, preventing operation of the TDAFP. Uncontrolled cooldown is mitigated by FCHV0312 tripping on high speed. The Train A and Train B MDAFPs are available to supply feedwater to all four steam generators.

A number of cables associated with steam generator B ARV ABPV0002 are run in this area. Damage to these cables could cause the ARV to spuriously open and could prevent control from the control room. If this occurs, operators may need to control or close ABPV0002 using local controller ABFHC0002 in room 1509.

Cable 12RLK01AA supplies power to RL005/RL006 from switch NK4206. The PFSSD components on RL005/RL006 supplied by NK4206 are ABHV0005 and ABHV0006. Loss of power will fail the valves open, which is desired for operation of the turbine driven auxiliary feedwater pump (TDAFP).

Cable 12RPY09AA supplies 120 VAC power from NN0208 to BOP instrument rack RP053DA. Damage to this cable will affect the following PFSSD components:

- ALPY0038A - ESFAS LOW SUCTION PRESSURE SIGNAL CONVERTER
- ALPT0038 - ESFAS LOW SUCTION PRESSURE TRANSMITTER
- ABPIC0002A - STM GEN B ATM STEAM DUMP PRESSURE CONTROLLER
- ABHS0002 - ABPV0002 HANDSWITCH
- ALPI0026A - TDAFW PUMP PAL02 SUCTION PRESSURE

Low suction pressure (LSP) on 2 out of 3 AFW pressure transmitters (ALPT0037, ALPT0038 and ALPT0039) coincident with an auxiliary feedwater actuation signal (AFAS) will swap the AFW supply to ESW. Loss of power to ALPT0038 and ALPY0038A will satisfy 1/3 LSP logic, placing the LSP signal logic in a 1 out of 2 configuration. In addition, damage to cable 12ALI08BA will prevent operation of ALPT0038 but ALPT0037 and ALPT0039 are unaffected. Therefore, low suction pressure or loss of power on ALPT0037 or ALPT0039 will provide the permissive to swap if an AFAS is present.

Loss of power to ABPIC0002A and ABHS0002 could prevent operation of steam generator B ARV ABPV0002 from the control room. If this occurs, operators may need to control or close ABPV0002 using local controller ABFHC0002 in room 1509.

Loss of power to ALPI0026A will provide false indication of TDAFP suction pressure. In addition, other cables (12ALI07KD, 12ALI07KE and 12ALI07KF) associated with pressure transmitter ALPT0026 are located in this area. Damage to these cables will prevent indication of TDAFP suction pressure. The transmitter does not initiate any automatic functions and the

TDAFP is not credited for a fire in this area. Train A and Train B MDAFP suction pressure indicators are unaffected.

Panel SA036C monitors pressure transmitter signals on ALPT0038 and provides AFAS outputs. Power cables 12SAK21CA and 12SAY21CA associated with SA036C are run in this area. Damage to these cables could result in a loss of power to the panel but will not prevent automatic operation of low suction pressure (LSP) swapover since the remaining 2 channels are available. AFAS is not credited for PFSSD but is analyzed for potential adverse impacts.

Based on the above discussion, the TDAFP may be affected but both MDAFPs are available to provide feedwater to the steam generators. Steam generator B ARV ABPV0002 may need to be controlled or closed using local controller ABFHC0002. Uncontrolled blowdown through the TDAFP is mitigated by FCHV0312 automatically tripping on high speed.

Up to three ARVs can fail closed or open without impacting ability to achieve and maintain hot standby according to thermal hydraulic analysis WCNOC-CP-002. With at least one ARV unaffected, no E-1F9900 OMA is required to address ARV closure or control. Reference Attachment 4, MSO Evaluation Scenario ID PWROG 23.

5.2.2 Load Shedder / Emergency Load Sequencer

The load shedder and emergency load sequencers are included in the PFSSD design to evaluate the impact of spurious operation or mal-operation. The load shedder/emergency load sequencer operates upon presence of the following conditions:

1. An undervoltage (UV) on a safeguards bus,
2. A safety injection signal (SIS) or a containment spray actuation signal (CSAS), or
3. An undervoltage on a safeguards bus with a SIS or CSAS.

Eight inputs (four undervoltage (UV) inputs and four degraded voltage inputs) on each safeguards bus (NB01 and NB02) monitor voltage conditions on that bus. An undervoltage condition on two of four UV relays on each bus will actuate the load shedder/sequencer and send a signal to start the associated diesel generator. In addition, degraded voltage sensed by two of four degraded voltage potential transformers (PTs) will, after a time delay, provide a signal to open the offsite feeder breakers on the associated bus.

The outputs from each safeguards bus (NB01 and NB02) are divided into 4 separation groups; 1, 2, 3 and 4 and routed to two control panels, NF039A and NF039B. The input section of each control panel also receives group 1, 2, 3 and 4 instrument power (120VAC). The inputs then pass through isolation devices, at which point all inputs to NF039A become separation group 1 and all inputs to NF039B become separation group 4. Interruption of either the inputs or the instrument power from one separation group would impact the associated input channel but would not impact the other 3 input channels.

Cable 12NFY01CA supplies 120 VAC power to LSELS panel NF039A. Cable 12NFY01DA supplies 120 VAC power to LSELS panel NF039B. Panels NF039A and NF039B have four sources of Class 1E 120 VAC power, each from separate 120 VAC distribution switchboards, two on Train A and two on Train B. The LSELS system operates when a degraded voltage condition exists on 2 out of 4 sensors on a single 4,160-Volt Class 1E bus. Loss of one source of AC power to each panel will have no adverse impact on PFSSD since 120 VAC power remains available from the remaining three sources.

Cables 12NFK01CA and 12NFK01DA are associated with separation group 2 UV relays on buses NB01 and NB02, respectively. Cables 12NFY01EA and 12NFY01FA are associated with separation group 2 degraded voltage PTs on buses NB01 and NB02, respectively. Cables associated with the remaining three UV relays and PTs from separation groups 1, 3 and 4 do not run in fire area C-25.

Automatic functioning of the bus NB01 and NB02 emergency load shedder / sequencer is unaffected by a fire in area C-25 because of the presence of circuits for only one of the four load shed/sequencer initiators. Therefore, a spurious start of the Train A and Train B diesel generators due to a false undervoltage condition on two of the four circuits is not credible.

Based on the above discussion, the Train A and Train B load shed/sequencers are available if a fire occurs in this area. Off-site power to both trains is unaffected based on Calculation XX-E-013, Appendix 2.

5.2.3 Process Monitoring

Process monitoring is required to achieve and maintain safe shutdown. Some of the process instruments credited for safe shutdown could be affected by a fire in area C-25. These instruments, as well as the available redundant capability, are described in the following paragraphs.

Steam generator level indication is required to support the decay heat removal function. Each steam generator has one wide range and four narrow range level transmitters. At least one level transmitter is required on each steam generator being used for heat removal. Cables 12AEI08GB, 12AEI08EB, 12AEI08FB, 12AEI12BB and 12AEI12CB associated with AELT0502 (SG B WR), AELT0519 (SG A NR), AELT0549 (SG D NR), AELT0552 (SG B NR) and AELT0553 (SG C NR), respectively, are run in fire area C-25. Cables for the remaining level transmitters are not run in fire area C-25. Therefore, at least one level indicator on all four steam generators is available.

RCS hot and cold leg temperature indication is required on at least one loop to verify sufficient flow through the steam generators to ensure RCS decay heat removal. The following table lists the RCS temperature elements credited for PFSSD.

RCS Hot and Cold Leg Temperature Elements Used for PFSSD	
COMPONENT	**FUNCTION**
BBTE0413A	RCS Hot Leg Temperature Element (WR) Loop 1
BBTE0413B	RCS Cold Leg Temperature Element (WR) Loop 1
BBTE0423A	RCS Hot Leg Temperature Element (WR) Loop 2
BBTE0423B	RCS Cold Leg Temperature Element (WR) Loop 2
BBTE0433A	RCS Hot Leg Temperature Element (WR) Loop 3
BBTE0433B	RCS Cold Leg Temperature Element (WR) Loop 3
BBTE0443A	RCS Hot Leg Temperature Element (WR) Loop 4
BBTE0443B	RCS Cold Leg Temperature Element (WR) Loop 4

Temperature elements BBTE0413B, BBTE0423B, BBTE0433A and BBTE0443A, as well as associated temperature indicators, could be affected by a fire in this area due to damage to cables 12BBI15EB, 12BBI15HB, 12BBI15JB, 12BBI15KB, 12SBS16BA and 12SBS16HA. The remaining temperature elements/indicators are unaffected. Therefore, RCS hot and cold leg

temperature indication on a single loop could be affected, which does not meet the PFSSD logic identified on drawing E-1F9201.

Procedure EMG ES-04, Attachment B Section B1 provides alternate indication in the control room that may be used to verify natural circulation flow. One of these methods verifies that steam generator pressure is stable or decreasing. Based on Section 5.2.1, cooldown is assured using loops 1, 3 and 4. Based on Section 5.2.7, steam generators A, C and D pressure indication is available. These pressure instruments, along with their respective indicators in the control room, can be used, per EMG ES-04, to verify heat removal in loops 1, 3 and 4.

The configuration is acceptable because, in the event of a fire in area C-25, cooldown can be performed using RCS loops 1, 3 and 4. RCS temperature elements BBTE0413A, BBTE0433B and BBTE0443B as well as steam generator pressure transmitters ABPT0514 or ABPT0516 (Loop 1), ABPT0534 or ABPT0536 (Loop 3) and ABPT0544 or ABPT0546 (Loop 4) will provide indication of flow through the steam generators.

Pressurizer level indication is required to be available to ensure sufficient make-up inventory is provided to compensate for RCS fluid shrinkage during cooldown and losses from the system. Pressurizer level indication is provided by level transmitters BBLT0459 and BBLT0460. Cable 12SBS16GA associated with BBLT0460 is run in area C-25, so BBLI0460 may not be available. Cables for BBLT0459 do not run through fire area C-25 and are unaffected by a fire. Therefore, pressurizer level indication is available for a fire in area C-25 using BBLI0459A.

Based on the above discussion, process monitoring is available if a fire occurs in fire area C-25.

References: E-15000, XX-E-013, E-13AE08, E-13AE12, E-13BB15, E-13BB16, E-13SB16, E-1F9201, E-1F9203, E-1F9301, M-12AE02, M-12BB01, M-12BB02

5.2.4 Residual Heat Removal

Hot shutdown mode of PFSSD requires isolation of the RCS to RHR flow path by maintaining either BBPV8702A or EJHV8701A closed and either BBPV8702B or EJHV8701B closed. Cold shutdown mode of PFSSD requires RHR taking suction from the RCS. RHR pump suction from the RCS is controlled by valves BBPV8702A and EJHV8701A (Train A) and BBPV8702B and EJHV8701B (Train B). Both trains of RHR are available if a fire occurs in this area.

Damage to cable 12BBI15NB, associated with pressure transmitter BBPT0403, could initiate a false High-1 RCS pressure signal and open the contacts on relay K734. This false High-1 pressure signal would prevent remote opening of valves BBPV8702A and BBPV8702B. Therefore, a fire in this area may require a cold shutdown repair or a containment entry to open valve BBPV8702A or BBPV8702B prior to initiating RHR for cold shutdown.

Based on the above discussion, RHR is available using either train but suction from the RCS may need to be manually aligned prior to starting the RHR pumps.

5.2.5 Reactor Protection System

The Reactor Protection System (RPS) monitors specified input parameters and initiates reactor protection features whenever those parameters are outside specified limits. Field installed transmitters continuously monitor various parameters and report the results to one of four process cabinets, one per channel. Signals are then sent from the process cabinets to both solid state protection cabinets, one on each train. The cabinets and associated channel are listed in the following table.

Process Cabinets	Solid State Protection Cabinets
Cabinet SB038 - Channel 1 Cabinet SB042 - Channel 2 Cabinet SB037 - Channel 3 Cabinet SB041 - Channel 4	Cabinet SB029A - Train A Input Cabinet Cabinet SB029B - Train A Logic Cabinet Cabinet SB029C - Train A Output Cabinet 1 Cabinet SB029D - Train A Output Cabinet 2 Cabinet SB032A - Train B Input Cabinet Cabinet SB032B - Train B Logic Cabinet Cabinet SB032C - Train B Output Cabinet 1 Cabinet SB032D - Train B Output Cabinet 2

The RPS is actuated upon 2/3 or 2/4 coincident logic, depending on the input parameter. This ensures that a loss of a single channel will not prevent the system from performing its function.

Cables 12SBS01BD, 12SBS02BD and 12SBY09DA associated with reactor protection system channel 2 run through this area. These cables supply power from separation group 2 power supplies to panels SB029A, SB032A and SB042. Damage to these cables could cause a loss of RPS channel 2, but channels 1, 3 and 4 remain available. Therefore, the RPS is available if a fire occurs in this area.

References: XX-E-013, E-15000, E-13NN01, E-13SB01, E-13SB02, E-13SB03, E-13SB04, E-13SB05, E-13SB09, E-1F9431, E-1F9432, E-1F9433, J-10SA

5.2.6 Source Range Monitoring

PFSSD requires source range (SR) flux monitoring to be available to provide indication of cold shutdown reactivity conditions. Source range monitoring is provided by source range monitors SENE0031, SENE0032, SENY0060A & B, and SENY0061A & B.

Cable 12SES02AA supplies power to SE054B from NN0211. Panel SE054B is associated with source range neutron indicator SENI0032B. Loss of power to the panel will prevent SENI0032B from operating. Cables 12SES02BB and 12SES02BC are instrument cables associated with source range channel 2 preamp SE0032. Damage to these cables will prevent operation of source range indicator SENI0032B. Source range monitoring remains available using SENI0031B, SENI0060A/B and SENI0061A/B.

References: XX-E-013, E-15000, E-13SE02, E-1F9101

5.2.7 Safety Injection and Containment Spray

A spurious safety injection signal (SIS) could cause the safety injection pumps to operate. A spurious containment spray actuation signal (CSAS) could cause the containment spray pumps to operate, depleting inventory in the RWST. These conditions are not desirable for PFSSD at Wolf Creek.

Safety injection (SI) is initiated automatically by any of the following conditions:

1. Two out of three high containment pressures monitored by pressure transmitters GNPT0934, GNPT0935 and GNPT0936.
2. Two out of four low pressurizer pressures monitored by pressure transmitters BBPT0455, BBPT0456, BBPT0457 and BBPT0458.
3. Two out of three low steam line pressures on any steam generator monitored by ABPT0514, ABPT0515 and ABPT0516 on SG A; ABPT0524, ABPT0525 and ABPT0526 on SG B; ABPT0534, ABPT0535 and ABPT0536 on SG C; and ABPT0544, ABPT0545 and ABPT0546 on SG D. Two out of three logic must be satisfied on a single steam generator line. Low pressure on a single pressure transmitter co-incident

with low pressure on another pressure transmitter on a different steam generator line will not initiate SIS.

Containment spray (CS) is initiated automatically by two out of four high containment pressures monitored by pressure transmitters GNPT0934, GNPT0935, GNPT0936 and GNPT0937.

Cables 12ABI21KA, 12ABI21NA, 12ABI21SA and 12ABI21VA associated with steam line pressure transmitters ABPT0515, ABPT0525, ABPT0535 and ABPT0545 run in fire area C-25. Cables for the remaining steam line pressure transmitters are unaffected by a fire in area C-25. Therefore, a spurious SI signal due to low steam line pressure will not occur in the event of a fire in area C-25.

A cable (12BBI16LB) associated with pressurizer pressure transmitter BBPT0456 is run in area C-25. Cables associated with the remaining pressurizer pressure transmitters are unaffected by a fire in area C-25. Therefore, a spurious SI signal due to low pressurizer pressure will not occur in the event of a fire in area C-25.

A cable (12GNI05BA) associated with containment pressure transmitter GNPT0936 is run in area C-25. Cables associated with the remaining containment pressure transmitters are unaffected by a fire in area C-25. Therefore, a spurious SI and CSAS due to high containment pressure will not occur in the event of a fire in area C-25.

Based on the above discussion, a spurious SIS and CSAS cannot occur if a fire occurs in this area.

References: E-15000, XX-E-013, E-13AB21, E-13BB16, E-13GN05, E-1F9431, E-1F9432, E-1F9433, M-12AB01, M-12BB02, M-12GN01

5.2.8 Pressurizer Pressure Control

The pressurizer pressure control system is included in the PFSSD analysis because spurious operation of the pressurizer pressure control system could have adverse consequences on PFSSD. A valid high-pressure signal will open the pressurizer PORVs and pressurizer spray valves, which is not desired for PFSSD.

An instrument cable (12BBI16LB) associated with pressurizer pressure transmitter BBPT0456 is run in fire area C-25. Damage to this cable could send a spurious high-pressure signal to the Ovation pressure control system. As discussed in Calculation XX-E-013, Appendix 1, damage to a single pressure input channel will not cause the spurious operation of the pressurizer spray valves or PORVs due to the Ovation 4-channel validation logic, which uses the 2nd highest signal as the validated signal and has built-in logic to detect and ignore a failed input.

Based on the above discussion, pressurizer PORVs and pressure spray valves will not spuriously operate if a fire occurs in this area.

1.0 GENERAL AREA DESCRIPTION

Fire area C-26 is located on the 2032 elevation of the Control Building and includes the room listed in Table C-26-1.

Table C-26-1
Rooms Located in Fire Area C-26

ROOM #	DESCRIPTION
C26	North Small Elec Chase 2032 Elevation

Fire area C-26 is protected with an automatic fire suppression and detection system. The area is bounded on all sides by minimum 3-hour fire resistance rated construction.

2.0 PRIMARY EQUIPMENT USED FOR PFSSD

Table C-26-2 lists each system credited for post-fire safe shutdown and provides a discussion regarding the availability of the system to perform its Post Fire Safe Shutdown (PFSSD) function if a severe fire occurs in this area. For a summary of the potential fire impact on some of the more significant PFSSD equipment, see Section 8.0 of the Fire Area Analysis Narrative section.

Table C-26-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-26

System	System Name	PFSSD Function*	Comments
AB	Main Steam	R, M, H, P, S	Steam generator ARV ABPV0003 may spuriously open or power to the ARV controller could be lost. The ARV can be closed using local controller ABFHC0003. Steamline pressure transmitters ABPT0526 and ABPT0536 may be affected. Redundant steamline pressure transmitters are unaffected.
AC	Main Turbine	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-26.
AE	Main Feedwater	H, P	Steam generator level indicators AELI0503, AELI0518, AELI0528, AELI0538 and AELI0548 may be affected. The remaining steam generator level indicators are unaffected.
AL	Aux. Feedwater System	H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-26.
AP	Condensate Storage System	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-26.
BB	Reactor Coolant System	R, M, H, P, S	Pressurizer pressure transmitter BBPT0457 may be affected. Pressurizer pressure indication is available using BBPI0455A, BBPI0456 or BBPI0458.
BG	Chemical and Volume Control System	R, M, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-26.
BM	Steam Generator Blowdown System	R, M, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-26.
BN	Borated Refueling Water Storage System	R, M, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-26.
EF	Essential Service Water System	H, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-26.
EG	Component Cooling Water System	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-26.
EJ	Residual Heat Removal System	M, H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-26.

Table C-26-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-26

System	System Name	PFSSD Function*	Comments
EM	High Pressure Coolant Injection	R, M	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-26.
EN	Containment Spray	R, M	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-26.
EP	Safety Injection Accumulators	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-26.
FB	Auxiliary Steam	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-26.
FC	Auxiliary Turbines	R, H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-26.
GD	ESW Pump House HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-26.
GF	AFW Pump Room Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-26.
GK	Control Room and Class 1E Switchgear Room Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-26.
GL	Auxiliary Building HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-26.
GM	Emergency Diesel Generator Room HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-26.
GN	Containment Coolers	S	Containment pressure transmitter GNPT0935 may be affected. Redundant containment pressure transmitters are unaffected.
JE	Diesel Fuel Oil	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-26.
KA	Instrument Air	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-26.
KC	Fire Protection	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-26.
KH	Service Gas	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-26.
KJ	Standby Diesel Engine	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-26.

Table C-26-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-26

System	System Name	PFSSD Function*	Comments
MA	Main Generation	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-26.
MR	Startup Transformer	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-26.
NB	4.16 kV System	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-26.
NE	Standby Diesel Generator	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-26.
NF	Load Shed and Emergency Load Sequencing	S	All PFSSD functions associated with load shed/emergency load sequencing system are satisfied. Separation group 3 power supply cables for load shedder/sequencer logic and input cabinets NF039A and NF039B could be affected. Redundant AC power is available from separation groups 1, 2 and 4 power supplies.
NG	480V Load Centers and MCCs	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-26.
NK	125VDC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-26.
NN	120VAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-26.
PA	13.8kV	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-26.
PB	4.16kV	H, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-26.
PG	480V Load Centers and MCCs	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-26.
PK	125VDC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-26.
PL	Local Instrument Panels	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-26.
PN	120VAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-26.
QB	Standby AC Lighting	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-26.
QD	Emergency Lighting	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-26.

Table C-26-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-26

System	System Name	PFSSD Function*	Comments
RL	Control Room MCB	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-26.
RP	Miscellaneous Control Panels	R, M, H, P, S	Power to panel RP053DB could be affected. Power to panels RP053A, RP053B and RP147 is unaffected.
SA	ESFAS	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-26.
SB	Reactor Protection System	R, S	RPS Channel 3 could be affected. RPS Channels 1, 2 and 4 are unaffected.
SC	Reactor Instrumentation	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-26.
SE	Ex-Core Neutron Monitoring	R, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-26.
SY	Switchyard	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-26.

3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD

This section describes operator actions that may need to be performed inside or outside the control room to achieve and maintain hot standby if a fire occurs in area C-26. This section also describes cold shutdown repairs that may need to be made to achieve and maintain cold shutdown conditions. Operator actions are proceduralized in OFN KC-016.

3.1 ACTIONS OUTSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

Operator Manual Actions (OMAs) are those actions outside the main control room required to achieve and maintain hot standby. OMAs are identified in E-1F9900 and were determined from thermal hydraulic analysis WCNOC-CP-002. Applicable E-1F9900 OMAs are annotated herein. All other actions outside the control room are desirable for plant control in support of hot standby but not required to achieve and maintain hot standby.

3.1.1 Steam Generator Atmospheric Relief Valves

Steam Generator C ARV ABPV0003 may need to be closed using local controller ABFHC0003 in fire area A-23. Emergency lighting is available, and access is available without having to traverse area C-26.

3.2 ACTIONS INSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

None

3.3 ACTIONS TO ACHIEVE AND MAINTAIN COLD SHUTDOWN

None

4.0 CONCLUSION

With one exception, redundant Post Fire Safe Shutdown capability exists if a severe fire occurs in fire area C-26. For the exception, a feasible manual action is available and is unaffected by the fire. Manual actions are documented in Section 3.0.

5.0 DETAILED ANALYSIS

This section describes the detailed component-by-component and cable-by-cable analysis for a fire in area C-26.

5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA C-26

There are no PFSSD components located in fire area C-26. This fire area only contains cables associated with PFSSD equipment located in other areas.

5.2 PFSSD CABLE EVALUATION

Table C-26-3 lists all the PFSSD cables (S. in E-15000) located in fire area C-26. The applicable evaluation section is also listed in Table C-26-3.

Table C-26-3

5.2.1 Steam Generator Atmospheric Relief Valves

PFSSD requires at least two steam generator atmospheric relief valves (ARV) be controlled and the other two closed. The ARVs are pneumatically operated using air from the compressed air system (KA) or nitrogen from the nitrogen accumulators. The valves open by pneumatic pressure and close by spring action. A pressure transmitter installed on the outlet side of the steam generator sends a signal to a controller and automatically controls the associated ARV position. Alternatively, each ARV can be controlled manually from the control room or the auxiliary shutdown panel by placing the pressure indicating controller (PIC) in manual.

Cable 13RPY09AA supplies 120 VAC power to Train A BOP instrument rack RP053DB. The only PFSSD components controlled by RP053DB are ABPIC0003A, ABPIC0003B, ABHS0003, ABPT0003 and ABPY0003. These components are associated with steam generator C ARV ABPV0003. Loss of power to these components due to damage to cable 13RPY09AA will cause ABPV0003 to fail closed, which is the desired PFSSD position for a fire in this area.

Other cables associated with steam generator C ARV ABPV0003 are run in this area. Damage to these cables could prevent control or isolation of the ARV. If ARV ABPV0003 spuriously opens, it can be closed using local controller ABFHC0003 located in fire area A-23.

Up to three ARVs can fail closed or open without impacting ability to achieve and maintain hot standby according to thermal hydraulic analysis WCNOC-CP-002. With at least one ARV unaffected, no E-1F9900 OMA is required to address ARV closure or control. Reference Attachment 4, MSO Evaluation Scenario ID PWROG 23.

Based on the above discussion, ARV ABPV0003 could fail in the open or closed position but no action is necessary to mitigate the failed ARV. If operators want to control or close the ARV, it can be controlled using local controller ABFHC0003 in fire area A-23.

5.2.2 Safety Injection and Containment Spray

A spurious safety injection signal (SIS) could cause the safety injection pumps to operate. A spurious containment spray actuation signal (CSAS) could cause the containment spray pumps to operate, depleting inventory in the RWST. These conditions are not desirable for PFSSD at Wolf Creek.

Safety injection (SI) is initiated automatically by any of the following conditions:

1. Two out of three high containment pressures monitored by pressure transmitters GNPT0934, GNPT0935 and GNPT0936.
2. Two out of four low pressurizer pressures monitored by pressure transmitters BBPT0455, BBPT0456, BBPT0457 and BBPT0458.
3. Two out of three low steam line pressures on any steam generator monitored by ABPT0514, ABPT0515 and ABPT0516 on SG A; ABPT0524, ABPT0525 and ABPT0526 on SG B; ABPT0534, ABPT0535 and ABPT0536 on SG C; and ABPT0544, ABPT0545 and ABPT0546 on SG D. Two out of three logic must be satisfied on a single steam generator line. Low pressure on a single pressure transmitter co-incident with low pressure on another pressure transmitter on a different steam generator line will not initiate SIS.

Containment spray (CS) is initiated automatically by two out of four high containment pressures monitored by pressure transmitters GNPT0934, GNPT0935, GNPT0936 and GNPT0937.

Cables associated with containment pressure transmitter GNPT0935, pressurizer pressure transmitter BBPT0457 and steamline pressure transmitters ABPT0526 and ABPT0536 are run in fire area C-26. Cables for the remaining SIS/CSAS initiators are not run in fire area C-26. Consequently, a spurious CSAS and SIS is not credible if a fire occurs in area C-26 due to the absence of 2/3 or 2/4 CSAS and SIS initiator circuits.

References: E-15000, XX-E-013, E-13AB21, E-13BB16, E-13GN05, E-1F9431, E-1F9432, E-1F9433, M-12AB01, M-12BB02, M-12GN01

5.2.3 Steam Generator Level Indication

Steam generator level indication is required to ensure adequate auxiliary feedwater flow to the steam generators to support the decay heat removal function. Automatic signals (turbine trip, feedwater isolation, reactor trip, auxiliary feedwater actuation) based on steam generator level are not credited in the PFSSD analysis and maloperation of these signals is not adverse to PFSSD.

The available success path if a fire occurs in area C-26 credits MDAFP B to supply SGs A and D and the TDAFP to supply SGs A, B and/or D. Therefore, level indication on any two of SGs A, B and D is required.

A cable associated with SG A narrow range level transmitter AELT0518 is run in fire area C-26. Cables for the remaining level transmitters on SG A are unaffected by a fire in area C-26. Therefore, level indication on steam generator A is available.

A cable associated with SG B narrow range level transmitter AELT0528 is run in fire area C-26. Cables for the remaining level transmitters on SG B are unaffected by a fire in area C-26. Therefore, level indication on steam generator B is available.

Cables associated with SG C wide range level transmitter AELT0503 and narrow range level transmitter AELT0538 are run in fire area C-26. Cables for the remaining level transmitters on SG C are unaffected by a fire in area C-26. Therefore, level indication on steam generator C is available.

A cable associated with SG D narrow range level transmitter AELT0548 is run in fire area C-26. Cables for the remaining level transmitters on SG D are unaffected by a fire in area C-26. Therefore, level indication on steam generator D is available.

Based on the above discussion, level indication on all four steam generators is assured if a fire occurs in fire area C-26.

5.2.4 Deleted

5.2.5 Load Shedder / Emergency Load Sequencer

The load shedder and emergency load sequencers are included in the PFSSD design to evaluate the impact of spurious operation or mal-operation. The load shedder/emergency load sequencer operates upon presence of the following conditions:

1. An undervoltage (UV) on a safeguards bus,
2. A safety injection signal (SIS) or a containment spray actuation signal (CSAS), or
3. An undervoltage on a safeguards bus with a SIS or CSAS.

Eight inputs (four undervoltage (UV) inputs and four degraded voltage inputs) on each safeguards bus (NB01 and NB02) monitor voltage conditions on that bus. An undervoltage condition on two of four UV relays on each bus will actuate the load shedder/sequencer and send a signal to start the associated diesel generator. In addition, degraded voltage sensed by two of four degraded voltage potential transformers (PTs) will, after a time delay, provide a signal to open the offsite feeder breakers on the associated bus.

The outputs from each safeguards bus (NB01 and NB02) are divided into 4 separation groups; 1, 2, 3 and 4 and routed to two control panels, NF039A and NF039B. The input section of each control panel also receives group 1, 2, 3 and 4 instrument power (120VAC). The inputs then pass through isolation devices, at which point all inputs to NF039A become separation group 1 and all inputs to NF039B become separation group 4. Interruption of either the inputs or the instrument power from one separation group would impact the associated input channel but would not impact the other 3 input channels.

Cables 13NFK01CA and 13NFK01DA are associated with separation group 3 UV relays on buses NB01 and NB02, respectively. Cables 13NFY01GA and 13NFY01HA are associated with separation group 3 degraded voltage PTs on buses NB01 and NB02, respectively. Cables associated with the remaining three UV relays and PTs from separation groups 1, 2 and 4 do not run in fire area C-26.

Separation group 3 120 VAC instrument power supply cables 13NFY01EA and 13NFY01FA for load shedder/sequencer logic and input cabinets NF039A and NF039B, respectively, run in fire area C-26. Damage to these cables could cause a loss of separation group 3 120 VAC instrument power to the group 3 input panels, and therefore loss of input channel 3. Channels 1, 2 and 4 instrument AC power remains available from separation groups 1, 2 and 4 power supplies.

Automatic functioning of the bus NB01 and NB02 emergency load shedder / sequencer is unaffected by a fire in area C-26 because of the presence of circuits for only one of the four load shed/sequencer initiators. Therefore, a spurious start of the Train A and Train B diesel generators due to a false undervoltage condition on two of the four circuits is not credible.

Based on the above discussion, the Train A and Train B load shed/sequencers are available if a fire occurs in this area. Off-site power to both trains is unaffected based on Calculation XX-E-013, Appendix 2.

References: XX-E-013, E-15000, E-11005, E-11NB02, E-13NF01, E-092, E-10NF, E-1F9411A, E-1F9411B, E-1F9412A, E-1F9412B, J-104-00347

5.2.6 Reactor Protection System

The Reactor Protection System (RPS) monitors specified input parameters and initiates reactor protection features whenever those parameters are outside specified limits. Field installed transmitters continuously monitor various parameters and report the results to one of four process cabinets, one per channel. Signals are then sent from the process cabinets to both solid state protection cabinets, one on each train. The cabinets and associated channel are listed in the following table.

Process Cabinets	Solid State Protection Cabinets
Cabinet SB038 - Channel 1 Cabinet SB042 - Channel 2 Cabinet SB037 - Channel 3 Cabinet SB041 - Channel 4	Cabinet SB029A - Train A Input Cabinet Cabinet SB029B - Train A Logic Cabinet Cabinet SB029C - Train A Output Cabinet 1 Cabinet SB029D - Train A Output Cabinet 2 Cabinet SB032A - Train B Input Cabinet Cabinet SB032B - Train B Logic Cabinet Cabinet SB032C - Train B Output Cabinet 1 Cabinet SB032D - Train B Output Cabinet 2

The RPS is actuated upon 2/3 or 2/4 coincident logic, depending on the input parameter. This ensures that a loss of a single channel will not prevent the system from performing its function.

Cables 13SBS01CD, 13SBS02CD and 13SBY09EA associated with reactor protection system channel 3 run through this area. These cables supply power from separation group 3 power supplies to panels SB029A, SB032A and SB037, respectively. Damage to these cables could cause a loss of RPS channel 3, but channels 1, 2 and 4 remain unaffected. Therefore, the RPS is available if a fire occurs in this area.

References: XX-E-013, E-15000, E-13NN01, E-13SB01, E-13SB02, E-13SB03, E-13SB04, E-13SB05, E-13SB09, E-1F9431, E-1F9432, E-1F9433, J-10SA

5.2.7 Pressurizer Pressure Control

The pressurizer pressure control system is included in the PFSSD analysis because spurious operation of the pressurizer pressure control system could have adverse consequences on PFSSD. A validated high-pressure signal will open the pressurizer PORVs and pressurizer spray valves, which is not desired for PFSSD.

An instrument cable (13BBI16MB) associated with pressurizer pressure transmitter BBPT0457 is run in fire area C-26. Damage to this cable could send a spurious high-pressure signal to the Ovation pressure control system. As discussed in Calculation XX-E-013, Appendix 1, damage to a single pressure input channel will not cause the spurious operation of the pressurizer spray valves or PORVs due to the Ovation 4-channel validation logic, which uses the 2nd highest signal as the validated signal and has built-in logic to detect and ignore a failed input.

Based on the above discussion, pressurizer PORVs and pressurizer spray valves will not spuriously open if a fire occurs in this area.

2.0 PRIMARY EQUIPMENT USED FOR PFSSD 3
3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD 3
4.0 CONCLUSION 3
5.0 DETAILED ANALYSIS 3

1.0 GENERAL AREA DESCRIPTION

Fire area C-27 is located on the 2047 elevation of the Control Building and includes the rooms listed in Table C-27-1.

Table C-27-1
Rooms Located in Fire Area C-27

ROOM #	DESCRIPTION
3601	Main Control Room
3603	Shift Managers Office
3604	Foyer
3605	Equipment Cabinet Area
3606	Emergency Equipment Storage Room
3616	Vestibule

Fire area C-27 is protected with an automatic Halon system in the cable trenches and automatic smoke detection in the control cabinets. The area is separated on all sides by minimum 3-hour fire resistance rated barriers.

2.0 PRIMARY EQUIPMENT USED FOR PFSSD

In the event of a fire in the control room, hot standby is achieved using certain Train B equipment per OFN RP-017, Control Room Evacuation. This equipment has been designed with the capability to isolate it from the control room to ensure a fire in this area does not prevent operation of the credited equipment.

3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD

In the event of a fire in the main control room that requires evacuation and shutdown from outside the control room, procedure OFN RP-017 will be utilized to achieve and maintain hot standby. If the severity of the fire requires the plant be brought to cold shutdown, procedure OFN RP-017A will be utilized.

4.0 CONCLUSION

Post-fire safe shutdown is assured if a fire occurs in this area.

5.0 DETAILED ANALYSIS

The detailed analysis for a fire in the Main Control Room is contained in document E-1F9915.

3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD

This section describes operator actions that may need to be performed inside or outside the control room to achieve and maintain hot standby if a fire occurs in area C-28. This section also describes cold shutdown repairs that may need to be made to achieve and maintain cold shutdown conditions. Operator actions are proceduralized in OFN KC-016.

3.1 ACTIONS OUTSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

None

3.2 ACTIONS INSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

None

3.3 ACTIONS TO ACHIEVE AND MAINTAIN COLD SHUTDOWN

None

4.0 CONCLUSION

Post-fire safe shutdown is unaffected by a fire in fire area C-28.

5.0 DETAILED ANALYSIS

This section describes the detailed component-by-component and cable-by-cable analysis for a fire in area C-28.

5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA C-28

There are no PFSSD components located in fire area C-28. This fire area only contains cables associated with PFSSD equipment located in other areas.

5.2 PFSSD CABLE EVALUATION

Table C-28-4 lists all the PFSSD cables (S. in E-15000) located in fire area C-28. The applicable evaluation section is also listed in Table C-28-4.

Table C-28-4
PFSSD Cables Located in Fire Area C-28

Cable #	Location	Primary PFSSD Equipment	Cable Function (P) Power (C) Control (I) Instrumentation	Evaluation Section	Comments
11QDK01AA	3602, 3607, 3608	QD01, QD02, QD03, QD04, QD05, QD06	P	5.2.1	Control Room Emergency Lights

5.2.1 Control Room Emergency Lights

Emergency lighting is provided in the control room to ensure adequate lighting during a station blackout or in the event a fire damages cables associated with the normal and standby lighting system. Emergency lights are supplied power from Class 1E 125 VDC breaker NK5120.

The control room has four sources of lighting; 1) Normal (QA); 2) Standby (QB); 3) Emergency (QD); and 4) Self-contained battery units (QD). The normal lighting system is not evaluated in the PFSSD analysis and is assumed lost.

The control building standby lighting system is powered by the Train A 480 VAC Class 1E electrical system through breakers NG01AHF1 and NG01AHF2. Power availability on NG01AHF1 and NG01AHF2 is monitored by auxiliary relays 27XQB1 and 27XQB2 in panel RP330. Upon loss of power to both NG01AHF1 and NG01AHF2, the relay coils are de-energized and the normally open contacts close. This energizes the contactor control relay which closes a contact and energizes the control room emergency DC lighting panel NK051A, which automatically illuminates the 125 VDC (QD System) emergency lights in the control room.

Cable 11QDK01AA provides power from emergency lighting panel NK051A to emergency lights QD01 through QD06. Damage to cable 11QDK01AA will disrupt power from NK051A to the QD lights, causing a loss of emergency DC lighting in the control room.

Self-contained Appendix R battery units are provided in the control room to provide minimum lighting for post-fire safe shutdown. Three units are provided in the front panel area, each with two light heads, to provide illumination on the main control boards. Two additional units are provided in the corridor area and two units are provided in the back panel area, each with two light heads. The Appendix R battery units are capable of providing minimum illumination for 8 hours, during which time action can be taken by maintenance to restore the normal or standby lighting system.

Based on the above discussion, sufficient lighting exists in the control room to achieve and maintain PFSSD.

1.0 GENERAL AREA DESCRIPTION

Fire area C-29 is located on the 2047 elevation of the Control Building and includes the room listed in Table C-29-1.

Table C-29-1
Rooms Located in Fire Area C-29

ROOM #	DESCRIPTION
3609	SAS Room

Fire area C-29 is protected with automatic smoke detection. The area is separated on all sides by minimum 3-hour fire resistance rated barriers.

2.0 PRIMARY EQUIPMENT USED FOR PFSSD

Fire area C-29 contains no post-fire safe shutdown cables or equipment. Therefore, both trains of PFSSD equipment are available if a fire occurs in this area.

3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD

Not applicable to fire area C-29.

4.0 CONCLUSION

Post-fire safe shutdown is assured if a fire occurs in this area.

5.0 DETAILED ANALYSIS

A detailed analysis is not required since this area contains no PFSSD cables or components.

Fire area C-30 is located on the 2047 elevation of the Control Building and includes the rooms listed in Table C-30-1.

Table C-30-1
Rooms Located in Fire Area C-30

ROOM #	DESCRIPTION
3617	South Electrical Chase - 2047 Elevation

Fire area C-30 is protected by an automatic wet-pipe sprinkler system. In addition, automatic fire detection is installed throughout. The automatic suppression and detection system meets the requirements of 10CFR50, Appendix R, Section III.G.2.c.

2.0 PRIMARY EQUIPMENT USED FOR PFSSD

Table C-30-2 lists each system credited for post-fire safe shutdown and provides a discussion regarding the availability of the system to perform its Post Fire Safe Shutdown (PFSSD) function if a severe fire occurs in this area. For a summary of the area analysis results, see Section 8.0 of the Fire Area Analysis Narrative section.

Table C-30-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-30

System	System Name	PFSSD Function*	Comments
AB	Main Steam	R, M, H, P, S	Cables associated with S/G D ARV ABPV0004 may be damaged, preventing control of this valve from the control room. The ARV can be isolated by closing valves KAV1429 and KAV1365 to isolate air and nitrogen to the ARV. Steam line pressure transmitters ABPT0516 and ABPT0546 may be affected. The remaining steam line pressure transmitters are unaffected. The capability to isolate the MSIVs and bypass valves using hand switch ABHS0079 may be affected. The MSIVs and bypass valves can be isolated using hand switch ABHS0080. A number of main steam valves located downstream of the MSIVs could open. This will have no adverse impact on PFSSD since the MSIVs and bypass valves can be isolated. Main steam to TDAFP valves ABHV0005 and ABHV0006 could close, preventing operation of the TDAFP. See AL discussion for auxiliary feedwater availability.
AC	Main Turbine	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-30.
AE	Main Feedwater	H, P	All PFSSD functions associated with the main feedwater system are satisfied. Steam generator (SG) level indication is available on SG B using wide range level transmitter AELT0502 and narrow range level transmitters AELT0528, AELT0529 and AELT0552. Steam generator level indication is available on SG C using wide range level transmitter AELT0503 and narrow range level transmitters AELT0538, AELT0539 and AELT0553. The capability to isolate the MFIVs using hand switch AEHS0081 may be affected. Isolate the MFIVs using hand switch AEHS0080.
AL	Aux. Feedwater System	H, P	Train B motor driven auxiliary feedwater pump (MDAFP) and the turbine driven auxiliary feedwater pump may be affected. Train A MDAFP is available to supply auxiliary feedwater to SGs B and C. Steam generator A flow transmitter ALFT0007 and steam generator D flow transmitter ALFT0001 may be affected. Steam generator B flow transmitter ALFT0009 and steam generator C flow transmitter ALFT0011 are unaffected.
AP	Condensate Storage System	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-30.

Table C-30-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-30

System	System Name	PFSSD Function*	Comments
BB	Reactor Coolant System	R, M, H, P, S	All PFSSD functions associated with the reactor coolant system are satisfied. All four seal water injection valves will remain open. When transferring to RHR, valve BBPV8702A may need to be manually opened or a cold shutdown repair performed to provide a suction source from the RCS to RHR pump A. Pressurizer PORV BBPCV0456A may open and block valve BBHV8000B may not close. If this occurs, Operators can close the PORV by placing BBHIS0456A in the CLOSE position. Pressure indicator BBPI0406 may not function. Pressure indicator BBPI0405 is unaffected. Reactor vessel head vent valve BBHV8002B could spuriously open. The remaining head vent valves are unaffected and will remain closed to isolate the head vent flow path. RCS temperature recorders BBTR0433 and BBTR0443 on loops 3 and 4 could lose power. Temperature indication on loops 1 and 2 remains available. Pressurizer pressure transmitter BBPT0458 could be affected. The remaining pressurizer pressure transmitters are unaffected. Pressurizer pressure indication is available using BBPI0455A, BBPI0456 and BBPI0457.
BG	Chemical and Volume Control System	R, M, S	All PFSSD functions associated with the chemical and volume control system are satisfied. Train A Centrifugal Charging Pump (CCP) is available to provide charging flow from the RWST to the RCP seals and the BIT injection flowpath. Train B CCP miniflow valve BGHV8111 may be affected. Train A CCP miniflow valve BGHV8110 is unaffected. Valve BGHV8105 may be affected. Redundant valve BGHV8106 is unaffected and can be closed using hand switch BGHIS8106 to isolate flow to the regenerative heat exchanger. VCT isolation valve BGLCV0112C may be affected but redundant valve BGLCV0112B can be isolated using BGHIS0112B. CCP B to RCP seal injection valve BGHV8357B could be affected. Redundant Train A CCP to RCP seal injection valve BGHV8357A is unaffected. VCT level transmitter BGLT0185 may be affected. VCT level transmitter BGLT0112 is unaffected. Excess letdown valve BGHV8154B could spuriously open. Redundant valve BGHV8153B is unaffected. RCP seal flow indication is available using BGFI0215A. RCP seal flow indicator BGFI0215B may be affected.
BM	Steam Generator Blowdown System	R, M, H	All PFSSD functions associated with the steam generator blowdown system are satisfied. Steam generator blowdown is isolated by closing valves BMHV0001, BMHV0002, BMHV0003 and BMHV0004 using BMHIS0001C, BMHIS0002C, BMHIS0003C and BMHIS0004C, located on the BM157 panel in the radwaste control room.

Table C-30-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-30

System	System Name	PFSSD Function*	Comments
BN	Borated Refueling Water Storage System	R, M, H	The RWST is available to provide a suction source to Centrifugal Charging Pump A via valve BNLCV0112D. RWST level indication is available using BNLI0930, BNLI0931 and BNLI0932.
EF	Essential Service Water System	H, S	All PFSSD functions associated with the Essential Service Water (ESW) system are satisfied. A number of components associated with Train B ESW may be affected. Train A ESW is available.
EG	Component Cooling Water System	S	All PFSSD functions associated with the Component Cooling Water (CCW) system are satisfied. Train B CCW may be affected. Train A CCW is available. CCW flow to the RCP thermal barrier could be temporarily disrupted due to closure of valves EGHV0062 and EGHV0071. Valves EGHV0132 and EGHV0126 can be opened from the control room to restore CCW flow to the thermal barriers. RCP seal injection is unaffected. CCW to RCP flow indicator EGFI0129 could be affected. CCW to RCP flow indicator EGFI0128 is unaffected. Valve EGHV0102 could be affected, preventing operation of Train B RHR. Valve EGHV0101 is unaffected.
EJ	Residual Heat Removal System	M, H, P	All PFSSD functions associated with Residual Heat Removal (RHR) system are satisfied. The Train B RHR pump may be affected but the Train A RHR pump is available. Loss of RCS inventory through the RHR flow path is prevented by maintaining valves EJHV8701A and EJHV8701B closed. Valve EJHV8701A can be opened from the control room when transitioning to RHR for cold shutdown. RHR pump B mini-flow valve EJFCV0611 is affected but RHR pump A mini-flow valve EJFCV0610 is available. RHR Train B to SI Pump B isolation valve EJHV8804B could spuriously open. RHR Train A to CVCS valve EJHV8804A is unaffected. Train B RHR pump discharge to RCS cold leg isolation valve EJHV8809B is affected. Train A RHR pump discharge to RCS cold leg isolation valve EJHV8809A is unaffected. Valve EJHV8840 could spuriously open in the event of a fire in this area. This will not affect hot standby, however the valve will need to be locally closed prior to entering shutdown cooling mode. RHR Train B flow control valve EJHCV0607 could be affected. RHR Train A flow control valve EJHCV0606 is unaffected.

Table C-30-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-30

System	System Name	PFSSD Function*	Comments
EM	High Pressure Coolant Injection	R, M	Train B safety injection pump PEM01B could spuriously start. Injection will not occur with the reactor at normal pressure. The pump can be stopped by opening breaker NB0202, but this action is not required for PFSSD. Charging flow from CCP A to the RCS is available through the BIT by opening valves EMHV8803A and EMHV8801A. Prevent flow diversion through the SIS test line when charging through the BIT by maintaining valve EMHV8964 closed.
EN	Containment Spray	R, M	Containment spray pump PEN01B could spuriously start and valve ENHV0012 could open, causing containment spray. Pump PEN01B can be stopped by opening breaker NB0203 in area C-10. Containment spray pump PEN01A is unaffected.
EP	Safety Injection Accumulators	H	The PFSSD Decay Heat Removal function associated with the Safety Injection Accumulators is satisfied. Accumulator injection lines can be isolated by closing valves EPHV8808A, EPHV8808B, EPHV8808C and EPHV8808D. It may be necessary to make a containment entry to manually close EPHV8808B and EPHV8808D prior to the RCS reaching 1000 psig.
FB	Auxiliary Steam	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-30.
FC	Auxiliary Turbines	R, H, P	Turbine driven auxiliary feedwater pump steam trap valve FCFV0310 may not close. Uncontrolled blowdown through this 1-inch line will not cause unacceptable RCS cooldown and will not impact PFSSD. Turbine driven steam generator feedwater pump B main steamline low point drain valve FCHV0103 may not close. This will have no adverse impact on PFSSD since the MSIVs and MSIV bypass valves can be isolated using ABHS0080.
GD	ESW Pump House HVAC	S	The PFSSD function associated with ESW pump house HVAC is satisfied. The Train B ESW pump room ventilation system could be affected. The Train A ESW pump room ventilation system is unaffected.
GF	AFW Pump Room Coolers	S	The PFSSD function associated with the Auxiliary Feedwater Pump Room Coolers is satisfied. Train B motor driven auxiliary feedwater pump room cooler SGF02B may be affected. Train A motor driven auxiliary feedwater pump room cooler SGF02A is unaffected.
GK	Control Room and Class 1E Switchgear Room Coolers	S	The PFSSD function associated with the Control Room and Class 1E Switchgear Room Coolers is satisfied. Train B control room A/C unit SGK04B may be affected. Train A control room A/C unit SGK04A is unaffected. Train B Class 1E electrical equipment room A/C unit SGK05B may be affected. Train A Class 1E electrical equipment room A/C unit SGK05A is unaffected.

Table C-30-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-30

System	System Name	PFSSD Function*	Comments
GL	Auxiliary Building HVAC	S	The PFSSD function associated with the Auxiliary Building HVAC system is satisfied. Train B CCW pump room cooler SGL11B may be affected. Train A CCW pump room cooler SGL11A is unaffected.
GM	Emergency Diesel Generator Room HVAC	S	The PFSSD function associated with the emergency diesel generator room HVAC system is satisfied. The Train B emergency diesel generator exhaust damper GMHZ0019 could be affected. The Train A diesel generator room HVAC system is unaffected.
GN	Containment Coolers	S	The PFSSD function associated with the containment coolers is satisfied. Train B containment coolers SGN01B and SGN01D could be affected. Train A containment coolers SGN01A and SGN01C are available. Containment pressure transmitter GNPT0934 could be affected. The remaining three pressure transmitters are unaffected.
JE	Diesel Fuel Oil	S	The PFSSD function associated with the Diesel Fuel Oil System is satisfied. The Train B emergency fuel oil transfer pump PJE01B may be affected. The Train A emergency fuel oil transfer pump PJE01A is unaffected. The Train B emergency diesel generator day tank level transmitter JELT0021 may be affected. The Train A day tank level transmitter is unaffected.
KA	Instrument Air	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-30.
KC	Fire Protection	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-30.
KH	Service Gas	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-30.
KJ	Standby Diesel Engine	S	The PFSSD function associated with the Standby Diesel System is satisfied. The Train B diesel engine may be affected. The Train A diesel engine is unaffected.
MA	Main Generation	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-30.
MR	Startup Transformer	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-30.
NB	4.16 kV System	S	The PFSSD function associated with the class 1E 4.16 kV system is satisfied. A loss of off-site and on-site power to NB02 may occur. On-site and off-site power to NB01 is unaffected.
NE	Standby Diesel Generator	S	The PFSSD function associated with the standby diesel generator system is satisfied. The Train B standby diesel generator could be affected. The Train A standby diesel generator is unaffected.

Table C-30-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-30

System	System Name	PFSSD Function*	Comments
NF	Load Shed and Emergency Load Sequencing	S	The PFSSD function associated with the load shed/emergency load sequencing system is satisfied. Cables associated with one of the four undervoltage (UV) relays and degraded voltage potential transformers on Trains A and B are run in fire area C-30. Emergency load shed/sequencer operates when 2/4 UV relays sense undervoltage on the bus. Therefore, automatic operation of the load shed/sequencer is unaffected.
NG	480V Load Centers and MCCs	S	The PFSSD function associated with the class 1E 480 volt load centers is satisfied. A loss of off-site and on-site power to Train B 480 VAC Class 1E load centers and MCCs could occur. Off-site and on-site power to Train A 480 VAC Class 1E load centers and MCCs is available.
NK	125VDC	S	Train B class 1E 125 VDC power could be disrupted to control room panels RL001/RL002, RL005/RL006, RL017/RL018, RL019/RL020, RL021/RL022 and RL023/RL024. Train A class 1E 125 VDC power is unaffected. The normal source of power to NK02 and NK04, through the Train B 480 V distribution system, could be disrupted. 125 VDC battery sets NK012 and NK014 are unaffected. Train B class 1E 125 VDC power could be disrupted to RPS output panel SB032D. 125 VDC power is available to Train A RPS output panel SB029D.
NN	120VAC	S	The backup source of power to Train B Class 1E electrical distribution switchboards NN02 and NN04 could be affected. The normal source of power to NN02 and NN04 is unaffected due to the availability of 125 VDC battery sets NK012 and NK014. Train A Class 1E electrical distribution switchboards NN01 and NN03 are unaffected.
PA	13.8kV	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-30.
PB	4.16kV	H, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-30.
PG	480V Load Centers and MCCs	S	Power from PG20GBR217 to RL023 could be affected. Power from PG19GCR217 to RL023 is unaffected. Load Center PG20 could lose power due to loss of PG2001. Redundant capability is available.
PK	125VDC	S	The PFSSD function associated with the non-class 1E 125 VDC system is satisfied. Battery charger PK22 may be affected. Battery set PK12 will maintain 125 VDC power to PK02. Also, Train A non-class 1E 125 VDC system is unaffected.
PL	Local Instrument Panels	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-30.
PN	120VAC	S	Power from PN0833 to RL017/RL018 may be affected. Power from PN0835 to RL021/RL022 may be affected. Power from PN0736 and PN0738 to RL017/RL018 and RL021/RL022 is unaffected.

Table C-30-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-30

System	System Name	PFSSD Function*	Comments
QB	Standby AC Lighting	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-30.
QD	Emergency Lighting	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-30.
RL	Control Room MCB	S	The PFSSD function associated with the control room panels is satisfied. Train B Class 1E 125 VDC power to RL001/RL002, RL005/RL006, RL017/RL018, RL019/RL020, RL021/RL022 and RL023/RL024 could be disrupted. The components either fail in the desired PFSSD position or the redundant Train A component is available. Train A Class 1E 125 VDC power is unaffected. Non class 1E (separation group 6) 120 VAC power to panels RL017/RL018, RL021/RL022 and RL023/RL024 could be affected. Non class 1E (separation group 5) 120 VAC power to panels RL017/RL018, RL021/RL022 and RL023/RL024 is unaffected.
RP	Miscellaneous Control Panels	R, M, H, P, S	Power to BOP instrument rack RP053B could be disrupted. BOP instrument racks RP053A, RP053D and RP147 are unaffected. Train B 120 VAC control power to panel RP068 could be affected. Train A 120 VAC control power to panel RP068 is unaffected. Control room lockout relays 86XRP5, 86XRP6 and 86XRP7 could be affected, preventing operation of Train B and turbine driven auxiliary feedwater. Train A auxiliary feedwater remains available. Power to Group 2 Process Control Rack RP047 could be affected. This will not affect PFSSD as discussed in Section 5.2.12.
SA	ESFAS	S	125 VDC and 120 VAC power to panel SA036B could be lost, resulting in a loss of Channel 4 Engineered Safety Features Actuation System (ESFAS). Redundant Channels 1 and 2 are unaffected. Status panel input for GKHZ0040A/B, SGK04B and SGK05B could be affected. This will not adversely impact PFSSD.

Table C-30-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-30

System	System Name	PFSSD Function*	Comments
SB	Reactor Protection System	R, S	All PFSSD functions associated with the reactor protection system are satisfied. A loss of power to input channel 4 in SB029A and SB032A could occur. Input channels 1, 2 and 3 remain available. Train B output cabinet SB032D could lose power. Train A output cabinets are unaffected. Train B reactor trip switchgear SB102B could be affected. Train A reactor trip switchgear SB102A is unaffected. Channel 4 process protection panel SB041 could lose power. Process protection channels 1, 2 and 3 remain available. A number of process monitoring instruments at the ASP could be affected. Redundant process monitoring instruments in the main control room are unaffected.
SC	Reactor Instrumentation	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-30.
SE	Ex-Core Neutron Monitoring	R, P	All PFSSD functions associated with the ex-core neutron monitoring system are satisfied. SR monitor signal processor SENY0061B, SR monitor amplifier SENY0061A and source range recorder for SENY0061B could be affected. Source Range monitoring remains available using SENE0031, SENE0032 and SENY0060A/B
SY	Switchyard	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-30.
UU	Supervisory System	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-30.

* R - Reactivity Control; M - Reactor Coolant Makeup; H - Decay Heat Removal; P - Process Monitoring; S - Support Function

3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD

This section describes operator actions that may need to be performed inside or outside the control room to achieve and maintain hot standby if a fire occurs in area C-30. This section also describes cold shutdown repairs that may need to be made to achieve and maintain cold shutdown conditions. Operator actions are proceduralized in OFN KC-016.

3.1 ACTIONS OUTSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

Operator Manual Actions (OMAs) are those actions outside the main control room required to achieve and maintain hot standby. OMAs are identified in E-1F9900 and were determined from thermal hydraulic analysis WCNOC-CP-002. Applicable E-1F9900 OMAs are annotated herein. All other actions outside the control room are desirable for plant control in support of hot standby but not required to achieve and maintain hot standby.

3.1.1 Steam Generator Atmospheric Relief Valves

Cables associated with S/G ARV ABPV0004 may be damaged, preventing control of this valve from the control room. The ARV can be isolated by closing valve KAV1429 and nitrogen is isolated by closing valve KAV1365. The air and nitrogen supply valves are located in fire area A-23 and access is available without having to traverse area C-30.

3.1.2 Steam Generator Blowdown Isolation

Blowdown may not be isolable using BMHIS0001A, BMHIS0002A, BMHIS0003A and BMHIS0004A. Therefore, it may be necessary to isolate blowdown using BMHIS0001C, BMHIS0002C, BMHIS0003C and BMHIS0004C located on BM157 in the Radwaste Control room.

3.1.3 **Containment Spray Pump** (OMA, refer to E-1F9900)

Containment spray pump PEN01B could spuriously start and valve ENHV0012 could open, causing containment spray. The pump can be stopped by opening breaker NB0203 in area C-10. Access is available without traversing area C-30 and emergency lighting is provided.

3.2 ACTIONS INSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

3.2.1 Main Steam Isolation Valves and MSIV Bypass Valves

The capability to isolate the MSIVs and bypass valves using hand switch ABHS0079 may be affected. The MSIVs and bypass valves can be isolated using hand switch ABHS0080.

3.2.2 Main Feedwater Isolation Valves

The capability to isolate the MFIVs using hand switch AEHS0081 may be affected. Isolate the MFIVs using hand switch AEHS0080.

3.2.3 Volume Control Tank

Valve BGLCV0112C may not close in response to a signal from the control room. Redundant valve BGLCV0112B can be isolated using BGHIS0112B on RL001.

3.2.4 Thermal Barrier Cooling

CCW flow to the thermal barrier cooling coils could be lost due to the spurious closure of valves EGHV0062 and EGHV0071. If this occurs, operators could open bypass valves EGHV0132 (EGHV0062 bypass) and EGHV0126 (EGHV0071 bypass) using EGHIS0132 and

EGHIS0126, respectively. Otherwise, operators should close EGHV0061 using EGHIS0061 to prevent a steam bubble from damaging the CCW piping. CCW to RCP flow indicator EGFI0128 is available to diagnose a loss of CCW flow to the RCP thermal barriers.

3.2.5 Charging

If necessary, to establish an alternate makeup and boration flowpath, the Train A CCP is available to charge through the BIT and valves EMHV8801A and EMHV8803A can be opened using EMHIS8801A and EMHIS8803A.

3.2.6 Component Cooling Water

Train B CCW could be affected by a fire in this area. If this occurs, swap to Train A CCW using normal operating procedures if Train A CCW is not already running.

3.2.7 Pressurizer PORV/Block Valve

Pressurizer PORV BBPCV0456A could spuriously open and block valve BBHV8000B may not close. If this occurs, Operators can close the PORV by placing BBHIS0456A in the CLOSE position. Pressurizer pressure indication is available using BBPI0455A, BBPI0456 and BBPI0457 located on RL002.

3.3 ACTIONS TO ACHIEVE AND MAINTAIN COLD SHUTDOWN

3.3.1 RHR

A number of Train B RHR components, including the Train B RHR pump, may be affected by a fire in this area. Use Train A RHR for shutdown cooling. Valve BBPV8702A may need to be manually opened, or a cold shutdown repair performed, when aligning Train A RHR.

Valve EJHV8840 could spuriously open in the event of a fire in this area. This will not affect hot standby, however the valve will need to be locally closed prior to entering shutdown cooling mode.

3.3.2 Safety Injection Accumulators

It may be necessary to make a containment entry to close SI Accumulator injection valves EPHV8808B and EPHV8808D if these valves are unresponsive from the control room. Otherwise, nitrogen pressure can be relieved from the tanks to prevent injection. Valves EPHV8808A and EPHV8808C are unaffected.

4.0 CONCLUSION

With some exceptions, redundant Post Fire Safe Shutdown capability exists if a severe fire occurs in area C-30. For those exceptions, feasible manual actions are available and are unaffected by the fire. Manual actions are documented in Section 3.0.

5.0 DETAILED ANALYSIS

This section describes the detailed component-by-component and cable-by-cable analysis for a fire in area C-30.

5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA C-30

There are no PFSSD components located in area C-30. This fire area only contains cables associated with PFSSD equipment located in other areas.

5.2 PFSSD CABLE EVALUATION

Table C-30-3 lists all the PFSSD cables (S. in E-15000) located in fire area C-30. The applicable evaluation section is also listed in Table C-30-3.

Table C-30-3
PFSSD Cables Located in Fire Area C-30

Cable #	Location	Primary PFSSD Equipment	Cable Function (P) Power (C) Control (I) Instrumentation	Evaluation Section	Comments
14ABI20HE	3617	ABPY0004	I	5.2.1	SG D Atmospheric Relief Valve I/P Converter

5.2.1 Steam Generator Atmospheric Relief Valves

PFSSD requires at least two steam generator atmospheric relief valves (ARVs) be controlled and the other two closed. The ARVs are pneumatically operated using air from the compressed air system (KA) or nitrogen from the nitrogen accumulators. The valves open by pneumatic pressure and close by spring action. The valves are automatically controlled by a pressure transmitter installed on the outlet side of the steam generator. Alternatively, each valve can be controlled manually from the control room or the auxiliary shutdown panel by placing the pressure indicating controller (PIC) in manual.

As discussed in Section 5.2.8, a fire in this area could affect the Train B motor driven auxiliary feedwater pump (MDAFP) and the turbine driven auxiliary feedwater pump (TDAFP). Therefore, only the Train A MDAFP is available to feed steam generators B and C. Consequently, steam generator ARVs ABPV0001 and ABPV0004 need to be isolated and steam generator ARVs ABPV0002 and ABPV0003 need to be controlled.

Cables associated with steam generator ARV ABPV0004 are run in area C-30. Damage to these cables could prevent isolating ABPV0004 from the control room. If this occurs, an operator can close it by isolating air and nitrogen supply valves KAV1429 and KAV1365, respectively in fire area A-23. Cables for the remaining ARVs are not run in area C-30 and, therefore, the PFSSD function for controlling two steam generators is satisfied.

Up to three ARVs can fail closed or open without impacting ability to achieve and maintain hot standby according to thermal hydraulic analysis WCNOC-CP-002. With at least one ARV unaffected, no E-1F9900 OMA is required to address ARV closure or control. Reference Attachment 4, MSO Evaluation Scenario ID PWROG 23.

Based on the above discussion, steam generator atmospheric relief valve control can be achieved.

References: E-15000, XX-E-013, E-13AB20B, E-1F9101, M-12AB01

5.2.2 Safety Injection and Containment Spray

A spurious safety injection signal (SIS) could cause the safety injection pumps to operate. A spurious containment spray actuation signal (CSAS) could cause the containment spray pumps to operate, depleting inventory in the RWST. These conditions are not desirable for PFSSD at Wolf Creek.

Safety injection (SI) is initiated automatically by any of the following conditions:

1. Two out of three high containment pressures monitored by pressure transmitters GNPT0934, GNPT0935 and GNPT0936.
2. Two out of four low pressurizer pressures monitored by pressure transmitters BBPT0455, BBPT0456, BBPT0457 and BBPT0458.
3. Two out of three low steam line pressures on any steam generator monitored by ABPT0514, ABPT0515 and ABPT0516 on SG A; ABPT0524, ABPT0525 and ABPT0526 on SG B; ABPT0534, ABPT0535 and ABPT0536 on SG C; and ABPT0544, ABPT0545 and ABPT0546 on SG D. Two out of three logic must be satisfied on a single steam generator line. Low pressure on a single pressure transmitter co-incident with low pressure on another pressure transmitter on a different steam generator line will not initiate SIS.

Containment spray (CS) is initiated automatically by two out of four high containment pressures monitored by pressure transmitters GNPT0934, GNPT0935, GNPT0936 and GNPT0937.

A cable associated with containment pressure transmitter GNPT0934 is run in area C-30. Cables associated with the remaining containment pressure transmitters are not run in area C-

30. Therefore, a spurious CSAS cannot occur due to a fire in this area. Also, a spurious SIS due to high containment pressure cannot occur.

A cable associated with pressurizer pressure transmitter BBPT0458 is run in area C-30. Cables associated with the remaining pressurizer pressure transmitters do not run in area C-30. Consequently, a fire in area C-30 cannot cause a spurious SIS due to low pressurizer pressure.

Cables associated with steam line pressure transmitters ABPT0516 and ABPT0546 are run in area C-30. Cables associated with the remaining steamline pressure transmitters do not run in area C-30. Consequently, a spurious two out of three logic for low steam line pressure initiation of SIS cannot be satisfied if a fire occurs in area C-30.

Based on the above discussion, a spurious SIS and CSAS cannot occur if a fire occurs in this area.

5.2.3 Main Steam Isolation Valves Downstream Components

Cables for several main steam (AB) valves located downstream of the main steam isolation valves (MSIVs) are located in this area. These valves are used for PFSSD to isolate the main steam lines in the event the MSIVs or MSIV bypass valves fail to close. Damage to these cables could cause the associated component to fail open.

Cable 16RLY01GA supplies 120 VAC power to control room panel RL023/RL024. At RL023/RL024, the power is split and supplies power to FCHV0103, ABLV0050 and ABLV0052, as well as other non-PFSSD components. These components are required to be functional for PFSSD in the event the MSIVs and MSIV bypass valves cannot be isolated. Loss of power will cause the valves to remain open.

As discussed in Sections 5.2.4 and 5.2.5, the MSIVs and the MSIV bypass valves can be isolated using hand switch ABHS0080 if a fire occurs in area C-30. Therefore, these downstream valves can fail open with no adverse impact on PFSSD.

References: E-15000, XX-E-013, E-13AB08, E-13AB11A, E-13AB11B, E-13AB11C, E-13RL01, E-13RL07, E-1F9103, E-1F9424E, M-12AB03

5.2.4 Main Steam Isolation Bypass Valves

Each of the four MSIV bypass valves (ABHV0012, ABHV0015, ABHV0018 and ABHV0021) has two redundant solenoids that control the position of the associated valve. The bypass valves are normally closed with the solenoids de-energized. Both solenoids need to be energized to open the valve. One of the solenoids on each valve is on separation group 1 (Train A) and are controlled by hand switch ABHS0080. The other solenoids on each valve are on separation group 4 (Train B) and are controlled by hand switch ABHS0079.

Separation group 4 MSIV bypass solenoid valve cables are run in this area. Damage to these cables could impact the ability to close the valves using hand switch ABHS0079. Redundant means are available to ensure the MSIV bypass valves are closed. Hand switch ABHS0080 is unaffected by the fire and can be used to close the bypass valves if they are open at the time of the fire.

References: E-15000, XX-E-013, E-13AB23B, E-1F9101, M-12AB02

5.2.5 Steam Generator Main Steam Isolation Valves (MSIVs)

PFSSD requires the MSIVs be closed to prevent reactivity addition due to uncontrolled cooldown. The MSIVs are closed from the control room using all close hand switches ABHS0079 or ABHS0080.

Each MSIV is designed to utilize system fluid (main steam) as the motive force to open and close. The valve actuation (open or close) is accomplished through positioning a series of six electric solenoid pilot valves to either direct the system fluid to the Upper Piston Chamber (UPC) and/or the Lower Piston Chamber (LPC), or vent either or both piston chambers. The six solenoid pilot valves are divided into two trains (3 per train) that are independently powered and controlled. Either train can independently perform the PFSSD function to close the valve and isolate main steam. This is done by actuating either all close hand switch ABHS0079 (separation group 4) or ABHS0080 (separation group 1) to de-energize the associated solenoid valves.

The following table identifies the solenoids and associated control cables for each hand switch.

MSIV	ABHS0079 (Sep Group 4)		ABHS0080 (Sep Group 1)	
	Solenoids	Cable	Solenoids	Cable
ABHV0011	MV2, MV4, MV6	14ABK28BH	MV1, MV3, MV5	11ABK29BH
ABHV0014	MV2, MV4, MV6	14ABK29AH	MV1, MV3, MV5	11ABK28AH
ABHV0017	MV2, MV4, MV6	14ABK28AH	MV1, MV3, MV5	11ABK29AH
ABHV0020	MV2, MV4, MV6	14ABK29BH	MV1, MV3, MV5	11ABK28BH

All 4 cables associated with the 12 separation group 4 solenoid valves are run in area C-30. Cable damage due to a fire will likely result in disruption of power to the solenoids, which will close the valves. The four separation group 1 cables associated with hand switch ABHS0080 are unaffected by a fire in area C-30. Therefore, hand switch ABHS0080 is available to close the four MSIVs.

Cable 14ABK30BB provides 125 VDC power to Train B main steam and feedwater isolation actuation system (MSFIS) cabinet SA075B from NK5423. Damage to this cable would disrupt power to the separation group 4 solenoids and close the MSIVs, which is the desired PFSSD position. In addition, the Train A MSFIS is unaffected by the fire and ABHS0080 is available to close the MSIVs.

Based on the above discussion, hand switch ABHS0080 is available to close the MSIVs in the event of a fire in area C-30.

References: E-15000, XX-E-013, E-13AB27, E-13AB28, E-13AB29, E-13AB30, E-1F9101, M-12AB02

5.2.6 Steam Generator Level Indication

The decay heat removal function for PFSSD requires the use of two RCS loops and two Steam Generators. Steam generator (SG) level indication is required to support this function. A fire in area C-30 uses MDAFP A to supply SGs B and C. Therefore, level indication on steam generators B and C is required.

Cables associated with SGs B and C level transmitters AELT0527 (SGB NR) and AELT0537 (SGC NR) run in this area. Damage to these cables could prevent accurate level indication on AELI0527 and AELI0537 in the main control room. Cables associated with the remaining level transmitters on steam generators B and C do not run in this area. Therefore, level indication will be available on steam generators B and C using the following level transmitters:

Steam Generator	Available Level Indication
B	AELI0502 (WR), AELI0528 (NR), AELI0529 (NR), AELI0552 (NR)
C	AELI0503 (WR), AELI0538 (NR), AELI0539 (NR), AELI0553 (NR)

Cables associated with SGs A, B, C and D level indication at the auxiliary shutdown panel (ASP) are run in fire area C-30. The ASP is not credited if a fire occurs in this area so loss of indication at the ASP will have no adverse impact on PFSSD.

Based on the above discussion, steam generator B and C level indication is assured if a fire occurs in area C-30.

References: E-15000, XX-E-013, E-13AE08, E-13SB16, E-1F9203, M-12AE02

5.2.7 Steam Generator Main Feedwater Isolation Valves

PFSSD requires that either the main feedwater isolation valves (MFIVs) be closed, or the main feedwater pumps be stopped to prevent overfilling the steam generators. Flow diversion from auxiliary feedwater (AFW) to the main feedwater system piping is prevented by check valves AEV0420, AEV0421, AEV0422 and AEV0423. Closure of the main feedwater isolation valves is not required to prevent AFW flow diversion.

Each MFIV is designed to utilize system fluid (feedwater) as the motive force to open and close. The valve actuation (open or close) is accomplished through positioning a series of six electric solenoid pilot valves to either direct the system fluid to the Upper Piston Chamber (UPC) and/or the Lower Piston Chamber (LPC), or vent either or both piston chambers. The six solenoid pilot valves are divided into two trains (3 per train) that are independently powered and controlled. Either train can independently perform the PFSSD function to close the valve and isolate main feedwater. This is done by actuating either all close hand switch AEHS0080 (separation group 1) or AEHS0081 (separation group 4) to de-energize the associated solenoid valves.

The following table identifies the solenoids and associated control cables for each hand switch.

MFIV	AEHS0080 (Sep Group 1)		AEHS0081 (Sep Group 4)	
	Solenoids	Cable	Solenoids	Cable
AEFV0039	MV1, MV3, MV5	11AEK16AH	MV2, MV4, MV6	14AEK17AH
AEFV0040	MV1, MV3, MV5	11AEK17AH	MV2, MV4, MV6	14AEK16AH
AEFV0041	MV1, MV3, MV5	11AEK16BH	MV2, MV4, MV6	14AEK17BH
AEFV0042	MV1, MV3, MV5	11AEK17BH	MV2, MV4, MV6	14AEK16BH

All 4 cables associated with the 12 separation group 4 solenoid valves are run in area C-30. Cable damage due to a fire will likely result in disruption of power to the solenoids, which will close the valves. The four separation group 4 cables associated with hand switch AEHS0080 are unaffected by a fire in area C-30. Therefore, hand switch AEHS0080 is available to close the four MFIVs.

Cable 14ABK30BB provides 125 VDC power to Train B main steam and feedwater isolation actuation system (MSFIS) cabinet SA075B from NK5423. Damage to this cable would disrupt power to the separation group 4 solenoids and close the MFIVs, which is the desired PFSSD position. In addition, the Train A MSFIS is unaffected by the fire and AEHS0080 is available to close the MFIVs.

Based on the above discussion, MFIV isolation is assured using hand switch AEHS0080.

References: E-15000, XX-E-013, E-13AB30, E-13AE14, E-13AE15, E-13AE16, E-13AE17, E-1F9201, J-104-00296, M-12AE02, M-630-00044

5.2.8 Auxiliary Feedwater

The PFSSD design requires the use of one auxiliary feedwater pump (AFP) supplying water to at least two steam generators. The turbine driven auxiliary feedwater pump (TDAFP) is normally aligned to supply all four steam generators. The Train A motor driven auxiliary feedwater pump (MDAFP) is aligned to supply steam generators B and C. The Train B MDAFP is aligned to supply steam generators A and D.

The normal source of water to the AFPs is the condensate storage tank (CST). The emergency supply is from the essential service water (ESW) system. For commercial concerns, the CST is the preferred source and contains sufficient volume to supply the entire AFW demand to achieve cold shutdown.

Motor operated valves (MOVs) in the system allow operators to line up the auxiliary feedwater system as required to achieve and maintain safe shutdown. Damage to the MOV circuits due to a fire could prevent operators from lining up the system from the control room.

Several PFSSD cables associated with various components of the auxiliary feedwater system (AL) run through fire area C-30. These cables are identified in Table C-30-3. Damage to these cables could prevent operation of the TDAFP and the Train B MDAFP. In addition, motor operated valves in the flowpath from the Train B MDAFP to steam generators A and D and from the TDAFP to steam generators B and C could spuriously close. Cables associated with the Train A MDAFP, as well as the suction and discharge valves, are unaffected by a fire in this area.

Panels SA036A, SA036B and SA036C monitor pressure transmitter signals on ALPT0037, ALPT0039 and ALPT0038, respectively. A spurious low CST pressure due to fire damage to cables associated with two of these pressure transmitters could swap the water source to ESW. This is only a commercial concern and should be prevented if possible. An instrument cable associated with ALPT0039 runs in this area. Damage to this cable could cause a spurious low CST pressure signal but will not initiate swapover to the ESW system since cables for the remaining two pressure transmitters are unaffected.

Power cables associated with SA036B are run in this area. Damage to these cables could result in a loss of power to the panel but panels SA036A and SA036C remain available. Therefore, automatic operation of low suction pressure (LSP) swapover is available.

A cable associated with the Train B MDAFP room cooler is run in this area. Damage to this cable could prevent operation of the cooler. The Train A MDAFP room cooler is unaffected.

Based on the above discussion, auxiliary feedwater is assured if a fire occurs in area C-30 using Train A MDAFP supplying auxiliary feedwater to steam generators B and C.

References: E-15000, XX-E-013, E-13AL01A, E-13AL01B, E-13AL02B, E-13AL03A, E-13AL03B, E-13AL04B, E-13AL05A, E-13AL05B, E-13AL07B, E-13AL08, E-13AL09, E-13GF01, E-13SA21, E-1F9202, E-1F9203, E-1F9204, E-1F9402A, E-1F9402B, E-1F9444, J-10SA, M-12AL01, M-12GF01

5.2.9 Reactor Coolant Pump (RCP) Seal Injection

PFSSD requires RCP seal injection to provide a boron injection path, provide makeup to the RCS to maintain hot standby inventory and prevent damage to the RCP seals. The Component Cooling Water (CCW) system is an alternative means of cooling the RCP seals.

A fire in area C-30 could damage power and control cables associated with all four RCP seal injection valves (BBHV8351A, BBHV8351B, BBHV8351C and BBHV8351D). The seal injection valves are normally open and de-energized with the circuit breaker maintained in the OFF position. The valves are not high/low pressure interface valves so three-phase hot shorts do not have to be considered and, consequently, damage to the power cables will not cause the valves to spuriously close. Damage to the control cables will not cause the valves to close because the power and control circuits are de-energized. Therefore, a fire in this area will not cause the seal injection valves to close.

Cable 14BGG52BC is associated with centrifugal charging pump (CCP) B to RCP seal injection valve BGHV8357B. Redundant Train A CCP to RCP seal injection valve BGHV8357A is unaffected.

Cable 14BGI51BA is associated with RCP seal total flow transmitter BGFT0215B. Damage to this cable could cause a loss of seal flow indication on BGFI0215B. RCP seal total flow indicator BGFI0215A is unaffected by a fire in area C-30 and can be used to diagnose a loss of RCP seal injection.

Based on the above discussion, RCP seal injection is unaffected. RCP seal total flow indicator BGFI0215A can be used to diagnose a loss of RCP seal injection in the event of a loss of the operating charging pump.

References: E-15000, XX-E-013, E-13BB04, E-13BG51, E-13BG52, E-1F9102, E-1F9302, E-1F9303, M-12BB03, M-12BG03

5.2.10 Component Cooling Water

The component cooling water system is required for PFSSD to provide cooling water to the CCP oil coolers, seal water heat exchanger, RHR heat exchanger and RHR pump seal cooler. In addition, the CCW system provides cooling to the RCP thermal barriers and is credited as a backup to RCP seal injection for maintaining seal cooling.

Cables associated with components on the Train B CCW system run through area C-30. Damage to these cables due to a fire could prevent operation of the associated equipment and prevent operation of Train B CCW. Cables associated with redundant Train A CCW are run in a different fire area and are unaffected by the fire.

Cables associated with Train B CCW pump room cooler SGL11B run in area C-30. Damage to these cables could prevent operation of the unit. Cables associated with redundant Train A CCW and room cooler SGL11A are run in a different fire area and are unaffected by the fire.

To ensure an operable flow path from CCW to the RCP thermal barriers, either valves EGHV0071 or EGHV0126 must be open and either EGHV0058 or EGHV0127 must be open. In addition, either valves EGHV0062 or EGHV0132 must be open and either EGHV0061 or EGHV0133 must be open. Also, when operating the Train A CCW system, valve EGHV0015 needs to be open to ensure a return flow path to the suction side of the CCW pumps and EGHV0053 needs to be open to ensure CCW flow to the service loop.

Cables associated with valves EGHV0062, EGHV0071, EGHV0127 and EGHV0133 run through area C-30. If the fire affects cables associated with EGHV0062 and EGHV0071, the valves may spuriously close. If this occurs, Operators could open valves EGHV0132 and

EGHV0126 using associated hand switches EGHIS0132 and EGHIS0126 on RL020 to restore thermal barrier cooling.

If the Train B CCW system is operating at the time of the fire, operators may need to swap to Train A CCW using hand switches in the control room. If the Train A CCW system is operating at the time of the fire, the CCW system is in the protected lineup except that EGHV0126 and/or EGHV0132 may need to be opened from the control room.

Cable 14EGI19BB is associated with CCW to RCP flow transmitter EGFT0129. Damage to this cable could prevent operators from diagnosing a loss of CCW flow to the RCP thermal barriers using flow indicator EGFI0129. CCW to RCP flow indicator EGFI0128 is unaffected by a fire in area C-30 and can be used to diagnose a loss of CCW flow to the RCP thermal barriers.

Based on the above discussion, Train A CCW is available to provide cooling to essential PFSSD components as well as provide cooling to the RCP thermal barriers. Loss of CCW flow to the RCP thermal barriers can be diagnosed using flow indicator EGFI0128.

References: E-15000, XX-E-013, E-13EG01C, E-13EG01D, E-13EG05A, E-13EG05B, E-13EG05D, E-13EG09, E-13EG10, E-13EG13, E-13EG15, E-13EG16, E-13EG18, E-13EG18A, E-13EG19, E-13GL06, E-1F9303, E-1F9401A, E-1F9401B, E-1F9444, M-12EG01, M-12EG02, M-12EG03, M-12GL02

5.2.11 Residual Heat Removal (RHR)

PFSSD requires one train of residual heat removal (RHR) to be available for shutdown cooling. The RHR system is not used for hot standby.

Hot shutdown requires isolation of the RCS to RHR flow path by maintaining either BBPV8702A or EJHV8701A closed and either BBPV8702B or EJHV8701B closed. Cold shutdown requires RHR taking suction from the RCS. RHR pump suction from the RCS is controlled by valves BBPV8702A and EJHV8701A (Train A) and BBPV8702B and EJHV8701B (Train B). The PFSSD methodology credits Train A RHR to achieve cold shutdown if a fire occurs in area C-30.

A control cable associated with RHR pump B (PEJ01B) could be damaged, causing a spurious pump start or preventing the pump from being started. Cables associated with RHR pump A are unaffected by a fire in area C-30.

Cables 14BBG12AF and 14BBG12AG are control cables associated with BBPV8702A. An inter-cable (cable-to-cable) hot short between cables 14BBG12AF and 14BBG12AG will bypass the control room hand switch and provide the permissive to open BBPV8702A. Valve EJHV8701A will remain closed since cables associated with this valve are not run through area C-30. Furthermore, BBPV8702A and EJHV8701A are administratively maintained closed with the breaker locked open. The 3-phase power cables associated with both valves are not run in this area, so a 3-phase hot short is not credible.

Cables 14BBG12BF and 14BBG12BG are control cables associated with BBPV8702B. An inter-cable (cable-to-cable) hot short between cables 14BBG12BF and 14BBG12BG will bypass the control room hand switch and provide the permissive to open BBPV8702B. Valve EJHV8701B will remain closed since cables associated with this valve are not run through area C-30. Furthermore, BBPV8702B and EJHV8701B are administratively maintained closed with the breaker locked open. The 3-phase power cables associated with both valves are not run in this area, so a 3-phase hot short is not credible.

An open circuit in cable 14BBG12AF could prevent remote opening of valve BBPV8702A when transitioning to RHR Train A. If this occurs, a cold shutdown repair or a containment entry will be necessary to open the valve. Valve EJHV8701B can be controlled from the control room.

Valve EGHV0101 is the Train A CCW to RHR Heat Exchanger control valve. Valve EGHV0102 is the Train B CCW to RHR Heat Exchanger control valve. These valves are normally closed during power operation. PFSSD requires that the valve on the operating train of CCW be closed until shutdown cooling mode is entered, at which time the valve on the operating train of RHR needs to be open. As stated in Section 5.2.10, the Train B CCW system may not be available to supply cooling water to the Train B RHR heat exchanger. Cables 14EGG07BA, 14EGG07BB and 14EGG07BC are associated with valve EGHV0102. Damage to the cables could prevent operation of EGHV0102 and damage to cable 14EGG07BC could cause the valve to spuriously open. Valve EGHV0101 is unaffected by a fire in this area.

When RHR pumps are operating, the associated mini-flow valve (EJFCV0610 or EJFCV0611) needs to be controlled. The mini-flow valves prevent RHR pump overheating by re-circulating water from the discharge side of the RHR heat exchanger to the suction side of the RHR pump. The mini-flow valve opens when the flow indicator measures low flow and closes on high flow. Damage to cable 14EJG08BC could prevent mini-flow valve EJFCV0611 from operating properly. If the Train B RHR pump spuriously starts and EJFCV0611 fails to operate, the pump could be damaged. This is a commercial concern only since Train A RHR pump and mini-flow valve EJFCV0610 are unaffected by a fire in this area.

The RHR heat exchanger discharge control valve on the operating train (EJHCV0606 (Train A) or EJHCV0607 (Train B)) needs to be available. Cable 16EJI12BA, which is associated with EJHCV0607, runs through area C-30. Cable 16RLY01DA provides 120 VAC power to RL017/RL018 (EJHY0607) from PN0833. Damage to these cables could result in a loss of valve EJHCV0607. Valve EJHCV0606 is unaffected by a fire in this area.

RHR pump A discharge to CVCS control valve EJHV8804A needs to be closed when operating the Train A RHR system. RHR pump B discharge to SI Pump B control valve EJHV8804B needs to be closed when operating the Train B RHR system. Damage to cable 14EJG04BC could cause valve EJHV8804B to spuriously open. The Train A RHR system is credited for a fire in this area so spurious opening of EJHV8804B will have no adverse impact on PFSSD. Cables associated with EJHV8804A do not run in area C-30.

Cables associated with Train B RHR pump discharge to RCS cold leg isolation valve EJHV8809B run in area C-30. Damage to these cables could prevent operating the valve from the control room. Cables associated with Train A RHR pump discharge to RCS cold leg isolation valve EJHV8809A do not run in area C-30. Consequently, valve EJHV8809A is unaffected by a fire in area C-30.

The cold shutdown mode of PFSSD requires isolation of hot leg recirculation. Valve EJHV8840 is used to isolate RHR flow to the RCS hot leg loops 2 and 3. This valve is normally closed and is required to be closed for cold shutdown. During hot standby, the valve can be in any position. Cables associated with valve EJHV8840 run through area C-30. Damage to cables 14EJG09AC and 14EJG09AD would likely result in valve EJHV8840 remaining in its as-is normally closed position, which is the preferred PFSSD position. However, two proper intra-cable hot shorts in cable 14EJG09AD or one intra-cable hot short in cable 14EJG09AD combined with a short to ground on conductor U1 would spuriously open the valve.

As stated above, the position of valve EJHV8840 (open or closed) will not affect hot standby. The valve needs to be closed for cold shutdown. The valve has been modified to address NRC IN 92-18 and can be closed manually prior to entering shutdown cooling mode. The torque and limit switches are not bypassed by postulated damage to these cables.

Based on the above discussion, the Train B RHR system could be affected by a fire in this area but the Train A RHR system is available. Valve BBPV8702A may need to be manually opened

and valve EJHV8840 may need to be manually closed when transitioning to Train A RHR for shutdown cooling.

References: E-15000, XX-E-013, E-13BB12A, E-13BB12B, E-13EG07A, E-13EJ01, E-13EJ04B, E-13EJ08, E-13EJ09C, E-13EJ12, E-13RL01, E-13RL04, E-1F9205, E-1F9301, E-1F9401A, E-1F9421, M-12BB01, M-12EJ01

5.2.12 Pressurizer Power Operated Relief Valves and Associated Block Valves

PFSSD requires that either the pressurizer power operated relief valve (PORV) or its associated block valve be closed. Cables and components associated with PORV BBPCV0456A and associated block valve BBHV8000B are run through area C-30. Cables and components associated with PORV BBPCV0455A and associated block valve BBHV8000A are not located in area C-30.

The pressurizer PORVs are not considered high/low pressure interfaces. The valves are supplied power by an ungrounded 125 VDC system. Therefore, based on GL 86-10, consideration of multiple proper polarity hot shorts is not required. A single proper polarity hot short still needs to be considered.

In the event a fire causes BBPCV0456A to open and damages BBHV8000B cables, Operators can close BBPCV0456A by placing hand switch BBHIS0456A, located on RL021, in the close position. Pressurizer level and RCS pressure indication are available to diagnose a failed open PORV using BBLI0459A and BBPI0405, respectively. In addition, pressurizer pressure indication is available using BBPI0455A, BBPI0456 and BBPI0457.

An instrument cable (14BBI16NB) associated with pressurizer pressure transmitter BBPT0458 is run in fire area C-30. Damage to this cable could send a spurious high-pressure signal to the pressure control system. However, as discussed in Calculation XX-E-013, Appendix 1, damage to a single pressure channel will not cause the spurious operation of the pressurizer PORVs.

Based on the above discussion, pressurizer PORV BBPCV0456A could spuriously open due to damage to the PORV control cables and block valve BBHV8000B may not close due to cable damage. The PORV can be closed using hand switch BBHIS0456A in the main control room.

References: XX-E-013, E-15000, M-12BB02, E-13BB39, E-13BB40, E-13BB16, E-1F9301, E-1F9421, CR 13079, DCP 12944, DCP 13324

5.2.13 Reactor Coolant System (RCS) Pressure Indication

The PFSSD design requires RCS pressure indication to be available. RCS pressure indication is provided in the control room using BBPI0405 or BBPI0406. A cable (14BBI16BB) associated with pressure transmitter BBPT0406 is located in fire area C-30. Damage to this cable could prevent RCS pressure indication on BBPI0406.

Cables associated with redundant RCS pressure transmitter BBPT0405 are unaffected by a fire in this area. Therefore, RCS pressure indication is available using BBPI0405.

References: E-15000, XX-E-013, E-13BB16, E-1F9201, E-1F9205, M-12BB04

5.2.14 Reactor Head Vent Valves

PFSSD requires that one of the two reactor vessel head vent valves on each flow path (2 flow paths total) be closed to prevent uncontrolled depressurization of the RCS. Either BBHV8001A or BBHV8002A and either BBHV8001B or BBHV8002B needs to be closed.

A cable (14BBK30DA) associated with one of the four head vent valves (BBHV8002B) runs through area C-30. Cables for remaining head vent valves BBHV8001A, BBHV8002A and BBHV8001B are not run through C-30 and are unaffected by the fire. Therefore, at least one valve on each flow path can be controlled and spurious opening of BBHV8002B will have no adverse impact on PFSSD.

References: E-15000, XX-E-013, E-13BB30, E-1F9301, M-12BB04

5.2.15 Centrifugal Charging Pumps

At least one centrifugal charging pump (CCP) is required for PFSSD to provide RCP seal cooling, reactivity control and inventory control. These functions are accomplished using a CCP taking suction from the refuelling water storage tank (RWST) and injecting through the RCP seals. RCP seal injection provides approximately 20 gpm makeup to the RCS and provides adequate boron concentration to maintain sub-critical reactivity conditions. If RCP seal injection is unavailable, reactivity and inventory control is provided by lining up the CCPs to the boron injection tank (BIT). The normal charging pump (NCP) is not credited and is assumed lost.

A control cable associated with Train B Centrifugal Charging Pump (CCP) PBG05B runs through area C-30. Damage to this cable could prevent operation of the pump. Redundant Train A CCP cables are run in a separate fire area and are unaffected by a fire.

Control cables associated with Train B charging pump miniflow valve BGHV8111 are run through area C-30. Redundant Train A cables for miniflow valve BGHV8110 are run in a different area and are unaffected by a fire in area C-30.

Cables associated with RWST to charging pump B control valve BNLCV0112E are run in this area. Damage to these cables could prevent opening or cause spurious closure of the valve. Redundant valve BNLCV0112D is unaffected by a fire in area C-30.

Based on the above discussion, the Train A CCP is available if a fire occurs in area C-30.

References: XX-E-013, E-15000, E-13BG01A, E-13BG11C, E-13BN01A, E-1F9102, E-1F9302, E-1F9401A, M-12BG03, M-12BN01

5.2.16 Charging Flow to Regenerative Heat Exchanger Isolation Valves

PFSSD requires charging flow to be directed to the RCS through the RCP seals and/or the boron injection tank. To ensure adequate flow to the RCS, flow diversion to the regenerative heat exchanger needs to be prevented. Valves BGHV8105 and BGHV8106 are included in the PFSSD equipment list to accomplish this task. Manual valve BG8402B is also included to provide an alternate means of closing this flow path during alternate safe shutdown using OFN-RP-017.

A control cable associated with BGHV8105 is run in area C-30 and could be damaged by a fire, preventing valve BGHV8105 from being closed from the control room. Cables associated with valve BGHV8106, and its hand switch (BGHIS8106), are unaffected by a fire in area C-30. Therefore, valve BGHV8106 is available to isolate flow to the regenerative heat exchanger.

References: E-15000, XX-E-013, E-13BG11A, E-1F9102, E-1F9302, M-12BG03

5.2.17 Volume Control Tank (VCT) Discharge Valves

PFSSD requires isolation of the Volume Control Tank (VCT) discharge to charging pumps suction using either valve BGLCV0112B or BGLCV0112C. Power and control cables associated with BGLCV0112C are run in area C-30. Damage to these cables could prevent closing this valve from the control room. Cables associated with BGLCV0112B are unaffected by a fire in this area.

Cable 14BGI51DA is an instrumentation cable for VCT level transmitter BGLT0185. Damage to this cable could send a false VCT low-low level signal and close relay K647 on the close circuit for valve BGLCV0112C. This would fail the valve closed if all other permissives are met, which is the desired PFSSD position. Therefore, damage to this cable will have no adverse impact on the ability to isolate the VCT discharge flow path.

Based on the above discussion, valve BGLCV0112B can be isolated using BGHIS0112B in the main control room.

References: E-15000, XX-E-013, E-13BG12A, E-13BG51, E-1F9102, E-1F9302, M-12BG03

5.2.18 Excess Letdown

The excess letdown flowpath is required to be isolated to prevent uncontrolled depressurization of the RCS. Therefore, either normally closed valve BGHV8153A or BGHV8154A must be maintained closed and either normally closed valve BGHV8153B or BGHV8154B must be maintained closed.

One cable associated with BGHV8154B runs through fire area C-30. Therefore, the remaining valves are unaffected by a fire in area C-30 and will remain closed.

References: E-15000, XX-E-013, E-1F9301, E-13BG48, M-12BG01

5.2.19 Steam Generator Blowdown to Blowdown Flash Tank Isolation Valves

The reactivity control function requires the steam generator blowdown to blowdown flash tank valves (BMHV0001, BMHV0002, BMHV0003, and BMHV0004) be closed to prevent reactivity addition from uncontrolled cooldown. Cables associated with these valves are run in area C-30. An open circuit in these cables will fail the valves closed, which is the desired PFSSD position. A hot short on these cables could prevent the valves from being closed using hand switches BMHIS0001A, BMHIS0002A, BMHIS0003A and BMHIS0004A in the main control room.

Redundant capability exists for closing valves BMHV0001, BMHV0002, BMHV0003 and BMHV0004. The redundant means uses BMHIS0001C, BMHIS0002C, BMHIS0003C and BMHIS0004C, located on the BM157 panel in the radwaste control room. Access is available without traversing area C-30.

Although the configuration is not in literal compliance with 10CFR50, Appendix R, feasible manual actions are available and are unaffected by the fire.

Thermal hydraulic analysis WCNOC-CP-002 shows insignificant impact on SG inventory even with all four blowdown valves open. Therefore, no E-1F9900 OMA is required to close blowdown valves to achieve and maintain hot standby. Reference Attachment 4, MSO Evaluation Scenario ID PWROG 34.

References: E-15000, XX-E-013, E-13BM06A, E-1F9101, M-12BM01

5.2.20 Refueling Water Storage Tank (RWST) and Containment Sump Isolation Valves

To prevent draindown of the RWST into the containment sump, PFSSD requires that either valve BNHV8812A or valve EJHV8811A and valve BNHV8812B or valve EJHV8811B be closed during hot standby. For cold shutdown, the operating train containment sump valve (EJHV8811A or EJHV8811B) must be maintained closed to prevent flow diversion from the RCS to the containment sump. Valves BNHV8812A and BNHV8812B are normally open and valves EJHV8811A and EJHV8811B are normally closed.

Cable 14BNG03BC, associated with valve BNHV8812B, runs through area C-22. Damage to this cable could prevent closing this valve from the control room or could cause the valve to spuriously close. In addition, cable damage could prevent the valve from automatically closing when valve EJHV8811B reaches full open position.

A control cable (14EJG06BC) associated with valve EJHV8811B runs through fire area C-30. Damage to this cable will not result in valve EJHV8811B opening as long as valve BNHV8812B remains open. If valve BNHV8812B is fully closed, it will provide a permissive for valve EJHV8811B to open. If valve EJHV8811B opens due to damage to cable 14EJG06BC, draindown will not occur since valve BNHV8812B is closed.

Cable 14BNI07FA, associated with RWST level transmitter BNLT0933, is run in area C-30. Circuits for the remaining three RWST level transmitters are not run in area C-30. Therefore, RWST level indication is available using BNLI0930, BNLI0931 and BNLI0932.

Based on the above discussion, draindown of the RWST to the containment sump is not credible if a fire occurs in area C-30.

References: E-15000, XX-E-013, E-13BN03A, E-13EJ06B, E-13BN07, E-1F9102, E-1F9204, E-1F9205, M-12BN01, M-12EJ01, M-10BN

5.2.21 Essential Service Water

Either the Train A or the Train B essential service water (ESW) system is required to be available to ensure PFSSD. The ESW system supplies water to the following PFSSD components on the associated train:

- CCP room cooler
- RHR pump room cooler
- Class 1E switchgear room A/C condenser
- diesel generator engine cooling
- control room A/C condenser
- auxiliary feedwater pump room cooler
- motor and turbine driven auxiliary feedwater pump suction (backup to CST)

- containment air coolers
- electrical penetration room cooler
- component cooling water pump room cooler
- component cooling water heat exchanger
- component cooling water system makeup

A number of components associated with Train B ESW system could be affected by a fire in this area. The Train B ESW pump and a number of Train B ESW control valves could spuriously operate or may not operate when required. The Train B ESW pump room supply fan and associated dampers may not operate. Therefore, the Train B ESW system cannot be relied on if a fire occurs in this area.

The service water system provides the normal source of water to the ESW piping. Service water supply to and return from the ESW piping is each controlled by two valves installed in series. One of the two valves on each leg is required to be closed for PFSSD to prevent flow diversion from the credited ESW system. As discussed in the previous paragraph, the Train B ESW system may not be available if a fire occurs in this area. One valve (EFHV0025) on the Train A service water to ESW piping supply line and one valve (EFHV0039) on the Train A ESW to service water return line may be affected by the fire and may not close on a signal from the control room. Redundant valves EFHV0023 and EFHV0041 are unaffected by the fire and will close on a signal from the control room. Therefore, the ESW/service water cross connects can be isolated if a fire occurs in this area. In addition, check valve EFV0470 is installed between valves EFHV0023 and EFHV0025 and will prevent flow diversion from Train A ESW to the service water system. Also, check valve EFV0471 is installed between valves EFHV0024 and EFHV0026 and will prevent flow diversion from Train B ESW to the service water system.

Cable 14RPY10BA supplies 120 VAC control power to the automatic and manual start circuits for the Train B ESW pump room supply fan CGD01B. The control power is supplied via this cable to control room panel RP068. If power is lost due to damage to this cable, then the Train B ESW pump room supply fan will not start either automatically, when the ESW pump starts, or manually from the control room. If this occurs, the Train A ESW pump room supply fan remains unaffected by the fire.

Cables 14GDY01BA, 14GDY01BB and 14GDY01BD are associated with Train B ESW pump room supply fan CGD01B. Damage to these cables could prevent operation of the supply fan. Train A ESW pump room supply fan CGD01A is unaffected by a fire in this area.

The Train A ESW system is unaffected by a fire in area C-30 and ESW remains available in the event of a fire in this area.

References: E-15000, XX-E-013, E-13EF02, E-13EF02A, E-13EF03, E-13EF04, E-13EF05, E-13EF06A, E-13EF07A, E-13EF08A, E-13EF09A, E-13EF11, E-13RP10, E-K3EF01A, E-K3EF08, E-K3GD01A, E-K3GD04, E-K3GD04A, J-201-00133, E-1F9402A, E-1F9402B, E-1F9403, E-1F9424B, E-1F9443, M-12EF01, M-12EF02, M-K2EF01, M-K2GD01

5.2.22 Safety Injection (SI) Pumps

The preferred PFSSD condition of the SI pumps is off. Therefore, a spurious start of the SI pumps should be avoided or mitigated. A control cable (14EMB01BB) associated with Train B SI pump PEM01B runs through area C-30 and could cause a spurious start of the pump and prevent stopping the pump from the control room.

If the Train B SI pump spuriously starts with the reactor at normal pressure, PFSSD will be assured. The pump will not discharge into the RCS due to the pressure differential between the RCS (approximately 2,235 psig) and the SI pump shutoff pressure (approximately 1,565 psig). In addition, the setpoint of the discharge relief valve (EM8853B) to the Recycle Holdup

Tank is 1,825 psig. Therefore, no inventory is lost from the RWST if the SI pumps spuriously start. With the SI pump operating with no flow, damage to the pump could occur, which is a commercial concern since the SI pump is not credited in the PFSSD analysis. If necessary, the pump can be stopped by opening breaker NB0202, but this action is not required for PFSSD.

Based on the above discussion, spurious operation of the Train B SI pump will not adversely impact PFSSD.

References: XX-E-013, E-15000, E-13EM01, E-1F9102, E-1F9302, M-12EM01, M-721-00096, WCRE-01

5.2.23 Boron Injection Tank Flowpath

The Boron Injection Tank (BIT) flowpath is credited for reactivity control and reactor coolant makeup. For reactivity control, the BIT flowpath is credited as an alternate source of boration in the event RCP seal injection is unavailable. Based on Calculation XX-E-013, RCP seal injection will provide sufficient boration to achieve and maintain cold shutdown reactivity conditions. Therefore, the BIT flowpath is not required for reactivity control if RCP seal injection is available. Since RCP seal injection is limited to 5 gpm per seal or 20 gpm total injection to the RCS, an additional RCS charging flowpath is required for adequate RCS makeup during plant transition from hot standby to cold shutdown. The BIT injection path was selected as the additional RCS charging flowpath.

As discussed in Section 5.2.9, RCP seal injection is available in the event of a fire in area C-30. In addition, the letdown and excess letdown flowpaths can be isolated if a fire occurs in this area. Therefore, boration and inventory control through the BIT is not required to ensure PFSSD.

A cable associated with Train B BIT inlet valve EMHV8803B is run in this area. Damage to this cable could prevent opening the valve from the control room. Train B BIT outlet valve EMHV8801B is unaffected by a fire in this area. Cables associated with redundant Train A valve EMHV8803A are unaffected by a fire in this area. Therefore, BIT injection is available using the Train A CCP and valves EMHV8803A and EMHV8801A.

To prevent CCP flow diversion through the SIS test line when charging through the BIT, valves EMHV8843 and EMHV8882 need to be closed. If either or both of these valves cannot be closed, then closing or maintaining closed either valve EMHV8871 or EMHV8964 will prevent flow in the SIS test line. Cables associated with EMHV8843 and EMHV8871 are run in this area. Damage to these cables could cause the valves to open. Cables associated with EMHV8964 do not run in area C-30. Therefore, valve EMHV8964 can be controlled to prevent flow through the SIS test line when charging through the BIT.

Based on the above discussion, the BIT flowpath is available to provide a charging flowpath using the Train A CCP.

References: E-15000, XX-E-013, E-13EM02A, E-13EM02B, E-13EM02C, E-13EM04, E-13EM04A, E-1F9302, M-12EM01, M-12EM02

5.2.24 Containment Spray (CS) Pumps

Spurious start of the CS pumps may complicate PFSSD due to the possible depletion of inventory in the RWST. Therefore, a spurious start of the CS pumps should be avoided or mitigated. A control cable (14ENB01BB) associated with Train B CS pump PEN01B runs through area C-30 and could cause a spurious start of the pump. The cable damage could prevent stopping the pump from the control room.

Normally closed valve ENHV0012 could open due to damage to associated control cables. If this occurs coincident with a running Train B CS pump, water would flow from the containment spray nozzles, depleting inventory in the RWST.

The total flow in the containment spray system during injection phase with one pump operating is 3,165 gpm (M-10EN). Based on calculation XX-E-013, Appendix 1, a maximum of 214,260 gallons of water can be lost from the RWST to maintain sufficient volume to achieve cold shutdown.

As stated previously, level indication in the RWST is available, so operators have the ability to diagnose a reducing RWST inventory. The time available to mitigate containment spray is:

214,260 gallons / 3,165 gpm = 67.7 minutes

Based on the above discussion, there is 67.7 minutes available to mitigate containment spray. This is an OMA. Refer to E-1F9900 for details. Reference Attachment 4, MSO Evaluation Scenario ID PWROG 16.

References: XX-E-013, E-15000, E-13EN01, E-13EN03, E-1F9102, E-1F9302, E-1F9424B, E-1F9433, M-10EN, M-12EN01

5.2.25 Safety Injection Accumulator Isolation Valves

PFSSD requires isolation of the SI accumulators prior to reducing RCS pressure below the injection pressure to avoid unnecessary accumulator discharge. This is accomplished by closing valves EPHV8808A, EPHV8808B, EPHV8808C and EPHV8808D. These valves are normally open with the MCC breaker administratively locked in the open position. Cables for valves EPHV8808B and EPHV8808D are run in area C-30.

Since the breakers for these valves are normally open, damage to these cables will not cause the valves to spuriously change position. However, damage to the cables will prevent closing the associated valve from the control room after power is restored.

The SI accumulators need to be isolated during cold shutdown, prior to the RCS reaching 1000 psig. If necessary, a containment entry can be made to manually close the valves.

References: E-15000, XX-E-013, E-13EP02A, E-1F9201, M-12EP01, CKL EP-120

5.2.26 TDAFP Steam Trap Drain Valve

Valve FCFV0310 is an isolation valve on the 1-inch steam trap line associated with the TDAFP. Solenoid valve FCFY0310 controls the position of valve FCFV0310. PFSSD requires this valve to be closed to prevent uncontrolled loss of steam through this flow path.

Cable 14FCK21AA is a control cable associated with valve FCFV0310. Inter or intra-cable hot shorts could cause the valve to spuriously open. There are no energized 125 VDC cables in the same conduit as cable 14FCK21AA, so inter-cable hot shorts causing the valve to open are not possible. An intra-cable hot short from conductor 2 to conductor 1 will energize the solenoid and open the valve. This can be mitigated by depressing the close pushbutton on hand switch FCHIS0310. However, since this is a momentary contact switch, the operator would have to maintain the button in the depressed position.

Uncontrolled blowdown through this 1-inch line is bounded by the main steam line break analysis and loss of steam through this line will not result in uncontrolled cooldown. Therefore, if the valve remains open, PFSSD is assured.

References: E-15000, XX-E-013, E-13FC21, E-1F9202, M-12FC02

5.2.27 Control Room Air Conditioning

Control room air conditioning is required to be available to satisfy the PFSSD support function. Two redundant and independent air conditioning units (SGK04A and SGK04B) are provided to satisfy this function. At least one unit is required to be available for PFSSD.

Several cables associated with Train B Control Room A/C Unit SGK04B and associated dampers are run in this area. Damage to these cables could prevent operation of the unit.

The Train A control room A/C unit is unaffected by a fire in this area. Therefore, control room air conditioning is available if a fire occurs in area C-30.

References: XX-E-013, E-15000, E-13GK02A, E-13GK02C, E-13GK02D, E-13SA20, E-1F9442, M-12GK01, M-622.1A-00007

5.2.28 Class 1E Electrical Equipment Room Air Conditioning

The PFSSD support function requires Class 1E electrical equipment air conditioning on the operating train of equipment. Class 1E electrical equipment air conditioning is provided by units SGK05A (Train A) and SGK05B (Train B).

Cables associated with Train B Class 1E electrical equipment room A/C unit SGK05B are run in area C-30. Damage to these cables could prevent operation of the unit.

Cables associated with Train A Class 1E electrical equipment room A/C unit SGK05A are unaffected by a fire in this area. Therefore, room cooling for Train A Class 1E electrical equipment remains available.

References: XX-E-013, E-15000, E-13GK13A, E-13SA20, E-1F9444, M-12GK03, M-622.1A-00002

5.2.29 Standby Diesel Generation

Cables associated with the Train B diesel generator are run in this area. Also, cables associated with the Train B diesel generator room exhaust damper GMHZ0019 run in this area. Damage to these cables could prevent operation of the Train B diesel generator.

A fire in area C-30 could cause a loss of several Train B components, however, Train A components are available and are unaffected by the fire. Based on calculation XX-E-013, off-site power is available on Train A if a fire occurs in area C-30. Therefore, neither diesel generator is required if a fire occurs in this area and mal-operation of the Train B diesel generator will have no adverse impact on safe shutdown.

References: XX-E-013, E-15000, E-12KJ01, E-13GM01A, E-13GM04A, E-13JE01, E-13JE01A, E-13JE04, E-13KJ03A, E-13KJ07, E-13NE11, E-13NE13, E-1F9411A, E-1F9411B, E-1F9412A, E-1F9412B, E-1F9444, M-12GM01, M-12JE01

5.2.30 Containment Coolers

PFSSD requires containment cooling to maintain the containment environment within EQ limits. Cables associated with Train B containment coolers are run in area C-30. Damage to these cables could prevent operation of the Train B containment coolers. Circuits associated with Train A containment coolers are run in a separate fire area and are unaffected by a fire in area C-30.

As discussed earlier, Train A ESW is available if a fire occurs in area C-30. Therefore, the Train A containment coolers will have the necessary service water flow to ensure proper operation.

References: E-15000, XX-E-013, E-13GN02A, E-1F9441, M-12GN01

5.2.31 Class 1E 4.16 kV ESF Switchgear Bus NB01 and NB02

Bus NB02 supplies power to Train B Engineered Safety Features (ESF) components. A fire in area C-30 could damage cables associated with NB02 and disrupt power to all Train B ESF components.

Control cables associated with bus NB02 Synchro-scope and associated switches are run in area C-30. Damage to these cables could prevent some of the monitoring functions for NB02 but would not cause a loss of the NB02 bus.

Redundant Train A ESF components, supplied by NB01, are unaffected by a fire in area C-30. Therefore, loss of power to Train B components due to a fire in area C-30 will not impact the ability to achieve and maintain safe shutdown.

References: XX-E-013, E-15000, E-13NB04, E-13NB05, E-13NB06, E-13NB14, E-13NB15, E-1F9423, E-1F9426, KD-7496

5.2.32 Load Shedder / Emergency Load Sequencer

The load shedder and emergency load sequencers are included in the PFSSD design to evaluate the impact of spurious operation or mal-operation. The load shedder/emergency load sequencer operates upon presence of the following conditions:

1. An undervoltage (UV) on a safeguards bus,
2. A safety injection signal (SIS) or a containment spray actuation signal (CSAS), or
3. An undervoltage on a safeguards bus with a SIS or CSAS.

Eight inputs (four undervoltage (UV) inputs and four degraded voltage inputs) on each safeguards bus (NB01 and NB02) monitor voltage conditions on that bus. An undervoltage condition on two of four UV relays on each bus will actuate the load shedder/sequencer and send a signal to start the associated diesel generator. In addition, degraded voltage sensed by two of four degraded voltage potential transformers (PTs) will, after a time delay, provide a signal to open the offsite feeder breakers on the associated bus.

Cables 14NFK01CA and 14NFK01DA for one of the four UV relays on each bus are run in fire area C-30. Also, cables 14NFY01EA and 14NFY01FA associated with one of the four degraded voltage PTs on each bus are run in fire area C-30. Cables associated with the remaining three UV relays and PTs do not run in fire area C-30. Therefore, automatic functioning of the bus NB01 and NB02 emergency load shedder / sequencer is unaffected by a fire in area C-30 and a spurious start of the associated diesel generator due to a false undervoltage condition on two of the four circuits is not credible.

Cable 14NFK01AA is a DC power cable that runs from NK5412 to NF039C. Damage to this cable could prevent an auto start of the Train B emergency diesel generator upon degraded voltage on 2/4 Train B undervoltage relays or 2/4 input of Train B degraded voltage PTs.

Separation group 4 power cables 14NFY01GA and 14NFY01HA associated with NF039A, NF039B and NF039C are run in this area. Separation groups 1, 2 and 3 power cables associated with these panels are unaffected. Therefore, power to the load shedder/sequencer panels is available.

Based on the above discussion, the Train B emergency diesel generator may not be available if a fire occurs in this area but the Train A load shedder/sequencer is unaffected. In addition, off-site power to Train A components is unaffected based on Calculation XX-E-013, Appendix 2.

References: XX-E-013, E-15000, E-11NB01, E-11NB02, E-12NF01, E-13NF01, E-10NF, E-1F9411A, E-1F9411B, E-1F9412A, E-1F9412B, E-1F9402A, E-1F9402B, E-1F9403, E-1F9425, E-1F9426

5.2.33 Train B 480 Volt Class 1E Load Centers

Cables associated with Train B 480 VAC Class 1E load centers NG02, NG04 and motor control center (MCC) NG06E are run in area C-30. In addition, as stated in other sections, loss of power to these load centers could occur due to loss of Train B off-site and on-site power. Therefore, Train B load centers and associated equipment may not be available if a fire occurs in this area.

Cable 14PKK11AA is associated with 480 VAC breaker NG0409. NG0409 supplies 480 VAC power to Train B 125 VDC battery charger PK22, which energizes the PK02 bus. Damage to this cable could disable power to the battery charger but will not de-energize PK02 due to the installed batteries. Battery set PK12 will maintain 125 VDC power to PK02. In addition, NG0102 is unaffected and will continue to supply power to Train A 125 VDC battery charger PK21.

Redundant Train A components, supplied by NG01, NG03 and NG05E are unaffected by a fire in area C-30. Therefore, loss of power to Train B 480 VAC Class 1E load centers NG02, NG04 and MCC NG06E will not impact the ability to achieve and maintain safe shutdown.

References: XX-E-013, E-15000, E-11NG02, E-13NG01A, E-13NG10A, E-13NG11A, E-13NG11B, E-13PK11, E-K3NG10A, E-1F9411B, E-1F9412B, E-1F9422C, E-1F9423, E-1F9424A. E-1F9424B, E-1F9424C, E-1F9424D

5.2.34 Class 1E 125 VDC Distribution System

Power cables associated with the Class 1E 125 VDC electrical distribution system are run in area C-30. These cables supply 125 VDC power to various PFSSD loads. The cables and supplied PFSSD equipment are summarized in the following table.

CABLE	NK BREAKER	CONTROL PANEL	PFSSD Components
14RLK01AA	NK04407	RL001/002	BGHV8153B, BGHV8154B
14RLK01BA	NK04409	RL005/006	FCFY0310
14RLK01CA	NK04412	RL017/018	EMHV8843, EMHV8871
14RLK01DA	NK04413	RL019/020	EGTV0030, GMHZ0019
14RLK01EA	NK04414	RL021/022	BBHV8001B, BBHV8002B

CABLE	NK BREAKER	CONTROL PANEL	PFSSD Components
14RLK01FA	NK04411	RL023/024	BMHV0001, BMHV0002, BMHV0003, BMHV0004

Damage to these cables could cause a loss of power to the associated components. This is acceptable for PFSSD since the components fail in the desired PFSSD position upon loss of power, or the redundant Train A component is available to perform the PFSSD function.

References: XX-E-013, E-15000, E-13BB30, E-13BG48, E-13BM06A, E-13EG16, E-13EM04, E-13EM04A, E-13FC21, E-13GM04A, E-13RL01, E-13RL02, E-13RL03, E-13RL04, E-13RL05, E-13RL06, E-13RL07, E-1F9101, E-1F9202, E-1F9301, E-1F9302, E-1F9401A, E-1F9422B, E-1F9444, M-12BB04, M-12BG01, M-12BM01, M-12EG02, M-12EM01, M-12EM02, M-12FC02, M-12GM01

5.2.35 BOP Instrument Racks

BOP instrument racks RP053A, RP053B, RP053D and RP147 are credited in the PFSSD analysis. The following table identifies the PFSSD components served by each instrument rack.

Instrument Rack	PFSSD Components
RP053A (RP053AA, RP053AB, RP053AC)	ALHV0009, ALHV0011 ALPY0037A, EGFT0128, EGPSL0077, GDTSL0001, JELSL0001C
RP053B (RP053BA, RP053BB, RP053BC)	ALHV0007, ALPY0039A, EGFT0129, EGPSL0078, GDTSL0011, JELSL0021C
RP053D (RP053DA, RP053DB)	ALPY0038A
RP147 (RP147A, RP147B)	ALHV0005

Cables 14RPY09BA and 14RPY09CA supply 120 VAC power to BOP instrument rack RP053B. Damage to these cables could cause a loss of function of panel RP053B and associated PFSSD components. Redundant components are supplied by the remaining BOP instrument racks.

Instrument racks RP053A, RP053D and RP147 are unaffected by the fire. Therefore, loss of PFSSD components associated with RP053B will not adversely impact PFSSD.

5.2.36 Control Room Lockout Relays

Cables associated with control room lockout relays 86XRP5, 86XRP6 and 86XRP7 are run in area C-30. Equipment controlled by the relays is identified in the table below.

Panel RP335 PFSSD Relays	
Relay #	**Description**
86XRP5	Train B MDAFP from CST and ESW Supply Valves (ALHV0034 and ALHV0030)
86XRP6	ESW to TDAFP Supply Valve (ALHV0033)
86XRP7	Train B MDAFP (PAL01B)

Damage to these cables could prevent operation of associated equipment. Train A equipment, located in a separate fire area, is available and is unaffected by the fire.

References: XX-E-013, E-15000, E-13AL01B, E-13AL02B, E-13AL04B, E-13RP12, E-13RP14, E-13RP15, E-093-00095, E-093-00096, E-1F9202, E-1F9204

5.2.37 Reactor Protection System

The Reactor Protection System (RPS) monitors specified input parameters and initiates reactor protection features whenever those parameters are outside specified limits. Field installed transmitters continuously monitor various parameters and report the results to one of four process cabinets, one per channel. Signals are then sent from the process cabinets to both solid state protection cabinets, one on each train. The cabinets and associated channel are listed in the following table:

Process Cabinets	Solid State Protection Cabinets
Cabinet SB038 - Channel 1 Cabinet SB042 - Channel 2 Cabinet SB037 - Channel 3 Cabinet SB041 - Channel 4	Cabinet SB029A - Train A Input Cabinet Cabinet SB029B - Train A Logic Cabinet Cabinet SB029C - Train A Output Cabinet 1 Cabinet SB029D - Train A Output Cabinet 2 Cabinet SB032A - Train B Input Cabinet Cabinet SB032B - Train B Logic Cabinet Cabinet SB032C - Train B Output Cabinet 1 Cabinet SB032D - Train B Output Cabinet 2

The RPS is actuated upon 2/3 or 2/4 coincident logic, depending on the input parameter. This ensures that a loss of a single channel will not prevent the system from performing its function. Loss of power to a single cabinet will render the channel or Train inoperative.

Cables associated with RPS channel 4 run through this area. These cables supply power from separation group 4 power supplies to panels SB029A, SB032A, SB032D and SB041. Power cables associated with RPS channels 1, 2 and 3 are run in a separate fire area.

Based on the above discussion, the reactor protection system is available if a fire occurs in this area.

5.2.38 Reactor Trip Switchgear

The reactor trip switchgear is required to ensure the ability to manually trip the reactor. The reactor is tripped using either hand switch SBHS0001 or SBHS0042 in the main control room. Each hand switch has contacts associated with Train A reactor trip switchgear SB102A and Train B reactor trip switchgear SB102B.

Cable 14SBS12BC, associated with separation group 4 trip circuits, is run in area C-30. A hot short in this cable could cause a spurious reactor trip, which is the desired PFSSD condition. An open circuit will prevent a manual reactor trip on Train B reactor trip switchgear SB102B.

Cables associated with separation group 1 trip circuits are unaffected by a fire in area C-30. Therefore, operation of either hand switch SBHS0001 or SBHS0042 will cause a reactor trip on redundant Train A reactor trip switchgear SB102A.

References: XX-E-013, E-15000, E-13SB12A, E-1F9101

5.2.39 Process Monitoring Instrumentation

Circuits for a number of process instruments are run in area C-30. These circuits run from various process monitoring panels to the auxiliary shutdown panel (ASP) and provide indication at the ASP for control outside the control room.

Damage to these cables will not cause a loss of process monitoring capability in the main control room. Therefore, damage to these cables due to a fire in area C-30 will not adversely impact PFSSD.

References: XX-E-013, E-15000, E-13SB16, E-1F9201, E-1F9301, M-12BB01, M-12BB02, M-12BB04

5.2.40 Source Range Monitoring

PFSSD requires source range (SR) flux monitoring to be available. Source range monitoring is provided by source range monitors SENE0031, SENE0032, SENY0060A & B, and SENY0061A & B.

Cable 14SES07BA is a power cable associated with SR monitor signal processor SENY0061B. Cable 14SES07CA is a power cable associated with SR monitor amplifier SENY0061A. Damage to these cables could prevent operation of the associated source range monitor.

Cable 14SES07BC is an instrumentation cable associated with SR monitor signal processor SENY0061B. This cable runs from SENY0061B to the source range recorder on RL020. Damage to this cable could prevent operation of the recorder. Source Range monitoring remains available for a fire in area C-30 using SENE0031, SENE0032 and SENY0060A/B.

For a more detailed evaluation on Source Range monitoring, see Calculation XX-E-013, Attachment 3.

References: E-15000, XX-E-013, E-13SE07, E-1F9101

5.2.41 RCS Hot and Cold Leg Temperature Indication

PFSSD requires RCS hot and cold leg temperature indication on at least one loop to verify flow through the steam generators. The temperature elements and control room indicators used for this purpose are listed in the following table.

RCS Hot and Cold Leg Temperature Elements/Indicators Used for PFSSD		
ELEMENT	**INDICATOR**	**FUNCTION**
BBTE0413A	BBTI0413A	RCS Hot Leg Temperature Element (WR) Loop 1
BBTE0413B	BBTI0413B	RCS Cold Leg Temperature Element (WR) Loop 1
BBTE0423A	BBTR0423	RCS Hot Leg Temperature Element (WR) Loop 2
BBTE0423B	BBTI0423B	RCS Cold Leg Temperature Element (WR) Loop 2
BBTE0433A	BBTR0433	RCS Hot Leg Temperature Element (WR) Loop 3
BBTE0433B	BBTR0433	RCS Cold Leg Temperature Element (WR) Loop 3
BBTE0443A	BBTR0443	RCS Hot Leg Temperature Element (WR) Loop 4
BBTE0443B	BBTR0433	RCS Cold Leg Temperature Element (WR) Loop 4

Cable 16RLY01EA supplies 120 VAC power to control room panel RL021/RL022. At RL021/RL022, the power is split and supplies power to BBTR0433 and BBTR0443, as well as other non-PFSSD components. Damage to this cable could disrupt power to BBTR0433 and BBTR0443. Consequently, loops 3 and 4 RCS temperature indication could be lost. However, RCS temperature indication on loops 1 and 2 remains available. Therefore, the PFSSD function is satisfied.

References: E-15000, XX-E-013, E-13BB15, E-13RL01, E-13RL06, E-1F9201, E-1F9421, M-12BB01

5.2.42 Load Center PG20 Incoming Feeder Breaker PG2001

Load center feeder breaker PG2001 is credited for PFSSD because it supplies power to credited non-safety related loads. Cable 16PGG13DA, associated with PG2001, runs in this area. Damage to this cable will trip the breaker.

Breaker PG2001 supplies power to the following PFSSD components:

- PG20GBR217 – MCB Misc. Power Circuits RL023
- PG20GER5 – Instr. Bus Transformer Alt. Feed XPN08D

PFSSD components powered from PG20GBR217 are associated with MSIV downstream components. The MSIVs are unaffected by a fire in this area and can be closed from the control room. Therefore, the MSIV downstream components are not required if a fire occurs in this area.

PG20GER5 is credited as one source of power to PN08. The redundant source of power from NG02BBF1 could also be affected by a fire in this area as discussed in Section 5.2.33. Redundant components powered from inverter PN07 are unaffected by a fire in this area.

Based on the above discussion, loss of breaker PG2001 will have no adverse impact on PFSSD.

References: XX-E-013, E-15000, E-11PG20, E-11PG21, E-11PK02, E-13PG10, E-13PG11, E-13PG13, E-13RL07, E-1F9421, E-1F9422C, E-1F9424E, KD-7496

5.2.43 Normal Pressurizer Spray

The normal pressurizer spray valves are included in the PFSSD design because spurious operation of pressurizer sprays can cause a decrease in pressure which can lead to boiling in the core. The pressurizer spray valves are part of the pressurizer pressure control system.

The pressurizer normal spray valves (BBPCV0455B and BBPCV0455C) operate off a signal from the Ovation pressurizer pressure control system. The operation of the pressure control system is discussed in Calculation XX-E-013.

An instrument cable (14BBI16NB) associated with pressurizer pressure transmitter BBPT0458 is run in fire area C-30. Damage to this cable could send a spurious high-pressure signal to the pressure control system. However, as discussed in Calculation XX-E-013, Appendix 1, damage to a single pressure channel will not cause the spurious operation of the pressurizer spray valves due to the Ovation 4-channel validation logic, which uses the 2nd highest signal as the validated signal and has built-in logic to detect and ignore a failed input.

Based on the above discussion, the pressurizer spray valves will not spuriously open if a fire occurs in this area.

5.2.44 120 VAC Distribution Panel PN410

120 VAC distribution panel PN410 supplies power to NSSS control panels RP043 and RP047.

Inverter PN04 supplies power to 120 VAC distribution panel PN410 (via cables 16PNY02AA and 16PNY02AB), which in turn supplies redundant 120 VAC power to NSSS control cabinets RP043 and RP047. For PFSSD, cabinet RP043 houses relays BGLCV0459X and BGLCV0460X, which are associated with letdown isolation valves BGLCV0459 and BGLCV0460, respectively. Cabinet RP047 includes controls for pressurizer PORVs and pressurizer spray.

Damage to cables 16PNY02AA and/or 16PNY02AB will disrupt power to panel PN410. Redundant power to RP043 and RP047 is available from 120 VAC distribution panel PN310. Therefore, loss of power to PN410 will not adversely impact PFSSD.

1.0 GENERAL AREA DESCRIPTION

Fire area C-31 is located on the 2047 elevation of the Control Building and includes the rooms listed in Table C-31-1.

Table C-31-1
Rooms Located in Fire Area C-31

ROOM #	DESCRIPTION
3618	North Electrical Chase - 2047 Elevation

Fire area C-31 is protected with an automatic wet-pipe sprinkler system and automatic fire detection. The area is separated from adjacent areas by minimum 3-hour fire resistant construction.

2.0 PRIMARY EQUIPMENT USED FOR PFSSD

Table C-31-2 lists each system credited for post-fire safe shutdown and provides a discussion regarding the availability of the system to perform its Post Fire Safe Shutdown (PFSSD) function if a severe fire occurs in this area. For a summary of the potential fire impact on some of the more significant PFSSD equipment, see Section 8.0 of the Fire Area Analysis Narrative section.

Table C-31-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-31

System	System Name	PFSSD Function*	Comments
AB	Main Steam	R, M, H, P, S	Steam generator A ARV control may be lost. Steam generator B, C and D ARVs are unaffected. Cooldown is assured using Aux Feedwater Pump B supplying steam generator D and the Turbine Driven Auxiliary Feedwater Pump supplying steam generators B, C and D. Train B MDAFP can be used to supply steam generator A if ABPV0001 spuriously opens.
AC	Main Turbine	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-31.
AE	Main Feedwater	H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-31.
AL	Aux. Feedwater System	H, P	All PFSSD functions associated with the auxiliary feedwater system are satisfied. Train A MDAFP may be affected. Train B MDAFP is available to supply SGs A and D. Suction is available from the CST and Train B ESW. However, as stated in AB System above, steam generator A ARV control may be lost. The TDAFP is available to supply all four steam generators. However, suction may only be available from Train B ESW system and, as stated in AB System above, steam generator A ARV control may be lost.
AP	Condensate Storage System	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-31.
BB	Reactor Coolant System	R, M, H, P, S	RCP thermal barrier cooling could be affected due to spurious closure of BBHV0013, BBHV0014, BBHV0015 and BBHV0016.
BG	Chemical and Volume Control System	R, M, S	Train A centrifugal charging pump (CCP) may not be available due to potential loss of CCW to the oil cooler. The Train B CCP is available to provide inventory control and boration through the reactor coolant pump (RCP) seals and boron injection tank (BIT) if necessary.
BM	Steam Generator Blowdown System	R, M, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-31.
BN	Borated Refueling Water Storage System	R, M, H	RWST level indicator BNLI0930 could be affected. RWST level indication is available using BNLI0931, BNLI0932 and BNLI0933.
EF	Essential Service Water System	H, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-31.

Table C-31-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-31

System	System Name	PFSSD Function*	Comments
EG	Component Cooling Water System	S	All PFSSD functions associated with the component cooling water system are satisfied. A number of Train A CCW system components could be affected. The Train B CCW system is unaffected. CCW flow to the RCP thermal barriers could be affected as discussed in BB System comments above. CCW flow indicators EGFI0128 and EGFI0129 are unaffected. Valve EGHV0101 could spuriously open or may not open when operating Train A RHR. Valve EGHV0102 is unaffected.
EJ	Residual Heat Removal System	M, H, P	All PFSSD functions associated with the residual heat removal system are satisfied. Train A RHR may not be available due to the inability to control valve EJHV8804A. Train B RHR is unaffected.
EM	High Pressure Coolant Injection	R, M	BIT outlet valve EMHV8801A may be affected, but valve EMHV8801B is available to ensure an available BIT flowpath using Train B CCP.
EN	Containment Spray	R, M	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-31.
EP	Safety Injection Accumulators	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-31.
FB	Auxiliary Steam	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-31.
FC	Auxiliary Turbines	R, H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-31.
GD	ESW Pump House HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-31.
GF	AFW Pump Room Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-31.
GK	Control Room and Class 1E Switchgear Room Coolers	S	Train A control room A/C unit SGK04A may be affected. Train B control room A/C unit SGK04B is unaffected.
GL	Auxiliary Building HVAC	S	Train A CCW pump room cooler SGL11A could be affected. Train B CCW pump room cooler SGL11B is unaffected.
GM	Emergency Diesel Generator Room HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-31.

Table C-31-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-31

System	System Name	PFSSD Function*	Comments
GN	Containment Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-31.
JE	Diesel Fuel Oil	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-31.
KA	Instrument Air	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-31.
KC	Fire Protection	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-31.
KH	Service Gas	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-31.
KJ	Standby Diesel Engine	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-31.
MA	Main Generation	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-31.
MR	Startup Transformer	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-31.
NB	4.16 kV System	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-31.
NE	Standby Diesel Generator	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-31.
NF	Load Shed and Emergency Load Sequencing	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-31.
NG	480V Load Centers and MCCs	S	Train A 480 V MCC NG03C could be affected. Redundant Train B 480 V MCCs are unaffected.
NK	125VDC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-31.
NN	120VAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-31.
PA	13.8kV	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-31.
PB	4.16kV	H, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-31.
PG	480V Load Centers and MCCs	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-31.

Table C-31-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-31

System	System Name	PFSSD Function*	Comments
PK	125VDC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-31.
PL	Local Instrument Panels	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-31.
PN	120VAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-31.
QB	Standby AC Lighting	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-31.
QD	Emergency Lighting	S	The 125 VDC emergency lights in the control room could be affected. Self-contained battery powered lighting units are available to provide lighting in the control room.
RL	Control Room MCB	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-31.
RP	Miscellaneous Control Panels	R, M, H, P, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-31.
SA	ESFAS	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-31.
SB	Reactor Protection System	R, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-31.

3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD

This section describes operator actions that may need to be performed inside or outside the control room to achieve and maintain hot standby if a fire occurs in area C-31. This section also describes cold shutdown repairs that may need to be made to achieve and maintain cold shutdown conditions. Operator actions are proceduralized in OFN KC-016.

3.1 ACTIONS OUTSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

Operator Manual Actions (OMAs) are those actions outside the main control room required to achieve and maintain hot standby. OMAs are identified in E-1F9900 and were determined from thermal hydraulic analysis WCNOC-CP-002. Applicable E-1F9900 OMAs are annotated herein. All other actions outside the control room are desirable for plant control in support of hot standby but not required to achieve and maintain hot standby.

3.1.1 Steam Generator ARVs

It may be necessary to fail close ABPV0001 by isolating air and nitrogen to the valve using KAV1435 (air) and KAV1364 (Nitrogen) then venting air from the regulator. These valves are located in area A-23 and emergency lighting is available. Per calculation WCNOC-CP-002, this action is not required to ensure safe shutdown.

3.2 ACTIONS INSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

3.2.1 Auxiliary Feedwater

If steam generator A ARV ABPV0001 control is lost, use the Turbine Driven Auxiliary Feedwater Pump to supply steam generators B, C and/or D and control steam release using ARVs ABPV0002, ABPV0003 and/or ABPV0004.

3.2.2 Component Cooling Water

Train A CCW could be affected by a fire in this area. If this occurs, swap to Train B CCW using normal operating procedures if Train B CCW is not already running.

3.2.3 Reactor Coolant Pump Seal Cooling

Thermal barrier cooling could be affected. RCP seal injection could temporarily be disrupted until the Train B CCP is lined up. The Train B CCP can be started and lined up from the control room.

3.3 ACTIONS TO ACHIEVE AND MAINTAIN COLD SHUTDOWN

None

4.0 CONCLUSION

With some exceptions, redundant Post Fire Safe Shutdown capability exists from the main control room if a severe fire occurs in area C-31. For those exceptions, feasible manual actions are available and are unaffected by the fire. Manual actions are documented in Section 3.0.

5.0 DETAILED ANALYSIS

This section describes the detailed component-by-component and cable-by-cable analysis for a fire in area C-31.

5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA C-31

PFSSD components (S. in E-15000) located in area C-31 are shown in Table C-31-3. An evaluation of each component is provided in the sections that follow. The applicable evaluation section is listed in Table C-31-3.

Table C-31-3 PFSSD Equipment Located in Fire Area C-31				
Room #	**PFSSD Equipment**	**Description**	**Evaluation Section**	**Comments**
3618	TB36111	Terminal Box Valve EMHV8801A Control Circuit	5.2.9	

5.2 PFSSD CABLE EVALUATION

Table C-31-4 lists all the PFSSD cables (S. in E-15000) located in fire area C-31. The applicable evaluation section is also listed in Table C-31-4.

Table C-31-4
PFSSD Cables Located in Fire Area C-31

Cable #	Location	Primary PFSSD Equipment	Cable Function (P) Power (C) Control (I) Instrumentation	Evaluation Section	Comments

5.2.1 Steam Generator Atmospheric Relief Valves

PFSSD requires at least two steam generator atmospheric relief valves (ARV) be controlled and the other two closed. The ARVs are pneumatically operated using air from the compressed air system (KA) or nitrogen from the nitrogen accumulators. The valves open by pneumatic pressure and close by spring action. A pressure transmitter installed on the outlet side of the steam generator sends a signal to a controller and automatically controls the associated ARV position. Alternatively, each ARV can be controlled manually from the control room or the auxiliary shutdown panel by placing the pressure indicating controller (PIC) in manual.

Cable 11ABI20EE is associated with steam generator A ARV ABPV0001 I/P converter. Damage to this cable could prevent controlling the ARV from the main control room. If necessary, ABPV0001 can be failed closed by isolating air and nitrogen to the valve using KAV1435 (air) and KAV1364 (Nitrogen) then venting air from the regulator. These valves are located in area A-23 and emergency lighting is available.

Steam generator ARVs ABPV0002, ABPV0003 and ABPV0004 are unaffected by a fire in this area and remain available to control steam release through steam generators B, C and D.

Up to three ARVs can fail closed or open without impacting ability to achieve and maintain hot standby according to thermal hydraulic analysis WCNOC-CP-002. With at least one ARV unaffected, no E-1F9900 OMA is required to address ARV closure or control. Reference Attachment 4, MSO Evaluation Scenario ID PWROG 23.

Based on the above discussion, ARV ABPV0001 could fail in the open or closed position but no action is necessary to mitigate the failed ARV. If operators want to close the ARV, it can be failed closed by isolating air and nitrogen to the valve using KAV1435 (air) and KAV1364 (Nitrogen) then venting air from the regulator.

5.2.2 Auxiliary Feedwater

The PFSSD design requires the use of one auxiliary feedwater pump (AFP) supplying water to at least two steam generators. The turbine driven auxiliary feedwater pump (TDAFP) is normally aligned to supply all four steam generators. The Train A motor driven auxiliary feedwater pump (MDAFP) is aligned to supply steam generators B and C. The Train B MDAFP is aligned to supply steam generators A and D.

The normal source of water to the AFPs is the condensate storage tank (CST). The emergency supply is from the essential service water (ESW) system. For commercial concerns, the CST is the preferred source and contains sufficient volume to supply the entire auxiliary feedwater (AFW) demand to achieve cold shutdown.

The suction isolation valve from the condensate storage tank (CST) to the Train A MDAFP (ALHV0035) may be affected, causing the valve to spuriously close. In addition, the essential service water (ESW) source to Train A MDAFP may be affected due to damage to cables associated with ALHV0031. Therefore, the Train A MDAFP may not be available.

The suction isolation valve from the condensate storage tank (CST) to the TDAFP (ALHV0036) may be affected, causing the valve to spuriously close. In addition, the Train A ESW source to the TDAFP may be affected due to damage to cables associated with ALHV0032. The Train B ESW supply to the TDAFP remains available since valve ALHV0033 is unaffected.

As discussed in Section 5.2.1, steam generator A ARV ABPV0001 control could be lost. Therefore, it may be necessary to cool down using steam generators B, C and/or D.

Auxiliary feedwater is assured using Train B MDAFP supplying steam generators A and D and the TDAFP supplying steam generators A, B, C and D, although steam generator A ARV control may be affected.

5.2.3 Refueling Water Storage Tank Level Indication

The RWST is credited in the PFSSD analysis as the primary source of borated water to achieve cold shutdown. The Wolf Creek Technical Specifications ensure the minimum quantity and boron concentration is maintained to achieve cold shutdown. Therefore, RWST level transmitters, indicators and circuits are not evaluated for level control.

The RWST level transmitters and associated circuits are included in the PFSSD analysis because of the automatic functions they perform. The function of the four level transmitters is to monitor RWST level and send a signal to ESFAS upon low level sensed by 2 out of 4 level transmitters. A low level signal on 2 out of 4 RWST level transmitters, coincident with a safety injection signal, will initiate a swapover of the RHR suction source from RWST to the containment sump. A spurious swapover will not adversely affect PFSSD, but if the fire prevents valves BNHV8812A and/or BNHV8812B from reaching their full closed position, the RWST will drain to the containment sump.

An instrument cable for refueling water storage tank (RWST) level transmitter BNLT0930 runs through fire area C-31. Cables for the remaining three RWST level transmitters are unaffected. In addition, a fire in area C-31 will not cause a spurious safety injection signal.

Based on the above discussion, a fire in area C-31 will not cause the RWST to drain to the containment sump.

References: E-15000, XX-E-013, E-13BN03, E-13BN03A, E-13BN07, E-1F9205, M-10BN, M-12BN01, M-12EJ01

5.2.4 Component Cooling Water

For PFSSD, the component cooling water (CCW) system is used to provide cooling to the centrifugal charging pump (CCP) oil cooler, the seal water heat exchanger, the RHR heat exchanger and the RHR pump seal cooler. In addition, the CCW system provides cooling to the RCP thermal barriers and is credited as a backup to RCP seal injection for maintaining seal cooling.

Valves EFHV0051 and EFHV0059 control ESW flow to the Train A CCW heat exchanger. Valve EFHV0051 is required to be open and valve EFHV0059 is required to remain closed for PFSSD. Damage to cables associated with these valves could cause spurious operation of the valves and prevent proper ESW water flow to the Train A CCW heat exchanger. Train B ESW to Train B CCW heat exchanger water flow is unaffected by a fire in area C-31.

Cables associated with valves EGHV0015, EGHV0053 and EGHV0061 are run in area C-31. Damage to these cables could cause spurious operation of the valves. Spurious closure of EGHV0015 and/or EGHV0053 will prevent water flow to/from Train A CCW to the seal water heat exchanger and RCP thermal barriers, as well as a number of non-PFSSD components. Spurious closure of EGHV0061 will prevent Train A and Train B CCW flow to/from the RCP thermal barriers.

Power and control cables associated with valves BBHV0013, BBHV0014, BBHV0015 and BBHV0016 could be affected by a fire in this area. Cable damage could cause the valves to spuriously close. If this occurs, CCW flow to the RCP thermal barriers would be lost. In

addition, if valve EGHV0061 were to spuriously close, CCW flow to the RCP thermal barriers would be lost.

Spurious operation of BBHV0013, BBHV0014, BBHV0015, BBHV0016, EGHV0015, EGHV0053 and EGHV0061 will not adversely impact PFSSD. Train B CCW is unaffected by a fire in this area. If valve EGHV0061 closes, RCP seal injection remains available from the B Train CCP to protect the RCP seals. Loss of thermal barrier cooling would be indicated in the control room as a reduction in flow on flow indicators EGFI0128 and EGFI0129. Therefore, operators can diagnose a loss of thermal barrier cooling.

Pressure transmitter EGPT0077 monitors Train A CCW pump discharge and provides a signal to start the second Train A CCW pump if discharge header pressure is low. The pressure transmitter also provides annunciation in the main control room. Damage to the cable associated with this transmitter could provide false pressure annunciation and prevent operation of the automatic swap feature. Train B CCW pressure transmitter EGPT0078 is unaffected by a fire in area C-31.

A control cable associated with Train A CCW pump room cooler motor DSGL11A is run in area C-31. Damage to this cable could prevent operation of the room cooler. Cables associated with Train B CCW room cooler SGL11B are not run in area C-31. Therefore, the Train B CCW room cooler is available.

Based on the above discussion, the Train B CCW system is unaffected by a fire in this area and can be used to supply cooling water to associated Train B equipment.

References: E-15000, XX-E-013, E-13BB03, E-13BB28, E-13EF04, E-13EG01A, E-13EG01B, E-13EG05A, E-13EG05B, E-13EG09A, E-13EG13, E-13GL06, E-1F9401A, J-02EG01A, J-02EG01B, J-02EG01C, J-110-00211, M-12EF02, M-12EG01, M-12EG02, M-12EG03

5.2.5 Residual Heat Removal System

PFSSD requires one train of residual heat removal (RHR) to be available for shutdown cooling. The RHR system is not used for hot standby.

Cables 11EJG04AA, 11EJG04AB and 11EJG04AC are power and control cables associated with normally closed valve EJHV8804A. This valve is required to remain closed when aligning Train A RHR for cold shutdown. For hot standby, the valve can be in any position. Damage to these cables could cause the valve to open, which would cause flow diversion from Train A RHR to the charging pump suction header. Train B valve EJHV8804B is unaffected by a fire in area C-31.

Valve EGHV0101 is the Train A CCW to RHR Heat Exchanger control valve. Valve EGHV0102 is the Train B CCW to RHR Heat Exchanger control valve. These valves are normally closed during power operation. PFSSD requires that the valve on the operating train of CCW be closed until shutdown cooling mode is entered, at which time the valve on the operating train of RHR needs to be open. As stated in Section 5.2.2, the Train A CCW system may not be available to supply cooling water to the Train A RHR heat exchanger. Cables 11EGG07AA, 11EGG07AB and 11EGG07AC are associated with valve EGHV0101. Damage to the cables could prevent operation of EGHV0101 and damage to cable 11EGG07AC could cause the valve to spuriously open. Valve EGHV0102 is unaffected by a fire in this area.

The Train B CCW system is available to supply cooling water to the Train B RHR heat exchanger. Cables associated with valves EGHV0102 and EJHV8804B are not run in area C-31. Therefore, the Train B RHR system is available to provide decay heat removal if a fire occurs in area C-31.

References: E-15000, XX-E-013, E-13EG07, E-13EJ04A, E-1F9205, M-12BG03, M-12EJ01

5.2.6 Control Room Air Conditioning

PFSSD requires control room air conditioning to be available. Cables associated with Train A control room A/C unit SGK04A are run in this area. In addition, cables associated with SGK04A supply and return dampers GKHZ0029B and GKHZ0029A, respectively, are run in this area. Damage to these cables could prevent operation of the unit.

Cable 11SAZ19EA provides status indication of SGK04A supply and return dampers GKHZ0029A and GKHZ0029B. Cable 11SAZ19JA provides status indication of Train A control room A/C unit SGK04A. Damage to these cables could prevent operation of the associated equipment.

Cables associated with Train B control room A/C unit SGK04B and associated dampers are run in a separate fire area. Therefore, the Train B control room A/C unit is unaffected by a fire in this area.

References: XX-E-013, E-15000, E-13GK02B, E-13GK02C, E-13SA19, E-1F9442, M-12GK01, M-622.1A-00007

5.2.7 Train A 480 VAC Load Centers

PFSSD requires 480 VAC power to energize necessary PFSSD equipment. Power cables that supply 480 VAC power from NG0306 to 480 VAC motor control center (MCC) NG03C incoming breaker NG03CAF1 are run in area C-31. Train A PFSSD equipment powered from NG03C is identified in the following table.

Train A 480 Volt MCC NG03C	
MCC Breaker	**Description**
NG03CCF3	Train A MDAFW Supply from ESW Valve ALHV0031
NG03CCF4	TDAFW Supply from ESW Valve ALHV0032
NG03CDF2	Train A CCW Pump Room Cooler DSGL11A
NG03CEF3	Train A MDAFW Pump from CST Valve ALHV0035
NG03CEF4	TDAFW Suction from CST Valve ALHV0036
NG03CGF4	Train A Control Room A/C Inlet Damper GKHZ29A
NG03CHF2	Train A ESW Return from Train A CCW Hx Valve EFHV0059
NG03CHF3	Train A CCW Return from Nuc Aux Comp Valve EGHV0015
NG03CJF1	Train A CCW to RHR Heat Exchanger Valve EGHV0101
NG03CJF3	Train A CCW to Nuclear Aux Components (EGHV0053)
NG03CKF3	CCW Return from RCP Thermal Barriers Valve EGHV0061
NG03CLF115	Train A CR A/C Dampers GKHZ0029A and GKHZ0029B
NG03CMF1	Train A ESW to CCW Hx Valve EFHV0051
NG03CMF4	Train A RHR to CCP Suction Valve EJHV8804A

Train B 480 VAC MCCs are unaffected by a fire in this area and are available to supply power to redundant Train B equipment. Therefore, a fire in area C-31 will not impact the ability to supply power to required Train B 480 VAC equipment.

References: XX-E-013, E-15000, E-1F9424C, E-11001, E-11NG01, E-11NG01A

5.2.8 Control Room Emergency Lights

Emergency lighting is provided in the control room to ensure adequate lighting during a station blackout or in the event a fire damages cables associated with the normal and standby lighting system. Emergency lights are supplied power from Class 1E 125 VDC breaker NK5120.

The control room has four sources of lighting; 1) Normal (QA); 2) Standby (QB); 3) Emergency (QD); and 4) Self-contained battery units (QD). The normal lighting system is not evaluated in the PFSSD analysis and is assumed lost. Cable 11QDK01AA is a 125 VDC power cable that runs from NK051A to the control room DC emergency lights. Damage to this cable will prevent operation of the DC emergency lights.

Self-contained Appendix R battery units are provided in the control room to provide minimum lighting for post-fire safe shutdown. Three units are provided in the front panel area, each with two light heads, to provide illumination on the main control boards. Two additional units are provided in the corridor area and two units are provided in the back panel area, each with two light heads. The Appendix R battery units are capable of providing minimum illumination for 8 hours, during which time action can be taken by maintenance to restore the normal or standby lighting system.

Based on the above discussion, sufficient lighting exists in the control room to achieve and maintain PFSSD.

References: E-15000, XX-E-013, E-093-00064, E-11NK01, E-13NG01A, E-13QB03, E-13QD01, E-1L3604, E-1L8900

5.2.9 Boron Injection Tank Flow Path Valves

The Boron Injection Tank (BIT) flowpath is credited for reactivity control and reactor coolant makeup. For reactivity control, the BIT flowpath is credited as an alternate source of boration in the event RCP seal injection is unavailable. Based on Calculation XX-E-013, RCP seal injection will provide sufficient boration to achieve and maintain cold shutdown reactivity conditions. Therefore, the BIT flowpath is not required for reactivity control if RCP seal injection is available. Since RCP seal injection is limited to 5 gpm per seal or 20 gpm total injection to the RCS, an additional RCS charging flowpath is required for adequate RCS makeup during plant transition from hot standby to cold shutdown. The BIT injection path was selected as the additional RCS charging flowpath.

Train A BIT outlet valve EMHV8801A may be affected by a fire in this area. Cable 11EMG02CF and 11EMG02CG associated with EMHV8801A, are run in this area. Cable 11EMG02CF is a fire resistive cable and will not be damaged by a fire. However, cable 11EMG02CG is not fire resistive and damage to this cable could prevent opening the valve and could prevent a flowpath from Train A CCP to the RCS via the BIT. Redundant Train B valve EMHV8801B is unaffected by a fire in this area so the Train B CCP flowpath to the RCS via the BIT is available.

Also, a fire in this area could cause valve EMHV8801A to open, creating a BIT Train A flowpath into the RCS, possibly overfilling the pressurizer. However, there are no SIS circuits in this area, with which a fire could cause a spurious SIS starting the CCP. Thus, even with the flowpath, a fire cannot produce the flow to cause overfill of the pressurizer. Additionally, neither EMHV8803A nor EMHV8803B, the Charging Pump Discharge Header To BIT Isolation Valves, are affected by a fire in this area. Therefore, a fire in this area will not create a flowpath from the CCPs to the RCS.

The SIS test line is required to be isolated when charging through the BIT to prevent inventory loss. Valve EMHV8871 is unaffected by the fire in this area and is available to ensure the SIS test line remains isolated.

A fire in area C-31 uses CCP B, since circuits and support systems for CCP B are unaffected by the fire in this area.

Based on the above discussion, charging through the BIT is unaffected by a fire in this area using Train B CCP and valves EMHV8801B and EMHV8803B. The SI test line can be isolated using valve EMHV8871.

1.0 GENERAL AREA DESCRIPTION

Fire area C-32 is located on the 2047 elevation of the Control Building and includes the room listed in Table C-32-1.

Table C-32-1
Rooms Located in Fire Area C-32

ROOM #	DESCRIPTION
C32	South Small Elec Chase 2047 Elevation

Fire area C-32 is protected with an automatic fire suppression and detection system. The area is bounded on all sides by minimum 3-hour fire rated construction.

2.0 PRIMARY EQUIPMENT USED FOR PFSSD

Table C-32-2 lists each system credited for post-fire safe shutdown and provides a discussion regarding the availability of the system to perform its Post Fire Safe Shutdown (PFSSD) function if a severe fire occurs in this area. For a summary of the area analysis results, see Section 8.0 of the Fire Area Analysis Narrative section.

Table C-32-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-32

System	System Name	PFSSD Function*	Comments
AB	Main Steam	R, M, H, P, S	It may be necessary to isolate SG B ARV using local control station ABFHC0002. Steam generators A, C and D ARVs are unaffected. Steam line pressure transmitters ABPT0515, ABPT0525, ABPT0535, ABPT0545 may be affected. The remaining steam line pressure transmitters are unaffected. Valves ABHV0005 and ABHV0006 could be affected, preventing operation of the turbine driven auxiliary feedwater pump. Both motor driven auxiliary feedwater pumps are available.
AC	Main Turbine	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-32.
AE	Main Feedwater	H, P	Steam generator level transmitters AELT0519 (SG A NR), AELT0549 (SG D NR), AELT0552 (SG B NR) and AELT0553 (SG C NR) may be affected. The remaining level transmitters are unaffected.
AL	Aux. Feedwater System	H, P	All PFSSD functions associated with the auxiliary feedwater system are satisfied. The turbine driven auxiliary feedwater pump (TDAFP) may not be available. The motor driven auxiliary feedwater pumps are unaffected.
AP	Condensate Storage System	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-32.
BB	Reactor Coolant System	R, M, H, P, S	RCS Temperature elements BBTE0413B and BBTE0433A, as well as associated temperature indicators, could be affected by a fire in this area. The remaining temperature elements/indicators are unaffected. Pressurizer pressure transmitter BBPT0456 may be affected. The remaining pressurizer pressure transmitters are unaffected. When transferring to RHR, valve BBPV8702A or BBPV8702B may need to be manually opened to provide a suction source from the RCS to RHR pump A or B. Pressurizer pressure indication is available using BBPI0455A, BBPI0457 or BBPI0458.
BG	Chemical and Volume Control System	R, M, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-32.
BM	Steam Generator Blowdown System	R, M, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-32.
BN	Borated Refueling Water Storage System	R, M, H	Level transmitter BNLT0931 may be affected. Level transmitters BNLT0930, BNLT0932 and BNLT0933 are available.

Table C-32-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-32

System	System Name	PFSSD Function*	Comments
EF	Essential Service Water System	H, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-32.
EG	Component Cooling Water System	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-32.
EJ	Residual Heat Removal System	M, H, P	Both trains of RHR are available. However, as discussed in the BB system comments, it may be necessary to manually open BBPV8702A or BBPV8702B.
EM	High Pressure Coolant Injection	R, M	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-32.
EN	Containment Spray	R, M	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-32.
EP	Safety Injection Accumulators	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-32.
FB	Auxiliary Steam	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-32.
FC	Auxiliary Turbines	R, H, P	The TDAFP speed control valve FCFV0313 and trip and throttle valve FCHV0312 could be affected. The motor driven auxiliary feedwater pumps are available.
GD	ESW Pump House HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-32.
GF	AFW Pump Room Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-32.
GK	Control Room and Class 1E Switchgear Room Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-32.
GL	Auxiliary Building HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-32.
GM	Emergency Diesel Generator Room HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-32.

Table C-32-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-32

System	System Name	PFSSD Function*	Comments
GN	Containment Coolers	S	Containment pressure transmitter GNPT0936 may be affected. The remaining containment pressure transmitters are unaffected.
JE	Diesel Fuel Oil	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-32.
KA	Instrument Air	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-32.
KC	Fire Protection	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-32.
KH	Service Gas	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-32.
KJ	Standby Diesel Engine	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-32.
MA	Main Generation	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-32.
MR	Startup Transformer	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-32.
NB	4.16 kV System	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-32.
NE	Standby Diesel Generator	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-32.
NF	Load Shed and Emergency Load Sequencing	S	All PFSSD functions associated with load shed/emergency load sequencing system are satisfied. Separation group 2 power supply cables for load shedder/sequencer logic and input cabinets NF039A and NF039B could be affected. Redundant AC power is available from separation groups 1, 3 and 4 power supplies.
NG	480V Load Centers and MCCs	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-32.
NK	125VDC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-32.
NN	120VAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-32.
PA	13.8kV	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-32.
PB	4.16kV	H, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-32.

Table C-32-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-32

System	System Name	PFSSD Function*	Comments
PG	480V Load Centers and MCCs	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-32.
PK	125VDC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-32.
PL	Local Instrument Panels	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-32.
PN	120VAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-32.
QB	Standby AC Lighting	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-32.
QD	Emergency Lighting	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-32.
RL	Control Room MCB	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-32.
RP	Miscellaneous Control Panels	R, M, H, P, S	Power to lockout relays 86XRP1, 86XRP2 and 86XRP3 could be affected. This will not impact PFSSD.
SA	ESFAS	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-32.
SB	Reactor Protection System	R, S	RPS Channel 2 could be affected. RPS Channels 1, 3 and 4 are unaffected.
SC	Reactor Instrumentation	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-32.
SE	Ex-Core Neutron Monitoring	R, P	Source range indicator SENI0032B could be affected. Source range indication remains available using SENI0031B, SENI0060A/B and SENI0061A/B.
SY	Switchyard	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-32.
UU	Supervisory System	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-32.

3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD

This section describes operator actions that may need to be performed inside or outside the control room to achieve and maintain hot standby if a fire occurs in area C-32. This section also describes cold shutdown repairs that may need to be made to achieve and maintain cold shutdown conditions. Operator actions are proceduralized in OFN KC-016.

3.1 ACTIONS OUTSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

Operator Manual Actions (OMAs) are those actions outside the main control room required to achieve and maintain hot standby. OMAs are identified in E-1F9900 and were determined from thermal hydraulic analysis WCNOC-CP-002. Applicable E-1F9900 OMAs are annotated herein. All other actions outside the control room are desirable for plant control in support of hot standby but not required to achieve and maintain hot standby.

3.1.1 Steam Generator ARVs

If damage occurs to cables associated with ABPV0002, local control station ABFHC0002, located in room 1509, can be used to close ARV ABPV0002.

3.2 ACTIONS INSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

None

3.3 ACTIONS TO ACHIEVE AND MAINTAIN COLD SHUTDOWN

3.3.1 Residual Heat Removal

It may be necessary to either perform a cold shutdown repair or manually open valve BBPV8702A or BBPV8702B when transitioning to RHR.

4.0 CONCLUSION

Redundant post-fire safe shutdown capability is unaffected by a fire in area C-32.

5.0 DETAILED ANALYSIS

This section describes the detailed component-by-component and cable-by-cable analysis for a fire in area C-32.

5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA C-32

There are no PFSSD components located in fire area C-32. This fire area only contains cables associated with PFSSD equipment located in other areas.

5.2 PFSSD CABLE EVALUATION

Table C-32-3 lists all the PFSSD cables (S. in E-15000) located in fire area C-32. The applicable evaluation section is also listed in Table C-32-3.

Table C-32-3

5.2.1 Auxiliary Feedwater and Steam Generator Atmospheric Relief Valves

The PFSSD design requires the use of one auxiliary feedwater pump (AFP) supplying water to at least two steam generators. Atmospheric relief valves on the two steam generators being fed need to be controlled and atmospheric relief valves on the remaining two steam generators need to be closed. The Train A motor driven auxiliary feedwater pump (MDAFP) is aligned to supply steam generators B and C. The Train B MDAFP is aligned to supply steam generators A and D. The turbine driven auxiliary feedwater pump (TDAFP) is normally aligned to supply all four steam generators.

The normal source of water to the AFPs is the condensate storage tank (CST). The emergency supply is from the essential service water (ESW) system. For commercial concerns, the CST is the preferred source and contains sufficient volume to supply the entire auxiliary feedwater (AFW) demand to achieve cold shutdown.

Cables associated with ABHV0005, ABHV0006, FCHV0312 and FCFV0313 are run in area C-32. Damage to these cables could either cause all four valves to spuriously open at the same time, causing uncontrolled blowdown through the TDAFP, or prevent operation of one or more valve, preventing operation of the TDAFP. Uncontrolled cooldown is mitigated by FCHV0312 tripping on high speed. The Train A and Train B MDAFPs are available to supply feedwater to all four steam generators.

Cables 12ABI20FJ, 12ABI20FL, 12ABI20FM and 12ABI20FN associated with steam generator B ARV ABPV0002 are run in this area. Damage to these cables could cause the ARV to spuriously open and could prevent control from the control room. If this occurs, operators may need to control or close ABPV0002 using local controller ABFHC0002 in room 1509.

Cable 12RLK01AA supplies power to RL005/RL006 from switch NK4206. The PFSSD components on RL005/RL006 supplied by NK4206 are ABHV0005 and ABHV0006. Loss of power will fail the valves open, which is desired for operation of the turbine driven auxiliary feedwater pump (TDAFP).

Cable 12RPY09AA supplies 120 VAC power from NN0208 to BOP instrument rack RP053DA. Damage to this cable will affect the following PFSSD components:

- ALPY0038A - ESFAS LOW SUCTION PRESSURE SIGNAL CONVERTER
- ALPT0038 - ESFAS LOW SUCTION PRESSURE TRANSMITTER
- ABPIC0002A - STM GEN B ATM STEAM DUMP PRESSURE CONTROLLER
- ABHS0002 - ABPV0002 HANDSWITCH
- ALPI0026A - TDAFW PUMP PAL02 SUCTION PRESSURE

Low suction pressure (LSP) on 2 out of 3 AFW pressure transmitters (ALPT0037, ALPT0038 and ALPT0039) coincident with an auxiliary feedwater actuation signal (AFAS) will swap the AFW supply to ESW. Loss of power to ALPT0038 and ALPY0038A will satisfy 1/3 LSP logic, placing the LSP signal logic in a 1 out of 2 configuration. In addition, damage to cable 12ALI08BA will prevent operation of ALPT0038 but ALPT0037 and ALPT0039 are unaffected. Therefore, low suction pressure or loss of power on ALPT0037 or ALPT0039 will provide the permissive to swap if an AFAS is present.

Loss of power to ABPIC0002A and ABHS0002 could prevent operation of steam generator B ARV ABPV0002 from the control room. If this occurs, operators may need to control or close ABPV0002 using local controller ABFHC0002 in room 1509.
Loss of power to ALPI0026A will provide false indication of TDAFP suction pressure. In addition, one other cable (12ALI07KF) associated with pressure indicator ALPI0026A is located in this area. Damage to these cables will prevent indication of TDAFP suction pressure in the main control room. The transmitter does not initiate any automatic functions and the TDAFP is not credited for a fire in this area. Train A and Train B MDAFP suction pressure indicators are unaffected.

Panel SA036C monitors pressure transmitter signals on ALPT0038 and provides AFAS outputs. Power cables 12SAK21CA and 12SAY21CA associated with SA036C are run in this area. Damage to these cables could result in a loss of power to the panel but will not prevent automatic operation of low suction pressure (LSP) swapover since the remaining 2 channels are available. AFAS is not credited for PFSSD but is analyzed for potential adverse impacts.

Based on the above discussion, the TDAFP may be affected but both MDAFPs are available to provide feedwater to the steam generators. Steam generator B ARV ABPV0002 may need to be controlled or closed using local controller ABFHC0002. Uncontrolled blowdown through the TDAFP is mitigated by FCHV0312 automatically tripping on high speed.

Up to three ARVs can fail closed or open without impacting ability to achieve and maintain hot standby according to thermal hydraulic analysis WCNOC-CP-002. With at least one ARV unaffected, no E-1F9900 OMA is required to address ARV closure or control. Reference Attachment 4, MSO Evaluation Scenario ID PWROG 23.

5.2.2 Load Shedder / Emergency Load Sequencer

The load shedder and emergency load sequencers are included in the PFSSD design to evaluate the impact of spurious operation or mal-operation. The load shedder/emergency load sequencer operates upon presence of the following conditions:

1. An undervoltage (UV) on a safeguards bus,
2. A safety injection signal (SIS) or a containment spray actuation signal (CSAS), or
3. An undervoltage on a safeguards bus with a SIS or CSAS.

Eight inputs (four undervoltage (UV) inputs and four degraded voltage inputs) on each safeguards bus (NB01 and NB02) monitor voltage conditions on that bus. An undervoltage condition on two of four UV relays on each bus will actuate the load shedder/sequencer and send a signal to start the associated diesel generator. In addition, degraded voltage sensed by two of four degraded voltage potential transformers (PTs) will, after a time delay, provide a signal to open the offsite feeder breakers on the associated bus.

The outputs from each safeguards bus (NB01 and NB02) are divided into 4 separation groups; 1, 2, 3 and 4 and routed to two control panels, NF039A and NF039B. The input section of each control panel also receives group 1, 2, 3 and 4 instrument power (120VAC). The inputs then pass through isolation devices, at which point all inputs to NF039A become separation group 1 and all inputs to NF039B become separation group 4. Interruption of either the inputs or the instrument power from one separation group would impact the associated input channel, but would not impact the other 3 input channels.

Cable 12NFY01CA supplies 120 VAC power to LSELS panel NF039A. Cable 12NFY01DA supplies 120 VAC power to LSELS panel NF039B. Panels NF039A and NF039B have four sources of Class 1E 120 VAC power, each from separate 120 VAC distribution switchboards, two on Train A and two on Train B. The LSELS system operates when a degraded voltage condition exists on 2 out of 4 sensors on a single 4,160-Volt Class 1E bus. Loss of one source of AC power to each panel will have no adverse impact on PFSSD since 120 VAC power remains available from the remaining three sources.

Cables 12NFK01CA and 12NFK01DA are associated with separation group 2 UV relays on buses NB01 and NB02, respectively. Cables 12NFY01EA and 12NFY01FA are associated with separation group 2 degraded voltage PTs on buses NB01 and NB02, respectively. Cables

associated with the remaining three UV relays and PTs from separation groups 1, 3 and 4 do not run in fire area C-32.

Automatic functioning of the bus NB01 and NB02 emergency load shedder / sequencer is unaffected by a fire in area C-32 because of the presence of circuits for only one of the four load shed/sequencer initiators. Therefore, a spurious start of the Train A and Train B diesel generators due to a false undervoltage condition on two of the four circuits is not credible.

Based on the above discussion, the Train A and Train B load shed/sequencers are available if a fire occurs in this area. Off-site power to both trains is unaffected based on Calculation XX-E-013, Appendix 2.

References: XX-E-013, E-15000, E-11005, E-13NF01, E-10NF, E-1F9411A, E-1F9411B, E-1F9412A, E-1F9412B, J-104-00347

5.2.3 Process Monitoring

Process monitoring is required to achieve and maintain safe shutdown. Some of the process instruments credited for safe shutdown could be affected by a fire in area C-32. These instruments, as well as the available redundant capability, are described in the following paragraphs.

Steam generator level indication is required to support the decay heat removal function. Each steam generator has one wide range and four narrow range level transmitters. At least one level transmitter is required on each steam generator being used for heat removal. Cables 12AEI08EB, 12AEI08FB, 12AEI12BB and 12AEI12CB associated with AELT0519 (SG A NR), AELT0549 (SG D NR), AELT0552 (SG B NR) and AELT0553 (SG C NR), respectively, are run in fire area C-25. Cables for the remaining level transmitters are not run in fire area C-25. Therefore, at least one level indicator on all four steam generators is available.

RCS hot and cold leg temperature indication is required on at least one loop to verify sufficient flow through the steam generators to ensure RCS decay heat removal. The following table lists the RCS temperature elements credited for PFSSD.

RCS Hot and Cold Leg Temperature Elements Used for PFSSD	
COMPONENT	**FUNCTION**
BBTE0413A	RCS Hot Leg Temperature Element (WR) Loop 1
BBTE0413B	RCS Cold Leg Temperature Element (WR) Loop 1
BBTE0423A	RCS Hot Leg Temperature Element (WR) Loop 2
BBTE0423B	RCS Cold Leg Temperature Element (WR) Loop 2
BBTE0433A	RCS Hot Leg Temperature Element (WR) Loop 3
BBTE0433B	RCS Cold Leg Temperature Element (WR) Loop 3
BBTE0443A	RCS Hot Leg Temperature Element (WR) Loop 4
BBTE0443B	RCS Cold Leg Temperature Element (WR) Loop 4

Temperature elements BBTE0413B and BBTE0433A, as well as associated temperature indicators, could be affected by a fire in this area due to damage to cables 12BBI15EB and 12BBI15KB. In addition, loops 2 and 4 temperature indication at the auxiliary shutdown panel (ASP) using BBTI0423X and BBTI0443A could be affected due to damage to cables 12SBS16BA and 12SBS16HA. The remaining temperature elements/indicators are unaffected. A fire in this area does not require temperature indication at the ASP. Therefore, RCS hot and cold leg temperature indication remains available on loops 2 and 4.

Cable 12SBS16GA is associated with narrow range pressurizer level indicator BBLI0460B located at the auxiliary shutdown panel. Cables associated with pressurizer level indication in the main control room are unaffected. Therefore, pressurizer level indication is available.

Based on the above discussion, process monitoring is available if a fire occurs in fire area C-32.

References: E-15000, XX-E-013, E-13AE08, E-13AE12, E-13BB15, E-13BB16, E-13SB09, E-13SB16, E-1F9201, E-1F9203, E-1F9301, M-12AE02, M-12BB01, M-12BB02

5.2.4 Residual Heat Removal

Hot shutdown mode of PFSSD requires isolation of the RCS to RHR flow path by maintaining either BBPV8702A or EJHV8701A closed and either BBPV8702B or EJHV8701B closed. Cold shutdown mode of PFSSD requires RHR taking suction from the RCS. RHR pump suction from the RCS is controlled by valves BBPV8702A and EJHV8701A (Train A) and BBPV8702B and EJHV8701B (Train B). Both trains of RHR are available if a fire occurs in this area.

Damage to cable 12BBI15NB, associated with pressure transmitter BBPT0403, could initiate a false High-1 RCS pressure signal and open the contacts on relay K734. This false High-1 pressure signal would prevent remote opening of valves BBPV8702A and BBPV8702B. Therefore, a fire in this area may require a cold shutdown repair or a containment entry to open valve BBPV8702A or BBPV8702B prior to initiating RHR for cold shutdown.

Based on the above discussion, RHR is available using either train but suction from the RCS may need to be manually aligned prior to starting the RHR pumps.

References: E-15000, XX-E-013, E-13BB12A, E-13BB12B, E-13BB15, E-1F9205, M-12BB01

5.2.5 Reactor Protection System

The Reactor Protection System (RPS) monitors specified input parameters and initiates reactor protection features whenever those parameters are outside specified limits. Field installed transmitters continuously monitor various parameters and report the results to one of four process cabinets, one per channel. Signals are then sent from the process cabinets to both solid state protection cabinets, one on each train. The cabinets and associated channel are listed in the following table.

Process Cabinets	Solid State Protection Cabinets
Cabinet SB038 - Channel 1 Cabinet SB042 - Channel 2 Cabinet SB037 - Channel 3 Cabinet SB041 - Channel 4	Cabinet SB029A - Train A Input Cabinet Cabinet SB029B - Train A Logic Cabinet Cabinet SB029C - Train A Output Cabinet 1 Cabinet SB029D - Train A Output Cabinet 2 Cabinet SB032A - Train B Input Cabinet Cabinet SB032B - Train B Logic Cabinet Cabinet SB032C - Train B Output Cabinet 1 Cabinet SB032D - Train B Output Cabinet 2

The RPS is actuated upon 2/3 or 2/4 coincident logic, depending on the input parameter. This ensures that a loss of a single channel will not prevent the system from performing it's function.

Cables 12SBS01BD, 12SBS02BD and 12SBY09DA associated with reactor protection system channel 2 run through this area. These cables supply power from separation group 2 power supplies to panels SB029A, SB032A and SB042. Damage to these cables could cause a loss

of RPS channel 2, but channels 1, 3 and 4 remain available. Therefore, the RPS is available if a fire occurs in this area.

References: XX-E-013, E-15000, E-13NN01, E-13SB01, E-13SB02, E-13SB03, E-13SB04, E-13SB05, E-13SB09, E-1F9431, E-1F9432, E-1F9433, J-10SA

5.2.6 Source Range Monitoring

PFSSD requires source range (SR) flux monitoring to be available to provide indication of cold shutdown reactivity conditions. Source range monitoring is provided by source range monitors SENE0031, SENE0032, SENY0060A & B, and SENY0061A & B.

Cable 12SES02AA supplies power to SE054B from NN0211. Panel SE054B is associated with source range neutron monitor SENE0032B. Loss of power to the panel will prevent SENE0032B from operating. Source range indication remains available using SENI0031B, SENI0060A/B and SENI0061A/B.

References: XX-E-013, E-15000, E-13SE02, E-1F9101

5.2.7 Safety Injection and Containment Spray

A spurious safety injection signal (SIS) could cause the safety injection pumps to operate. A spurious containment spray actuation signal (CSAS) could cause the containment spray pumps to operate, depleting inventory in the RWST. These conditions are not desirable for PFSSD at Wolf Creek.

Safety injection (SI) is initiated automatically by any of the following conditions:

1. Two out of three high containment pressures monitored by pressure transmitters GNPT0934, GNPT0935 and GNPT0936.
2. Two out of four low pressurizer pressures monitored by pressure transmitters BBPT0455, BBPT0456, BBPT0457 and BBPT0458.
3. Two out of three low steam line pressures on any steam generator monitored by ABPT0514, ABPT0515 and ABPT0516 on SG A; ABPT0524, ABPT0525 and ABPT0526 on SG B; ABPT0534, ABPT0535 and ABPT0536 on SG C; and ABPT0544, ABPT0545 and ABPT0546 on SG D. Two out of three logic must be satisfied on a single steam generator line. Low pressure on a single pressure transmitter co-incident with low pressure on another pressure transmitter on a different steam generator line will not initiate SIS.

Containment spray (CS) is initiated automatically by two out of four high containment pressures monitored by pressure transmitters GNPT0934, GNPT0935, GNPT0936 and GNPT0937.

Cables 12ABI21KA, 12ABI21NA, 12ABI21SA and 12ABI21VA associated with steam line pressure transmitters ABPT0515, ABPT0525, ABPT0535, ABPT0545 run in fire area C-32. Cables for the remaining steam line pressure transmitters are unaffected by a fire in area C-32. Therefore, a spurious SI signal due to low steam line pressure will not occur in the event of a fire in area C-32.

A cable (12BBI16LB) associated with pressurizer pressure transmitter BBPT0456 is run in area C-32. Cables associated with the remaining pressurizer pressure transmitters are unaffected by a fire in area C-32. Therefore, a spurious SI signal due to low pressurizer pressure will not occur in the event of a fire in area C-32.

A cable (12GNI05BA) associated with containment pressure transmitter GNPT0936 is run in area C-32. Cables associated with the remaining containment pressure transmitters are unaffected by a fire in area C-32. Therefore, a spurious SI and CSAS due to high containment pressure will not occur in the event of a fire in area C-32.

Based on the above discussion, a spurious SIS and CSAS cannot occur if a fire occurs in this area.

References: E-15000, XX-E-013, E-13AB21, E-13BB16, E-13GN05, E-1F9431, E-1F9432, E-1F9433, M-12AB01, M-12BB02, M-12GN01

5.2.8 Refueling Water Storage Tank

The RWST is credited in the PFSSD analysis as the primary source of borated water to achieve cold shutdown. The Wolf Creek Technical Specifications ensure the minimum quantity and boron concentration is maintained to achieve cold shutdown. Therefore, RWST level transmitters, indicators and circuits are not evaluated for level control.

The RWST level transmitters and associated circuits are included in the PFSSD analysis because of the automatic functions they perform. A low-low level in the RWST on 2 out of 4 RWST level transmitters, coincident with a safety injection signal, will provide a permissive for containment sump isolation valves EJHV8811A and EJHV8811B to open. This could cause the RWST to drain to the containment sump if the associated RWST to RHR valve does not close.

A cable (12BNI07DA) associated with refueling water storage tank (RWST) level transmitter BNLT0931 runs in fire area C-32. Cables for the remaining three RWST level transmitters are unaffected. Therefore, a spurious low-low level in the RWST is not credible if a fire occurs in this area.

Based on the above discussion, the RWST is available if a fire occurs in area C-32.

References: E-15000, XX-E-013, E-13BN07, E-13EJ06A, E-13EJ06B, E-1F9102, E-1F9201, E-1F9205, E-1F9302, M-12BN01, M-12EJ01, M-767-00162, M-767-00165, M-767-00168, M-767-00189

5.2.9 Relay Rack RP334

Cable 12RPK09BA supplies 125 VDC power from NK4201 to auxiliary relay rack RP334. The only relays in RP334 that are required for PFSSD are 86XRP1, 86XRP2 and 86XRP3. These are lockout relays used to isolate the control room if a fire occurs in the control room. Loss of DC power to the relays will prevent isolating the control room but will not cause a spurious control room isolation signal. Control room isolation is not required if a fire occurs in area C-32. Therefore, loss of DC power will not impact PFSSD.

References: XX-E-013, E-15000, E-13RP09, E-093-00093

5.2.10 Pressurizer Pressure Control

The pressurizer pressure control system is included in the PFSSD analysis because spurious operation of the pressurizer pressure control system could have adverse consequences on PFSSD. A valid high pressure signal will open the pressurizer PORVs and pressurizer spray valves, which is not desired for PFSSD.

An instrument cable (12BBI16LB) associated with pressurizer pressure transmitter BBPT0456 is run in fire area C-32. Damage to this cable could send a spurious high-pressure signal to the Ovation pressure control system. As discussed in Calculation XX-E-013, Appendix 1, damage to a single pressure input channel will not cause the spurious operation of the pressurizer spray valves or PORVs due to the Ovation 4-channel validation logic, which uses the 2nd highest signal as the validated signal and has built-in logic to detect and ignore a failed input.

Based on the above discussion, pressurizer PORVs and pressure spray valves will not spuriously operate if a fire occurs in this area.

3.1 ACTIONS OUTSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY 11
3.2 ACTIONS INSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY 11
3.3 ACTIONS TO ACHIEVE AND MAINTAIN COLD SHUTDOWN 12
4.0 CONCLUSION 12
5.0 DETAILED ANALYSIS 12
5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA C-33 12
5.2 PFSSD CABLE EVALUATION 13

1.0 GENERAL AREA DESCRIPTION

Fire area C-33 is located on the 2073-6 elevation of the Control Building and includes the rooms listed in Table C-33-1.

Table C-33-1
Rooms Located in Fire Area C-33

ROOM #	DESCRIPTION
3804	South Electrical Chase - 2073-6 Elevation

Fire area C-33 is protected by an automatic wet-pipe sprinkler system. In addition, automatic fire detection is installed throughout. The automatic suppression and detection system meets the requirements of 10CFR50, Appendix R, Section III.G.2.c.

2.0 PRIMARY EQUIPMENT USED FOR PFSSD

Table C-33-2 lists each system credited for post-fire safe shutdown and provides a discussion regarding the availability of the system to perform its Post Fire Safe Shutdown (PFSSD) function if a severe fire occurs in this area. For a summary of the area analysis results, see Section 8.0 of the Fire Area Analysis Narrative section.

Table C-33-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-33

System	System Name	PFSSD Function*	Comments
AB	Main Steam	R, M, H, P, S	Cables associated with S/G ARV ABPV0004 may be damaged, preventing control of this valve from the control room. The ARV can be isolated using ABPIC0004B at the auxiliary shutdown panel (RP118B). Steam line pressure transmitters ABPT0516 and ABPT0546 may be affected. The remaining steam line pressure transmitters are unaffected. The capability to isolate the MSIVs and bypass valves using hand switch ABHS0079 may be affected. The MSIVs and bypass valves can be isolated using hand switch ABHS0080. A number of main steam valves located downstream of the MSIVs could open. This will have no adverse impact on PFSSD since the MSIVs and bypass valves can be isolated.
AC	Main Turbine	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-33.
AE	Main Feedwater	H, P	All PFSSD functions associated with the main feedwater system are satisfied. Steam generator (SG) level indication is available on SG B using wide range level transmitter AELT0502 and narrow range level transmitters AELT0528, AELT0529 and AELT0552. Steam generator level indication is available on SG C using wide range level transmitter AELT0503 and narrow range level transmitters AELT0538, AELT0539 and AELT0553. The capability to isolate the MFIVs using hand switch AEHS0081 may be affected. Isolate the MFIVs using hand switch AEHS0080.
AL	Aux. Feedwater System	H, P	All PFSSD functions associated with the auxiliary feedwater system are satisfied. Train B motor driven auxiliary feedwater pump (MDAFP) and the turbine driven auxiliary feedwater pump may be affected. Train A MDAFP is available to supply auxiliary feedwater to SGs B and C. Steam generator A flow transmitter ALFT0007 may be affected. Steam generators B, C and D flow transmitters are unaffected.
AP	Condensate Storage System	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-33.

Table C-33-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-33

System	System Name	PFSSD Function*	Comments
BB	Reactor Coolant System	R, M, H, P, S	All PFSSD functions associated with the reactor coolant system are satisfied. All four seal water injection valves will remain open. When transferring to RHR, valve BBPV8702A may need to be manually opened or a cold shutdown repair performed to provide a suction source from the RCS to RHR pump A. Pressurizer PORV BBPCV0456A may open and block valve BBHV8000B may not close. If this occurs, Operators can close the PORV by placing BBHIS0456A in the CLOSE position. Pressure indicator BBPI0406 may not function. Pressure indicator BBPI0405 is unaffected. Reactor vessel head vent valve BBHV8002B could spuriously open. The remaining head vent valves are unaffected and will remain closed to isolate the head vent flow path. RCS temperature recorders BBTR0433 and BBTR0443 on loops 3 and 4 could lose power. Temperature indication on loops 1 and 2 remains available. Pressurizer pressure transmitter BBPT0458 could be affected. The remaining pressurizer pressure transmitters are unaffected. Pressurizer pressure indication is available using BBPI0455A, BBPI0456 and BBPI0457.
BG	Chemical and Volume Control System	R, M, S	All PFSSD functions associated with the chemical and volume control system are satisfied. Train A Centrifugal Charging Pump (CCP) is available to provide charging flow from the RWST. Train B CCP miniflow valve BGHV8111 may be affected. Train A CCP miniflow valve BGHV8110 is unaffected. Valve BGHV8105 may be affected. Redundant valve BGHV8106 is unaffected and can be closed using hand switch BGHIS8106 to isolate flow to the regenerative heat exchanger. VCT isolation valve BGLCV0112C may be affected but redundant valve BGLCV0112B can be isolated using BGHIS0112B. CCP B to RCP seal injection valve BGHV8357B could be affected. Redundant Train A CCP to RCP seal injection valve BGHV8357A is unaffected. VCT level transmitter BGLT0185 may be affected. VCT level transmitter BGLT0112 is unaffected. Excess letdown valve BGHV8154B could spuriously open. Redundant valve BGHV8153B is unaffected. RCP seal flow indication is available using BGFI0215A. RCP seal flow indicator BGFI0215B may be affected.
BM	Steam Generator Blowdown System	R, M, H	All PFSSD functions associated with the steam generator blowdown system are satisfied. Steam generator blowdown is isolated by closing valves BMHV0001, BMHV0002, BMHV0003 and BMHV0004 using BMHIS0001C, BMHIS0002C, BMHIS0003C and BMHIS0004C, located on the BM157 panel in the radwaste control room.
BN	Borated Refueling Water Storage System	R, M, H	The RWST is available to provide a suction source to Centrifugal Charging Pump A via valve BNLCV0112D. RWST level indication is available using BNLI0930, BNLI0931 and BNLI0932.

Table C-33-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-33

System	System Name	PFSSD Function*	Comments
EF	Essential Service Water System	H, S	All PFSSD functions associated with the Essential Service Water (ESW) system are satisfied. A number of components associated with Train B ESW may be affected. Train A ESW is available.
EG	Component Cooling Water System	S	All PFSSD functions associated with the Component Cooling Water (CCW) system are satisfied. Train B CCW may be affected. Train A CCW is available. CCW flow to the RCP thermal barrier could be temporarily disrupted due to closure of valves EGHV0062 and EGHV0071. Valves EGHV0132 and EGHV0126 can be opened from the control room to restore CCW flow to the thermal barriers. CCW to RCP flow indicator EGFI0129 could be affected. CCW to RCP flow indicator EGFI0128 is unaffected. Valve EGHV0102 could be affected, preventing operation of Train B RHR. Valve EGHV0101 is unaffected.
EJ	Residual Heat Removal System	M, H, P	All PFSSD functions associated with Residual Heat Removal (RHR) system are satisfied. The Train B RHR pump may be affected but the Train A RHR pump is available. Loss of RCS inventory through the RHR flow path is prevented by maintaining valves EJHV8701A and EJHV8701B closed. Valve EJHV8701A can be opened from the control room when transitioning to RHR for cold shutdown. RHR pump B mini-flow valve EJFCV0611 is affected but RHR pump A mini-flow valve EJFCV0610 is available. RHR Train B to SI Pump B isolation valve EJHV8804B could spuriously open. RHR Train A to CVCS valve EJHV8804A is unaffected. Train B RHR pump discharge to RCS cold leg isolation valve EJHV8809B is affected. Train A RHR pump discharge to RCS cold leg isolation valve EJHV8809A is unaffected. Valve EJHV8840 could spuriously open in the event of a fire in this area. This will not affect hot standby, however the valve will need to be locally closed prior to entering shutdown cooling mode. RHR Train B flow control valve EJHCV0607 could be affected. RHR Train A flow control valve EJHCV0606 is unaffected.
EM	High Pressure Coolant Injection	R, M	Train B safety injection pump PEM01B could spuriously start. Injection will not occur with the reactor at normal pressure. The pump can be stopped by opening breaker NB0202, but this action is not required for PFSSD. Charging flow from CCP A to the RCS is available through the BIT by opening valves EMHV8803A and EMHV8801A. Prevent flow diversion through the SIS test line when charging through the BIT by maintaining valve EMHV8964 closed.
EN	Containment Spray	R, M	Containment spray pump PEN01B could spuriously start and valve ENHV0012 could open, causing containment spray. Pump PEN01B can be stopped by opening breaker NB0203 in area C-10. Containment spray pump PEN01A is unaffected.

Table C-33-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-33

System	System Name	PFSSD Function*	Comments
EP	Safety Injection Accumulators	H	The PFSSD Decay Heat Removal function associated with the Safety Injection Accumulators is satisfied. Accumulator injection lines can be isolated by closing valves EPHV8808A, EPHV8808B, EPHV8808C and EPHV8808D. It may be necessary to make a containment entry to manually close EPHV8808B and EPHV8808D prior to the RCS reaching 1000 psig.
FB	Auxiliary Steam	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-33.
FC	Auxiliary Turbines	R, H, P	Turbine driven auxiliary feedwater pump steam trap valve FCFV0310 may not close. Uncontrolled blowdown through this 1-inch line will not cause unacceptable RCS cooldown and will not impact PFSSD. Turbine driven steam generator feedwater pump B main steamline low point drain valve FCHV0103 may not close. This will have no adverse impact on PFSSD since the MSIVs and MSIV bypass valves can be isolated using ABHS0080.
GD	ESW Pump House HVAC	S	The PFSSD function associated with ESW pump house HVAC is satisfied. The Train B ESW pump room ventilation system could be affected. The Train A ESW pump room ventilation system is unaffected.
GF	AFW Pump Room Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-33.
GK	Control Room and Class 1E Switchgear Room Coolers	S	The PFSSD function associated with the Control Room and Class 1E Switchgear Room Coolers is satisfied. Train B control room A/C unit SGK04B may be affected. Train A control room A/C unit SGK04A is unaffected. Train B Class 1E electrical equipment room A/C unit SGK05B may be affected. Train A Class 1E electrical equipment room A/C unit SGK05A is unaffected. Train B control room A/C dampers GKHZ0040A and GKHZ0040B could be affected. Train A control room A/C dampers are unaffected.
GL	Auxiliary Building HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-33.
GM	Emergency Diesel Generator Room HVAC	S	The PFSSD function associated with the emergency diesel generator room HVAC system is satisfied. The Train B emergency diesel generator exhaust damper GMHZ0019 could be affected. The Train A diesel generator room HVAC system is unaffected.
GN	Containment Coolers	S	The PFSSD function associated with the containment coolers is satisfied. Train B containment coolers SGN01B and SGN01D could be affected. Train A containment coolers SGN01A and SGN01C are available. Containment pressure transmitter GNPT0934 could be affected. The remaining three pressure transmitters are unaffected.

Table C-33-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-33

System	System Name	PFSSD Function*	Comments
JE	Diesel Fuel Oil	S	The PFSSD function associated with the Diesel Fuel Oil System is satisfied. The Train B emergency fuel oil transfer pump PJE01B may be affected. The Train A emergency fuel oil transfer pump PJE01A is unaffected. The Train B emergency diesel generator day tank level transmitter JELT0021 may be affected. The Train A day tank level transmitter is unaffected.
KA	Instrument Air	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-33.
KC	Fire Protection	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-33.
KH	Service Gas	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-33.
KJ	Standby Diesel Engine	S	The PFSSD function associated with the Standby Diesel System is satisfied. The Train B diesel engine may be affected. The Train A diesel engine is unaffected.
MA	Main Generation	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-33.
MR	Startup Transformer	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-33.
NB	4.16 kV System	S	The PFSSD function associated with the class 1E 4.16 kV system is satisfied. A loss of off-site and on-site power to NB02 may occur. On-site and off-site power to NB01 is unaffected.
NE	Standby Diesel Generator	S	The PFSSD function associated with the standby diesel system is satisfied. The Train B standby diesel generator could be affected. The Train A standby diesel generator is unaffected.
NF	Load Shed and Emergency Load Sequencing	S	The PFSSD function associated with the load shed/emergency load sequencing system is satisfied. Cables associated with one of the four undervoltage (UV) relays and degraded voltage potential transformers on Trains A and B are run in fire area C-33. Emergency load shed/sequencer operates when 2/4 UV relays sense undervoltage on the bus. Therefore, automatic operation of the load shed/sequencer is unaffected.
NG	480V Load Centers and MCCs	S	The PFSSD function associated with the class 1E 480 volt load centers is satisfied. A loss of off-site and on-site power to Train B 480 VAC Class 1E load centers and MCCs could occur. Off-site and on-site power to Train A 480 VAC Class 1E load centers and MCCs is available.
NK	125VDC	S	Train B class 1E 125 VDC power could be disrupted to control room panels RL001/RL002, RL005/RL006, RL017/RL018, RL019/RL020, RL021/RL022 and RL023/RL024. Train A class 1E 125 VDC power is unaffected. The normal source of power to NK02 and NK04, through the Train B 480 V distribution system, could be disrupted. 125 VDC battery sets NK012 and NK014 are unaffected. Train B class 1E 125 VDC power could be disrupted to RPS output panel SB032D. 125 VDC power is available to Train A RPS output panel SB029D.

Table C-33-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-33

System	System Name	PFSSD Function*	Comments
NN	120VAC	S	The backup source of power to Train B Class 1E electrical distribution switchboards NN02 and NN04 could be affected. The normal source of power to NN02 and NN04 is unaffected due to the availability of 125 VDC battery sets NK012 and NK014. Train A Class 1E electrical distribution switchboards NN01 and NN03 are unaffected.
PA	13.8kV	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-33.
PB	4.16kV	H, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-33.
PG	480V Load Centers and MCCs	S	Power from PG20GBR217 to RL023 could be affected. Power from PG19GCR217 to RL023 is unaffected. Load Center PG20 could lose power due to loss of PG2001. Redundant capability is available.
PK	125VDC	S	The PFSSD function associated with the non-class 1E 125 VDC system is satisfied. Battery charger PK22 may be affected. Battery set PK12 will maintain 125 VDC power to PK02. Also, Train A non-class 1E 125 VDC system is unaffected.
PL	Local Instrument Panels	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-33.
PN	120VAC	S	Power from PN0833 to RL017/RL018 may be affected. Power from PN0835 to RL021/RL022 may be affected. Power from PN0736 and PN0738 to RL017/RL018 and RL021/RL022 is unaffected.
QB	Standby AC Lighting	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-33.
QD	Emergency Lighting	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-33.
RL	Control Room MCB	S	The PFSSD function associated with the control room panels is satisfied. Train B Class 1E 125 VDC power to panels RL001/RL002, RL005/RL006, RL017/RL018, RL019/RL020, RL021/RL022 and RL023/RL024 could be disrupted. The components either fail in the desired PFSSD position or the redundant Train A component is available. Train A Class 1E 125 VDC power is unaffected. Non class 1E (separation group 6) 120 VAC power to panels RL017/RL018, RL021/RL022 and RL023/RL024 could be affected. Non class 1E (separation group 5) 120 VAC power to panels RL017/RL018, RL021/RL022 and RL023/RL024 is unaffected.
RP	Miscellaneous Control Panels	R, M, H, P, S	Power to BOP instrument rack RP053B could be disrupted. BOP instrument racks RP053A, RP053D and RP147 are unaffected. Train B 120 VAC control power to panel RP068 could be affected. Train A 120 VAC control power to panel RP068 is unaffected. Power to Group 2 Process Control Rack RP047 could be affected. This will not affect PFSSD as discussed in Section 5.2.12.

Table C-33-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-33

System	System Name	PFSSD Function*	Comments
SA	ESFAS	S	125 VDC and 120 VAC power to panel SA036B could be lost, resulting in a loss of Channel 4 Engineered Safety Features Actuation System (ESFAS). Redundant Channels 1, 2 and 3 ESFAS are unaffected. Status panel input for GKHZ0040A/B, SGK04B and SGK05B could be affected. This will not adversely impact PFSSD.
SB	Reactor Protection System	R, S	All PFSSD functions associated with the reactor protection system are satisfied. A loss of power to input channel 4 in SB029A and SB032A could occur. Input channels 1, 2 and 3 remain available. Train B output cabinet SB032D could lose power. Train A output cabinets are unaffected. Channel 4 process protection panel SB041 could lose power. Process protection channels 1, 2 and 3 remain available. Train B reactor trip switchgear SB102B could be affected. Train A reactor trip switchgear SB102A is unaffected.
SC	Reactor Instrumentation	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-33.
SE	Ex-Core Neutron Monitoring	R, P	All PFSSD functions associated with the ex-core neutron monitoring system are satisfied. The source range recorder for source range monitor SENY0061B could be affected. Source range monitoring remains available using SENE0031, SENE0032 and SENY0060A/B
SY	Switchyard	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-33.
UU	Supervisory System	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-33.

* R - Reactivity Control; M - Reactor Coolant Makeup; H - Decay Heat Removal; P - Process Monitoring; S - Support Function

3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD

This section describes operator actions that may need to be performed inside or outside the control room to achieve and maintain hot standby if a fire occurs in area C-33. This section also describes cold shutdown repairs that may need to be made to achieve and maintain cold shutdown conditions. Operator actions are proceduralized in OFN KC-016.

3.1 ACTIONS OUTSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

Operator Manual Actions (OMAs) are those actions outside the main control room required to achieve and maintain hot standby. OMAs are identified in E-1F9900 and were determined from thermal hydraulic analysis WCNOC-CP-002. Applicable E-1F9900 OMAs are annotated herein. All other actions outside the control room are desirable for plant control in support of hot standby but not required to achieve and maintain hot standby.

3.1.1 Steam Generator Atmospheric Relief Valves

Cables associated with S/G ARV ABPV0004 may be damaged, preventing control of this valve from the control room. The ARV can be isolated using ABPIC0004B at the auxiliary shutdown panel (RP118B).

3.1.2 Steam Generator Blowdown Isolation

Blowdown may not be isolable using BMHIS0001A, BMHIS0002A, BMHIS0003A and BMHIS0004A. Therefore, it may be necessary to isolate blowdown using BMHIS0001C, BMHIS0002C, BMHIS0003C and BMHIS0004C located on BM157 in the Radwaste Control room.

3.1.3 **Containment Spray Pump** (OMA, refer to E-1F9900)

Containment spray pump PEN01B could spuriously start and valve ENHV0012 could open, causing containment spray. The pump can be stopped by opening breaker NB0203 in area C-10. Access is available without traversing area C-33 and emergency lighting is provided.

3.2 ACTIONS INSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

3.2.1 Main Steam Isolation Valves and MSIV Bypass Valves

The capability to isolate the MSIVs and bypass valves using hand switch ABHS0079 may be affected. The MSIVs and bypass valves can be isolated using hand switch ABHS0080.

3.2.2 Main Feedwater Isolation Valves

The capability to isolate the MFIVs using hand switch AEHS0081 may be affected. Isolate the MFIVs using hand switch AEHS0080.

3.2.3 Volume Control Tank

Valve BGLCV0112C may not close in response to a signal from the control room. Redundant valve BGLCV0112B can be isolated using BGHIS0112B on RL001.

3.2.4 Thermal Barrier Cooling

CCW flow to the thermal barrier cooling coils could be lost due to the spurious closure of valves EGHV0062 and EGHV0071. If this occurs, operators could open bypass valves EGHV0132 (EGHV0062 bypass) and EGHV0126 (EGHV0071 bypass) using EGHIS0132 and EGHIS0126, respectively. Otherwise, operators should close EGHV0061 using EGHIS0061 to

prevent a steam bubble from damaging the CCW piping. CCW to RCP flow indicator EGFI0128 is available to diagnose a loss of CCW flow to the RCP thermal barriers.

3.2.5 Charging

If necessary to establish an alternate makeup and boration flowpath, the Train A CCP is available to charge through the BIT and valves EMHV8801A and EMHV8803A can be opened using EMHIS8801A and EMHIS8803A.

3.2.6 Component Cooling Water

Train B CCW could be affected by a fire in this area. If this occurs, swap to Train A CCW using normal operating procedures if Train A CCW is not already running.

3.2.7 Pressurizer PORV/Block Valve

Pressurizer PORV BBPCV0456A could spuriously open and block valve BBHV8000B may not close. If this occurs, Operators can close the PORV by placing BBHIS0456A in the CLOSE position. Pressurizer pressure indication is available using BBPI0455A, BBPI0456 and BBPI0457 located on RL002.

3.3 ACTIONS TO ACHIEVE AND MAINTAIN COLD SHUTDOWN

3.3.1 RHR

A number of Train B RHR components, including the Train B RHR pump, may be affected by a fire in this area. Use Train A RHR for shutdown cooling. Valve BBPV8702A may need to be manually opened, or a cold shutdown repair performed, when aligning Train A RHR.

Valve EJHV8840 could spuriously open in the event of a fire in this area. This will not affect hot standby, however the valve will need to be locally closed prior to entering shutdown cooling mode.

3.3.2 Safety Injection Accumulators

It may be necessary to make a containment entry to close SI Accumulator injection valves EPHV8808B and EPHV8808D if these valves are unresponsive from the control room. Otherwise, nitrogen pressure can be relieved from the tanks to prevent injection. Valves EPHV8808A and EPHV8808C are unaffected.

4.0 CONCLUSION

With some exceptions, redundant Post Fire Safe Shutdown capability exists if a severe fire occurs in area C-33. For those exceptions, feasible manual actions are available and are unaffected by the fire. Manual actions are documented in Section 3.0.

5.0 DETAILED ANALYSIS

This section describes the detailed component-by-component and cable-by-cable analysis for a fire in area C-33.

5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA C-33

There are no PFSSD components located in area C-33. This fire area only contains cables associated with PFSSD equipment located in other areas.

5.2 PFSSD CABLE EVALUATION

Table C-33-3 lists all the PFSSD cables (S. in E-15000) located in fire area C-33. The applicable evaluation section is also listed in Table C-33-3.

Table C-33-3

5.2.1 Steam Generator Atmospheric Relief Valves

PFSSD requires at least two steam generator atmospheric relief valves (ARVs) be controlled and the other two closed. The ARVs are pneumatically operated using air from the compressed air system (KA) or nitrogen from the nitrogen accumulators. The valves open by pneumatic pressure and close by spring action. The valves are automatically controlled by a pressure transmitter installed on the outlet side of the steam generator. Alternatively, each valve can be controlled manually from the control room or the auxiliary shutdown panel by placing the pressure indicating controller (PIC) in manual.

As discussed in Section 5.2.8, a fire in this area could affect the Train B motor driven auxiliary feedwater pump (MDAFP) and the turbine driven auxiliary feedwater pump (TDAFP). Therefore, only the Train A MDAFP is available to feed steam generators B and C. Consequently, steam generator ARVs ABPV0001 and ABPV0004 need to be isolated and steam generator ARVs ABPV0002 and ABPV0003 need to be controlled.

Cables associated with steam generator ARV ABPV0004 are run in area C-33. Damage to these cables could prevent isolating ABPV0004 from the control room. Because of the fail-close design of the valve, it is unlikely that spurious signals due to cable damage will cause the valve to open. However, in the unlikely event the valve opens, an operator can close it using the associated PIC (ABPIC0004B) at the auxiliary shutdown panel (RP118B). Cables for the remaining ARVs are not run in area C-33 and, therefore, the PFSSD function for controlling two steam generators is satisfied.

Up to three ARVs can fail closed or open without impacting ability to achieve and maintain hot standby according to thermal hydraulic analysis WCNOC-CP-002. With at least one ARV unaffected, no E-1F9900 OMA is required to address ARV closure or control. Reference Attachment 4, MSO Evaluation Scenario ID PWROG 23.

Based on the above discussion, steam generator atmospheric relief valve control can be achieved.

References: E-15000, XX-E-013, E-13AB20B, E-1F9101, M-12AB01

5.2.2 Safety Injection and Containment Spray

A spurious safety injection signal (SIS) could cause the safety injection pumps to operate. A spurious containment spray actuation signal (CSAS) could cause the containment spray pumps to operate, depleting inventory in the RWST. These conditions are not desirable for PFSSD at Wolf Creek.

1. Two out of three high containment pressures monitored by pressure transmitters GNPT0934, GNPT0935 and GNPT0936.
2. Two out of four low pressurizer pressures monitored by pressure transmitters BBPT0455, BBPT0456, BBPT0457 and BBPT0458.
3. Two out of three low steam line pressures on any steam generator monitored by ABPT0514, ABPT0515 and ABPT0516 on SG A; ABPT0524, ABPT0525 and ABPT0526 on SG B; ABPT0534, ABPT0535 and ABPT0536 on SG C; and ABPT0544, ABPT0545 and ABPT0546 on SG D. Two out of three logic must be satisfied on a single steam generator line. Low pressure on a single pressure transmitter co-incident with low pressure on another pressure transmitter on a different steam generator line will not initiate SIS.

Containment spray (CS) is initiated automatically by two out of four high containment pressures monitored by pressure transmitters GNPT0934, GNPT0935, GNPT0936 and GNPT0937.

A cable associated with containment pressure transmitter GNPT0934 is run in area C-33. Cables associated with the remaining containment pressure transmitters are not run in area C-

33. Therefore, a spurious CSAS cannot occur due to a fire in this area. Also, a spurious SIS due to high containment pressure cannot occur.

A cable associated with pressurizer pressure transmitter BBPT0458 is run in area C-33. Cables associated with the remaining pressurizer pressure transmitters do not run in area C-33. Consequently, a fire in area C-33 cannot cause a spurious SIS due to low pressurizer pressure.

Cables associated with steam line pressure transmitters ABPT0516 and ABPT0546 are run in area C-33. Cables associated with the remaining steamline pressure transmitters do not run in area C-33. Consequently, a spurious two out of three logic for low steam line pressure initiation of SIS cannot be satisfied if a fire occurs in area C-33.

Based on the above discussion, a spurious SIS and CSAS cannot occur if a fire occurs in this area.

5.2.3 Main Steam Isolation Valves Downstream Components

Cables for several main steam (AB) valves located downstream of the main steam isolation valves (MSIVs) are located in this area. These valves are used for PFSSD to isolate the main steam lines in the event the MSIVs or MSIV bypass valves fail to close. Damage to these cables could cause the associated component to fail open.

Cable 16RLY01GA supplies 120 VAC power to control room panel RL023/RL024. At RL023/RL024, the power is split and supplies power to FCHV0103, ABLV0050 and ABLV0052, as well as other non-PFSSD components. These components are required to be functional for PFSSD in the event the MSIVs and MSIV bypass valves cannot be isolated. Loss of power will cause the valves to remain open.

As discussed in Sections 5.2.4 and 5.2.5, the MSIVs and the MSIV bypass valves can be isolated using hand switch ABHS0080 if a fire occurs in area C-33. Therefore, these downstream valves can fail open with no adverse impact on PFSSD.

References: E-15000, XX-E-013, E-13AB08, E-13AB11A, E-13AB11B, E-13AB11C, E-13RL01, E-13RL07, E-1F9103, E-1F9424E, M-12AB03

5.2.4 Main Steam Isolation Bypass Valves

Each of the four MSIV bypass valves (ABHV0012, ABHV0015, ABHV0018 and ABHV0021) has two redundant solenoids that control the position of the associated valve. The bypass valves are normally closed with the solenoids de-energized. Both solenoids need to be energized to open the valve. One of the solenoids on each valve is on separation group 1 (Train A) and is controlled by hand switch ABHS0080. The other solenoids on each valve are on separation group 4 (Train B) and are controlled by hand switch ABHS0079.

Cable 14ABK23FE is associated with steam line isolation signal relay K627. Upon receipt of a steam line isolation signal, the relay contact opens and the bypass valves close. An open circuit in one of the two conductors will produce the same result as a steam line isolation signal, which is desired for PFSSD. A hot short between the conductors will bypass the contact and prevent a steam line isolation signal from closing the valves.

Cable 14ABK23FF is associated with hand switch ABHS0079 on the Train B MSIV bypass valve control circuit. An open circuit in one of the two conductors will de-energize the respective solenoid and close the bypass valves. A hot short between the conductors will bypass the handswitch contact and prevent closure of the valves using the handswitch.

Cable 14ABK23FG is associated with reset switch ABHS0100 on the Train B MSIV bypass valve control circuit. An open circuit will have no impact on the ability to close the bypass valves. A hot short between the conductors will act as a reset signal and maintain the auxiliary relay energized, maintaining the four Train B bypass valve solenoids energized and therefore providing the Train B permissive to open the valves.

Redundant means are available to ensure the MSIV bypass valves are closed. Hand switch ABHS0080 is unaffected by the fire and can be used to ensure one of the two solenoids on each bypass valve are de-energized.

5.2.5 Steam Generator Main Steam Isolation Valves (MSIVs)

PFSSD requires the MSIVs be closed to prevent reactivity addition due to uncontrolled cooldown. The MSIVs are closed from the control room using all close hand switches ABHS0079 or ABHS0080.

Each MSIV is designed to utilize system fluid (main steam) as the motive force to open and close. The valve actuation (open or close) is accomplished through positioning a series of six electric solenoid pilot valves to either direct the system fluid to the Upper Piston Chamber (UPC) and/or the Lower Piston Chamber (LPC), or vent either or both piston chambers. The six solenoid pilot valves are divided into two trains (3 per train) that are independently powered and controlled. Either train can independently perform the PFSSD function to close the valve and isolate main steam. This is done by actuating either all close hand switch ABHS0079 (separation group 4) or ABHS0080 (separation group 1) to de-energize the associated solenoid valves.

The following table identifies the solenoids and associated control cables for each hand switch.

MSIV	ABHS0079 (Sep Group 4)		ABHS0080 (Sep Group 1)	
	Solenoids	Cable	Solenoids	Cable
ABHV0011	MV2, MV4, MV6	14ABK28BH	MV1, MV3, MV5	11ABK29BH

ABHV0017	MV2, MV4, MV6	14ABK28AH	MV1, MV3, MV5	11ABK29AH
ABHV0020	MV2, MV4, MV6	14ABK29BH	MV1, MV3, MV5	11ABK28BH

All 4 cables associated with the 12 separation group 4 solenoid valves are run in area C-33. Cable damage due to a fire will likely result in disruption of power to the solenoids, which will close the valves. The four separation group 1 cables associated with hand switch ABHS0080 are unaffected by a fire in area C-33. Therefore, hand switch ABHS0080 is available to close the four MSIVs.

Cable 14ABK30BB provides 125 VDC power to Train B main steam and feedwater isolation actuation system (MSFIS) cabinet SA075B from NK5423. Damage to this cable would disrupt power to the separation group 4 solenoids and close the MSIVs, which is the desired PFSSD position. In addition, the Train A MSFIS is unaffected by the fire and ABHS0080 is available to close the MSIVs.

Based on the above discussion, hand switch ABHS0080 is available to close the MSIVs in the event of a fire in area C-33.

References: E-15000, XX-E-013, E-13AB27, E-13AB28, E-13AB29, E-13AB30, E-1F9101, M-12AB02

5.2.6 Steam Generator Level Indication

The decay heat removal function for PFSSD requires the use of two RCS loops and two Steam Generators. Steam generator (SG) level indication is required to support this function. A fire in area C-33 uses MDAFP A to supply SGs B and C. Therefore, level indication on steam generators B and C is required.

Cables associated with SGs B and C level transmitters AELT0527 (SGB NR) and AELT0537 (SGC NR) run in this area. Cables associated with the remaining level transmitters on steam generators B and C do not run in this area. Therefore, level indication will be available on steam generators B and C using the following level transmitters:

Steam Generator	Available Level Indication
B	AELI0502 (WR), AELI0528 (NR), AELI0529 (NR), AELI0552 (NR)
C	AELI0503 (WR), AELI0538 (NR), AELI0539 (NR), AELI0553 (NR)

Circuits associated with steam generator level indication at the auxiliary shutdown panel (RP118B) are run in area C-33. Damage to these circuit will affect AELI0504A (SG D Wide Range Level Indicator at RP118B), AELI0517X (SG A Narrow Range Level Indicator at RP118B) and AELI0537X (SG C Narrow Range Level Indicator at RP118B). Damage to these circuits will not impact the redundant level indicators in the main control room.

Based on the above discussion, steam generator B and C level indication is assured if a fire occurs in area C-33.

References: E-15000, XX-E-013, E-13AE08, E-13SB16, E-1F9203, M-12AE02

5.2.7 Steam Generator Main Feedwater Isolation Valves

PFSSD requires that either the main feedwater isolation valves (MFIVs) be closed, or the main feedwater pumps be stopped to prevent overfilling the steam generators. Flow diversion from auxiliary feedwater (AFW) to the main feedwater system piping is prevented by check valves AEV0420, AEV0421, AEV0422 and AEV0423. Closure of the main feedwater isolation valves is not required to prevent AFW flow diversion.

Each MFIV is designed to utilize system fluid (feedwater) as the motive force to open and close. The valve actuation (open or close) is accomplished through positioning a series of six electric solenoid pilot valves to either direct the system fluid to the Upper Piston Chamber (UPC) and/or the Lower Piston Chamber (LPC), or vent either or both piston chambers. The six solenoid pilot valves are divided into two trains (3 per train) that are independently powered and controlled. Either train can independently perform the PFSSD function to close the valve and isolate main feedwater. This is done by actuating either all close hand switch AEHS0080 (separation group 1) or AEHS0081 (separation group 4) to de-energize the associated solenoid valves.

The following table identifies the solenoids and associated control cables for each hand switch.

MFIV	AEHS0080 (Sep Group 1)		AEHS0081 (Sep Group 4)	
	Solenoids	Cable	Solenoids	Cable
AEFV0039	MV1, MV3, MV5	11AEK16AH	MV2, MV4, MV6	14AEK17AH
AEFV0040	MV1, MV3, MV5	11AEK17AH	MV2, MV4, MV6	14AEK16AH
AEFV0041	MV1, MV3, MV5	11AEK16BH	MV2, MV4, MV6	14AEK17BH
AEFV0042	MV1, MV3, MV5	11AEK17BH	MV2, MV4, MV6	14AEK16BH

All 4 cables associated with the 12 separation group 4 solenoid valves are run in area C-33. Cable damage due to a fire will likely result in disruption of power to the solenoids, which will close the valves. The four separation group 4 cables associated with hand switch AEHS0080 are unaffected by a fire in area C-33. Therefore, hand switch AEHS0080 is available to close the four MFIVs.

Cable 14ABK30BB provides 125 VDC power to Train B main steam and feedwater isolation actuation system (MSFIS) cabinet SA075B from NK5423. Damage to this cable would disrupt power to the separation group 4 solenoids and close the MFIVs, which is the desired PFSSD position. In addition, the Train A MSFIS is unaffected by the fire and AEHS0080 is available to close the MFIVs.

Based on the above discussion, MFIV isolation is assured using hand switch AEHS0080.

References: E-15000, XX-E-013, E-13AB30, E-13AE14, E-13AE15, E-13AE16, E-13AE17, E-1F9201, J-104-00296, M-12AE02, M-630-00044

5.2.8 Auxiliary Feedwater

The PFSSD design requires the use of one auxiliary feedwater pump (AFP) supplying water to at least two steam generators. The turbine driven auxiliary feedwater pump (TDAFP) is normally aligned to supply all four steam generators. The Train A motor driven auxiliary feedwater pump (MDAFP) is aligned to supply steam generators B and C. The Train B MDAFP is aligned to supply steam generators A and D.

The normal source of water to the AFPs is the condensate storage tank (CST). The emergency supply is from the essential service water (ESW) system. For commercial concerns, the CST is the preferred source and contains sufficient volume to supply the entire AFW demand to achieve cold shutdown.

Motor operated valves (MOVs) in the system allow operators to line up the auxiliary feedwater system as required to achieve and maintain safe shutdown. Damage to the MOV circuits due to a fire could prevent operators from lining up the system from the control room.

Several PFSSD cables associated with various components of the auxiliary feedwater system (AL) run through fire area C-33. These cables are identified in Table C-33-3. Damage to these cables could prevent operation of the TDAFP and the Train B MDAFP. In addition, motor operated valves in the flowpath from the Train B MDAFP to steam generators A and D and from the TDAFP to steam generators B and C could spuriously close. Cables associated with the Train A MDAFP, as well as the suction and discharge valves, are unaffected by a fire in this area.

Panels SA036A, SA036B and SA036C monitor pressure transmitter signals on ALPT0037, ALPT0039 and ALPT0038, respectively. A spurious low CST pressure due to fire damage to cables associated with two of these pressure transmitters could swap the water source to ESW. This is only a commercial concern and should be prevented if possible. An instrument cable associated with ALPT0039 runs in this area. Damage to this cable could cause a spurious low CST pressure signal but will not initiate swapover to the ESW system since cables for the remaining two pressure transmitters are unaffected.

Power cables associated with SA036B are run in this area. Damage to these cables could result in a loss of power to the panel but panels SA036A and SA036C remain available. Therefore, automatic operation of low suction pressure (LSP) swapover is available.

Based on the above discussion, auxiliary feedwater is assured if a fire occurs in area C-33 using Train A MDAFP supplying auxiliary feedwater to steam generators B and C.

References: E-15000, XX-E-013, E-13AL01A, E-13AL01B, E-13AL02B, E-13AL03A, E-13AL03B, E-13AL04B, E-13AL05A, E-13AL05B, E-13AL07B, E-13AL08, E-13AL09, E-13SA21, E-1F9202, E-1F9203, E-1F9204, E-1F9402A, E-1F9402B, J-10SA, M-12AL01

5.2.9 Reactor Coolant Pump (RCP) Seal Injection

PFSSD requires RCP seal injection to provide a boron injection path, provide makeup to the RCS and provide cooling to the RCP seals. The redundant boron injection and makeup path is through the boron injection tank (BIT). The redundant seal cooling method uses thermal barrier cooling.

A fire in area C-33 could damage power and control cables associated with all four RCP seal injection valves (BBHV8351A, BBHV8351B, BBHV8351C and BBHV8351D). The seal injection valves are normally open and de-energized with the circuit breaker maintained in the OFF position. The valves are not high/low pressure interface valves so three-phase hot shorts do not have to be considered and, consequently, damage to the power cables will not cause the valves to spuriously close. Damage to the control cables will not cause the valves to close because the power and control circuits are de-energized. Therefore, a fire in this area will not cause the seal injection valves to close.

Cable 14BGG52BC is associated with centrifugal charging pump (CCP) B to RCP seal injection valve BGHV8357B. Redundant Train A CCP to RCP seal injection valve BGHV8357A is unaffected.

Cable 14BGI51BA is associated with RCP seal total flow transmitter BGFT0215B. Damage to this cable could cause a loss of seal flow indication on BGFI0215B. RCP seal total flow indicator BGFI0215A is unaffected by a fire in area C-33 and can be used to diagnose a loss of RCP seal injection.

Based on the above discussion, RCP seal injection may be lost, but alternative means exist to ensure boration, inventory control, and RCP seal integrity. RCP seal total flow indicator BGFI0215A can be used to diagnose a loss of RCP seal injection in the event of a loss of the operating charging pump.

References: E-15000, XX-E-013, E-13BB04, E-13BG51, E-13BG52, E-1F9102, E-1F9302, E-1F9303, M-12BB03, M-12BG03

5.2.10 Component Cooling Water

For PFSSD, the component cooling water (CCW) system is used to provide cooling to the centrifugal charging pump (CCP) oil cooler, seal water heat exchanger, the RHR heat exchanger and the RHR pump seal cooler. In addition, the CCW system provides cooling to the RCP thermal barriers and is credited as a backup to RCP seal injection for maintaining seal cooling.

Cables associated with components on the Train B CCW system run through area C-33. Damage to these cables due to a fire could prevent operation of the associated equipment and prevent operation of Train B CCW. Cables associated with redundant Train A CCW are run in a different fire area and are unaffected by the fire.

To ensure an operable flow path from CCW to the RCP thermal barriers, either valves EGHV0071 or EGHV0126 must be open and either EGHV0058 or EGHV0127 must be open. In addition, either valves EGHV0062 or EGHV0132 must be open and either EGHV0061 or EGHV0133 must be open. Also, when operating the Train A CCW system, valve EGHV0015 needs to be open to ensure a return flow path to the suction side of the CCW pumps and EGHV0053 needs to be open to ensure CCW flow to the service loop.

Cables associated with valves EGHV0062, EGHV0071, EGHV0127 and EGHV0133 run through area C-33. If the fire affects cables associated with EGHV0062 and EGHV0071, the valves may spuriously close. If this occurs, Operators could open valves EGHV0132 and EGHV0126 using associated hand switches EGHIS0132 and EGHIS0126 on RL020.

If the Train B CCW system is operating at the time of the fire, operators may need to swap to Train A CCW using hand switches in the control room. If the Train A CCW system is operating at the time of the fire, the CCW system is in the protected lineup except that EGHV0126 and/or EGHV0132 may need to be opened from the control room.

Cable 14EGI19BB is associated with CCW to RCP flow transmitter EGFT0129. Damage to this cable could prevent operators from diagnosing a loss of CCW flow to the RCP thermal barriers using flow indicator EGFI0129. CCW to RCP flow indicator EGFI0128 is unaffected by a fire in area C-33 and can be used to diagnose a loss of CCW flow to the RCP thermal barriers.

Based on the above discussion, Train A CCW is available to provide cooling to essential PFSSD components as well as provide cooling to the RCP thermal barriers. Loss of CCW flow to the RCP thermal barriers can be diagnosed using flow indicator EGFI0128.

References: E-15000, XX-E-013, E-13EG01C, E-13EG01D, E-13EG05A, E-13EG05B, E-13EG09, E-13EG10, E-13EG13, E-13EG15, E-13EG16, E-13EG18, E-13EG18A, E-13EG19, E-1F9303, E-1F9401A, E-1F9401B, M-12EG01, M-12EG02, M-12EG03

5.2.11 Residual Heat Removal (RHR)

PFSSD requires one train of residual heat removal (RHR) to be available for shutdown cooling. The RHR system is not used for hot standby.

Hot shutdown requires isolation of the RCS to RHR flow path by maintaining either BBPV8702A or EJHV8701A closed and either BBPV8702B or EJHV8701B closed. Cold shutdown requires RHR taking suction from the RCS. RHR pump suction from the RCS is controlled by valves BBPV8702A and EJHV8701A (Train A) and BBPV8702B and EJHV8701B (Train B). The PFSSD methodology credits Train A RHR to achieve cold shutdown if a fire occurs in area C-33.

A control cable associated with RHR pump B (PEJ01B) could be damaged, causing a spurious pump start or preventing the pump from being started. Cables associated with RHR pump A are unaffected by a fire in area C-33.

Cables 14BBG12AF and 14BBG12AG are control cables associated with BBPV8702A. An inter-cable (cable-to-cable) hot short between cables 14BBG12AF and 14BBG12AG will bypass the control room hand switch and provide the permissive to open BBPV8702A. Valve EJHV8701A will remain closed since cables associated with this valve are not run through area C-33. Furthermore, BBPV8702A and EJHV8701A are administratively maintained closed with the breaker locked open. The 3-phase power cables associated with both valves are not run in this area, so a 3-phase hot short is not credible.

Cables 14BBG12BF and 14BBG12BG are control cables associated with BBPV8702B. An inter-cable (cable-to-cable) hot short between cables 14BBG12BF and 14BBG12BG will bypass the control room hand switch and provide the permissive to open BBPV8702B. Valve EJHV8701B will remain closed since cables associated with this valve are not run through area C-33. Furthermore, BBPV8702B and EJHV8701B are administratively maintained closed with the breaker locked open. The 3-phase power cables associated with both valves are not run in this area, so a 3-phase hot short is not credible.

An open circuit in cable 14BBG12AF could prevent remote opening of valve BBPV8702A when transitioning to RHR Train A. If this occurs, a cold shutdown repair or a containment entry will be necessary to open the valve. Valve EJHV8701B can be controlled from the control room.

Valve EGHV0101 is the Train A CCW to RHR Heat Exchanger control valve. Valve EGHV0102 is the Train B CCW to RHR Heat Exchanger control valve. These valves are normally closed during power operation. PFSSD requires that the valve on the operating train of CCW be closed until shutdown cooling mode is entered, at which time the valve on the operating train of RHR needs to be open. As stated in Section 5.2.10, the Train B CCW system may not be available to supply cooling water to the Train B RHR heat exchanger. Cable 14EGG07BC is associated with valve EGHV0102. Damage to the cable could prevent operation of EGHV0102 and could cause the valve to spuriously open. Valve EGHV0101 is unaffected by a fire in this area.

When RHR pumps are operating, the associated mini-flow valve (EJFCV0610 or EJFCV0611) needs to be controlled. The mini-flow valves prevent RHR pump overheating by re-circulating water from the discharge side of the RHR heat exchanger to the suction side of the RHR pump. The mini-flow valve opens when the flow indicator measures low flow and closes on high flow. Damage to cable 14EJG08BC could prevent mini-flow valve EJFCV0611 from operating properly. If the Train B RHR pump spuriously starts and EJFCV0611 fails to operate, the pump could be damaged. This is a commercial concern only since Train A RHR pump and mini-flow valve EJFCV0610 are unaffected by a fire in this area.

The RHR heat exchanger discharge control valve on the operating train (EJHCV0606 (Train A) or EJHCV0607 (Train B)) needs to be available. Cable 16EJI12BA, which is associated with EJHCV0607, runs through area C-33. Cable 16RLY01DA provides 120 VAC power to RL017/RL018 (EJHY0607) from PN0833. Damage to these cables could result in a loss of valve EJHCV0607. Valve EJHCV0606 is unaffected by a fire in this area.

RHR pump A discharge to CVCS control valve EJHV8804A needs to be closed when operating the Train A RHR system. RHR pump B discharge to SI Pump B control valve EJHV8804B needs to be closed when operating the Train B RHR system. Damage to cable 14EJG04BC could cause valve EJHV8804B to spuriously open. The Train A RHR system is credited for a fire in this area so spurious opening of EJHV8804B will have no adverse impact on PFSSD. Cables associated with EJHV8804A do not run in area C-33.

Cables associated with Train B RHR pump discharge to RCS cold leg isolation valve EJHV8809B run in area C-33. Damage to these cables could prevent operating the valve from the control room. Cables associated with Train A RHR pump discharge to RCS cold leg isolation valve EJHV8809A do not run in area C-33. Consequently, valve EJHV8809A is unaffected by a fire in area C-33.

The cold shutdown mode of PFSSD requires isolation of hot leg recirculation. Valve EJHV8840 is used to isolate RHR flow to the RCS hot leg loops 2 and 3. This valve is normally closed and is required to be closed for cold shutdown. During hot standby, the valve can be in any position. Cables associated with valve EJHV8840 run through area C-33. Damage to cables 14EJG09AC and 14EJG09AD would likely result in valve EJHV8840 remaining in its as-is normally closed position, which is the preferred PFSSD position. However, two proper intra-cable hot shorts in cable 14EJG09AD or one intra-cable hot short in cable 14EJG09AD combined with a short to ground on conductor U1 would spuriously open the valve.

As stated above, the position of valve EJHV8840 (open or closed) will not affect hot standby. The valve needs to be closed for cold shutdown. The valve has been modified to address NRC IN 92-18 and can be closed manually prior to entering shutdown cooling mode. The torque and limit switches are not bypassed by postulated damage to these cables.

Based on the above discussion, the Train B RHR system could be affected by a fire in this area but the Train A RHR system is available. Valve BBPV8702A may need to be manually opened and valve EJHV8840 may need to be manually closed when transitioning to Train A RHR for shutdown cooling.

References: E-15000, XX-E-013, E-13BB12A, E-13BB12B, E-13EJ01, E-13EJ04B, E-13EJ08, E-13EJ09A, E-13EJ12, E-13RL01, E-13RL04, E-1F9205, E-1F9301, E-1F9401A, E-1F9421, M-12BB01, M-12EJ01

5.2.12 Pressurizer Power Operated Relief Valves and Associated Block Valves

PFSSD requires that either the pressurizer power operated relief valve (PORV) or its associated block valve be closed. Cables and components associated with PORV BBPCV0456A and associated block valve BBHV8000B are run through area C-33. Cables and components associated with PORV BBPCV0455A and associated block valve BBHV8000A are not located in area C-33.

The pressurizer PORVs are not considered high/low pressure interfaces. The valves are supplied power by an ungrounded 125 VDC system. Therefore, based on GL 86-10, consideration of multiple proper polarity hot shorts is not required. A single proper polarity hot short still needs to be considered.

In the event a fire causes BBPCV0456A to open and damages BBHV8000B cables, Operators can close BBPCV0456A by placing hand switch BBHIS0456A, located on RL021, in the close position. Pressurizer level and RCS pressure indication are available to diagnose a failed open PORV using BBLI0459A and BBPI0405, respectively. In addition, pressurizer pressure indication is available using BBPI0455A, BBPI0456 and BBPI0457.

An instrument cable (14BBI16NB) associated with pressurizer pressure transmitter BBPT0458 is run in fire area C-33. Damage to this cable could send a spurious high-pressure signal to the pressure control system. However, as discussed in Calculation XX-E-013, Appendix 1, damage to a single pressure channel will not cause the spurious operation of the pressurizer PORVs.

Based on the above discussion, pressurizer PORV BBPCV0456A could spuriously open due to damage to the PORV control cables and block valve BBHV8000B may not close due to cable damage. The PORV can be closed using hand switch BBHIS0456A in the main control room.

References: XX-E-013, E-15000, M-12BB02, E-13BB39, E-13BB40, E-13BB16, E-1F9301, CR13079, DCP 12944, DCP 13324

5.2.13 Reactor Coolant System (RCS) Pressure Indication

The PFSSD design requires RCS pressure indication to be available. RCS pressure indication is provided in the control room using BBPI0405 or BBPI0406. A cable (14BBI16BB) associated with pressure transmitter BBPT0406 is located in fire area C-33. Damage to this cable could prevent RCS pressure indication on BBPI0406.

Cables associated with redundant RCS pressure transmitter BBPT0405 are unaffected by a fire in this area. Therefore, RCS pressure indication is available using BBPI0405.

Based on the above discussion, RCS pressure indication is available in the control room using BBPI0405 if a fire occurs in area C-33.

References: E-15000, XX-E-013, E-13BB16, E-1F9201, E-1F9205, M-12BB04

5.2.14 Reactor Head Vent Valves

PFSSD requires that one of the two reactor vessel head vent valves on each flow path (2 flow paths total) be closed to prevent uncontrolled depressurization of the RCS. Either BBHV8001A or BBHV8002A and either BBHV8001B or BBHV8002B needs to be closed.

A cable (14BBK30DA) associated with one of the four head vent valves (BBHV8002B) runs through area C-33. Cables for remaining head vent valves BBHV8001A, BBHV8002A and BBHV8001B are not run through C-33 and are unaffected by the fire. Therefore, at least one valve on each flow path can be controlled and spurious opening of BBHV8002B will have no adverse impact on PFSSD.

References: E-15000, XX-E-013, E-13BB30, E-1F9301, M-12BB04

5.2.15 Centrifugal Charging Pumps

A control cable associated with Train B Centrifugal Charging Pump (CCP) PBG05B runs through area C-33. Damage to this cable could prevent operation of the pump. Redundant Train A CCP cables are run in a separate fire area and are unaffected by a fire.

Control cables associated with Train B charging pump miniflow valve BGHV8111 are run through area C-33. Redundant Train A cables for miniflow valve BGHV8110 are run in a different area and are unaffected by a fire in area C-33.

Cables associated with RWST to charging pump B control valve BNLCV0112E are run in this area. Damage to these cables could prevent opening or cause spurious closure of the valve. Redundant valve BNLCV0112D is unaffected by a fire in area C-33.

Based on the above discussion, the Train A CCP is available if a fire occurs in area C-33.

References: XX-E-013, E-15000, E-13BG01A, E-13BG11C, E-13BN01A, E-1F9102, E-1F9302, E-1F9401A, M-12BG03, M-12BN01

5.2.16 Charging Flow to Regenerative Heat Exchanger Isolation Valves

PFSSD requires charging flow to be directed to the RCS through the RCP seals and/or the boron injection tank. To ensure adequate flow to the RCS, flow diversion to the regenerative heat exchanger needs to be prevented. Valves BGHV8105 and BGHV8106 are included in the PFSSD equipment list to accomplish this task. Manual valve BG8402B is also included to provide an alternate means of closing this flow path during alternate safe shutdown using OFN-RP-017.

A control cable associated with BGHV8105 is run in area C-33 and could be damaged by a fire, preventing valve BGHV8105 from being closed from the control room. Cables associated with valve BGHV8106, and its hand switch (BGHIS8106), are unaffected by a fire in area C-33. Therefore, valve BGHV8106 is available to isolate flow to the regenerative heat exchanger.

References: E-15000, XX-E-013, E-13BG11A, E-1F9102, E-1F9302, M-12BG03

5.2.17 Volume Control Tank (VCT) Discharge Valves

PFSSD requires isolation of the Volume Control Tank (VCT) discharge to charging pumps suction using either valve BGLCV0112B or BGLCV0112C. Cables associated with BGLCV0112C are run in area C-33. Damage to these cables could prevent closing this valve from the control room. Cables associated with BGLCV0112B are unaffected by a fire in this area.

Cable 14BGI51DA is an instrumentation cable for VCT level transmitter BGLT0185. Damage to this cable could send a false VCT low-low level signal and close relay K647 on the close circuit for valve BGLCV0112C. This would fail the valve closed if all other permissives are met, which is the desired PFSSD position. Therefore, damage to this cable will have no adverse impact on the ability to isolate the VCT discharge flow path.

Based on the above discussion, valve BGLCV0112B can be isolated using BGHIS0112B in the main control room.

References: E-15000, XX-E-013, E-13BG12A, E-13BG51, E-1F9102, E-1F9302, M-12BG03

5.2.18 Excess Letdown

The excess letdown flowpath is required to be isolated to prevent uncontrolled depressurization of the RCS. Therefore, either normally closed valve BGHV8153A or BGHV8154A must be maintained closed and either normally closed valve BGHV8153B or BGHV8154B must be maintained closed.

One cable associated with BGHV8154B runs through fire area C-33. Therefore, the remaining valves are unaffected by a fire in area C-33 and will remain closed.

References: E-15000, XX-E-013, E-1F9301, E-13BG48, M-12BG01

5.2.19 Steam Generator Blowdown to Blowdown Flash Tank Isolation Valves

The reactivity control function requires the steam generator blowdown to blowdown flash tank valves (BMHV0001, BMHV0002, BMHV0003, and BMHV0004) be closed to prevent reactivity addition from uncontrolled cooldown. Cables associated with these valves are run in area C-33. An open circuit in these cables will fail the valves closed, which is the desired PFSSD position. A hot short on these cables could prevent the valves from being closed using hand switches BMHIS0001A, BMHIS0002A, BMHIS0003A and BMHIS0004A in the main control room.

Redundant capability exists for closing valves BMHV0001, BMHV0002, BMHV0003 and BMHV0004. The redundant means uses BMHIS0001C, BMHIS0002C, BMHIS0003C and BMHIS0004C, located on the BM157 panel in the radwaste control room. Access is available without traversing area C-33.

Although the configuration is not in literal compliance with 10CFR50, Appendix R, feasible manual actions are available and are unaffected by the fire.

Thermal hydraulic analysis WCNOC-CP-002 shows insignificant impact on SG inventory even with all four blowdown valves open. Therefore, no E-1F9900 OMA is required to close blowdown valves to achieve and maintain hot standby. Reference Attachment 4, MSO Evaluation Scenario ID PWROG 34.

References: E-15000, XX-E-013, E-13BM06A, E-1F9101, M-12BM01

5.2.20 Refueling Water Storage Tank (RWST) and Containment Sump Isolation Valves

To prevent draindown of the RWST into the containment sump, PFSSD requires that either valve BNHV8812A or valve EJHV8811A and valve BNHV8812B or valve EJHV8811B be closed during hot standby. For cold shutdown, the operating train containment sump valve (EJHV8811A or EJHV8811B) must be maintained closed to prevent flow diversion from the RCS to the containment sump. Valves BNHV8812A and BNHV8812B are normally open and valves EJHV8811A and EJHV8811B are normally closed.

Cable 14BNG03BC, associated with valve BNHV8812B, runs through area C-33. Damage to this cable could prevent closure of the valve from the control room and could prevent automatic closure when valve EJHV8811B is fully open.

A control cable (14EJG06BC) associated with valve EJHV8811B runs through fire area C-33. Damage to this cable will not result in valve EJHV8811B opening as long as valve BNHV8812B remains open. If valve BNHV8812B is fully closed, it will provide a permissive for valve EJHV8811B to open. If valve EJHV8811B opens due to damage to cable 14EJG06BC, draindown will not occur since valve BNHV8812B is closed.

Cable 14BNI07FA, associated with RWST level transmitter BNLT0933, is run in area C-33. Circuits for the remaining three RWST level transmitters are not run in area C-33. Therefore, RWST level indication is available using BNLI0930, BNLI0931 and BNLI0932.

Based on the above discussion, draindown of the RWST to the containment sump is not credible if a fire occurs in area C-33.

References: E-15000, XX-E-013, E-13BN03A, E-13EJ06B, E-13BN07, E-1F9102, E-1F9204, E-1F9205, M-12BN01, M-12EJ01, M-10BN

5.2.21 Essential Service Water

Either the Train A or the Train B essential service water (ESW) system is required to be available to ensure PFSSD. The ESW system supplies water to the following PFSSD components on the associated train:

- CCP room cooler
- RHR pump room cooler
- Class 1E switchgear room A/C condenser
- diesel generator engine cooling
- control room A/C condenser
- auxiliary feedwater pump room cooler
- motor and turbine driven auxiliary feedwater pump suction (backup to CST)
- containment air coolers
- electrical penetration room cooler
- component cooling water pump room cooler
- component cooling water heat exchanger
- component cooling water system makeup

A number of components associated with Train B ESW system could be affected by a fire in this area. The Train B ESW pump and a number of Train B ESW control valves could spuriously operate or may not operate when required. The Train B ESW pump room supply fan and associated dampers may not operate. Therefore, the Train B ESW system cannot be relied on if a fire occurs in this area.

The service water system provides the normal source of water to the ESW piping. Service water supply to and return from the ESW piping is each controlled by two valves installed in series. One of the two valves on each leg is required to be closed for PFSSD to prevent flow diversion from the credited ESW system. As discussed in the previous paragraph, the Train B ESW system may not be available if a fire occurs in this area. One valve (EFHV0025) on the Train A service water to ESW piping supply line and one valve (EFHV0039) on the Train A ESW to service water return line may be affected by the fire and may not close on a signal from the control room. Redundant valves EFHV0023 and EFHV0041 are unaffected by the fire and will close on a signal from the control room. Therefore, the ESW/service water cross connects can be isolated if a fire occurs in this area. In addition, check valve EFV0470 is installed between valves EFHV0023 and EFHV0025 and will prevent flow diversion from Train A ESW to the service water system. Also, check valve EFV0471 is installed between valves EFHV0024 and EFHV0026 and will prevent flow diversion from Train B ESW to the service water system.

Cable 14RPY10BA supplies 120 VAC control power to the automatic and manual start circuits for the Train B ESW pump room supply fan CGD01B. The control power is supplied via this cable to control room panel RP068. If power is lost due to damage to this cable, then the Train B ESW pump room supply fan will not start either automatically, when the ESW pump starts, or manually from the control room. If this occurs, the Train A ESW pump room supply fan remains unaffected by the fire.

Cables 14GDY01BA, 14GDY01BB and 14GDY01BD are associated with Train B ESW pump room supply fan CGD01B. Damage to these cables could prevent operation of the supply fan. Train A ESW pump room supply fan CGD01A is unaffected by a fire in this area.

The Train A ESW system is unaffected by a fire in area C-33 and ESW remains available in the event of a fire in this area.

References: E-15000, XX-E-013, E-13EF02, E-13EF02A, E-13EF03, E-13EF04, E-13EF05, E-13EF06A, E-13EF07A, E-13EF08A, E-13EF09A, E-13EF11, E-13RP10, E-K3EF01A, E-K3EF08, E-K3GD01A, E-K3GD04, E-K3GD04A, J-201-00133, E-

1F9402A, E-1F9402B, E-1F9403, E-1F9424B, E-1F9443, M-12EF01, M-12EF02, M-K2EF01, M-K2GD01

5.2.22 Safety Injection (SI) Pumps

The preferred PFSSD condition of the SI pumps is off. Therefore, a spurious start of the SI pumps should be avoided or mitigated. A control cable (14EMB01BB) associated with Train B SI pump PEM01B runs through area C-33 and could cause a spurious start of the pump and prevent stopping the pump from the control room.

If the Train B SI pump spuriously starts with the reactor at normal pressure, PFSSD will be assured. The pump will not discharge into the RCS due to the pressure differential between the RCS (approximately 2,235 psig) and the SI pump shutoff pressure (approximately 1,565 psig). In addition, the setpoint of the discharge relief valve (EM8853B) to the Recycle Holdup Tank is 1,825 psig. Therefore, no inventory is lost from the RWST if the SI pumps spuriously start. With the SI pump operating with no flow, damage to the pump could occur, which is a commercial concern since the SI pump is not credited in the PFSSD analysis. If necessary, the pump can be stopped by opening breaker NB0202, but this action is not required for PFSSD.

Based on the above discussion, spurious operation of the Train B SI pump will not adversely impact PFSSD.

References: XX-E-013, E-15000, E-13EM01, E-1F9102, E-1F9302, M-12EM01, M-721-00096, WCRE-01

5.2.23 Boron Injection Tank Flowpath

The Boron Injection Tank (BIT) flowpath is credited for reactivity control and reactor coolant makeup. For reactivity control, the BIT flowpath is credited as an alternate source of boration in the event RCP seal injection is unavailable. Based on Calculation XX-E-013, RCP seal injection will provide sufficient boration to achieve and maintain cold shutdown reactivity conditions. Therefore, the BIT flowpath is not required for reactivity control if RCP seal injection is available. Since RCP seal injection is limited to 5 gpm per seal or 20 gpm total injection to the RCS, an additional RCS charging flowpath is required for adequate RCS makeup during plant transition from hot standby to cold shutdown. The BIT injection path was selected as the additional RCS charging flowpath.

As discussed in Section 5.2.9, RCP seal injection is available in the event of a fire in area C-33. In addition, the letdown and excess letdown flowpaths can be isolated if a fire occurs in this area. Therefore, boration and inventory control through the BIT is not required to ensure PFSSD.

To prevent CCP flow diversion through the SIS test line when charging through the BIT, valves EMHV8843 and EMHV8882 need to be closed. If either or both of these valves cannot be closed, then closing or maintaining closed either valve EMHV8871 or EMHV8964 will prevent flow in the SIS test line. Cables associated with EMHV8843 and EMHV8871 are run in this area. Damage to these cables could cause the valves to open. Cables associated with EMHV8964 do not run in area C-33. Therefore, valve EMHV8964 can be controlled to prevent flow through the SIS test line when charging through the BIT.

Based on the above discussion, the BIT flowpath is available to provide a charging flowpath using the Train A CCP.

References: E-15000, XX-E-013, E-13EM02A, E-13EM02B, E-13EM02C, E-13EM04, E-13EM04A, E-1F9302, M-12EM01, M-12EM02

5.2.24 Containment Spray (CS) Pumps

Spurious start of the CS pumps may complicate PFSSD due to the possible depletion of inventory in the RWST. Therefore, a spurious start of the CS pumps should be avoided or mitigated. A control cable (14ENB01BB) associated with Train B CS pump PEN01B runs through area C-33 and could cause a spurious start of the pump. The cable damage could prevent stopping the pump from the control room.

Normally closed valve ENHV0012 could open due to damage to associated control cables. If this occurs coincident with a running Train B CS pump, water would flow from the containment spray nozzles, depleting inventory in the RWST.

The total flow in the containment spray system during injection phase with one pump operating is 3,165 gpm (M-10EN). Based on calculation XX-E-013, Appendix 1, a maximum of 214,260 gallons of water can be lost from the RWST to maintain sufficient volume to achieve cold shutdown.

As stated previously, level indication in the RWST is available, so operators have the ability to diagnose a reducing RWST inventory. The time available to mitigate containment spray is:

214,260 gallons / 3,165 gpm = 67.7 minutes

Based on the above discussion, there is 67.7 minutes available to mitigate containment spray. This is an OMA. Refer to E-1F9900 for details. Reference Attachment 4, MSO Evaluation Scenario ID PWROG 16.

References: XX-E-013, E-15000, E-13EN01, E-13EN03, E-1F9102, E-1F9302, E-1F9424B, E-1F9433, M-10EN, M-12EN01

5.2.25 Safety Injection Accumulator Isolation Valves

PFSSD requires isolation of the SI accumulators prior to reducing RCS pressure below the injection pressure to avoid unnecessary accumulator discharge. This is accomplished by closing valves EPHV8808A, EPHV8808B, EPHV8808C and EPHV8808D. These valves are normally open with the MCC breaker administratively locked in the open position. Cables for valves EPHV8808B and EPHV8808D are run in area C-33.

Since the breakers for these valves are normally open, damage to these cables will not cause the valves to spuriously change position. However, damage to the cables will prevent closing the associated valve from the control room after power is restored.

The SI accumulators need to be isolated during cold shutdown, prior to the RCS reaching 1000 psig. If necessary, a containment entry can be made to manually close the valves.

References: E-15000, XX-E-013, E-13EP02A, E-1F9201, M-12EP01, CKL EP-120

5.2.26 TDAFP Steam Trap Drain Valve

Valve FCFV0310 is an isolation valve on the 1-inch steam trap line associated with the TDAFP. Solenoid valve FCFY0310 controls the position of valve FCFV0310. PFSSD requires this valve to be closed to prevent uncontrolled loss of steam through this flow path.

Cable 14FCK21AA is a control cable associated with valve FCFV0310. Inter or intra-cable hot shorts could cause the valve to spuriously open. There are no energized 125 VDC cables in the same conduit as cable 14FCK21AA, so inter-cable hot shorts causing the valve to open are not possible. An intra-cable hot short from conductor 2 to conductor 1 will energize the solenoid and open the valve. This can be mitigated by depressing the close pushbutton on

hand switch FCHIS0310. However, since this is a momentary contact switch, the operator would have to maintain the button in the depressed position.

Uncontrolled blowdown through this 1-inch line is bounded by the main steam line break analysis and loss of steam through this line will not result in uncontrolled cooldown. Therefore, if the valve remains open, PFSSD is assured.

References: E-15000, XX-E-013, E-13FC21, E-1F9202, M-12FC02

5.2.27 Control Room Air Conditioning

Control room air conditioning is required to be available to satisfy the PFSSD support function. Two redundant and independent air conditioning units (SGK04A and SGK04B) are provided to satisfy this function. At least one unit is required to be available for PFSSD.

Several cables associated with Train B Control Room A/C Unit SGK04B and associated dampers are run in this area. Damage to these cables could prevent operation of the unit.

The Train A control room A/C unit is unaffected by a fire in this area. Therefore, control room air conditioning is available if a fire occurs in area C-33.

References: XX-E-013, E-15000, E-13GK02D, E-13SA20, E-1F9442, M-12GK01, M-622.1A-00007

5.2.28 Class 1E Electrical Equipment Room Air Conditioning

The PFSSD support function requires Class 1E electrical equipment air conditioning on the operating train of equipment. Class 1E electrical equipment air conditioning is provided by units SGK05A (Train A) and SGK05B (Train B).

Cables associated with Train B Class 1E electrical equipment room A/C unit SGK05B are run in area C-33. Damage to these cables could prevent operation of the unit.

Cable 14SAZ20HA provides a control power signal from panel GK196C to status panel SA066B to monitor SGK05B control power. Damage to this cable could prevent operation of SGK05B.

Cables associated with Train A Class 1E electrical equipment room A/C unit SGK05A are unaffected by a fire in this area. Therefore, room cooling for Train A Class 1E electrical equipment remains available.

References: XX-E-013, E-15000, E-13GK13A, E-13SA20, E-1F9444, M-12GK03, M-622.1A-00002

5.2.29 Standby Diesel Generation

Cables associated with the Train B diesel generator are run in this area. Also, cables associated with the Train B diesel generator room exhaust damper GMHZ0019 run in this area. Damage to these cables could prevent operation of the Train B diesel generator.

A fire in area C-33 could cause a loss of several Train B components, however, Train A components are available and are unaffected by the fire. Based on calculation XX-E-013, off-site power is available on Train A if a fire occurs in area C-33. Therefore, neither diesel generator is required if a fire occurs in this area and mal-operation of the Train B diesel generator will have no adverse impact on safe shutdown.

References: XX-E-013, E-15000, E-12KJ01, E-13GM01A, E-13GM04A, E-13JE01, E-13JE04, E-13KJ03A, E-13KJ07, E-13NE11, E-13NE13, E-1F9411A, E-1F9411B, E-1F9412A, E-1F9412B, E-1F9444, M-12GM01, M-12JE01

5.2.30 Containment Coolers

PFSSD requires containment cooling to maintain the containment environment within EQ limits. Cables associated with Train B containment coolers are run in area C-33. Damage to these cables could prevent operation of the Train B containment coolers. Circuits associated with Train A containment coolers are run in a separate fire area and are unaffected by a fire in area C-33.

As discussed earlier, Train A ESW is available if a fire occurs in area C-33. Therefore, the Train A containment coolers will have the necessary service water flow to ensure proper operation.

References: E-15000, XX-E-013, E-13GN02A, E-1F9441, M-12GN01

5.2.31 Class 1E 4.16 kV ESF Switchgear Bus NB01 and NB02

Bus NB02 supplies power to Train B Engineered Safety Features (ESF) components. A fire in area C-33 could damage cables associated with NB02 and disrupt power to all Train B ESF components.

Control cables associated with bus NB02 Synchro-scope and associated switches are run in area C-33. Damage to these cables could prevent some of the monitoring functions for NB02 but would not cause a loss of the NB02 bus.

Redundant Train A ESF components, supplied by NB01, are unaffected by a fire in area C-33. Therefore, loss of power to Train B components due to a fire in area C-33 will not impact the ability to achieve and maintain safe shutdown.

References: XX-E-013, E-15000, E-13NB04, E-13NB05, E-13NB06, E-13NB14, E-13NB15, E-1F9423, E-1F9426, KD-7496

5.2.32 Load Shedder / Emergency Load Sequencer

The load shedder and emergency load sequencers are included in the PFSSD design to evaluate the impact of spurious operation or mal-operation. The load shedder/emergency load sequencer operates upon presence of the following conditions:

1. An undervoltage (UV) on a safeguards bus,
2. A safety injection signal (SIS) or a containment spray actuation signal (CSAS), or
3. An undervoltage on a safeguards bus with a SIS or CSAS.

Eight inputs (four undervoltage (UV) inputs and four degraded voltage inputs) on each safeguards bus (NB01 and NB02) monitor voltage conditions on that bus. An undervoltage condition on two of four UV relays on each bus will actuate the load shedder/sequencer and send a signal to start the associated diesel generator. In addition, degraded voltage sensed by two of four degraded voltage potential transformers (PTs) will, after a time delay, provide a signal to open the offsite feeder breakers on the associated bus.

Cables 14NFK01CA and 14NFK01DA for one of the four UV relays on each bus are run in fire area C-33. Also, cables 14NFY01EA and 14NFY01FA associated with one of the four degraded voltage PTs on each bus are run in fire area C-33. Cables associated with the remaining three UV relays and PTs do not run in fire area C-33. Therefore, automatic functioning of the bus NB01 and NB02 emergency load shedder / sequencer is unaffected by a

fire in area C-33 and a spurious start of the associated diesel generator due to a false undervoltage condition on two of the four circuits is not credible.

Separation group 4 power cables 14NFY01GA and 14NFY01HA associated with NF039A, NF039B and NF039C are run in this area. Separation groups 1, 2 and 3 power cables associated with these panels are unaffected. Therefore, power to the load shedder/sequencer panels is available.

Based on the above discussion, the Train A and Train B load shedder/sequencers are available if a fire occurs in this area. Off-site power to Train A components is unaffected based on Calculation XX-E-013, Appendix 2.

References: XX-E-013, E-15000, E-11005, E-11NB01, E-11NB02, E-12NF01, E-13NF01, E-10NF, E-1F9411A, E-1F9411B, E-1F9412A, E-1F9412B, E-1F9402A, E-1F9402B, E-1F9403, E-1F9425, E-1F9426

5.2.33 Train B 480 Volt Class 1E Load Centers

Cables associated with Train B 480 VAC Class 1E load centers NG02, NG04 and motor control center (MCC) NG06E are run in area C-33. In addition, as stated in other sections, loss of power to these load centers could occur due to loss of Train B off-site and on-site power. Therefore, Train B load centers and associated equipment may not be available if a fire occurs in this area.

Cable 14PKK11AA is associated with 480 VAC breaker NG0409. NG0409 supplies 480 VAC power to Train B 125 VDC battery charger PK22, which energizes the PK02 bus. Damage to this cable could disable power to the battery charger but will not de-energize PK02 due to the installed batteries. Battery set PK12 will maintain 125 VDC power to PK02. In addition, NG0102 is unaffected and will continue to supply power to Train A 125 VDC battery charger PK21.

Redundant Train A components, supplied by NG01, NG03 and NG05E are unaffected by a fire in area C-33. Therefore, loss of power to Train B 480 VAC Class 1E load centers NG02, NG04 and MCC NG06E will not impact the ability to achieve and maintain safe shutdown.

References: XX-E-013, E-15000, E-11NG02, E-13NG01A, E-13NG10A, E-13NG11A, E-13NG11B, E-13PK11, E-K3NG10A, E-1F9411B, E-1F9412B, E-1F9422C, E-1F9423, E-1F9424A. E-1F9424B, E-1F9424C, E-1F9424D

5.2.34 Class 1E 125 VDC Distribution System

Power cables associated with the Class 1E 125 VDC electrical distribution system are run in area C-33. These cables supply 125 VDC power to various PFSSD loads. The cables and supplied PFSSD equipment are summarized in the following table.

CABLE	NK BREAKER	CONTROL PANEL	PFSSD Components
14RLK01AA	NK04407	RL001/002	BGHV8153B, BGHV8154B
14RLK01BA	NK04409	RL005/006	FCFY0310
14RLK01CA	NK04412	RL017/018	EMHV8843, EMHV8871
14RLK01DA	NK04413	RL019/020	EGTV0030, GMHZ0019
14RLK01EA	NK04414	RL021/022	BBHV8001B, BBHV8002B
14RLK01FA	NK04411	RL023/024	BMHV0001, BMHV0002, BMHV0003, BMHV0004

Damage to these cables could cause a loss of power to the associated components. This is acceptable for PFSSD since the components fail in the desired PFSSD position upon loss of power, or the redundant Train A component is available to perform the PFSSD function.

References: XX-E-013, E-15000, E-13BB30, E-13BG48, E-13BM06A, E-13EG16, E-13EM04, E-13EM04A, E-13FC21, E-13GM04A, E-13RL01, E-13RL02, E-13RL03, E-13RL04, E-13RL05, E-13RL06, E-13RL07, E-1F9101, E-1F9202, E-1F9301, E-1F9302, E-1F9401A, E-1F9422B, E-1F9444, M-12BB04, M-12BG01, M-12BM01, M-12EG02, M-12EM01, M-12EM02, M-12FC02, M-12GM01

5.2.35 BOP Instrument Racks

BOP instrument racks RP053A, RP053B, RP053D and RP147 are credited in the PFSSD analysis. The following table identifies the PFSSD components served by each instrument rack.

Instrument Rack	PFSSD Components
RP053A (RP053AA, RP053AB, RP053AC)	ALHV0009, ALHV0011 ALPY0037A, EGFT0128, EGPSL0077, GDTSL0001, JELSL0001C
RP053B (RP053BA, RP053BB, RP053BC)	ALHV0007, ALPY0039A, EGFT0129, EGPSL0078, GDTSL0011, JELSL0021C
RP053D (RP053DA, RP053DB)	ALPY0038A
RP147 (RP147A, RP147B)	ALHV0005

Cables 14RPY09BA and 14RPY09CA supply 120 VAC power to BOP instrument rack RP053B. Damage to these cables could cause a loss of function of panel RP053B and associated PFSSD components. Redundant components are supplied by the remaining BOP instrument racks.

Instrument racks RP053A, RP053D and RP147 are unaffected by the fire. Therefore, loss of PFSSD components associated with RP053B will not adversely impact PFSSD.

References: E-15000, XX-E-013, E-13AL08, E-13AL09, E-13EG13, E-13JE01, E-13NN01, E-13RP09, E-1F9101, E-1F9202, E-1F9204, E-1F9401B, E-1F9411B, E-1F9411A, E-1F9424D, E-1F9443, E-K3GD01A, E-K3GD04, M-12AL01, M-12EG01, M-12JE01, M-K2GD01

5.2.36 Source Range Monitoring

PFSSD requires source range (SR) flux monitoring to be available. Source range monitoring is provided by source range monitors SENE0031, SENE0032, SENY0060A & B, and SENY0061A & B.

Cable 14SES07BC is an instrumentation cable associated with SR monitor signal processor SENY0061B. This cable runs from SENY0061B to the source range recorder on RL020. Damage to this cable could prevent operation of the recorder. Source Range monitoring remains available for a fire in area C-33 using SENE0031, SENE0032 and SENY0060A/B and SENY0061A.

For a more detailed evaluation on Source Range monitoring, see Calculation XX-E-013, Attachment 3.

References: E-15000, XX-E-013, E-13SE07, E-1F9101

5.2.37 Reactor Protection System

The Reactor Protection System (RPS) monitors specified input parameters and initiates reactor protection features whenever those parameters are outside specified limits. Field installed transmitters continuously monitor various parameters and report the results to one of four process cabinets, one per channel. Signals are then sent from the process cabinets to both solid state protection cabinets, one on each train. The cabinets and associated channel are listed in the following table:

Process Cabinets	Solid State Protection Cabinets
Cabinet SB038 - Channel 1 Cabinet SB042 - Channel 2 Cabinet SB037 - Channel 3 Cabinet SB041 - Channel 4	Cabinet SB029A - Train A Input Cabinet Cabinet SB029B - Train A Logic Cabinet Cabinet SB029C - Train A Output Cabinet 1 Cabinet SB029D - Train A Output Cabinet 2 Cabinet SB032A - Train B Input Cabinet Cabinet SB032B - Train B Logic Cabinet Cabinet SB032C - Train B Output Cabinet 1 Cabinet SB032D - Train B Output Cabinet 2

The RPS is actuated upon 2/3 or 2/4 coincident logic, depending on the input parameter. This ensures that a loss of a single channel will not prevent the system from performing its function. Loss of power to a single cabinet will render the channel or Train inoperative.

Cables associated with RPS channel 4 run through this area. These cables supply power from separation group 4 power supplies to panels SB029A, SB032A, SB032D and SB041. Power cables associated with RPS channels 1, 2 and 3 are run in a separate fire area.

Based on the above discussion, the reactor protection system is available if a fire occurs in this area.

5.2.38 Reactor Trip Switchgear

The reactor trip switchgear is required to ensure the ability to manually trip the reactor. The reactor is tripped using either hand switch SBHS0001 or SBHS0042 in the main control room. Each hand switch has contacts associated with Train A reactor trip switchgear SB102A and Train B reactor trip switchgear SB102B.

Cable 14SBS12BC, associated with separation group 4 trip circuits, is run in area C-33. A hot short in this cable could cause a spurious reactor trip, which is the desired PFSSD condition. An open circuit will prevent a manual reactor trip on Train B reactor trip switchgear SB102B.

Cables associated with separation group 1 trip circuits are unaffected by a fire in area C-33. Therefore, operation of either hand switch SBHS0001 or SBHS0042 will cause a reactor trip on redundant Train A reactor trip switchgear SB102A.

References: XX-E-013, E-15000, E-13SB12A, E-1F9101

5.2.39 RCS Hot and Cold Leg Temperature Indication

PFSSD requires RCS hot and cold leg temperature indication on at least one loop to verify flow through the steam generators. The temperature elements and control room indicators used for this purpose are listed in the following table.

RCS Hot and Cold Leg Temperature Elements/Indicators Used for PFSSD		
ELEMENT	**INDICATOR**	**FUNCTION**
BBTE0413A	BBTI0413A	RCS Hot Leg Temperature Element (WR) Loop 1
BBTE0413B	BBTI0413B	RCS Cold Leg Temperature Element (WR) Loop 1
BBTE0423A	BBTR0423	RCS Hot Leg Temperature Element (WR) Loop 2
BBTE0423B	BBTI0423B	RCS Cold Leg Temperature Element (WR) Loop 2
BBTE0433A	BBTR0433	RCS Hot Leg Temperature Element (WR) Loop 3
BBTE0433B	BBTR0433	RCS Cold Leg Temperature Element (WR) Loop 3
BBTE0443A	BBTR0443	RCS Hot Leg Temperature Element (WR) Loop 4
BBTE0443B	BBTR0433	RCS Cold Leg Temperature Element (WR) Loop 4

Cable 16RLY01EA supplies 120 VAC power to control room panel RL021/RL022. At RL021/RL022, the power is split and supplies power to BBTR0433 and BBTR0443, as well as other non-PFSSD components. Damage to this cable could disrupt power to BBTR0433 and BBTR0443. Consequently, loops 3 and 4 RCS temperature indication could be lost. However, RCS temperature indication on loops 1 and 2 remains available. Therefore, the PFSSD function is satisfied.

References: E-15000, XX-E-013, E-13BB15, E-13RL01, E-13RL06, E-1F9201, E-1F9421, M-12BB01

5.2.40 Load Center PG20 Incoming Feeder Breaker PG2001

Load center feeder breaker PG2001 is credited for PFSSD because it supplies power to credited non-safety related loads. Cable 16PGG13DA, associated with PG2001, runs in this area. Damage to this cable will trip the breaker.

Breaker PG2001 supplies power to the following PFSSD components:

- PG20GBR217 – MCB Misc. Power Circuits RL023
- PG20GER5 – Instr. Bus Transformer Alt. Feed XPN08D

PFSSD components powered from PG20GBR217 are associated with MSIV downstream components. The MSIVs are unaffected by a fire in this area and can be closed from the control room. Therefore, the MSIV downstream components are not required if a fire occurs in this area.

PG20GER5 is credited as one source of power to PN08. The redundant source of power from NG02BBF1 could also be affected by a fire in this area as discussed in Section 5.2.33. Redundant components powered from inverter PN07 are unaffected by a fire in this area.

Based on the above discussion, loss of breaker PG2001 will have no adverse impact on PFSSD.

References: XX-E-013, E-15000, E-11PG20, E-11PG21, E-11PK02, E-13PG10, E-13PG11, E-13PG13, E-13RL07, E-1F9421, E-1F9422C, E-1F9424E, KD-7496

5.2.41 120 VAC Distribution Panel PN410

120 VAC distribution panel PN410 supplies power to NSSS control panels RP043 and RP047.

Inverter PN04 supplies power to 120 VAC distribution panel PN410 (via cables 16PNY02AA and 16PNY02AB), which in turn supplies redundant 120 VAC power to NSSS control cabinets RP043 and RP047. For PFSSD, cabinet RP043 houses relays BGLCV0459X and BGLCV0460X, which are associated with letdown isolation valves BGLCV0459 and BGLCV0460, respectively. Cabinet RP047 includes controls for pressurizer PORVs and pressurizer spray.

Damage to cables 16PNY02AA and/or 16PNY02AB will disrupt power to panel PN410. Redundant power to RP043 and RP047 is available from 120 VAC distribution panel PN310. Therefore, loss of power to PN410 will not adversely impact PFSSD.

References: XX-E-013, E-15000, E-1F9421, DCP 13324

5.2.42 Normal Pressurizer Spray

The normal pressurizer spray valves are included in the PFSSD design because spurious operation of pressurizer sprays can cause a decrease in pressure which can lead to boiling in the core. The pressurizer spray valves are part of the pressurizer pressure control system.

The pressurizer normal spray valves (BBPCV0455B and BBPCV0455C) operate off a signal from the Ovation pressurizer pressure control system. The operation of the pressure control system is discussed in Calculation XX-E-013.

An instrument cable (14BBI16NB) associated with pressurizer pressure transmitter BBPT0458 is run in fire area C-33. Damage to this cable could send a spurious high-pressure signal to the pressure control system. However, as discussed in Calculation XX-E-013, Appendix 1, damage to a single pressure channel will not cause the spurious operation of the pressurizer spray valves due to the Ovation 4-channel validation logic, which uses the 2nd highest signal as the validated signal and has built-in logic to detect and ignore a failed input.

Based on the above discussion, the pressurizer spray valves will not spuriously open if a fire occurs in this area.

1.0 GENERAL AREA DESCRIPTION

Fire area C-34 is located on the 2073 elevation of the Control Building and includes the room listed in Table C-34-1.

Table C-34-1
Rooms Located in Fire Area C-34

ROOM #	DESCRIPTION
C34	South Small Elec Chase 2073 Elevation at CA-C6

Fire area C-34 is protected with an automatic fire suppression and detection system. The area is bounded on all sides by minimum 3-hour fire resistance rated construction.

2.0 PRIMARY EQUIPMENT USED FOR PFSSD

Table C-34-2 lists each system credited for post-fire safe shutdown and provides a discussion regarding the availability of the system to perform its Post Fire Safe Shutdown (PFSSD) function if a severe fire occurs in this area. For a summary of the potential fire impact on some of the more significant PFSSD equipment, see Section 8.0 of the Fire Area Analysis Narrative section.

Table C-34-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-34

System	System Name	PFSSD Function*	Comments
AB	Main Steam	R, M, H, P, S	All PFSSD functions associated with the main steam system are satisfied. Power to ARV ABPV0002 controller ABPIC0002A in the main control room could be lost. The ARV will remain closed or will fail closed. The remaining ARVs are unaffected. Main steam to TDAFP supply valves ABHV0005 and ABHV0006 may be affected. The motor driven auxiliary feedwater pumps are available.
AC	Main Turbine	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-34.
AE	Main Feedwater	H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-34.
AL	Aux. Feedwater System	H, P	All PFSSD functions associated with the auxiliary feedwater system are satisfied. Pressure transmitter ALPT0038 may be affected. Pressure transmitters ALPT0037 and ALPT0039 are unaffected. TDAFP suction pressure indicator ALPI0026A may be affected. Pressure indication for the MDAFPs remains available. Main steam to TDAFP supply valves ABHV0005 and ABHV0006 may be affected. The motor driven auxiliary feedwater pumps are available.
AP	Condensate Storage System	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-34.
BB	Reactor Coolant System	R, M, H, P, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-34.
BG	Chemical and Volume Control System	R, M, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-34.
BM	Steam Generator Blowdown System	R, M, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-34.
BN	Borated Refueling Water Storage System	R, M, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-34.
EF	Essential Service Water System	H, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-34.

Table C-34-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-34

System	System Name	PFSSD Function*	Comments
EG	Component Cooling Water System	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-34.
EJ	Residual Heat Removal System	M, H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-34.
EM	High Pressure Coolant Injection	R, M	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-34.
EN	Containment Spray	R, M	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-34.
EP	Safety Injection Accumulators	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-34.
FB	Auxiliary Steam	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-34.
FC	Auxiliary Turbines	R, H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-34.

3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD

This section describes operator actions that may need to be performed inside or outside the control room to achieve and maintain hot standby if a fire occurs in area C-34. This section also describes cold shutdown repairs that may need to be made to achieve and maintain cold shutdown conditions. Operator actions are proceduralized in OFN KC-016.

3.1 ACTIONS OUTSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

None

3.2 ACTIONS INSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

None

3.3 ACTIONS TO ACHIEVE AND MAINTAIN COLD SHUTDOWN

None

4.0 CONCLUSION

Post-fire safe shutdown is unaffected by a fire in fire area C-34.

5.0 DETAILED ANALYSIS

This section describes the detailed component-by-component and cable-by-cable analysis for a fire in area C-34.

5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA C-34

There are no PFSSD components located in fire area C-34. This fire area only contains cables associated with PFSSD equipment located in other areas.

5.2 PFSSD CABLE EVALUATION

Table C-34-3 lists all the PFSSD cables (S. in E-15000) located in fire area C-34. The applicable evaluation section is also listed in Table C-34-3.

Table C-34-3
PFSSD Cables Located in Fire Area C-34

Cable #	Location	Primary PFSSD Equipment	Cable Function (P) Power (C) Control (I) Instrumentation	Evaluation Section	Comments
12ALI08BA	C34	ALPT0038	I	5.2.1	ESFAS AFW Low Suction Press Transmitter
12NFK01CA	C34	NF039A	C	5.2.2	Load Shed / Sequencer Ch. 1 Logic

12SAZ23BA	C34	ABHV0006	C	5.2.1	Main STM Loop 3 To TDAFW Pump
12SBS01BD	C34	SB029A	P	5.2.3	120 VAC to SSPS A Input Panel from NN0210
12SBS02BD	C34	SB032A	P	5.2.3	120 VAC to SSPS B Input Panel from NN0209
12SBY09DA	C34	SB042	P	5.2.3	120 VAC to Process Protection Set 2 Panel from NN0212

5.2.1 Auxiliary Feedwater and Steam Generator ARVs

The PFSSD design requires the use of one auxiliary feedwater pump (AFP) supplying water to at least two steam generators. The Train A motor driven auxiliary feedwater pump (MDAFP) is aligned to supply steam generators B and C. The Train B MDAFP is aligned to supply steam generators A and D. The turbine driven auxiliary feedwater pump (TDAFP) is normally aligned to supply all four steam generators.

The normal source of water to the AFPs is the condensate storage tank (CST). The emergency supply is from the essential service water (ESW) system. For commercial concerns, the CST is the preferred source and contains sufficient volume to supply the entire auxiliary feedwater (AFW) demand to achieve cold shutdown.

Cable 12RPY09AA supplies 120 VAC power from NN0208 to BOP instrument rack RP053DA. Damage to this cable will affect the following PFSSD components:

- ALPY0038A - ESFAS LOW SUCTION PRESSURE SIGNAL CONVERTER
- ALPT0038 - ESFAS LOW SUCTION PRESSURE TRANSMITTER
- ABPIC0002A - STM GEN B ATM STEAM DUMP PRESSURE CONTROLLER
- ABHS0002 - ABPV0002 HANDSWITCH
- ALPI0026A - TDAFW PUMP PAL02 SUCTION PRESSURE

Low suction pressure (LSP) on 2 out of 3 AFW pressure transmitters (ALPT0037, ALPT0038 and ALPT0039) coincident with an auxiliary feedwater actuation signal (AFAS) will swap the AFW supply to ESW. Loss of power to ALPT0038 and ALPY0038A will satisfy 1/3 LSP logic, placing the LSP signal logic in a 1 out of 2 configuration. Therefore, low suction pressure or loss of power on another pressure transmitter will provide the permissive to swap if an AFAS is present. In addition, cable 12ALI08BA is an instrument cable associated with AFW suction pressure transmitter ALPT0038. Damage to this cable could cause a false pressure indication on ALPI0038 but will not satisfy the 2 out of 3 LSP logic.

Loss of power to ABPIC0002A and ABHS0002 will prevent control of steam generator B ARV ABPV0002 from the control room. If this occurs, the ARV will remain closed, which is the desired PFSSD position. The remaining three steam generator ARVs remain available.

Loss of power to ALPI0026A will provide false indication of TDAFP suction pressure. Suction pressure indication for the MDAFPs remains available.

Cable 12RLK01AA supplies 125 VDC power from NK4206 to RL005/006, where it's split and supplies control power to TDAFP main steam supply valves ABHV0005 and ABHV0006, as well as other non-PFSSD components. Cables 12SAZ23AA and 12SAZ23BA are control cables associated with TDAFP steam supply valves ABHV0005 and ABHV0006, respectively. Damage to these cables could cause a loss of control of these valves. In the event the valves cannot be opened, the motor driven auxiliary feedwater pumps are available to supply the required AFW demand.

Panel SA036C monitors pressure transmitter signals on ALPT0038 and provides AFAS outputs. Power cables 12SAK21CA and 12SAY21CA associated with SA036C are run in this area. Damage to these cables could result in a loss of power to the panel but will not prevent automatic operation of low suction pressure (LSP) swapover since the remaining 2 channels are available. AFAS is not credited for PFSSD but is analyzed for potential adverse impacts.

Based on the above discussion, auxiliary feedwater is assured if a fire occurs in area C-34 using Train B MDAFP supplying water to steam generators A and D and Train A MDAFP supplying water to steam generators B and C, however steam generator B ARV control could be lost.

5.2.2 Load Shedder / Emergency Load Sequencer

The load shedder and emergency load sequencers are included in the PFSSD design to evaluate the impact of spurious operation or mal-operation. The load shedder/emergency load sequencer operates upon presence of the following conditions:

1. An undervoltage (UV) on a safeguards bus,
2. A safety injection signal (SIS) or a containment spray actuation signal (CSAS), or
3. An undervoltage on a safeguards bus with a SIS or CSAS.

Eight inputs (four undervoltage (UV) inputs and four degraded voltage inputs) on each safeguards bus (NB01 and NB02) monitor voltage conditions on that bus. An undervoltage condition on two of four UV relays on each bus will actuate the load shedder/sequencer and send a signal to start the associated diesel generator. In addition, degraded voltage sensed by two of four degraded voltage potential transformers (PTs) will, after a time delay, provide a signal to open the offsite feeder breakers on the associated bus.

The outputs from each safeguards bus (NB01 and NB02) are divided into 4 separation groups; 1, 2, 3 and 4 and routed to two control panels, NF039A and NF039B. The input section of each control panel also receives group 1, 2, 3 and 4 instrument power (120VAC). The inputs then pass through isolation devices, at which point all inputs to NF039A become separation group 1 and all inputs to NF039B become separation group 4. Interruption of either the inputs or the instrument power from one separation group would impact the associated input channel, but would not impact the other 3 input channels.

Cables 12NFK01CA and 12NFK01DA are associated with separation group 2 UV relays on buses NB01 and NB02, respectively. Cables 12NFY01EA and 12NFY01FA are associated with separation group 2 degraded voltage PTs on buses NB01 and NB02, respectively. Cables associated with the remaining three UV relays and PTs from separation groups 1, 3 and 4 do not run in fire area C-34.

Separation group 2 120 VAC instrument power supply cables 12NFY01CA and 12NFY01DA for load shedder/sequencer logic and input cabinets NF039A and NF039B, respectively, run in fire area C-34. Damage to these cables could cause a loss of separation group 2 120 VAC instrument power to the group 3 input panels, and therefore loss of input channel 2. Channels 1, 3 and 4 instrument AC power remains available from separation groups 1, 3 and 4 power supplies.

Automatic functioning of the bus NB01 and NB02 emergency load shedder / sequencer is unaffected by a fire in area C-34 because of the presence of circuits for only one of the four load shed/sequencer initiators. Therefore, a spurious start of the Train A and Train B diesel generators due to a false undervoltage condition on two of the four circuits is not credible.

Based on the above discussion, the Train A and Train B load shed/sequencers are available if a fire occurs in this area. Off-site power to both trains is unaffected based on Calculation XX-E-013, Appendix 2.

5.2.3 Reactor Protection System

The Reactor Protection System (RPS) monitors specified input parameters and initiates reactor protection features whenever those parameters are outside specified limits. Field installed transmitters continuously monitor various parameters and report the results to one of four process cabinets, one per channel. Signals are then sent from the process cabinets to both solid state protection cabinets, one on each train. The cabinets and associated channel are listed in the following table.

Process Cabinets	Solid State Protection Cabinets
Cabinet SB038 - Channel 1 Cabinet SB042 - Channel 2 Cabinet SB037 - Channel 3 Cabinet SB041 - Channel 4	Cabinet SB029A - Train A Input Cabinet Cabinet SB029B - Train A Logic Cabinet Cabinet SB029C - Train A Output Cabinet 1 Cabinet SB029D - Train A Output Cabinet 2 Cabinet SB032A - Train B Input Cabinet Cabinet SB032B - Train B Logic Cabinet Cabinet SB032C - Train B Output Cabinet 1 Cabinet SB032D - Train B Output Cabinet 2

The RPS is actuated upon 2/3 or 2/4 coincident logic, depending on the input parameter. This ensures that a loss of a single channel will not prevent the system from performing its function. Loss of power to a single cabinet will render the channel or Train inoperative.

Cables associated with RPS channel 2 run through this area. These cables supply power from separation group 2 power supplies to panels SB029A, SB032A and SB042. Power cables associated with RPS channels 1, 3 and 4 are run in a separate fire area.

Damage to cables associated with the RPS due to a fire in this area could cause a loss of RPS channel 2 but channels 1, 3 and 4 remain available. Damage to these cables will not adversely impact the ability to achieve and maintain safe shutdown.

1.0 GENERAL AREA DESCRIPTION

Fire area C-35 is located on the 2016 elevation of the Control Building and includes the rooms listed in Table C-35-1.

Table C-35-1
Rooms Located in Fire Area C-35

ROOM #	DESCRIPTION
3401	West Corridor Elevation 2016-0
3406	East Center Corridor Elevation 2016-0
3412	East Corridor Elevation 2016-0

Fire area C-35 has no installed fire suppression or detection. Where redundant circuits are run through area C-35, and diverse means for achieving PFSSD are not available, circuits associated with the protected component are wrapped with a raceway fire barrier material meeting the requirements for a 3-hour fire rating. This fire barrier provides reasonable assurance that PFSSD can be achieved.

2.0 PRIMARY EQUIPMENT USED FOR PFSSD

Table C-35-2 lists each system credited for post-fire safe shutdown and provides a discussion regarding the availability of the system to perform its Post Fire Safe Shutdown (PFSSD) function if a severe fire occurs in this area. For a summary of the area analysis results, see Section 8.0 of the Fire Area Analysis Narrative section.

Table C-35-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-35

System	System Name	PFSSD Function*	Comments
AB	Main Steam	R, M, H, P, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-35.
AC	Main Turbine	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-35.
AE	Main Feedwater	H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-35.
AL	Aux. Feedwater System	H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-35.
AP	Condensate Storage System	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-35.
BB	Reactor Coolant System	R, M, H, P, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-35.
BG	Chemical and Volume Control System	R, M, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-35.
BM	Steam Generator Blowdown System	R, M, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-35.
BN	Borated Refueling Water Storage System	R, M, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-35.
EF	Essential Service Water System	H, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-35.
EG	Component Cooling Water System	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-35.
EJ	Residual Heat Removal System	M, H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-35.
EM	High Pressure Coolant Injection	R, M	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-35.
EN	Containment Spray	R, M	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-35.

Table C-35-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-35

System	System Name	PFSSD Function*	Comments
EP	Safety Injection Accumulators	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-35.
FB	Auxiliary Steam	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-35.
FC	Auxiliary Turbines	R, H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-35.
GD	ESW Pump House HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-35.
GF	AFW Pump Room Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-35.
GK	Control Room and Class 1E Switchgear Room Coolers	S	The Train B Class 1E electrical equipment room cooler SGK05B is affected. The Train A Class 1E electrical equipment room cooler SGK05A may shut down due to a spurious fire isolation signal. The fire isolation signal can be bypassed from the main control room using GKHS0101 on panel RP068 and SGK05A can be started.
GL	Auxiliary Building HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-35.
GM	Emergency Diesel Generator Room HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-35.
GN	Containment Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-35.
JE	Diesel Fuel Oil	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-35.
KA	Instrument Air	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-35.
KC	Fire Protection	S	Cables associated with Halon protection in class 1E electrical equipment switchboard rooms 3404, 3408, 3410 and 3414 could be damaged by a fire in area C-35, causing Halon release in these rooms and subsequent shutdown of SGK05A and SGK05B. This will not adversely impact PFSSD (See GK discussion).
KH	Service Gas	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-35.
KJ	Standby Diesel Engine	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-35.
MA	Main Generation	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-35.

3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD

This section describes operator actions that may need to be performed inside or outside the control room to achieve and maintain hot standby if a fire occurs in area C-35. This section also describes cold shutdown repairs that may need to be made to achieve and maintain cold shutdown conditions. Operator actions are proceduralized in OFN KC-016.

3.1 ACTIONS OUTSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

None

3.2 ACTIONS INSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

3.2.1 Class 1E Electrical Equipment Room Cooler SGK05A

If a fire occurs in area C-35, SGK05A may not respond to an automatic start signal or may shut down due to a fire isolation signal. If this occurs, start SGK05A by placing GKHS0101 in bypass and start the unit normally. GKHS0101 is located on panel RP068 in the main control room.

3.3 ACTIONS TO ACHIEVE AND MAINTAIN COLD SHUTDOWN

None

4.0 CONCLUSION

Post Fire Safe Shutdown is assured if a fire occurs in fire area C-35.

5.0 DETAILED ANALYSIS

This section describes the detailed component-by-component and cable-by-cable analysis for a fire in area C-35.

5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA C-35

PFSSD components (S. in E-15000) located in fire area C-35 are shown in Table C-35-3. An evaluation of each component and associated cables is provided in the sections that follow. The applicable evaluation section is listed in Table C-35-3.

Table C-35-3 PFSSD Equipment Located in Fire Area C-35				
Room #	**PFSSD Equipment**	**Description**	**Evaluation Section**	**Comments**
3401	KC230	Swbd and Swgr Room Fire Protection Panel	5.1.1	

5.1.1 Class 1E Electrical Equipment Room Coolers

Class 1E electrical equipment room coolers SGK05A and SGK05B are included in the PFSSD design to ensure proper room cooling for the operating train of safety-related electrical equipment.

Fire protection panel KC230 houses auxiliary contacts for automatic shutdown of Class 1E A/C Units SGK05A and SGK05B. In the event of a fire detection signal in any of the Class 1E switchgear rooms, auxiliary contacts in panel KC230 open, dropping power to relays 95XGK07 and 95XGK08 which in turn opens a contact associated with the SGK05A and SGK05B control circuit and stops the unit.

Cables 15GKK31CB and 16GKK31DB, associated with relays 95XGK07 and 95XGK08 are run in area C-35 which, if damaged, could cause a spurious shutdown of both SGK05A and SGK05B.

Cables 16KCQ21FA and 16KCQ21JA run from the main fire alarm panel (KC275A) to Halon releasing panel KC230, located on the 2016 elevation of the control building in fire area C-35. Panel KC275A monitors smoke detectors in Halon protected switchboard rooms that are conditioned by SGK05A. Upon receipt of the proper detection sequence at KC275A, a normally open auxiliary relay contact in KC275 closes and sends an equipment shutdown signal over cables 16KCQ21FA or 16KCQ21JA to KC230. The equipment shutdown signal received at KC230 initiates actuation of Halon in the affected room and shuts down SGK05A. If the cables are damaged in a fire and short circuit, Halon will be released into the Train A Class 1E electrical equipment rooms and class 1E A/C unit SGK05A will shut down.

Cables 16KCQ21EA and 16KCQ21HA run from the main fire alarm panel (KC275A) to Halon releasing panel KC230, located on the 2016 elevation of the control building in fire area C-35. Panel KC275A monitors smoke detectors in Halon protected switchboard rooms that are conditioned by SGK05B. Upon receipt of the proper detection sequence at KC275A, a normally open auxiliary relay contact in KC275 closes and sends an equipment shutdown signal over cables 16KCQ21EA or 16KCQ21HA to KC230. The equipment shutdown signal received at KC230 initiates actuation of Halon in the affected room and shuts down SGK05B. If the cables are damaged in a fire and short circuit, Halon will be released into the Train B Class 1E electrical equipment rooms and class 1E A/C unit SGK05B will shut down.

Power and control cables associated with SGK05A and SGK05B are run in area C-35. Cables associated with SGK05A have been wrapped with a 3-hour fire rated material which provides reasonable assurance that these cables will be unaffected by a fire in this area. However, the fire wrap does not provide protection for cable 15GKK31CB or fire protection panel KC230. Cables associated with SGK05B are not protected with fire wrap. This includes the 3-phase power cable for SGK05B. Therefore, a fire in area C-35 could disable SGK05B and could cause a spurious trip of SGK05A.

If SGK05A shuts down due to a spurious fire isolation signal, the fire isolation signal can be bypassed by placing hand switch GKHS0101, located on panel RP068, in bypass position. Then, the unit can be re-started from the control room using normal procedures.

Cable 11SAZ19KA provides status indication of Train A Class 1E electrical equipment room A/C unit SGK05A at status panel SA066A. Damage to this cable could prevent operation of SGK05A. However, the cable is protected by a 3-hour fire rated barrier within fire area C-35. Therefore, there is reasonable assurance that the cable will not be affected by a fire in area C-35.

Cable 14SAZ20HA provides status indication of Train B Class 1E electrical equipment room A/C unit SGK05B at status panel SA066B. Damage to this cable could prevent operation of SGK05B.

Based on the above discussion, the Train B Class 1E A/C unit SGK05B could be affected by a fire in this area but the Train A Class 1E A/C unit SGK05A is available.

1.0 GENERAL AREA DESCRIPTION

Fire area C-36 is located on the 2000 elevation of the Control Building and includes the room listed in Table C-36-1.

Table C-36-1
Rooms Located in Fire Area C-36

ROOM #	DESCRIPTION
C36	South Small Elec Chase at CA-C16, 2000 to 2016 Elevation

Fire area C-36 is protected with an automatic wet pipe sprinkler system but no smoke detection system. The area is bounded on all sides by minimum 3-hour fire resistance rated construction.

2.0 PRIMARY EQUIPMENT USED FOR PFSSD

Table C-36-2 lists each system credited for post-fire safe shutdown and provides a discussion regarding the availability of the system to perform its Post Fire Safe Shutdown (PFSSD) function if a severe fire occurs in this area. For a summary of the potential fire impact on some of the more significant PFSSD equipment, see Section 8.0 of the Fire Area Analysis Narrative section.

Table C-36-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-36

System	System Name	PFSSD Function*	Comments
AB	Main Steam	R, M, H, P, S	Steam generator ARV ABPV0002 may spuriously open. Steam generator ARVs ABPV0001, ABPV0003 and ABPV0004 are unaffected.
AC	Main Turbine	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-36.
AE	Main Feedwater	H, P	Steam generator B wide range water level transmitter AELT0502 may be affected. Remaining steam generator level transmitters are unaffected.
AL	Aux. Feedwater System	H, P	All PFSSD functions associated with the auxiliary feedwater system are satisfied. The turbine driven auxiliary feedwater pump (TDAFP) may not be available. The motor driven auxiliary feedwater pumps are unaffected.
AP	Condensate Storage System	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-36.
BB	Reactor Coolant System	R, M, H, P, S	Pressurizer level transmitter BBLT0460 may be affected. Redundant pressurizer level transmitter BBLT0459 is unaffected. RCS Temperature elements BBTE0423B and BBTE0443A, as well as associated temperature indicators, could be affected by a fire in this area. The remaining temperature elements/indicators are unaffected.
BG	Chemical and Volume Control System	R, M, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-36.
BM	Steam Generator Blowdown System	R, M, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-36.
BN	Borated Refueling Water Storage System	R, M, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-36.
EF	Essential Service Water System	H, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-36.
EG	Component Cooling Water System	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-36.
EJ	Residual Heat Removal System	M, H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-36.

Table C-36-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-36

System	System Name	PFSSD Function*	Comments
EM	High Pressure Coolant Injection	R, M	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-36.
EN	Containment Spray	R, M	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-36.
EP	Safety Injection Accumulators	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-36.
FB	Auxiliary Steam	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-36.
FC	Auxiliary Turbines	R, H, P	The TDAFP speed control valve FCFV0313 could be affected. The motor driven auxiliary feedwater pumps are available.
GD	ESW Pump House HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-36.
GF	AFW Pump Room Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-36.
GK	Control Room and Class 1E Switchgear Room Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-36.
GL	Auxiliary Building HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-36.
GM	Emergency Diesel Generator Room HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-36.
GN	Containment Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-36.
JE	Diesel Fuel Oil	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-36.
KA	Instrument Air	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-36.
KC	Fire Protection	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-36.
KH	Service Gas	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-36.

Table C-36-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-36

System	System Name	PFSSD Function*	Comments
KJ	Standby Diesel Engine	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-36.
MA	Main Generation	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-36.
MR	Startup Transformer	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-36.
NB	4.16 kV System	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-36.
NE	Standby Diesel Generator	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-36.
NF	Load Shed and Emergency Load Sequencing	S	All PFSSD functions associated with load shed/emergency load sequencing system are satisfied. Load shed/sequencer channel 2 could be affected. Channels 1, 3 and 4 are unaffected.
NG	480V Load Centers and MCCs	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-36.
NK	125VDC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-36.
NN	120VAC	S	One of two sources of 125 VDC power to swing inverter NN16 could be affected. The remaining source is unaffected. Swing inverter NN16 may not be able to supply power to bus NN02. Inverter NN12 is unaffected and can supply 120 VAC power to NN02.
PA	13.8kV	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-36.
PB	4.16kV	H, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-36.
PG	480V Load Centers and MCCs	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-36.
PK	125VDC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-36.
PL	Local Instrument Panels	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-36.
PN	120VAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-36.

Table C-36-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-36

System	System Name	PFSSD Function*	Comments
QB	Standby AC Lighting	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-36.
QD	Emergency Lighting	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-36.
RL	Control Room MCB	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-36.
RP	Miscellaneous Control Panels	R, M, H, P, S	120 VAC power to panel RP147A could be affected, preventing operation of ABPV0002 and FCFV0313. This will not adversely impact PFSSD as discussed in AB and FC summaries above.
SA	ESFAS	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-36.
SB	Reactor Protection System	R, S	120 VAC power to panel SB148A could be affected, preventing operation of BBLI0460B, BBTI0423X, AELI0502A and BBTI0443X at the auxiliary shutdown panel. Indication of these parameters in the main control room is unaffected.
SC	Reactor Instrumentation	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-36.
SE	Ex-Core Neutron Monitoring	R, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-36.
SY	Switchyard	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-36.
UU	Supervisory System	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-36.

3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD

This section describes operator actions that may need to be performed inside or outside the control room to achieve and maintain hot standby if a fire occurs in area C-36. This section also describes cold shutdown repairs that may need to be made to achieve and maintain cold shutdown conditions. Operator actions are proceduralized in OFN KC-016.

3.1 ACTIONS OUTSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

Operator Manual Actions (OMAs) are those actions outside the main control room required to achieve and maintain hot standby. OMAs are identified in E-1F9900 and were determined from thermal hydraulic analysis WCNOC-CP-002. Applicable E-1F9900 OMAs are annotated herein. All other actions outside the control room are desirable for plant control in support of hot standby but not required to achieve and maintain hot standby.

3.1.1 Steam Generator ARVs

If damage occurs to cables associated with ABPV0002, local control station ABFHC0002, located in fire area A-23, can be used to close ARV ABPV0002.

3.2 ACTIONS INSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

None

3.3 ACTIONS TO ACHIEVE AND MAINTAIN COLD SHUTDOWN

None

4.0 CONCLUSION

Post-fire safe shutdown is unaffected by a fire in fire area C-36.

5.0 DETAILED ANALYSIS

This section describes the detailed component-by-component and cable-by-cable analysis for a fire in area C-36.

5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA C-36

There are no PFSSD components located in fire area C-36. This fire area only contains cables associated with PFSSD equipment located in other areas.

5.2 PFSSD CABLE EVALUATION

Table C-36-3 lists all the PFSSD cables (S. in E-15000) located in fire area C-36. The applicable evaluation section is also listed in Table C-36-3.

Table C-36-3

5.2.1 Steam Generator Atmospheric Relief Valves

PFSSD requires at least two steam generator atmospheric relief valves (ARV) be controlled and the other two closed. The ARVs are pneumatically operated using air from the compressed air system (KA) or nitrogen from the nitrogen accumulators. The valves open by pneumatic pressure and close by spring action. A pressure transmitter installed on the outlet side of the steam generator sends a signal to a controller and automatically controls the associated ARV position. Alternatively, each ARV can be controlled manually from the control room or the auxiliary shutdown panel by placing the pressure indicating controller (PIC) in manual.

Cables associated with steam generator atmospheric relief valve ABPV0002 are run in area C-36. Cables associated with the remaining three steam generator atmospheric relief valves are unaffected by a fire in area C-36. If damage occurs to cables associated with ABPV0002 such that the ARV spuriously opens, local controller ABFHC0002, located in fire area A-23, can be used to close ARV ABPV0002.

Based on the above discussion, the spurious opening of ARV ABPV0002 will not adversely impact PFSSD and can be mitigated by a manual action if desired.

Up to three ARVs can fail closed or open without impacting ability to achieve and maintain hot standby according to thermal hydraulic analysis WCNOC-CP-002. With at least one ARV unaffected, no E-1F9900 OMA is required to address ARV closure or control. Reference Attachment 4, MSO Evaluation Scenario ID PWROG 23.

References: E-15000, XX-E-013, E-13AB20B, E-1F9101, M-12AB01, E-13AB06B

5.2.2 Auxiliary Feedwater

The PFSSD design requires the use of one auxiliary feedwater pump (AFP) supplying water to at least two steam generators. The Train A motor driven auxiliary feedwater pump (MDAFP) is aligned to supply steam generators B and C. The Train B MDAFP is aligned to supply steam generators A and D. The turbine driven auxiliary feedwater pump (TDAFP) is normally aligned to supply all four steam generators.

The normal source of water to the AFPs is the condensate storage tank (CST). The emergency supply is from the essential service water (ESW) system. For commercial concerns, the CST is the preferred source and contains sufficient volume to supply the entire auxiliary feedwater (AFW) demand to achieve cold shutdown.

Cable 12RPY09BA supplies 120 VAC power to RP147A. The only PFSSD component controlled by RP147A is ABPV0002. Therefore, loss of power to RP147A could prevent operation of ABPV0002.

Cables associated with TDAFP speed governing valve FCFV0313 are run through fire area C-36. Damage to these cables could prevent operation of the TDAFP. Main steam flow to the TDAFP can be isolated using FCHV0312. Loss of the TDAFP is acceptable since the Motor Driven Auxiliary Feedwater Pumps (MDAFP) are available. Therefore, the auxiliary feedwater requirement for decay heat removal is satisfied if a fire occurs in area C-36.

Cables associated with ALPT0026, TDAFW pump suction pressure transmitter, are run through area C-36. Loss of ALPT0026 is acceptable since either MDAFP is used for PFSSD if a fire occurs in area C-36.

Based on the above discussion, the TDAFP may not be available if a fire occurs in this area. This is acceptable since both MDAFPs are unaffected by a fire in this area.

References: E-15000, XX-E-013, E-11NK02, E-13AL07B, E-13FC24, E-13RP09, E-1F9101, E-1F9202, M-12AB02, M-12AL01, M-12FC02

5.2.3 Load Shedder / Emergency Load Sequencer

The load shedder and emergency load sequencers are included in the PFSSD design to evaluate the impact of spurious operation or mal-operation. The load shedder/emergency load sequencer operates upon presence of the following conditions:

1. An undervoltage (UV) on a safeguards bus,
2. A safety injection signal (SIS) or a containment spray actuation signal (CSAS), or
3. An undervoltage on a safeguards bus with a SIS or CSAS.

Eight inputs (four undervoltage (UV) inputs and four degraded voltage inputs) on each safeguards bus (NB01 and NB02) monitor voltage conditions on that bus. An undervoltage condition on two of four UV relays on each bus will actuate the load shedder/sequencer and send a signal to start the associated diesel generator. In addition, degraded voltage sensed by two of four degraded voltage potential transformers (PTs) will, after a time delay, provide a signal to open the offsite feeder breakers on the associated bus.

The outputs from each safeguards bus (NB01 and NB02) are divided into 4 separation groups; 1, 2, 3 and 4 and routed to two control panels, NF039A and NF039B. The input section of each control panel also receives group 1, 2, 3 and 4 instrument power (120VAC). The inputs then pass through isolation devices, at which point all inputs to NF039A become separation group 1 and all inputs to NF039B become separation group 4. Interruption of either the inputs or the instrument power from one separation group would impact the associated input channel, but would not impact the other 3 input channels.

Cables 12NFK01CA and 12NFK01DA are associated with separation group 2 UV relays on buses NB01 and NB02, respectively. Cables 12NFY01EA and 12NFY01FA are associated with separation group 3 degraded voltage PTs on buses NB01 and NB02, respectively. Cables associated with the remaining three UV relays and PTs from separation groups 1, 3 and 4 do not run in fire area C-36.

Automatic functioning of the bus NB01 and NB02 emergency load shedder / sequencer is unaffected by a fire in area C-36 because of the presence of circuits for only one of the four load shed/sequencer initiators. Therefore, a spurious start of the Train A and Train B diesel generators due to a false undervoltage condition on two of the four circuits is not credible.

Based on the above discussion, the Train A and Train B load shed/sequencers are available if a fire occurs in this area. Off-site power to both trains is unaffected based on Calculation XX-E-013, Appendix 2.

5.2.4 Process Monitoring

Process monitoring is required to achieve and maintain safe shutdown. Some of the process instruments credited for safe shutdown could be affected by a fire in area C-36. These instruments, as well as the available redundant capability, are described in the following paragraphs.

Steam generator level indication is required to support the decay heat removal function. At least one level transmitter is required on each steam generator being used for heat removal. Cables 12AEI08GB, associated with steam generator B wide range level transmitter AELT0502, and 12SBS16AA, associated with steam generator B wide range level indicator AELI0502A, are run in fire area C-36. Narrow range level indication on steam generator B

remains available. Cables for the remaining level transmitters are not run in fire area C-36. Therefore, level indication on all four steam generators is available.

RCS hot and cold leg temperature indication is required on at least one loop to verify flow through the steam generators. The following table lists the RCS temperature elements credited for PFSSD.

RCS Hot and Cold Leg Temperature Elements Used for PFSSD	
COMPONENT	**FUNCTION**
BBTE0413A	RCS Hot Leg Temperature Element (WR) Loop 1
BBTE0413B	RCS Cold Leg Temperature Element (WR) Loop 1
BBTE0423A	RCS Hot Leg Temperature Element (WR) Loop 2
BBTE0423B	RCS Cold Leg Temperature Element (WR) Loop 2
BBTE0433A	RCS Hot Leg Temperature Element (WR) Loop 3
BBTE0433B	RCS Cold Leg Temperature Element (WR) Loop 3
BBTE0443A	RCS Hot Leg Temperature Element (WR) Loop 4
BBTE0443B	RCS Cold Leg Temperature Element (WR) Loop 4

Temperature elements BBTE0423B and BBTE0443A, as well as associated temperature indicators, could be affected by a fire in this area. The remaining temperature elements/indicators are unaffected. Therefore, RCS hot and cold leg temperature indication remains available on loops 1 and 3.

Pressurizer level indication is required to be available to ensure pressurizer level does not go off-scale. Pressurizer level indication is provided by level transmitters BBLT0459 and BBLT0460. Circuits for BBLT0460 are run in area C-36, so BBLT0460 may not be available. Circuits for BBLT0459/BBLI0459A do not run through fire area C-36 and are unaffected by a fire. Therefore, pressurizer level indication is available for a fire in area C-36 using BBLT0459/BBLI0459A.

Cable 12SBY09GA supplies 120 VAC power from NN0217 to SB148A. Panel SB148A receives signals from certain field transmitters (BBLT0460, BBTE0423, AELT0502 and BBTE0443) and sends the signals to the control room and the auxiliary shutdown panel (ASP). This ensures reliable diagnostic instrumentation is available at the ASP if a fire occurs in the control room. Loss of 120 VAC power to SB148A will prevent signals from these transmitters from reaching the control room and the ASP. However, redundant diagnostic instrumentation remains available in the control room. Therefore, loss of AC power will not impact PFSSD.

Based on the above discussion, process monitoring is available if a fire occurs in fire area C-36.

References: E-15000, XX-E-013, E-13AE08, E-13BB15, E-13BB16, E-13NN01, E-13SB09, E-13SB16, E-1F9201, E-1F9203, E-1F9301, M-12AE02, M-12BB01, M-12BB02

5.2.5 Class 1E 120 VAC Electrical Distribution System

The Class 1E 120 VAC electrical distribution system provides power to vital instrumentation and control loads for shutdown and normal operation. Under normal conditions, the system is supplied by inverters connected to the 125 VDC NK battery system. Swing inverters allow the primary inverters to be taken out of service for maintainance or repair without disrupting power to the associated vital AC bus. In the event of a loss of power to the inverters, a backup source of power is automatically lined up. The backup power source originates from the 480 VAC electrical distribution system (NG).

Cables 12NNK01LA and 12NNK01LB supply 125 VDC power from NK0203 to manual transfer switch NK80. Damage to these cables will disrupt the 125 VDC power supply from NK0203 to swing inverter NN16. 125 VDC power from NK0403 to swing inverter NN16 is unaffected.

Cables 12NNY01GA and 12NNY01GB supply 120 VAC power from swing inverter NN16 to bus NN02 through a manual transfer switch in inverter NN12. Damage to these cables will disrupt the 120 VAC power supply from swing inverter NN16 to NN02.

Inverters NN12 and NN14 and 120 VAC vital distribution buses NN02 and NN04 are located in a separate fire area and are unaffected by a fire in area C-20. The 125 VDC and 480 VAC power supply to inverters NN12 and NN14 are unaffected by a fire in area C-20.

Based on the above discussion, the Train A and Train B vital 120 VAC electrical distribution system is unaffected by a fire in this area.

1.0 GENERAL AREA DESCRIPTION

Fire area C-37 is located on the 2000 elevation of the Control Building and includes the room listed in Table C-37-1.

Table C-37-1
Rooms Located in Fire Area C-37

ROOM #	DESCRIPTION
C37	North Small Elec Chase 2000 Elevation

Fire area C-37 is protected with an automatic fire suppression and detection system. The area is bounded on all sides by minimum 3-hour fire resistance rated construction.

2.0 PRIMARY EQUIPMENT USED FOR PFSSD

Table C-37-2 lists each system credited for post-fire safe shutdown and provides a discussion regarding the availability of the system to perform its Post Fire Safe Shutdown (PFSSD) function if a severe fire occurs in this area. For a summary of the potential fire impact on some of the more significant PFSSD equipment, see Section 8.0 of the Fire Area Analysis Narrative section.

Table C-37-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area C-37

System	System Name	PFSSD Function*	Comments
AB	Main Steam	R, M, H, P, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area C-37.

3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD

This section describes operator actions that may need to be performed inside or outside the control room to achieve and maintain hot standby if a fire occurs in area C-37. This section also describes cold shutdown repairs that may need to be made to achieve and maintain cold shutdown conditions. Operator actions are proceduralized in OFN KC-016.

3.1 ACTIONS OUTSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

None

3.2 ACTIONS INSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

None

3.3 ACTIONS TO ACHIEVE AND MAINTAIN COLD SHUTDOWN

None

4.0 CONCLUSION

Post-fire safe shutdown is unaffected by a fire in area C-37.

5.0 DETAILED ANALYSIS

This section describes the detailed component-by-component and cable-by-cable analysis for a fire in area C-37.

5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA C-37

There are no PFSSD components located in fire area C-37. This fire area only contains cables associated with PFSSD equipment located in other areas.

5.2 PFSSD CABLE EVALUATION

Table C-37-3 lists all the PFSSD cables (S. in E-15000) located in fire area C-37. The applicable evaluation section is also listed in Table C-37-3.

Table C-37-3
PFSSD Cables Located in Fire Area C-37

Cable #	Location	Primary PFSSD Equipment	Cable Function (P) Power (C) Control (I) Instrumentation	Evaluation Section	Comments
13NFK01CA	C37	127-3/DG	C	5.2.1	NB01 Undervoltage Relay
13NFK01DA	C37	127-3/DG	C	5.2.1	NB02 Undervoltage Relay
13NFY01GA	C37	PTNB117/B	C	5.2.1	NB01 Degraded Voltage Potential Transformer
13NFY01HA	C37	PTNB217/B	C	5.2.1	NB02 Degraded Voltage Potential Transformer
13NNK01KA	C37	NN15	P	5.2.2	125 VDC Power to Swing Inverter NN15
13NNK01KB	C37	NN15	P	5.2.2	125 VDC Power to Swing Inverter NN15
13NNY01FA	C37	NN13	P	5.2.2	120 VAC Power from NN15 to NN13
13NNY01FB	C37	NN13	P	5.2.2	120 VAC Power from NN15 to NN13

5.2.1 Load Shedder / Emergency Load Sequencer

The load shedder and emergency load sequencers are included in the PFSSD design to evaluate the impact of spurious operation or mal-operation. The load shedder/emergency load sequencer operates upon presence of the following conditions:

1. An undervoltage (UV) on a safeguards bus,
2. A safety injection signal (SIS) or a containment spray actuation signal (CSAS), or
3. An undervoltage on a safeguards bus with a SIS or CSAS.

Eight inputs (four undervoltage (UV) inputs and four degraded voltage inputs) on each safeguards bus (NB01 and NB02) monitor voltage conditions on that bus. An undervoltage condition on two of four UV relays on each bus will actuate the load shedder/sequencer and send a signal to start the associated diesel generator. In addition, degraded voltage sensed by two of four degraded voltage potential transformers (PTs) will, after a time delay, provide a signal to open the offsite feeder breakers on the associated bus.

Cables 13NFK01CA and 13NFK01DA are associated with one of the four UV relays on buses NB01 and NB02, respectively. Cables 13NFY01GA and 13NFY01HA are associated with one of the four degraded voltage PTs on buses NB01 and NB02, respectively. Cables associated with the remaining three UV relays and PTs do not run in fire area C-37.

Based on the above discussion, the Train A and Train B load shed/sequencers are available if a fire occurs in this area. Off-site power to both trains is unaffected based on Calculation XX-E-013, Appendix 2.

5.2.2 Class 1E 120 VAC Electrical Distribution System

The Class 1E 120 VAC electrical distribution system provides power to vital instrumentation and control loads for shutdown and normal operation. Under normal conditions, the system is supplied by inverters connected to the 125 VDC NK battery system. Swing inverters allow the primary inverters to be taken out of service for maintainance or repair without disrupting power to the associated vital AC bus. In the event of a loss of power to the inverters, a backup source of power is automatically lined up. The backup power source originates from the 480 VAC electrical distribution system (NG).

Cables 13NNK01KA and 13NNK01KB supply 125 VDC power from NK0303 to manual transfer switch NK79. Damage to these cables will disrupt the 125 VDC power supply from NK0303 to swing inverter NN15. 125 VDC power from NK0103 to swing inverter NN15 is unaffected.

Cables 13NNY01FA and 13NNY01FB supply 120 VAC power from swing inverter NN15 to bus NN03 through a manual transfer switch in inverter NN13. Damage to these cables will disrupt the 120 VAC power supply from swing inverter NN15 to NN03.

Inverters NN11 and NN13 and 120 VAC vital distribution buses NN01 and NN03 are located in a separate fire area and are unaffected by a fire in area C-19. The 125 VDC and 480 VAC power supply to inverters NN11 and NN13 are unaffected by a fire in area C-37.

Based on the above discussion, the Train A and Train B vital 120 VAC electrical distribution system is unaffected by a fire in this area.

1.0 GENERAL AREA DESCRIPTION

Fire area CST includes the area around and including the Condensate Storage Tank (CST). The CST is located outside on the northeast side of Containment.

Table CST-1
Rooms Located in Fire Area CST

ROOM #	DESCRIPTION
9101	Condensate Storage Tank Valve House
CST	Condensate Storage Tank

There is no automatic fire detection or suppression in the CST valve house. Manual fire suppression capabilities are present in the yard area adjacent to the CST. Based on the Fire Hazards Analysis (E-1F9905), the combustible loading around the CST is low.

2.0 PRIMARY EQUIPMENT USED FOR PFSSD

Table CST-2 lists each system credited for post-fire safe shutdown and provides a discussion regarding the availability of the system to perform its Post Fire Safe Shutdown (PFSSD) function if a severe fire occurs in this area. For a summary of the area analysis results, see Section 8.0 of the Fire Area Analysis Narrative section.

Table CST-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area CST

System	System Name	PFSSD Function*	Comments
AB	Main Steam	R, M, H, P, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area CST.

3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD

This section describes operator actions that may need to be performed inside or outside the control room to achieve and maintain hot standby if a fire occurs in area CST. This section also describes cold shutdown repairs that may need to be made to achieve and maintain cold shutdown conditions. Operator actions are proceduralized in OFN KC-016.

3.1 ACTIONS OUTSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

None

3.2 ACTIONS INSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

None

3.3 ACTIONS TO ACHIEVE AND MAINTAIN COLD SHUTDOWN

None

4.0 CONCLUSION

Post-fire safe shutdown is assured if a fire occurs in fire area CST.

5.0 DETAILED ANALYSIS

This section describes the detailed component-by-component and cable-by-cable analysis for a fire in area CST.

5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA CST

PFSSD components (S. in E-15000) located in fire area CST are shown in Table CST-3. An evaluation of each component and associated cables is provided in the sections that follow. The applicable evaluation section is listed in Table CST-3.

Table CST-3 PFSSD Equipment Located in Fire Area CST				
Room #	**PFSSD Equipment**	**Description**	**Evaluation Section**	**Comments**
CST	TAP01	Condensate Storage Tank	5.1.1	

5.1.1 Condensate Storage Tank

The Condensate Storage Tank (CST) is the primary source of water to the auxiliary feedwater (AFW) system. If the CST is unavailable, AFW pump suction can be taken from the essential service water (ESW) system. The ESW system is the safety-related suction source for AFW and is credited as a redundant source for PFSSD.

Catastrophic failure of the CST due to an exposure fire is not considered credible. Administrative controls limit the quantity of combustibles stored in the vicinity of the CST and normal in-situ combustible loading is low, per E-1F9905. The tank is made Stainless Steel and is insulated to protect against freezing. The administrative controls, low combustible loading, steel tank construction together with the large heat sink provided by the water in the tank provides reasonable assurance that the CST will remain available in the event of a fire.

In the unlikely event the CST is unavailable, the ESW system remains available to provide the required suction source for AFW. Therefore, a severe fire in the vicinity of the CST will not impact the ability to achieve and maintain safe shutdown.

5.0 DETAILED ANALYSIS 8
5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA D-1 8
5.2 PFSSD CABLE EVALUATION 12

1.0 GENERAL AREA DESCRIPTION

Fire area D-1 is located on the 2000'-0" elevation of the Diesel Generator Building and includes the rooms listed in Table D-1-1.

Table D-1-1
Rooms Located in Fire Area D-1

ROOM #	DESCRIPTION
5203	Train A Diesel Generator Room
5203A	Train A Diesel Engine Underground Fuel Tank Area

Except for the underground fuel tank area, fire area D-1 is protected with an automatic pre-action fire suppression system. In addition, automatic fire detection is installed throughout room 5203.

Fire Area D-1 contains cables and equipment for Train A safety-related and non-safety related components. Redundant Train B cables and components are located in a separate fire area divided by 3-hour fire rated construction. The 3-hour fire rated barrier provides reasonable assurance that a fire in area D-1 will not affect Train B components and therefore the ability to achieve and maintain safe shutdown in the event of a fire in area D-1 is assured.

2.0 PRIMARY EQUIPMENT USED FOR PFSSD

Table D-1-2 lists each system credited for post-fire safe shutdown and provides a discussion regarding the availability of the system to perform its Post Fire Safe Shutdown (PFSSD) function if a severe fire occurs in this area. For a summary of the area analysis results, see Section 8.0 of the Fire Area Analysis Narrative section.

None

3.2 ACTIONS INSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

None

3.3 ACTIONS TO ACHIEVE AND MAINTAIN COLD SHUTDOWN

None

4.0 CONCLUSION

Post-fire safe shutdown is assured if a fire occurs in area D-1.

5.0 DETAILED ANALYSIS

This section describes the detailed component-by-component and cable-by-cable analysis for a fire in area D-1.

5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA D-1

PFSSD components (S. in E-15000) located in fire area D-1 are shown in Table D-1-3. An evaluation of each component and associated cables is provided in the sections that follow. The applicable evaluation section is listed in Table D-1-3.

5.1.1 Standby Diesel Generators

The standby diesel generators are credited for PFSSD in the event a fire causes a loss of off-site power to the safety related electrical buses.

The Train A emergency diesel generator, as well as a number of associated components and cables, are located in fire area D-1. Consequently, a fire in this area could prevent operation of the Train A emergency diesel generator. The Train B emergency diesel generator as well as associated cables and components are unaffected by a fire in area D-1.

Based on the above discussion, a fire in area D-1 which affects the Train A emergency diesel generator will not adversely impact the ability to energize either safety related bus.

5.2.1 Containment Air Supply

Valve KAFV0029 is an isolation valve on the containment compressed air supply line. This valve is credited for PFSSD in the event of a fire in certain areas to isolate air to letdown isolation valves BGLCV0459 and BGLCV0460 and pressurizer spray valves BBPCV0455B and BBPCV0455C to fail the valves closed. Valve KAFV0029 is a diverse means of closing these valves if the fire prevents closing the valves using their respective control room hand switches.

Cable 11KAK02AA is a control cable associated with valve KAFV0029. Damage to this cable could prevent closure of the valve from the control room or could cause the valve to spuriously close. If the valve spuriously closes, PFSSD will not be affected as documented in WIP-E-1F9900-004-A-1.

A fire in area D-1 does not require closure of the air supply to containment to achieve PFSSD. Letdown isolation valves BGLCV0459 and BGLCV0460 are unaffected by a fire in this area and can be closed from the control room to isolate letdown. In addition, pressurizer spray valves BBPCV0455B and BBPCV0455C are unaffected by a fire in this area. Therefore, valve KAFV0029 is not credited for a fire in this area.

Based on the above discussion, damage to cable 11KAK02AA will have no adverse impact on the ability to achieve and maintain safe shutdown following a fire in this area.

1.0 GENERAL AREA DESCRIPTION

Fire area D-2 is located on the 2000'-0" elevation of the Diesel Generator Building and includes the rooms listed in Table D-2-1.

Table D-2-1
Rooms Located in Fire Area D-2

ROOM #	DESCRIPTION
5201	Train B Diesel Generator Room
5201A	Train B Diesel Engine Underground Fuel Tank Area

Except for the underground fuel tank area, fire area D-2 is protected with an automatic pre-action fire suppression system. In addition, automatic fire detection is installed throughout room 5201.

Fire Area D-2 contains cables and equipment for Train B safety-related and non-safety related components. Redundant Train A cables and components are located in a separate fire area divided by 3-hour fire rated construction. The 3-hour fire rated barrier provides reasonable assurance that a fire in area D-2 will not affect Train A components and therefore the ability to achieve and maintain safe shutdown in the event of a fire in area D-2 is assured.

2.0 PRIMARY EQUIPMENT USED FOR PFSSD

Table D-2-2 lists each system credited for post-fire safe shutdown and provides a discussion regarding the availability of the system to perform its Post Fire Safe Shutdown (PFSSD) function if a severe fire occurs in this area. For a summary of the area analysis results, see Section 8.0 of the Fire Area Analysis Narrative section.

Table D-2-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area D-2

System	System Name	PFSSD Function*	Comments
AB	Main Steam	R, M, H, P, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area D-2.
AC	Main Turbine	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area D-2.
AE	Main Feedwater	H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area D-2.
AL	Aux. Feedwater System	H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area D-2.
AP	Condensate Storage System	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area D-2.
BB	Reactor Coolant System	R, M, H, P, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area D-2.
BG	Chemical and Volume Control System	R, M, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area D-2.

3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD

This section describes operator actions that may need to be performed inside or outside the control room to achieve and maintain hot standby if a fire occurs in area D-2. This section also describes cold shutdown repairs that may need to be made to achieve and maintain cold shutdown conditions. Operator actions are proceduralized in OFN KC-016.

3.1 ACTIONS OUTSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

None

3.2 ACTIONS INSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

None

3.3 ACTIONS TO ACHIEVE AND MAINTAIN COLD SHUTDOWN

None

4.0 CONCLUSION

Post-fire safe shutdown is assured if a fire occurs in area D-2.

5.0 DETAILED ANALYSIS

This section describes the detailed component-by-component and cable-by-cable analysis for a fire in area D-2.

5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA D-2

PFSSD components (S. in E-15000) located in fire area D-2 are shown in Table D-2-3. An evaluation of each component and associated cables is provided in the sections that follow. The applicable evaluation section is listed in Table D-2-3.

5.1.1 Standby Diesel Generators

The standby diesel generators are credited for PFSSD in the event a fire causes a loss of off-site power to the safety related electrical buses.

The Train B emergency diesel generator, as well as a number of associated components and cables, are located in fire area D-2. Consequently, a fire in this area could prevent operation of the Train B emergency diesel generator. The Train A emergency diesel generator as well as associated cables and components are unaffected by a fire in area D-2.

Based on the above discussion, a fire in area D-2 which affects the Train B emergency diesel generator will not adversely impact the ability to energize either safety related bus.

5.2 PFSSD CABLE EVALUATION

Table D-2-4 lists all the PFSSD cables (S. in E-15000) located in fire area D-2. The applicable evaluation section is also listed in Table D-2-4.

All PFSSD cables that run in Fire Area D-2 terminate at their associated PFSSD equipment within Fire Area D-2. Therefore, all cable evaluations are included with the equipment evaluations in Section 5.1. Any possible combination of hot shorts, open circuits or shorts to ground could prevent operation or cause mal-operation of the associated Train B equipment. Cables associated with redundant Train A equipment are unaffected and therefore PFSSD can be achieved.

1.0 GENERAL AREA DESCRIPTION

Fire area ESWA includes the rooms listed in Table ESWA-1.

Table ESWA-1 Rooms Located in Fire Area ESWA	
ROOM #	**DESCRIPTION**
K105	Train A Essential Service Water (ESW) Pump Room
K105A	Train A ESW Duct Bank and Vaults

Fire Area ESWA contains cables and equipment for Train A ESW pump. Redundant Train B cables and components are located in a separate fire area divided by 3-hour fire rated construction. The 3-hour fire rated barrier provides reasonable assurance that a fire in area ESWA will not affect Train B ESW components and therefore the ability to achieve and maintain safe shutdown in the event of a fire in area ESWA is assured.

2.0 PRIMARY EQUIPMENT USED FOR PFSSD

Table ESWA-2 lists each system credited for post-fire safe shutdown and provides a discussion regarding the availability of the system to perform its Post Fire Safe Shutdown (PFSSD) function if a severe fire occurs in this area. For a summary of the area analysis results, see Section 8.0 of the Fire Area Analysis Narrative section.

Table ESWA-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area ESWA

System	System Name	PFSSD Function*	Comments
AB	Main Steam	R, M, H, P, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area ESWA.
AC	Main Turbine	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area ESWA.
AE	Main Feedwater	H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area ESWA.
AL	Aux. Feedwater System	H, P	Due to the potential loss of the Train A ESW system, the Train A MDAFP may not be available. The Train B ESW system remains available to ensure operability of the Train B MDAFP.
AP	Condensate Storage System	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area ESWA.
BB	Reactor Coolant System	R, M, H, P, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area ESWA.
BG	Chemical and Volume Control System	R, M, S	Due to the potential loss of the Train A ESW system, the Train A CCP may not be available. The Train B ESW system remains available to ensure operability of the Train B CCP.
BM	Steam Generator Blowdown System	R, M, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area ESWA.
BN	Borated Refueling Water Storage System	R, M, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area ESWA.
EF	Essential Service Water System	H, S	The Train A ESW system is affected. The Train B ESW system is unaffected.
EG	Component Cooling Water System	S	Due to the potential loss of the Train A ESW system, the Train A CCW system may not be available. The Train B ESW system remains available to ensure operability of the Train B CCW system.
EJ	Residual Heat Removal System	M, H, P	Due to the potential loss of the Train A ESW system, the Train A RHR pump may not be available. The Train B ESW system remains available to ensure operability of the Train B RHR pump.
EM	High Pressure Coolant Injection	R, M	The PFSSD function(s) associated with this system is(are) not affected by a fire in area ESWA.
EN	Containment Spray	R, M	The PFSSD function(s) associated with this system is(are) not affected by a fire in area ESWA.

Table ESWA-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area ESWA

System	System Name	PFSSD Function*	Comments
EP	Safety Injection Accumulators	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area ESWA.
FB	Auxiliary Steam	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area ESWA.
FC	Auxiliary Turbines	R, H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area ESWA.
GD	ESW Pump House HVAC	S	The Train A ESW pump room ventilation may be affected. The Train B ESW pump room ventilation is unaffected.
GF	AFW Pump Room Coolers	S	Due to the potential loss of the Train A ESW system, the Train A MDAFP room cooler may not be available. The Train B ESW system remains available to ensure operability of the Train B MDAFP room cooler.
GK	Control Room and Class 1E Switchgear Room Coolers	S	Due to the potential loss of the Train A ESW system, the Train A Class 1E electrical equipment room cooler may not be available. The Train B ESW system remains available to ensure operability of the Train B Class 1E electrical equipment room cooler.
GL	Auxiliary Building HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area ESWA.
GM	Emergency Diesel Generator Room HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area ESWA.
GN	Containment Coolers	S	Due to the potential loss of the Train A ESW system, the Train A containment coolers may not be available. The Train B ESW system remains available to ensure operability of the Train B containment coolers.
JE	Diesel Fuel Oil	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area ESWA.
KA	Instrument Air	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area ESWA.
KC	Fire Protection	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area ESWA.
KH	Service Gas	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area ESWA.
KJ	Standby Diesel Engine	S	The Train A diesel engine may be affected due to loss of Train A ESW. The Train B diesel generator is available.
MA	Main Generation	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area ESWA.
MR	Startup Transformer	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area ESWA.

Table ESWA-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area ESWA

System	System Name	PFSSD Function*	Comments
NB	4.16 kV System	S	The Train A NB system is not directly affected by a fire in this area since off-site power remains available. However, due to the potential loss of the Train A Class 1E Electrical Equipment Room Cooler (due to the potential loss of Train A ESW), the NB01 switchgear room temperature could increase beyond that allowed for the equipment to remain functional. Therefore, it is assumed that NB01 is unavailable. If operators require NB01, then they can enter SYS GK-200 to provide cooling to the Train A electrical equipment rooms from Train B Class 1E A/C Unit SGK05B.
NE	Standby Diesel Generator	S	The Train A diesel generator may be affected due to loss of Train A ESW. The Train B diesel generator is available.
NF	Load Shed and Emergency Load Sequencing	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area ESWA.
NG	480V Load Centers and MCCs	S	Train A ESW pump room MCC NG05E may be affected. Train B ESW pump room MCC NG06E is unaffected. Train A 480 VAC Load Centers and MCCs could be affected due to loss of NB01 (See NB System Comments). Train B 480 VAC Load Centers and MCCs are unaffected.
NK	125VDC	S	Train A Class 1E 125 VDC distribution switchboards could be affected due to the potential loss of Train A Class 1E Electrical Equipment A/C unit SGK05A. Operators can enter SYS GK-200 to provide cooling to the Train A electrical equipment rooms from Train B Class 1E A/C Unit SGK05B.
NN	120VAC	S	Train A Class 1E 120 VAC distribution switchboards could be affected due to the potential loss of Train A Class 1E Electrical Equipment A/C unit SGK05A. Operators can enter SYS GK-200 to provide cooling to the Train A electrical equipment rooms from Train B Class 1E A/C Unit SGK05B.
PA	13.8kV	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area ESWA.
PB	4.16kV	H, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area ESWA.
PG	480V Load Centers and MCCs	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area ESWA.
PK	125VDC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area ESWA.
PL	Local Instrument Panels	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area ESWA.
PN	120VAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area ESWA.

Table ESWA-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area ESWA

System	System Name	PFSSD Function*	Comments
QB	Standby AC Lighting	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area ESWA.
QD	Emergency Lighting	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area ESWA.
RL	Control Room MCB	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area ESWA.
RP	Miscellaneous Control Panels	R, M, H, P, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area ESWA.
SA	ESFAS	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area ESWA.
SB	Reactor Protection System	R, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area ESWA.
SC	Reactor Instrumentation	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area ESWA.
SE	Ex-Core Neutron Monitoring	R, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area ESWA.
SY	Switchyard	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area ESWA.
UU	Supervisory System	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area ESWA.

3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD

This section describes operator actions that may need to be performed inside or outside the control room to achieve and maintain hot standby if a fire occurs in area ESWA. This section also describes cold shutdown repairs that may need to be made to achieve and maintain cold shutdown conditions. Operator actions are proceduralized in OFN KC-016.

3.1 ACTIONS OUTSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

None

3.2 ACTIONS INSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

3.2.1 Component Cooling Water

If Train A component cooling water (CCW) is operating at the time of the fire, it may be necessary to swap to Train B CCW due to the potential loss of Train A ESW.

3.3 ACTIONS TO ACHIEVE AND MAINTAIN COLD SHUTDOWN

None

4.0 CONCLUSION

Post-fire safe shutdown is assured if a fire occurs in area ESWA.

5.0 DETAILED ANALYSIS

This section describes the detailed component-by-component and cable-by-cable analysis for a fire in area ESWA.

5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA ESWA

PFSSD components (S. in E-15000) located in fire area ESWA are shown in Table ESWA-3. An evaluation of each component and associated cables is provided in the sections that follow. The applicable evaluation section is listed in Table ESWA-3.

Table ESWA-3

5.1.1 Train A Essential Service Water (ESW)

This fire area contains equipment and cables associated with the Train A ESW system. Consequently, a fire in this area could result in a loss of Train A ESW, as well as all supported equipment. PFSSD equipment (excluding supported equipment) that requires Train A ESW is as follows:

- Train A containment air coolers
- Train A electrical penetration room cooler
- Train A component cooling water (CCW) pump room cooler
- Train A residual heat removal pump room cooler
- Train A centrifugal charging pump room cooler
- Train A class 1E electrical equipment A/C unit
- Train A control room A/C unit
- Train A motor driven auxiliary feedwater pump room cooler
- Train A auxiliary feedwater pump alternate supply (Note: condensate storage tank (CST) remains available)
- Turbine driven auxiliary feedwater pump alternate supply (Note: CST and Train B ESW remain available)
- Train A CCW heat exchanger
- Train A emergency diesel engine coolers

Loss of Train A ESW causes a loss of a number of Train A components. Therefore, Train A is not available in the event of a fire in the Train A ESW pump room. Train B ESW is unaffected and remains available to supply redundant Train B PFSSD equipment.

Based on the above discussion, a fire in area ESWA which affects the Train A ESW pump will not adversely impact the ability to safely shut down.

5.2 PFSSD CABLE EVALUATION

Table ESWA-4 lists all the PFSSD cables (S. in E-15000) located in fire area ESWA. The applicable evaluation section is also listed in Table ESWA-4.

All PFSSD cables that run in Fire Area ESWA terminate at their associated PFSSD equipment within Fire Area ESWA. Therefore, all cable evaluations are included with the equipment evaluations in Section 5.1. Any possible combination of hot shorts, open circuits or shorts to ground could prevent operation or cause mal-operation of the associated Train A equipment. Cables associated with redundant Train B equipment are unaffected and therefore PFSSD can be achieved.

1.0 GENERAL AREA DESCRIPTION

Fire area ESWB includes the rooms listed in Table ESWB-1.

Table ESWB-1 Rooms Located in Fire Area ESWB	
ROOM #	**DESCRIPTION**
K104	Train B Essential Service Water (ESW) Pump Room
K104A	Train B ESW Duct Bank and Vaults

Fire Area ESWB contains cables and equipment for Train B ESW pump. Redundant Train A cables and components are located in a separate fire area divided by 3-hour fire rated construction. The 3-hour fire rated barrier provides reasonable assurance that a fire in area ESWB will not affect Train A ESW components and therefore the ability to achieve and maintain safe shutdown in the event of a fire in area ESWB is assured.

2.0 PRIMARY EQUIPMENT USED FOR PFSSD

Table ESWB-2 lists each system credited for post-fire safe shutdown and provides a discussion regarding the availability of the system to perform its Post Fire Safe Shutdown (PFSSD) function if a severe fire occurs in this area. For a summary of the area analysis results, see Section 8.0 of the Fire Area Analysis Narrative section.

Table ESWB-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area ESWB

System	System Name	PFSSD Function*	Comments
AB	Main Steam	R, M, H, P, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area ESWB.
AC	Main Turbine	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area ESWB.
AE	Main Feedwater	H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area ESWB.
AL	Aux. Feedwater System	H, P	Due to the potential loss of the Train B ESW system, the Train B MDAFP may not be available. The Train A ESW system remains available to ensure operability of the Train A MDAFP.
AP	Condensate Storage System	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area ESWB.
BB	Reactor Coolant System	R, M, H, P, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area ESWB.
BG	Chemical and Volume Control System	R, M, S	Due to the potential loss of the Train B ESW system, the Train B CCP may not be available. The Train A ESW system remains available to ensure operability of the Train A CCP.
BM	Steam Generator Blowdown System	R, M, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area ESWB.
BN	Borated Refueling Water Storage System	R, M, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area ESWB.
EF	Essential Service Water System	H, S	The Train B ESW system is affected. The Train A ESW system is unaffected.
EG	Component Cooling Water System	S	Due to the potential loss of the Train B ESW system, the Train B CCW system may not be available. The Train A ESW system remains available to ensure operability of the Train A CCW system.
EJ	Residual Heat Removal System	M, H, P	Due to the potential loss of the Train B ESW system, the Train B RHR pump may not be available. The Train A ESW system remains available to ensure operability of the Train A RHR pump.
EM	High Pressure Coolant Injection	R, M	The PFSSD function(s) associated with this system is(are) not affected by a fire in area ESWB.
EN	Containment Spray	R, M	The PFSSD function(s) associated with this system is(are) not affected by a fire in area ESWB.

Table ESWB-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area ESWB

System	System Name	PFSSD Function*	Comments
EP	Safety Injection Accumulators	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area ESWB.
FB	Auxiliary Steam	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area ESWB.
FC	Auxiliary Turbines	R, H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area ESWB.
GD	ESW Pump House HVAC	S	Train B ESW pump room ventilation may be affected. Train A ESW pump room ventilation is unaffected.
GF	AFW Pump Room Coolers	S	Due to the potential loss of the Train B ESW system, the Train B MDAFP room cooler may not be available. The Train A ESW system remains available to ensure operability of the Train A MDAFP room cooler.
GK	Control Room and Class 1E Switchgear Room Coolers	S	Due to the potential loss of the Train B ESW system, the Train B Class 1E electrical equipment room cooler may not be available. The Train A ESW system remains available to ensure operability of the Train A Class 1E electrical equipment room cooler.
GL	Auxiliary Building HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area ESWB.
GM	Emergency Diesel Generator Room HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area ESWB.
GN	Containment Coolers	S	Due to the potential loss of the Train B ESW system, the Train B containment coolers may not be available. The Train A ESW system remains available to ensure operability of the Train A containment coolers.
JE	Diesel Fuel Oil	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area ESWB.
KA	Instrument Air	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area ESWB.
KC	Fire Protection	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area ESWB.
KH	Service Gas	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area ESWB.
KJ	Standby Diesel Engine	S	The Train B diesel engine may be affected due to loss of Train B ESW. The Train A diesel generator is available.
MA	Main Generation	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area ESWB.
MR	Startup Transformer	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area ESWB.

Table ESWB-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area ESWB

System	System Name	PFSSD Function*	Comments
NB	4.16 kV System	S	The Train B NB system is not directly affected by a fire in this area since off-site power remains available. However, due to the potential loss of the Train B Class 1E Electrical Equipment Room Cooler (due to the potential loss of Train B ESW), the NB02 switchgear room temperature could increase beyond that allowed for the equipment to remain functional. Therefore, it is assumed that NB02 is unavailable. If operators require NB02, then they can enter SYS GK-200 to provide cooling to the Train B electrical equipment rooms from Train A Class 1E A/C Unit SGK05A.
NE	Standby Diesel Generator	S	The Train B diesel generator may be affected due to loss of Train B ESW. The Train A diesel generator is available.
NF	Load Shed and Emergency Load Sequencing	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area ESWB.
NG	480V Load Centers and MCCs	S	Train B ESW pump room MCC NG06E may be affected. Train A ESW pump room MCC NG05E is unaffected. Train B 480 VAC Load Centers and MCCs could be affected due to loss of NB02 (See NB System Comments). Train A 480 VAC Load Centers and MCCs are unaffected.
NK	125VDC	S	Train B Class 1E 125 VDC distribution switchboards could be affected due to the potential loss of Train B Class 1E Electrical Equipment A/C unit SGK05B. Operators can enter SYS GK-200 to provide cooling to the Train B electrical equipment rooms from Train A Class 1E A/C Unit SGK05A.
NN	120VAC	S	Train B Class 1E 120 VAC distribution switchboards could be affected due to the potential loss of Train B Class 1E Electrical Equipment A/C unit SGK05B. Operators can enter SYS GK-200 to provide cooling to the Train B electrical equipment rooms from Train A Class 1E A/C Unit SGK05A.
PA	13.8kV	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area ESWB.
PB	4.16kV	H, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area ESWB.
PG	480V Load Centers and MCCs	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area ESWB.
PK	125VDC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area ESWB.
PL	Local Instrument Panels	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area ESWB.
PN	120VAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area ESWB.

Table ESWB-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area ESWB

System	System Name	PFSSD Function*	Comments
QB	Standby AC Lighting	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area ESWB.
QD	Emergency Lighting	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area ESWB.
RL	Control Room MCB	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area ESWB.
RP	Miscellaneous Control Panels	R, M, H, P, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area ESWB.
SA	ESFAS	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area ESWB.
SB	Reactor Protection System	R, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area ESWB.
SC	Reactor Instrumentation	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area ESWB.
SE	Ex-Core Neutron Monitoring	R, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area ESWB.
SY	Switchyard	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area ESWB.
UU	Supervisory System	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area ESWB.

* R - Reactivity Control; M - Reactor Coolant Makeup; H - Decay Heat Removal; P - Process Monitoring; S - Support Function

3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD

This section describes operator actions that may need to be performed inside or outside the control room to achieve and maintain hot standby if a fire occurs in area ESWB. This section also describes cold shutdown repairs that may need to be made to achieve and maintain cold shutdown conditions. Operator actions are proceduralized in OFN KC-016.

3.1 ACTIONS OUTSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

None

3.2 ACTIONS INSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

3.2.1 Component Cooling Water

If Train B component cooling water (CCW) is operating at the time of the fire, it may be necessary to swap to Train A CCW due to the potential loss of Train B ESW.

3.3 ACTIONS TO ACHIEVE AND MAINTAIN COLD SHUTDOWN

None

4.0 CONCLUSION

Post-fire safe shutdown is assured if a fire occurs in area ESWB.

5.0 DETAILED ANALYSIS

This section describes the detailed component-by-component and cable-by-cable analysis for a fire in area ESWB.

5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA ESWB

PFSSD components (S. in E-15000) located in fire area ESWB are shown in Table ESWB-3. An evaluation of each component and associated cables is provided in the sections that follow. The applicable evaluation section is listed in Table ESWB-3.

5.1.1 Train B Essential Service Water (ESW)

This fire area contains equipment and cables associated with the Train B ESW system. Consequently, a fire in this area could result in a loss of Train B ESW, as well as all supported equipment. PFSSD equipment (excluding supported equipment) that requires Train B ESW is as follows:

- Train B containment air coolers
- Train B electrical penetration room cooler
- Train B component cooling water (CCW) pump room cooler
- Train B residual heat removal pump room cooler
- Train B centrifugal charging pump room cooler
- Train B class 1E electrical equipment A/C unit
- Train B control room A/C unit
- Train B motor driven auxiliary feedwater pump room cooler
- Train B auxiliary feedwater pump alternate supply (Note: condensate storage tank (CST) remains available)
- Turbine driven auxiliary feedwater pump alternate supply (Note: CST and Train B ESW remain available)
- Train B CCW heat exchanger
- Train B emergency diesel engine coolers

Loss of Train B ESW causes a loss of a number of Train B components. Therefore, Train B is not available in the event of a fire in the Train B ESW pump room. Train A ESW is unaffected and remains available to supply redundant Train A PFSSD equipment.

Based on the above discussion, a fire in area ESWB which affects the Train B ESW pump will not adversely impact the ability to safely shut down.

5.2 PFSSD CABLE EVALUATION

Table ESWB-4 lists all the PFSSD cables (S. in E-15000) located in fire area ESWB. The applicable evaluation section is also listed in Table ESWB-4.

All PFSSD cables that run in Fire Area ESWB terminate at their associated PFSSD equipment within Fire Area ESWB. Therefore, all cable evaluations are included with the equipment evaluations in Section 5.1. Any possible combination of hot shorts, open circuits or shorts to ground could prevent operation or cause mal-operation of the associated Train B equipment. Cables associated with redundant Train A equipment are unaffected and therefore PFSSD can be achieved.

1.0 GENERAL AREA DESCRIPTION

Fire area ESWV consists of the essential service water pumphouse vaults and includes the rooms listed in Table ESWV-1.

Table ESWV-1
Rooms Located in Fire Area ESWV

ROOM #	DESCRIPTION
Z118A/AV1	ESW Access Vault
Z118B/AV2	ESW Access Vault
Z118C/AV3	ESW Access Vault
Z118D/AV4	ESW Access Vault
Z118E/AV5	ESW Access Vault
Z118F/AV6	ESW Access Vault

Fire area ESWV has no automatic suppression or detection installed.

2.0 PRIMARY EQUIPMENT USED FOR PFSSD

Fire area ESWV contains no post-fire safe shutdown cables or equipment. Therefore, both trains of PFSSD equipment are available if a fire occurs in this area.

3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD

Not applicable to fire area ESWV.

4.0 CONCLUSION

Post-fire safe shutdown is assured if a fire occurs in this area.

5.0 DETAILED ANALYSIS

A detailed analysis is not required since this area contains no PFSSD cables or components.

FIRE AREA F-1

1.0 GENERAL AREA DESCRIPTION

Fire area F-1 is located on the 2000, 2032 and 2047 elevations of the Fuel Building and includes the rooms listed in Table F-1-1.

Table F-1-1
Rooms Located in Fire Area F-1

ROOM #	DESCRIPTION
6101	Stair F-1
6102	Laydown Area 2000 El
6103	Cask Loading Pool 2000 El
6106	Spent Fuel Pool and Storage Racks
6201	Passage

6205	Fuel Transfer Canal
6210	New Fuel Storage Area
6301	General Floor Area 2047 El
6302	Laydown Area 2047 El

Fire area F-1 is protected with an automatic pre-action sprinkler system in the Laydown Area on the 2000 elevation. In addition, thermal fire detectors are installed in the Laydown Area and infrared fire detectors are installed to detect fires on the 2047 elevation.

2.0 PRIMARY EQUIPMENT USED FOR PFSSD

Table F-1-2 lists each system credited for post-fire safe shutdown and provides a discussion regarding the availability of the system to perform its Post Fire Safe Shutdown (PFSSD) function if a severe fire occurs in this area. For a summary of the potential fire impact on some of the more significant PFSSD equipment, see Section 8.0 of the Fire Area Analysis Narrative section.

Table F-1-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area F-1

System	System Name	PFSSD Function*	Comments
AB	Main Steam	R, M, H, P, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area F-1.
AC	Main Turbine	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area F-1.
AE	Main Feedwater	H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area F-1.
AL	Aux. Feedwater System	H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area F-1.
AP	Condensate Storage System	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area F-1.
BB	Reactor Coolant System	R, M, H, P, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area F-1.
BG	Chemical and Volume Control System	R, M, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area F-1.

3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD

This section describes operator actions that may need to be performed inside or outside the control room to achieve and maintain hot standby if a fire occurs in area F-1. This section also describes cold shutdown repairs that may need to be made to achieve and maintain cold shutdown conditions. Operator actions are proceduralized in OFN KC-016.

3.1 ACTIONS OUTSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

None

3.2 ACTIONS INSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

None

3.3 ACTIONS TO ACHIEVE AND MAINTAIN COLD SHUTDOWN

None

4.0 CONCLUSION

Post-fire safe shutdown is assured if a fire occurs in this area.

5.0 DETAILED ANALYSIS

This section describes the detailed component-by-component and cable-by-cable analysis for a fire in area F-1.

5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA F-1

There are no PFSSD components (S. in E-15000) located in fire area F-1. This fire area only contains PFSSD cables associated with components located in other fire areas.

5.2 PFSSD CABLE EVALUATION

Table F-1-3 lists all the PFSSD cables (S. in E-15000) located in fire area F-1. The applicable evaluation section is also listed in Table F-1-3.

Table F-1-3
PFSSD Cables Located in Fire Area F-1

Cable #	Location	Primary PFSSD Equipment	Cable Function (P) Power (C) Control (I) Instrumentation	Evaluation Section	Comments
11BNI07CA	6301	BNLT0930	I	5.2.1	RWST Level Transmitter
12BNI07DA	6301	BNLT0931	I	5.2.1	RWST Level Transmitter

5.2.1 Refueling Water Storage Tank

The RWST is credited in the PFSSD analysis as the primary source of borated water to achieve cold shutdown. The Wolf Creek Technical Specifications ensure the minimum quantity and boron concentration is maintained to achieve cold shutdown. Therefore, RWST level transmitters, indicators and circuits are not evaluated for level indication.

The RWST level transmitters and associated circuits are included in the PFSSD analysis because of the automatic functions they perform. A low-low level in the RWST on 2 out of 4 RWST level transmitters, coincident with a safety injection signal, will provide a permissive for containment sump isolation valves EJHV8811A and EJHV8811B to open. This could cause the RWST to drain to the containment sump if the associated RWST to RHR valve does not close.

Cables associated with refueling water storage tank (RWST) level transmitters BNLT0930 and BNLT0931 are run in fire area F-1. Damage to these cables could initiate a spurious low-low RWST level signal. A spurious SIS is not credible if a fire occurs in area F-1. Therefore, the open permissive will not occur for valves EJHV8811A and EJHV8811B. Consequently, a spurious RWST draindown is not credible if a fire occurs in this area.

Based on the above discussion, the RWST is available if a fire occurs in area F-1.

1.0 GENERAL AREA DESCRIPTION

Fire area F-2 is located on the 2000 elevation of the Fuel Building and includes the room listed in Table F-2-1.

Table F-2-1
Rooms Located in Fire Area F-2

ROOM #	DESCRIPTION
6104	Fuel Pool Cooling Heat Exchanger Room West

Fire area F-2 is protected with an automatic smoke detection system throughout. There is no automatic suppression installed. The area is separated from all adjacent areas by minimum 3-hour fire resistant rated construction.

2.0 PRIMARY EQUIPMENT USED FOR PFSSD

Table F-2-2 lists each system credited for post-fire safe shutdown and provides a discussion regarding the availability of the system to perform its Post Fire Safe Shutdown (PFSSD) function if a severe fire occurs in this area. For a summary of the potential fire impact on some of the more significant PFSSD equipment, see Section 8.0 of the Fire Area Analysis Narrative section.

Table F-2-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area F-2

System	System Name	PFSSD Function*	Comments
AB	Main Steam	R, M, H, P, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area F-2.

3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD

This section describes operator actions that may need to be performed inside or outside the control room to achieve and maintain hot standby if a fire occurs in area F-2. This section also describes cold shutdown repairs that may need to be made to achieve and maintain cold shutdown conditions. Operator actions are proceduralized in OFN KC-016.

3.1 ACTIONS OUTSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

None

3.2 ACTIONS INSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

None

3.3 ACTIONS TO ACHIEVE AND MAINTAIN COLD SHUTDOWN

None

4.0 CONCLUSION

Post-fire safe shutdown is assured if a fire occurs in this area.

5.0 DETAILED ANALYSIS

This section describes the detailed component-by-component and cable-by-cable analysis for a fire in area F-2.

5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA F-2

There are no PFSSD components (S. in E-15000) located in fire area F-2. This fire area only contains PFSSD cables associated with components located in other fire areas.

5.2 PFSSD CABLE EVALUATION

Table F-2-3 lists all the PFSSD cables (S. in E-15000) located in fire area F-2. The applicable evaluation section is also listed in Table F-2-3.

Table F-2-3
PFSSD Cables Located in Fire Area F-2

Cable #	Location	Primary PFSSD Equipment	Cable Function (P) Power (C) Control (I) Instrumentation	Evaluation Section	Comments
11BNI07CA	6104	BNLT0930	I	5.2.1	RWST Level Transmitter
12BNI07DA	6104	BNLT0931	I	5.2.1	RWST Level Transmitter
13BNI07EC	6104	BNLT0932	I	5.2.1	RWST Level Transmitter
14BNI07FA	6104	BNLT0933	I	5.2.1	RWST Level Transmitter
16PGA10CA	6104	PA0206	C	5.2.2	Load Centers PG12, PG16 and PG26 Fdr Bkr

5.2.1 Refueling Water Storage Tank

The RWST is credited in the PFSSD analysis as the primary source of borated water to achieve cold shutdown. The Wolf Creek Technical Specifications ensure the minimum quantity and boron concentration is maintained to achieve cold shutdown. Therefore, RWST level transmitters, indicators and circuits are not evaluated for level control.

The RWST level transmitters and associated circuits are included in the PFSSD analysis because of the automatic functions they perform. A low-low level in the RWST on 2 out of 4 RWST level transmitters, coincident with a safety injection signal, will provide a permissive for containment sump isolation valves EJHV8811A and EJHV8811B to open. This could cause the RWST to drain to the containment sump if the associated RWST to RHR valve does not close.

Cables associated with all four RWST level transmitters are run in this area. Damage to these cables could initiate a spurious low-low RWST level signal. A spurious SIS is not credible if a fire occurs in area F-2. Therefore, the open permissive will not occur for valves EJHV8811A and EJHV8811B. Consequently, a spurious RWST draindown is not credible if a fire occurs in this area.

Based on the above discussion, there is reasonable assurance that the RWST will be available if a fire occurs in area F-2.

5.2.2 Load Center Feeder Breaker PA0206

Load center feeder breaker PA0206 is credited for PFSSD because it supplies power to credited non-safety related loads. Cable 16PGA10CA is a control cable associated with breaker PA0206. An intra-cable hot short in this cable will trip PA0206. Breaker PA0206 supplies power to the following PFSSD components:

- PG12KAF4 – Main Steam Supply to 2nd Stage Reheat Valve ABHV0032
- PG12KAF5 – Main Steam Supply to Steam Seals Valve ABHV0046
- PG12KEF3 – Auxiliary Steam System Control Valve FBHV0080

PG12KAF4, PG12KAF5 and PG12KEF3 supply power to components downstream of the MSIVs. The MSIVs are unaffected by a fire in this area and can be closed from the control room using either hand switch ABHS0079 or ABHS0080. Therefore, the MSIV downstream components are not required if a fire occurs in this area.

Based on the above discussion, loss of breaker PA0206 due to a fire in area F-2 will not adversely impact PFSSD.

1.0 GENERAL AREA DESCRIPTION

Fire area F-3 is located on the 2000 elevation of the Fuel Building and includes the room listed in Table F-3-1.

Table F-3-1
Rooms Located in Fire Area F-3

ROOM #	DESCRIPTION
6105	Train A Fuel Pool Cooling Heat Exchanger Room

Fire area F-3 is protected with automatic smoke detection. The area is separated on all sides by minimum 3-hour fire resistance rated barriers.

2.0 PRIMARY EQUIPMENT USED FOR PFSSD

Fire area F-3 contains no post-fire safe shutdown cables or equipment. Therefore, both trains of PFSSD equipment are available if a fire occurs in this area.

3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD

Not applicable to fire area F-3.

4.0 CONCLUSION

Post-fire safe shutdown is assured if a fire occurs in this area.

5.0 DETAILED ANALYSIS

A detailed analysis is not required since this area contains no PFSSD cables or components.

None

3.3 ACTIONS TO ACHIEVE AND MAINTAIN COLD SHUTDOWN

None

4.0 CONCLUSION

Post-fire safe shutdown is assured if a fire occurs in this area.

5.0 DETAILED ANALYSIS

This section describes the detailed component-by-component and cable-by-cable analysis for a fire in area F-4.

5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA F-4

There are no PFSSD components (S. in E-15000) located in fire area F-4. This fire area only contains PFSSD cables associated with components located in other fire areas.

5.2 PFSSD CABLE EVALUATION

Table F-4-3 lists all the PFSSD cables (S. in E-15000) located in fire area F-4. The applicable evaluation section is also listed in Table F-4-3.

Table F-4-3
PFSSD Cables Located in Fire Area F-4

Cable #	Location	Primary PFSSD Equipment	Cable Function (P) Power (C) Control (I) Instrumentation	Evaluation Section	Comments
14BNI07FA	6203	BNLT0933	I	5.2.1	RWST Level Transmitter
15PGA10AA	6203	PA0105	C	5.2.2	Load Centers PG11, PG13 and PG25 Fdr Bkr

5.2.1 Refueling Water Storage Tank

The RWST is credited in the PFSSD analysis as the primary source of borated water to achieve cold shutdown. The Wolf Creek Technical Specifications ensure the minimum quantity and boron concentration is maintained to achieve cold shutdown. Therefore, RWST level transmitters, indicators and circuits are not evaluated for level control.

The RWST level transmitters and associated circuits are included in the PFSSD analysis because of the automatic functions they perform. A low-low level in the RWST on 2 out of 4 RWST level transmitters, coincident with a safety injection signal, will provide a permissive for containment sump isolation valves EJHV8811A and EJHV8811B to open. This could cause the RWST to drain to the containment sump if the associated RWST to RHR valve does not close.

A cable associated with refueling water storage tank (RWST) level transmitter BNLT0933 runs in fire area F-4. Cables for the remaining three RWST level transmitters are unaffected. Therefore, a spurious low-low level in the RWST is not credible if a fire occurs in this area.

Based on the above discussion, the RWST is available if a fire occurs in area F-4.

5.2.2 Load Center Feeder Breaker PA0105

Load center feeder breaker PA0105 is credited for PFSSD because it supplies power to credited non-safety related loads. Cable 15PGA10AA associated with PA0105 is run in this area. A fire induced short circuit in this cable will trip breaker PA0105.

Breaker PA0105 supplies power to the following PFSSD components:

- PG11JFR2 – Main Steam Supply to 2nd Stage Reheat Valve ABHV0031
- PG11KBR3 – Auxiliary Steam System Control Valve FBHV0081

PG11JFR2 and PG11KBR3 supply power to components downstream of the MSIVs. The MSIVs are unaffected by a fire in this area and can be closed from the control room using hand switch ABHS0079. Therefore, the MSIV downstream components are not required if a fire occurs in this area.

Based on the above discussion, loss of breaker PA0105 will not adversely affect PFSSD if a fire occurs in this area.

3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD

This section describes operator actions that may need to be performed inside or outside the control room to achieve and maintain hot standby if a fire occurs in area F-5. This section also describes cold shutdown repairs that may need to be made to achieve and maintain cold shutdown conditions. Operator actions are proceduralized in OFN KC-016.

3.1 ACTIONS OUTSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

None

3.2 ACTIONS INSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

None

3.3 ACTIONS TO ACHIEVE AND MAINTAIN COLD SHUTDOWN

None

4.0 CONCLUSION

Post-fire safe shutdown is assured if a fire occurs in this area.

5.0 DETAILED ANALYSIS

This section describes the detailed component-by-component and cable-by-cable analysis for a fire in area F-5.

5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA F-5

There are no PFSSD components (S. in E-15000) located in fire area F-5. This fire area only contains PFSSD cables associated with components located in other fire areas.

5.2 PFSSD CABLE EVALUATION

Table F-5-3 lists all the PFSSD cables (S. in E-15000) located in fire area F-5. The applicable evaluation section is also listed in Table F-5-3.

Table F-5-3
PFSSD Cables Located in Fire Area F-5

Cable #	Location	Primary PFSSD Equipment	Cable Function (P) Power (C) Control (I) Instrumentation	Evaluation Section	Comments
11BNI07CA	6202	BNLT0930	I	5.2.1	RWST Level Transmitter
12BNI07DA	6202	BNLT0931	I	5.2.1	RWST Level Transmitter
13BNI07EC	6202	BNLT0932	I	5.2.1	RWST Level Transmitter
14BNI07FA	6202	BNLT0933	I	5.2.1	RWST Level Transmitter
15PGA10AA	6202	PA0105	C	5.2.2	Load Centers PG11, PG13 and PG25 Fdr Bkr
16PGA10CA	6202	PA0206	C	5.2.2	Load Centers PG12, PG16 and PG26 Fdr Bkr

5.2.1 Refueling Water Storage Tank

The RWST is credited in the PFSSD analysis as the primary source of borated water to achieve cold shutdown. The Wolf Creek Technical Specifications ensure the minimum quantity and boron concentration is maintained to achieve cold shutdown. Therefore, RWST level transmitters, indicators and circuits are not evaluated for level control.

The RWST level transmitters and associated circuits are included in the PFSSD analysis because of the automatic functions they perform. A low-low level in the RWST on 2 out of 4 RWST level transmitters, coincident with a safety injection signal, will provide a permissive for containment sump isolation valves EJHV8811A and EJHV8811B to open. This could cause the RWST to drain to the containment sump if the associated RWST to RHR valve does not close.

Cables associated with all four RWST level transmitters are run in this area. Damage to these cables could initiate a spurious low-low RWST level signal. A spurious SIS is not credible if a fire occurs in area F-5. Therefore, the open permissive will not occur for valves EJHV8811A and EJHV8811B. Consequently, a spurious RWST draindown is not credible if a fire occurs in this area.

Based on the above discussion, there is reasonable assurance that the RWST will be available if a fire occurs in area F-5.

5.2.2 Load Center Feeder Breakers PA0105 and PA0206

Load center feeder breakers PA0105 and PA0206 are credited for PFSSD because they supply power to credited non-safety related loads.

Cable 15PGA10AA associated with PA0105 is run in this area. A fire induced short circuit in this cable will trip breaker PA0105.

Breaker PA0105 supplies power to the following PFSSD components:

- PG11JFR2 – Main Steam Supply to 2nd Stage Reheat Valve ABHV0031
- PG11KBR3 – Auxiliary Steam System Control Valve FBHV0081

PG11JFR2 and PG11KBR3 supply power to components downstream of the MSIVs. The MSIVs are unaffected by a fire in this area and can be closed from the control room using hand switch ABHS0079. Therefore, the MSIV downstream components are not required if a fire occurs in this area.

Cable 16PGA10CA is a control cable associated with breaker PA0206. An intra-cable hot short in this cable will trip PA0206.

Breaker PA0206 supplies power to the following PFSSD components:

- PG12KAF4 – Main Steam Supply to 2nd Stage Reheat Valve ABHV0032
- PG12KAF5 – Main Steam Supply to Steam Seals Valve ABHV0046
- PG12KEF3 – Auxiliary Steam System Control Valve FBHV0080

PG12KAF4, PG12KAF5 and PG12KEF3 supply power to components downstream of the MSIVs. The MSIVs are unaffected by a fire in this area and can be closed from the control room using either hand switch ABHS0079 or ABHS0080. Therefore, the MSIV downstream components are not required if a fire occurs in this area.

Based on the above discussion, loss of breakers PA0105 and PA0206 due to a fire in area F-5 will not adversely impact PFSSD.

3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD

This section describes operator actions that may need to be performed inside or outside the control room to achieve and maintain hot standby if a fire occurs in area F-7. This section also describes cold shutdown repairs that may need to be made to achieve and maintain cold shutdown conditions. Operator actions are proceduralized in OFN KC-016.

3.1 ACTIONS OUTSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

None

3.2 ACTIONS INSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

None

3.3 ACTIONS TO ACHIEVE AND MAINTAIN COLD SHUTDOWN

None

4.0 CONCLUSION

Post-fire safe shutdown is assured if a fire occurs in this area.

5.0 DETAILED ANALYSIS

This section describes the detailed component-by-component and cable-by-cable analysis for a fire in area F-7.

5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA F-7

There are no PFSSD components (S. in E-15000) located in fire area F-7. This fire area only contains PFSSD cables associated with components located in other fire areas.

5.2 PFSSD CABLE EVALUATION

Table F-7-3 lists all the PFSSD cables (S. in E-15000) located in fire area F-7. The applicable evaluation section is also listed in Table F-7-3.

Table F-7-3
PFSSD Cables Located in Fire Area F-7

Cable #	Location	Primary PFSSD Equipment	Cable Function (P) Power (C) Control (I) Instrumentation	Evaluation Section	Comments
11BNI07CA	6303	BNLT0930	I	5.2.1	RWST Level Transmitter
12BNI07DA	6303	BNLT0931	I	5.2.1	RWST Level Transmitter
13BNI07EC	6303	BNLT0932	I	5.2.1	RWST Level Transmitter

5.2.1 Refueling Water Storage Tank

The RWST is credited in the PFSSD analysis as the primary source of borated water to achieve cold shutdown. The Wolf Creek Technical Specifications ensure the minimum quantity and boron concentration is maintained to achieve cold shutdown. Therefore, RWST level transmitters, indicators and circuits are not evaluated for level control.

The RWST level transmitters and associated circuits are included in the PFSSD analysis because of the automatic functions they perform. A low-low level in the RWST on 2 out of 4 RWST level transmitters, coincident with a safety injection signal, will provide a permissive for containment sump isolation valves EJHV8811A and EJHV8811B to open. This could cause the RWST to drain to the containment sump if the associated RWST to RHR valve does not close.

Cables associated with three of four RWST level transmitters are run in this area. Damage to these cables could initiate a spurious low-low RWST level signal. A spurious SIS is not credible if a fire occurs in area F-7. Therefore, the open permissive will not occur for valves EJHV8811A and EJHV8811B. Consequently, a spurious RWST draindown is not credible if a fire occurs in this area.

Based on the above discussion, there is reasonable assurance that the RWST will be available if a fire occurs in area F-7.

4.0 CONCLUSION 11
5.0 DETAILED ANALYSIS 11
5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA RB 11
5.2 PFSSD CABLE EVALUATION 33

1.0 GENERAL AREA DESCRIPTION

The Reactor Building is divided into 11 fire areas as described in Table RB-1.

Table RB-1
Fire Areas Located Inside the Reactor Building

FIRE AREA	DESCRIPTION
RB-1	Area within the secondary shield wall, elevation 2000-0
RB-2	Area outside the secondary shield wall, elevation 2000-0
RB-3	North electrical penetration area, elevation 2026-0
RB-4	South electrical penetration area, elevation 2026-0
RB-5	Cable tray area, elevation 2047-6
RB-6	Reactor building elevation 2068-8
RB-7	West area, elevation 2026-0
RB-8	East area, elevation 2026-0
RB-9	Tendon access gallery
RB-10	Reactor building, elevation 2047-6 except cable tray area
RB-11	Area within primary shield wall

There are no physical barriers within the reactor building meeting the requirements of 10CFR50, Appendix R Section III.G.2.a. There are, however, substantial concrete barriers that would likely resist the spread of fire between adjacent sides. Separation of redundant PFSSD cables and equipment within non-inerted containments is required to meet one of the following requirements of Appendix R Section III.G.2:

III.G.2.d *Separation of cables and equipment and associated non-safety circuits of redundant trains by a horizontal distance of more than 20 feet with no intervening combustibles or fire hazards;*

III.G.2.e *Installation of fire detectors and an automatic fire suppression system in the fire area; or*

III.G.2.f *Separation of cables and equipment and associated non-safety circuits of redundant trains by a non-combustible radiant energy shield.*

Fire areas RB-3 and RB-4 have automatic fire detection and a fixed, manually charged fire suppression system installed. Each manually charged fire suppression system is comprised of closed sprinkler heads installed over cable tray concentrations in the area. Each fire detection system consists of line-type fire detection installed in the vicinity of the cable trays. Actuation of the fire detection system will alert operators of a fire in the area, and the sprinkler system piping can be charged by manually opening valves KCV0427 in the North pipe penetration room and KCHV0253 from the control room. This configuration was approved by the NRC in the SER and meets the intent of Appendix R, Section III.G.2.e stated above.

Each RCP is provided with an oil collection system meeting the Wolf Creek commitments to 10CFR50, Appendix R Section III.O. Linear heat detection is also installed above each reactor coolant pump (RCP). During power operation, fire hazards within the reactor building are limited to cables and lubricants contained within valve operators and motors and that allowed by administrative procedures. Cables are run in conduits and cable trays throughout the building.

Many of the cable trays are provided with metal covers on the top and/or bottom, which function to limit fire hazard potential of the enclosed cables. Cables are IEEE 383 rated, which are combustible, but tests have shown will self-extinguish if the ignition source is removed.

Eleven (11) fire detection zones are provided in containment. Each zone, when actuated, annunciates a specific location description in the control room which allows operators to identify the approximate location of the fire.

2.0 PRIMARY EQUIPMENT USED FOR PFSSD

Table RB-2 lists each system credited for post-fire safe shutdown and provides a discussion regarding the availability of the system to perform its Post Fire Safe Shutdown (PFSSD) function if a severe fire occurs in this area. For a summary of the area analysis results, see Section 8.0 of the Fire Area Analysis Narrative section.

Table RB-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area RB

System	System Name	PFSSD Function*	Comments
AB	Main Steam	R, M, H, P, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area RB. All three steam generator pressure indicators on all four steam generators are available.
AC	Main Turbine	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area RB.
AE	Main Feedwater	H, P	All PFSSD functions associated with the main feedwater system are satisfied. Steam generator level indication on at least two steam generators is available. See Section 5.1.9 for details.
AL	Aux. Feedwater System	H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area RB.
AP	Condensate Storage System	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area RB.
BB	Reactor Coolant System	R, M, H, P, S	All PFSSD functions associated with the reactor coolant system are satisfied. Loss of inventory through the head vent valves is prevented by maintaining valves BBHV8001A and either BBHV8001B or BBHV8002B closed. Pressurizer level indication is available using BBLI0460A unless a fire alarm is indicated on alarm windows 138, 139 or 148. If this is the case, then monitor BBLI0459A, BBLI0460A, BBLI0461 and BBLI0462 to determine an accurate level reading. At least three of these indicators should trend the same. Pressurizer pressure indication is available using BBPI0456 unless a fire alarm is indicated on alarm windows 138, 139 or 148. If this is the case, then monitor BBPI0455A, BBPI0456, BBPI0457 and BBPI0458 to determine an accurate pressure reading. At least three of these indicators should trend the same. A spurious SIS due to low pressurizer pressure on two out of four pressurizer pressure transmitters is mitigated by entering the EMG procedure network and, if necessary, placing EMHIS0004 and EMHIS0005 in pull-to-lock. When transferring to RHR, valves BBPV8702A or BBPV8702B may need to be manually opened to provide a suction source from the RCS to RHR pump A or B. It is expected that the fire will be extinguished, and the smoke cleared before this action is necessary. RCP thermal barrier cooling could be affected due to spurious closure of BBHV0013, BBHV0014, BBHV0015 and BBHV0016. All four reactor coolant pumps may not stop using the control room hand switch. RCP seal injection remains available. Therefore, the inability to stop the RCPs will have no adverse impact on PFSSD. Pressurizer spray valves BBPCV0455B and BBPCV0455C could spuriously open. If this occurs, pressurizer spray can be stopped by closing KAFV0029 using KAHIS0029 in the main control room.

Table RB-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area RB

System	System Name	PFSSD Function*	Comments
BG	Chemical and Volume Control System	R, M, S	All PFSSD functions associated with the chemical and volume control system are satisfied. A spurious opening of the excess letdown isolation valves can be mitigated by opening breaker NK4119 to fail close valves BGHV8153A and BGHV8154A and opening breaker NK4407 to fail close valves BGHV8153B and BGHV8154B. Breaker NK4119 is located in fire area C-16 and breaker NK4407 is located in fire area C-15. Letdown isolation valves BGLCV0459 and BGLCV0460 and letdown orifice valves BGHV8149A, BGHV8149B, and BGHV8149C may need to be failed closed by closing valve KAFV0029 using KAHIS0029 in the main control room.
BM	Steam Generator Blowdown System	R, M, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area RB.
BN	Borated Refueling Water Storage System	R, M, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area RB.
EF	Essential Service Water System	H, S	All PFSSD functions associated with the essential service water system are satisfied. Essential service water flow to the containment coolers is available by using either Train A or Train B containment isolation valves (EFHVXXXX).
EG	Component Cooling Water System	S	CCW flow to the RCP thermal barriers could be affected due to spurious closure of EGHV0062 and EGHV0132 and as discussed in BB System comments above. CCW flow indicators EGFI0128 and EGFI0129 are unaffected.
EJ	Residual Heat Removal System	M, H, P	All PFSSD functions associated with the residual heat removal system are satisfied. Draindown of the RCS and RWST to the containment sump is prevented by maintaining valves EJHV8811A and EJHV8811B closed. When transferring to RHR, valves EJHV8701A or EJHV8701B may need to be manually opened to provide a suction source from the RCS to RHR pump A or B. It is expected that the fire will be extinguished, and the smoke cleared before this action is necessary.
EM	High Pressure Coolant Injection	R, M	All PFSSD functions associated with the high-pressure coolant injection system are satisfied. A spurious start of the SI Pumps due to 2/4 low pressurizer pressure signals can be mitigated by entering the EMG procedure network and placing the pump control hand switches EMHIS0004 and EMHIS0005 on panel RL017 in pull-to-lock. Valve EMHV8964 is available to prevent loss of charging flow through the SIS test line.

Table RB-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area RB

System	System Name	PFSSD Function*	Comments
EN	Containment Spray	R, M	The PFSSD function(s) associated with this system is(are) not affected by a fire in area RB.
EP	Safety Injection Accumulators	H	A containment entry may be required to close EPHV8808A, EPHV8808B, EPHV8808C and EPHV8808D prior to the RCS reaching 1000 psig.
FB	Auxiliary Steam	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area RB.
FC	Auxiliary Turbines	R, H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area RB.
GD	ESW Pump House HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area RB.
GF	AFW Pump Room Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area RB.
GK	Control Room and Class 1E Switchgear Room Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area RB.
GL	Auxiliary Building HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area RB.
GM	Emergency Diesel Generator Room HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area RB.
GN	Containment Coolers	S	The PFSSD Support function associated with the Containment Coolers is satisfied. Either the Train A or Train B containment coolers are available, depending on the location of the fire. Containment pressure indicators GNPI0934, GNPI0935, GNPI0936 and GNPI0937 are available.
JE	Diesel Fuel Oil	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area RB.
KA	Instrument Air	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area RB.
KC	Fire Protection	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area RB.
KH	Service Gas	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area RB.
KJ	Standby Diesel Engine	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area RB.

Table RB-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area RB

System	System Name	PFSSD Function*	Comments
MA	Main Generation	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area RB.
MR	Startup Transformer	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area RB.
NB	4.16 kV System	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area RB.
NE	Standby Diesel Generator	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area RB.
NF	Load Shed and Emergency Load Sequencing	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area RB.
NG	480V Load Centers and MCCs	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area RB.
NK	125VDC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area RB.
NN	120VAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area RB.
PA	13.8kV	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area RB.
PB	4.16kV	H, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area RB.
PG	480V Load Centers and MCCs	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area RB.
PK	125VDC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area RB.
PL	Local Instrument Panels	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area RB.
PN	120VAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area RB.
QB	Standby AC Lighting	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area RB.
QD	Emergency Lighting	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area RB.

Table RB-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area RB

System	System Name	PFSSD Function*	Comments
RL	Control Room MCB	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area RB.
RP	Miscellaneous Control Panels	R, M, H, P, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area RB.
SA	ESFAS	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area RB.
SB	Reactor Protection System	R, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area RB.
SC	Reactor Instrumentation	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area RB.
SE	Ex-Core Neutron Monitoring	R, P	All PFSSD functions associated with the ex-core neutron monitoring system are satisfied. Source range monitoring is available using any available detector (SE02, SE04, SE06 or SE08), depending on the location of the fire.
SY	Switchyard	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area RB.
UU	Supervisory System	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area RB.

* R - Reactivity Control; M - Reactor Coolant Makeup; H - Decay Heat Removal; P - Process Monitoring; S - Support Function

3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD

This section describes operator actions that may need to be performed inside or outside the control room to achieve and maintain hot standby if a fire occurs in area RB. This section also describes cold shutdown repairs that may need to be made to achieve and maintain cold shutdown conditions. Operator actions are generally described in OFN KC-016.

3.1 ACTIONS OUTSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

Operator Manual Actions (OMAs) are those actions outside the main control room required to achieve and maintain hot standby. OMAs are identified in E-1F9900 and were determined from thermal hydraulic analysis WCNOC-CP-002. Applicable E-1F9900 OMAs are annotated herein. All other actions outside the control room are desirable for plant control in support of hot standby but not required to achieve and maintain hot standby.

3.1.1 Excess Letdown Isolation Valves

A spurious opening of the excess letdown isolation valves can be mitigated by opening breaker NK4119 to fail close valves BGHV8153A and BGHV8154A and opening breaker NK4407 to fail close valves BGHV8153B and BGHV8154B. Breaker NK4119 is located in fire area C-16 and breaker NK4407 is located in fire area C-15.

3.2 ACTIONS INSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

3.2.1 Safety Injection

A spurious Safety Injection Signal (SIS) can be mitigated by consulting EMG E-0 and terminating the spurious SIS.

3.2.2 Normal Pressurizer Spray

Pressurizer spray valves BBPCV0455B and BBPCV0455C could spuriously open. If this occurs, the spray can be stopped by isolating air to the valves. This can be accomplished by depressing the CLOSE push button on KAHIS0029 to close KAFV0029. KAHIS0029 is located on RL024. Pressurizer pressure indication is available using BBPI0456 unless a fire alarm is indicated on alarm windows 138, 139 or 148. If this is the case, then monitor BBPI0455A, BBPI0456, BBPI0457 and BBPI0458 to determine an accurate pressure reading. At least three of these indicators should trend the same.

3.2.3 Isolation of Letdown

A fire in area RB could prevent valves BGLCV0459 and BGLCV0460 from being closed using their associated control room hand switches. If this occurs, the valves can be closed by isolating air to the valves. This can be accomplished by depressing the CLOSE push button on KAHIS0029 to close KAFV0029. KAHIS0029 is located on RL024. Pressurizer level indication is available using BBLI0459A or BBLI0460A, depending on the location of the fire.

3.3 ACTIONS TO ACHIEVE AND MAINTAIN COLD SHUTDOWN

3.3.1 RHR Initiation

When transferring to RHR for cold shutdown, it may be necessary to make a containment entry to manually open BBPV8702A or BBPV8702B and EJHV8701A or EJHV8701B, if unresponsive from the control room. It is expected that the fire will be extinguished, and the smoke cleared before this action is necessary.

3.3.2 SI Accumulators

A containment entry may be required to close EPHV8808A, EPHV8808B, EPHV8808C and EPHV8808D prior to the RCS reaching 1000 psig. It is expected that the fire will be extinguished, and the smoke cleared before this action is necessary.

3.3.3 Excess Letdown Flowpath

It may be necessary to manually open BBHV8157A or BBHV8157B to establish a flowpath from the excess letdown heat exchanger to the PRT. It may also be necessary to close switch NK4119 to re-open valves BGHV8153A and BGHV8154A or close switch NK4407 to re-open BGHV8153B and BGHV8154B to establish a flowpath from the RCS to the excess letdown heat exchanger. Cable repairs may be necessary prior to closing these switches.

4.0 CONCLUSION

With some exceptions, redundant Post-Fire Safe Shutdown capability exists if a severe fire occurs in this area. For those exceptions, feasible manual actions are available and are unaffected by the fire. Manual actions are documented in Section 3.0.

5.0 DETAILED ANALYSIS

This section describes the detailed component-by-component and cable-by-cable analysis for a fire in area RB.

5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA RB

PFSSD components (S. in E-15000) located in fire area RB are shown in Table RB-3. An evaluation of each component and associated cables is provided in the sections that follow. The applicable evaluation section is listed in Table RB-3.

5.1.1 Source Range Monitoring

The reactivity control function of PFSSD requires source range flux monitoring to be available. The PFSSD logic uses four source range detectors and associated cables and components to establish source range monitoring. The four source range detectors are listed in Table RB-4.

Table RB-4
Source Range Detectors used for PFSSD

DETECTOR	DESCRIPTION
SE02	Source range channel N31 (SENE0031) Sep. Group 1
SE04	Post-Accident Source Range (SENY0060A/B) Sep. Group 1
SE06	Source range channel N32 (SENE0032) Sep. Group 2
SE08	Post-Accident Source Range (SENY0061A/B) Sep. Group 4

The two source range detectors (SE02 and SE06) are positioned at 0 and 180 degree locations and the post-accident detectors (SE04 and SE08) are positioned at 90 and 270 degree locations.

A fire in area RB-11 is not expected to involve all four source range detectors. The combustible loading is very low and consists mainly of polyethylene canisters surrounding the detectors and IEEE 383 rated cables running to the detectors. There are no transient combustibles in the area during power operation. A fire would most likely involve a single detector, but not all four.

Cables associated with the four source range detectors are run in conduit throughout the reactor building. The cables are adequately separated such that any single credible fire will not affect all four source range detectors. The worse-case credible fire scenario occurs on the North end of area RB-1 at the 2000'-0" elevation. A fire in this area could damage cables for source range detectors SE02, SE04 and SE08 but source range detector SE06 would not be affected due to horizontal separation greater than 20 feet with limited quantities of intervening combustibles. A fire in any other area of the reactor building will not affect more than two source range detectors.

Based on the above discussion, there is reasonable assurance that a fire in the reactor building will not affect source range monitoring capability on at least one source range monitor.

5.1.2 SI/RHR Discharge To RCS Loops 2 and 3 Check Valves

Check valves BB8949B and BB8949C are listed in the PFSSD component list in Calculation XX-E-013, Appendix 3 and are listed as S. components in E-15000. These check valves isolate high/low pressure interface boundaries by preventing backflow from the RCS to the RHR/SI systems.

The check valves are mechanical devices and have no electrical interface that, if damaged, could fail the valves in the wrong position. Although the check valves, or redundant counterparts, are not separated per the requirements of 10CFR50, Appendix R, a postulated fire in area RB-1 is not expected to prevent the operation of these check valves. The valves are normally closed due to high RCS pressure pushing the clapper against the valve seat. Given the low fire loading coupled with the large area volume, there is reasonable assurance that a fire in the area will not prevent the valves from performing their PFSSD function.

References: E-15000, XX-E-013, M-12BB01, M-13EM03

5.1.3 RCS Hot Leg To RHR Pump Suction Isolation Valves

The RCS to RHR pump flow path is required to be isolated during hot standby and at least one flow path be available for cold shutdown. RHR pump suction from the RCS is controlled by valves BBPV8702A and EJHV8701A (Train A) and BBPV8702B and EJHV8701B (Train B). For hot standby, either BBPV8702A or EJHV8701A and either BBPV8702B or EJHV8701B needs to be closed. During cold shutdown, the operating train RHR pump needs to draw suction from the RCS.

Valves BBPV8702A and BBPV8702B are located in fire area RB-1. Valve BBPV8702A is located between steam generator (SG) A and reactor coolant pump (RCP) A. Valve BBPV8702B is located between SG B and RCP B. These valves are separated by at least 20 feet of horizontal separation with limited quantities of intervening combustibles. A fire in the vicinity of Loop 1 could damage BBPV8702A but, due to horizontal separation, limited combustible loading, and large spatial volume, there is reasonable assurance that the fire will not affect valve BBPV8702B. Alternatively, a fire in the vicinity of Loop 4 could damage BBPV8702B but, due to horizontal separation, limited combustible loading, and large spatial volume, there is reasonable assurance that the fire will not affect valve BBPV8702A.

Cables for BBPV8702A are run in conduit to the North secondary shield wall then run West through the barrier opening into fire area RB-2. The cables enter a cable tray and run South to the South-West portion of the Reactor Building. The cables are then run in tray up to the South electrical penetration area (Fire Area RB-4) where they enter the Auxiliary Building through penetration ZSI233.

Cables for BBPV8702B are run in conduit to the South secondary shield wall then penetrate the shield wall into fire area RB-2. The cables enter a cable tray in the South portion of area RB-2 and run to the South-West portion of area RB-2 in a common tray as cables for valve BBPV8702A. The cables are then run in tray up to the South electrical penetration area (Fire Area RB-4) where they enter the Auxiliary Building through penetration ZSI233.

A fire in area RB-4 or in the South-West portion of area RB-2 could damage power and control cables for both valves BBPV8702A and BBPV8702B. The damage will not cause either valve to spuriously open unless a 3-phase inter-cable hot short occurs. Based on a review of E-15000 (Setroute), there are no normally energized 3-phase source conductors in the same raceway as the power cables for these valves, except in the cable penetration area (fire area RB-4). In fire area RB-4, 480 volt 3-phase power cables for valves BBPV8702A and BBPV8702B, and hydrogen mixing fan motors DCGN03B and DCGN03D are common in tray 124U2A32. All four cables then pass through penetration ZSI233 and enter the Auxiliary Building. Fire area RB-4 is provided with automatic fire detection and a fixed, manually charged fire suppression system. This arrangement satisfies Wolf Creek's commitments to 10 CFR 50, Appendix R for protection of redundant PFSSD circuits inside non-inerted containments and as approved by the NRC in SER Section 9.5.1.4. Therefore, a fire in this location is not postulated to cause a 3-phase hot short that spuriously opens valves BBPV8702A and BBPV8702B. In the unlikely event that valves BBPV8702A and/or BBPV8702B spuriously open, valves EJHV8701A and EJHV8701B will remain closed, as discussed below.

Valves EJHV8701A and EJHV8701B are located in fire area RB-2. Valve EJHV8701A is located in the North-West portion of area RB-2. Valve EJHV8701B is located in the South-West portion of area RB-2. The valves are separated by at least 20 feet of horizontal separation with limited quantities of intervening combustibles.

Cables for valve EJHV8701A are run primarily in tray to the North portion of area RB-2 then run up to the North electrical penetration area (Fire Area RB-3) and into the Auxiliary Building through penetration ZNI277.

Cables for valve EJHV8701B are run primarily in tray to the North portion of area RB-2 and share a common enclosure with cables for valve EJHV8701A. The cables run up to the North electrical penetration area (Fire Area RB-3) and into the Auxiliary Building through penetration ZNI277.

A fire in area RB-3 or in the North portion of area RB-2 could damage power and control cables associated with both valves EJHV8701A and EJHV8701B. The damage will not cause either valve to spuriously open unless a 3-phase inter-cable hot short occurs. However, power cables for valves EJHV8701A and EJHV8701B are not run in common raceway with any normally energized 3-phase power cables within the Reactor Building. Therefore, neither valve EJHV8701A nor EJHV8701B will spuriously open if a fire occurs in the Reactor Building.

When transferring to RHR for cold shutdown, it may be necessary to make a containment entry to manually open the required train valves if unresponsive from the control room. Since this action is required for cold shutdown, it is anticipated that the fire will be extinguished, and the smoke cleared.

Based on the above discussion, a fire in the Reactor Building will not impact the ability to maintain the RCS to RHR flow path closed during hot standby. A containment entry may be necessary for cold shutdown to open the appropriate flow path valves when transferring to RHR. This would require operators to traverse the fire affected area but can be accomplished well after the fire has been extinguished.

References: E-15000, XX-E-013, E-13BB12A, E-13BB12B, E-13EJ05A, E-13EJ05B, M-12BB01, M-12EJ01, E-1F9205, E-1F9301, E-1R2312A, E-1R2312B, E-1R2312C, E-1R2908A

5.1.4 RCS Hot and Cold Leg Temperature Elements

PFSSD requires RCS hot and cold leg temperature indication on at least one loop to verify natural circulation flow. The temperature elements used for this purpose are listed in Table RB-5.

Table RB-5
RCS Hot and Cold Leg Temperature Elements Used for PFSSD

COMPONENT	FUNCTION
BBTE0413A	RCS Hot Leg Temperature Element (WR) Loop 1
BBTE0413B	RCS Cold Leg Temperature Element (WR) Loop 1
BBTE0423A	RCS Hot Leg Temperature Element (WR) Loop 2
BBTE0423B	RCS Cold Leg Temperature Element (WR) Loop 2
BBTE0433A	RCS Hot Leg Temperature Element (WR) Loop 3
BBTE0433B	RCS Cold Leg Temperature Element (WR) Loop 3
BBTE0443A	RCS Hot Leg Temperature Element (WR) Loop 4
BBTE0443B	RCS Cold Leg Temperature Element (WR) Loop 4

Loops 1 and 4 temperature elements are located in the West portion of area RB-1. Loops 2 and 3 temperature elements are located in the East portion of area RB-1. Except for the lubricating oil contained in each reactor coolant pump (RCP), the area contains limited

quantities of combustible materials. The RCP lubricating oil is not considered a significant fire hazard potential due to the oil collection system installed to meet Wolf Creeks commitments to 10CFR50, Appendix R Section III.O.

Cables associated with separation group 1 temperature elements (BBTE0413A, BBTE0423A, BBTE0433B and BBTE0443B) are run from their respective terminal box to the North electrical penetration room (Fire Area RB-3), where they enter the Auxiliary Building through penetration ZNI287. All four cables share a common enclosure in area RB-3. The cable for BBTE0413A does not share a common enclosure with the other three except in area RB-3. Cables for BBTE0423A, BBTE0433B and BBTE0443B share a common tray enclosure in the Northeast and North portions of area RB-2. Cables for BBTE0433B and BBTE0443B share a common enclosure in the East and Southeast portions of area RB-2 as well as the South portion of area RB-1.

Cables associated with separation group 2 temperature elements (BBTE0413B, BBTE0423B, BBTE0433A and BBTE0443A) are run from their respective terminal box to a common unscheduled junction box located at elevation 2029' - 6" at the NW corner of the primary shield wall in area RB-1. From this junction box, the four cables are run together in conduit up to the 2047' - 6" elevation (Fire Area RB-10) then run West through the SG D shield wall and finally South to the area above the South electrical penetration area. The conduit then turns down and runs into the South electrical penetration area (Fire Area RB-4) where all four cables enter the Auxiliary Building through penetration ZSI243.

Due to the limited quantities of combustibles and the large open spaces in the reactor building, there are no credible fire scenarios that would cause a loss of all eight temperature elements. The worse-case scenario occurs if a fire starts on the West side of area RB-1 on the 2000 elevation, where cables for six temperature elements are run. These temperature elements include all four separation group 2 elements (BBTE0413B, BBTE0423B, BBTE0433A and BBTE0443A) and two separation group 1 elements (BBTE0413A and BBTE0443B). Cables for the remaining two temperature elements (BBTE0423A and BBTE0433B) would not be affected by this postulated fire.

In the worse-case scenario described above, only the RCS Hot Leg Temperature Element (WR) Loop 2 and the RCS Cold Leg Temperature Element (WR) Loop 3 would survive the fire. In addition, procedure EMG ES-04, Attachment B describes alternate indication that can be used to determine natural circulation flow. One of these methods verifies that steam generator pressure is decreasing. All steam generator pressure instruments are located outside containment and will be available if a fire occurs in the reactor building.

Although at least two RCS temperature elements would survive a postulated fire in containment, it would be difficult for operators to know which temperature elements they can rely on because there is no way to know the exact location of a fire without a containment entry. Therefore, the RCS temperature elements are not a reliable source of diagnostic information for a containment fire. As stated in the previous paragraph, steam generator pressure can be used to verify natural circulation.

Based on the above discussion, at least one hot leg temperature element and one cold leg temperature element would be available in the event of a fire in containment. However, the reliable temperature elements would be difficult to determine since the exact fire location would not be known. In the event of a fire in the reactor building, natural circulation flow can be verified using any steam generator pressure indicator.

5.1.5 Containment Sump Isolation Valves

Containment sump isolation valves EJHV8811A and EJHV8811B are required to be closed during hot standby and cold shutdown to prevent draindown of the RWST and RCS into the containment sump. Circuits associated with valve interlocks are run through the reactor building. If these circuits are damaged, it could provide a false permissive to allow valves EJHV8811A and EJHV8811B to open.

Position switch BBZS8702AA is associated with the interlock circuit for valve EJHV8811A. If cable 11EJG06AE is damaged during a fire, a short circuit could occur which would provide the open permissive for valve EJHV8811A. However, hand indicating switch EJHIS8811A, located in the control room, is unaffected by a fire in the reactor building and is available to ensure valve EJHV8811A remains closed. An open in this circuit has no impact on PFSSD.

Valve BBPV8702B position switch provides a permissive to allow EJHV8811B to open only when valve EJHV8701B is fully closed. If cable 14EJG06BE is damaged during a fire, a short circuit could occur which would provide the open permissive for valve EJHV8811B. However, hand indicating switch EJHIS8811B, located in the control room, is unaffected by a fire in the reactor building and is available to ensure valve EJHV8811B remains closed. An open in this circuit has no impact on PFSSD.

Position switch EJZS8701A provides a permissive to allow EJHV8811A to open only when valve EJHV8701A is fully closed. If cable 11EJG06AH is damaged during a fire, a short circuit could occur which would provide the open permissive for valve EJHV8811A. However, hand indicating switch EJHIS8811A, located in the control room, is unaffected by a fire in the reactor building and is available to ensure valve EJHV8811A remains closed. An open in this circuit has no impact on PFSSD.

Position switch EJZS8701BA provides a permissive to allow EJHV8811B to open only when valve EJHV8701B is fully closed. If cable 14EJG06BH is damaged during a fire, a short circuit could occur which would provide the open permissive for valve EJHV8811B. However, hand indicating switch EJHIS8811B, located in the control room, is unaffected by a fire in the reactor building and is available to ensure valve EJHV8811B remains closed. An open in this circuit has no impact on PFSSD.

Based on this discussion, a fire in the reactor building will not cause containment sump isolation valves EJHV8811A and EJHV8811B to spuriously open.

References: E-15000, XX-E-013, E-1F9205, E-13EJ06A, E-13EJ06B

5.1.6 Excess Letdown

For hot standby, PFSSD requires the excess letdown path be isolated to prevent uncontrolled depressurization of the RCS. To accomplish this, either normally closed valve BGHV8153A or BGHV8154A must be maintained closed and either normally closed valve BGHV8153B or BGHV8154B must be maintained closed. Circuits for all four valves are run through fire area RB.

All four valves are located within 10 feet of each other in area RB-1 near Reactor Coolant Pump D. The cable for valve BGHV8154A (11BGK48DA) runs from this area along the North side of area RB-2 and ends at the North electrical penetration area (RB-3) where it enters the Auxiliary Building through penetration ZNE277. The cable for valve BGHV8153A (11BGK48CA) runs from this area along the South side of area RB-2 and ends at the North electrical penetration area (RB-3) where it enters the Auxiliary Building through penetration ZNE278.

The cable for valve BGHV8154B (14BGK48BA) runs East from the valve through the SG C area and into the SE portion of area RB-2. The cable then runs West in a cable tray and into the South electrical penetration area (area RB-4) where it enters the Auxiliary Building through penetration ZSE233. The cable for valve BGHV8153B (14BGK48AA) runs South from the valve through the South secondary shield wall and drops into a tray where it runs up to the South electrical penetration area (area RB-4) and enters the Auxiliary Building through penetration ZSE234.

A fire in the SW portion of fire area RB-1, where all four valves are located, will not cause the valves to spuriously open, but could prevent operation of the valves from the control room. The valves will not spuriously open because the control cables are run in conduit with no other cables that have the proper voltage to energize and open the valves. In addition, an intra cable hot short in these cables will not spuriously open the valves. A ground fault equivalent hot short (GFEHS) from an external 125 VDC source through the ground plane in contact with conductor 2 in cable 'A' associated with these valves could open the valves. Fire testing (NUREG/CR-7100) has shown that GFEHS is plausible. Fire testing (NUREG/CR-7100) has also shown that intra-cable shorting occurs prior to inter-cable shorting. Intra-cable shorting between conductors 2 and N1 combined with GFEHS will blow the control power fuse and close the valves. Furthermore, two valves would have to spuriously open in this manner to establish an excess letdown flowpath. Based on this discussion, there is reasonable assurance that spurious opening of an excess letdown flowpath will not occur.

If a fire starts in the North end of area RB-2; the North electrical penetration area (area RB-3); or the South electrical penetration area (area RB-4), the fire could cause an inter-cable hot short, energize the control solenoid and open the valve. This would allow water flow through the separation group 1 or 4 flow path, depending on the location of the fire. If a fire starts anywhere else, at least one of the redundant excess letdown flow path valves on each line will remain closed.

A spurious opening of the excess letdown isolation valves can be mitigated by opening breaker NK4119 to fail close valves BGHV8153A and BGHV8154A and opening breaker NK4407 to fail close valves BGHV8153B and BGHV8154B. Breaker NK4119 is located in fire area C-16 and breaker NK4407 is located in fire area C-15. These actions are not critical because calculation WCNOC-CP-002 shows that with excess letdown valves open, there will be sufficient makeup to the RCS to ensure the core remains covered. Therefore, no E-1F9900 OMA is required for excess letdown isolation to achieve and maintain hot standby. Reference Attachment 4, MSO Evaluation Scenario ID PWROG 8.

For cold shutdown, it may be necessary to establish a letdown flowpath to prevent overfilling the pressurizer. Valves BBHV8157A and BBHV8157B are included in the PFSSD equipment list to ensure excess letdown can be placed in service. The cables for these valves are not included in the PFSSD design because the valves can be manually operated when transitioning to cold shutdown. The power supplies are included in the PFSSD design and are located outside of this fire area. If necessary, operators can disconnect power to the valves and manually open them. In addition, operators may need to repair one flow path from the RCS to the excess letdown heat exchanger to open these valves.

Based on the above discussion, excess letdown can be isolated for hot standby and repairs can be completed if excess letdown is needed for cold shutdown.

References: E-15000, XX-E-013, E-1F9301, E-13BB35, E-13BG48, E-1R2312A, E-1R2312B, E-1R2312C, E-1R2312D, E-1R2321, E-1R2322A, E-1R2412A, E-1R2422A, E-1R2908B

5.1.7 Letdown Isolation Valves and Letdown Orifice Isolation Valves

Letdown isolation valves BGLCV0459 and BGLCV0460 are isolation valves installed in series on the inlet side of the regenerative heat exchanger. PFSSD requires that one of these valves be closed or letdown orifice valves BGHV8149A, BGHV8149B, and BGHV8149C be closed to prevent loss of inventory through the letdown flow path.

Cables associated with BGLCV0459 and BGLCV0460 are routed in this fire area. Damage to the cables could prevent closing the valves from the control room using the respective hand switch.

Letdown orifice isolation valves BGHV8149A, BGHV8149B, and BGHV8149C are listed as PFSSD components because of the interlock between these valves and BGLCV0459 and BGLCV0460. The interlock prevents closure of the letdown valves when any one or more orifice isolation valves are open. Cables associated with all three letdown orifice isolation valves are located in this fire area. Damage to these cables could prevent closure of the valves from the control room using their respective hand switch. Therefore, a fire in area RB could prevent closure of all three letdown orifice isolation valves (BGHV8149A, BGHV8149B, and BGHV8149C) as well as the two letdown isolation valves (BGLCV0459 and BGLCV0460) using their respective hand switches in the control room.

Valves BGLCV0459, BGLCV0460, BGHV8149A, BGHV8149B, and BGHV8149C are air operated and fail in the closed position. The valves are located in containment. Instrument air to containment is controlled by valve KAFV0029, which is unaffected by a fire in area RB. Therefore, hand switch KAHIS0029 can be used to close the valve from the control room and isolate instrument air to containment. Pressurizer level indication is available using BBLI0459A and BBLI0460A.

Based on the above discussion, letdown valves BGLCV0459 and BGLCV0460 and letdown orifice valves BGHV8149A, BGHV8149B, and BGHV8149C can be closed from the control room if a fire occurs in area RB.

References: E-15000, XX-E-013, E-13BG10, E-13BG35, E-13KA02, M-12BG01, E-1F9301, M-12KA01

5.1.8 Excess Letdown Heat Exchanger

The excess letdown heat exchanger serves no PFSSD function except that flow to the heat exchanger needs to be isolated to prevent loss of inventory through the excess letdown flow path. As discussed previously, flow to the excess letdown heat exchanger is isolated by closing valves BGHV8153A or BGHV8154A and BGHV8153B or BGHV8154B.

References: E-15000, XX-E-013, M-12BG01

5.1.9 Steam Generator Level Transmitters

Steam generator level control on at least two steam generators is required for PFSSD. All three auxiliary feedwater pumps are available to supply feedwater to the steam generators. Cables for all 20 steam generator level transmitters are run throughout the reactor building. However, due to the limited quantities of combustible materials and horizontal separation between circuits, a single credible fire in the reactor building will not damage circuits for all 20 level transmitters.

As stated in Section 1.0, there are 11 line-type detection zones located in containment. Since detection is provided wherever significant fire hazards exist, there is reasonable assurance that a fire in containment would alarm one or more of these detection zones. A review was performed to determine the cable routing for each steam generator level transmitter and

compare the routing against the detection drawings to determine the available level transmitters if a fire is annunciated on each zone.

Control room alarm panel KC008 monitors the fire alarm system throughout the plant. In the event one or more of the containment detection zones alarms, KC008 will display a unique address for that zone. The operators can then determine the correct response to that alarm by entering procedure ALR KC-888, Fire Protection Panel KC008 Alarm Response. The alarm points are arranged by window number rather than zone number. The window number is incorporated in the address label.

Table RB-6 identifies each KC008 alarm window associated with the heat detection in containment as well as the unique address label displayed on KC008. The table also identifies the steam generator level transmitters that are unaffected by a fire in these zones.

Table RB-6

151 (Z220)	RB-RV HEAD EAST ALRM/151	AELT0501 AELT0517 AELT0518 AELT0519 AELT0551	AELT0502 AELT0527 AELT0528 AELT0529 AELT0552	AELT0503 AELT0537 AELT0538 AELT0539 AELT0553	AELT0504 AELT0547 AELT0548 AELT0549 AELT0554

Based on the above discussion, there is reasonable assurance that level indication will be available on at least two steam generators if a fire occurs in containment.

References: E-15000, XX-E-013, E-1F9203, E-13AE08, E-13AE12, E-1F2311, E-0F2321, E-1F2411, E-0F2421, E-1F2511, E-1F2521, E-1R2311, E-1R2312A, E-1R2312B, E-1R2312C, E-1R2312D, E-1R2312E, E-1R2321, E-1R2322A, E-1R2322B, E-1R2322C, E-1R2322D, E-1R2412A, E-1R2412B, E-1R2412C, E-1R2412D, E-1R2413, E-1R2422A, E-1R2422B, E-1R2422C, E-1R2422D, E-1R2512A, E-1R2512B, E-1R2512C, E-1R2512D, E-1R2901, E-1R2904E-1R2905, E-1R2907

5.1.10 Reactor Vessel Head Vent Valves

PFSSD requires that one of the two reactor vessel head vent valves on each flow path (2 flow paths total) be closed to prevent uncontrolled depressurization of the RCS. Either valve BBHV8001A or BBHV8002A and either BBHV8001B or BBHV8002B needs to be closed to satisfy PFSSD.

All four head vent valves are located in close proximity to each other on the 2047’-6” elevation of the reactor building near the reactor head. All four valves are normally closed and require operation of a hand switch in the control room to energize the control solenoid and open the valve.

In order for any of the valves to spuriously open, an inter-cable +125V DC hot short or a ground fault equivalent hot short (GFEHS) has to occur across conductor 2 in the associated control cable. This hot short has to occur prior to an intra-cable short occurring between conductors 2 and N2 in the associated cable because an intra-cable short between these conductors coincident with a GFEHS will open the circuit protective device and de-energize the control solenoid. Fire testing (NUREG/CR-7100) has shown that intra-cable shorting in thermoset cables occurs before inter-cable or GFEHS shorting. Therefore, there is reasonable assurance that inter-cable or GFEHS shorts will not cause two valves to open if a fire occurs in this area.

Cable 11BBK30AB is run in conduit from valve BBHV8001A to the North electrical penetration room (fire area RB-3) and enters the Auxiliary Building through penetration ZNI277. The conduit contains one other cable which is a computer cable associated with the valve. The cable does not carry the proper voltage to spuriously open the valve. Therefore, valve BBHV8001A will remain closed if a fire occurs in the reactor building.

Cable 14BBK30BB is run in conduit from valve BBHV8001B to the North wall of the reactor building. The conduit turns down to the 2000’-0” elevation where it runs West along the reactor building North wall. The cable then drops into a cable tray and runs along the West side of the building to the area below the South electrical penetration room. The tray then turns up into the South electrical penetration room where the cable enters the Auxiliary building through penetration ZSI234.

The conduit portion of the 14BBK30BB cable run contains one other cable, a computer cable, associated with valve BBHV8001B. The computer cable does not carry the proper voltage to spuriously open valve BBHV8001B. Therefore, fire damage to the cable in the area of the conduit run will not cause valve BBHV8001B to spuriously open. Where cable 14BBK30BB is run in tray, other cables in the tray may have the proper voltage and polarity to spuriously open valve BBHV8001B in the case of a hot short. If this should occur, valve BBHV8002B is unaffected by the fire, as discussed below.

Cable 14BBK30DB is run in conduit from valve BBHV8002B to the North wall of the reactor building. The cable then turns East in conduit approximately 15 feet where it drops to the

2000'-0" elevation. On the 2000'-0" elevation, the cable drops from a conduit into a cable tray where it runs along the East side of the building and rises up to the 2026'-0" elevation on the SE side of the building. The cable continues in tray to the South electrical penetration room where it enters the Auxiliary Building through penetration ZSI233.

The conduit portion of the 14BBK30DB cable run contains one other cable, a computer cable, associated with valve BBHV8002B. The computer cable does not carry the proper voltage to spuriously open valve BBHV8002B. Therefore, fire damage to the cable in the area of the conduit run will not cause valve BBHV8002B to spuriously open. Where cable 14BBK30DB is run in tray, other cables in the tray may have the proper voltage and polarity to spuriously open valve BBHV8002B in the case of a hot short. In this case, valve BBHV8001B is unaffected by the fire, as discussed above.

A fire in the reactor building will not affect the ability to maintain the reactor vessel head vent valve flow paths closed. Valve BBHV8001A will remain closed if the fire occurs anywhere in the building. Valve BBHV8001B will remain closed if the fire occurs anywhere except the West side of the 2000'-0" elevation, where it may spuriously open due to a cable-to-cable +125V DC hot short. Valve BBHV8002B will remain closed if the fire occurs anywhere except the East side of the 2000'-0" elevation, where it may spuriously open due to a cable-to-cable +125V DC hot short.

5.1.11 Essential Service Water Flow to Containment Coolers

PFSSD requires containment cooling to maintain the containment environment within EQ limits. Essential service water flow to Train A containment coolers is controlled by valves EFHV0031, EFHV0033, EFHV0045 and EFHV0049. Essential service water flow to Train B containment coolers is controlled by valves EFHV0032, EFHV0034, EFHV0046 and EFHV0050. All four valves on the associated train are required to be open to ensure a flow of service water to the containment coolers.

Valves EFHV0031, EFHV0032, EFHV0049 and EFHV0050 and associated circuits are located outside the reactor building and are unaffected by a fire in the reactor building.
Train A valves EFHV0033 and EFHV0045 are located in the NW portion of area RB-2. Circuits associated with these valves are run to the North electrical penetration room (fire area RB-3). A fire in these areas could prevent operation of valves EFHV0033 and EFHV0045 from the control room and could cause the spurious closure of the valves, causing Train A containment cooling to be lost.

Train B valves EFHV0034 and EFHV0046 are located in the SW portion of area RB-2. Circuits associated with these valves are run to the South electrical penetration room (fire area RB-4). A fire in these areas could prevent operation of valves EFHV0034 and EFHV0046 from the control room and could cause the spurious closure of the valves, causing Train B containment cooling to be lost.

Valves and circuits associated with Train A and Train B are separated from each other by more than 20 feet of horizontal distance and limited quantities of combustible materials are located between redundant components. The horizontal distance, lack of sufficient quantities of combustible material and the large volume of the reactor building provides reasonable assurance that a single credible fire will not affect both trains of valves. Therefore, containment cooling is assured if a fire occurs in the reactor building using either Train A or Train B containment coolers.

5.1.12 Boron Injection Tank Flow Diversion

A fire in the reactor building may require charging through the boron injection tank flow path due to possible momentary loss of coolant through the letdown flow path until either BGLCV0459 or BGLCV0460 are closed. This requires ensuring the SIS test lines are isolated to ensure charging flow is directed to the RCS.

Isolation of the SIS test lines is accomplished by either closing valves EMHV8843 and EMHV8882 or closing either EMHV8964 or EMHV8871. Cables associated with EMHV8843, EMHV8882 and EMHV8871 are run in the reactor building. Cables associated with valve EMHV8964 are not run in the reactor building.

A fire in certain areas of the reactor building could cause damage to cables associated with valves EMHV8843, EMHV8882 and EMHV8871 such that the valves spuriously open. However, valve EMHV8964 is unaffected by a fire in the reactor building and is available to ensure loss of charging flow through the SIS test line does not occur.

Isolation of the SIS test line is unaffected by a fire in the reactor building.

References: E-15000, XX-E-013, E-1F9302, E-13EM04, E-13EM04A, E-13EM05A, E-13EM12, M-12EM02

5.1.13 Safety Injection Accumulator Isolation Valves

PFSSD requires isolation of the SI accumulators prior to reducing RCS pressure below the injection pressure to avoid unnecessary accumulator discharge. This is accomplished by closing valves EPHV8808A, EPHV8808B, EPHV8808C and EPHV8808D. These valves are normally open with the MCC breaker locked in the open position. Cables for all four valves are run in the reactor building.

Since the breakers for these valves are normally open, damage to the associated cables will not cause the valves to spuriously change position. However, damage to the cables will prevent closing the associated valve from the control room after power is restored.
The SI accumulators need to be isolated during cold shutdown, prior to the RCS reaching 1000 psig. If necessary, a containment entry can be made to manually close the valves.

A fire in the reactor building may require a containment entry to close one or more accumulator valves if these valves are unresponsive from the control room. This may require the operator to traverse the fire affected area, but this action is not required until well after the fire is extinguished.

References: E-15000, XX-E-013, E-13EP02A, M-12EP01

5.1.14 Pressurizer Level Indication

Pressurizer level indication is required to be available to satisfy PFSSD. Pressurizer level transmitters BBLT0459 and BBLT0460 are used to establish pressurizer level. At least one of these transmitters is required to be available.

Both BBLT0459 and BBLT0460, and associated cables, are installed in fire area RB-4 within 20 feet of each other. This arrangement is acceptable due to the installation of an automatic fire detection system and a fixed, manually charged fire suppression system in area RB-4, as described earlier.

Conduit 121J2027 contains an instrument cable (11BBI16PA) for BBLT0459. This conduit is partially wrapped with Darmatt 1-hour fire barrier system to meet the requirements for a non-combustible radiant energy shield in the area where fire suppression and detection is not installed. The conduit is wrapped from the 2043'-6" elevation prior to exiting fire area RB-4 to the unscheduled junction box between conduits 121J2027 and 121J2051. This arrangement ensures at least 20 feet of horizontal separation exists between unprotected raceways carrying cables for BBLT0459 and BBLT0460 and meets the requirements of 10CFR50, Appendix R, Section III.G.2.d and III.G.2.f.

If a fire occurs in containment it would be difficult to accurately determine the location and therefore difficult to know which level transmitter to rely on. Pressurizer level transmitters BBLT0461 and BBLT0462 are also located in fire area RB-4. These transmitters are not included in the PFSSD component list because either BBLT0459 or BBLT0460 are available in the remaining fire areas. Therefore, it was not necessary to add BBLT0461 and BBLT0462, and associated level indicators, to the PFSSD equipment list. These level transmitters are being credited only for area RB to provide operators with additional level instruments to use.

As discussed in Section 1.0, the fire protection features in area RB-4 provide reasonable assurance that only one level transmitter will be damaged if the fire is in area RB-4. Level transmitter BBLT0460 and associated cable 12BBI16QA is located completely within area RB-4. If the fire is outside area RB-4, then there is reasonable assurance that pressurizer level indicator BBLI0460A will be available. Protectowire heat detection zones 203, 204 and 216 run in area RB-4. If a fire is detected in any of these zones as indicated by KC008 fire alarm windows 138, 139 or 148, then Operators should monitor all four level indicators to determine which is the faulted indicator and rely on the remaining three.

Based on the above discussion, pressurizer level indication is assured for a fire in the reactor building.

References: E-15000, XX-E-013, DCP 07037, E-1F9301, E-13BB16, E-1R2412A, E-1R2412B, E-1R2904, M-12BB02

5.1.15 Pressurizer Pressure Transmitters and Indicators

Pressurizer pressure transmitters BBPT0455, BBPT0456, BBPT0457 and BBPT0458 are included in the PFSSD design because they initiate Safety Injection on 2/4 low pressurizer pressure signals. Due to the installation of the Ovation DCS, a spurious high-pressure signal on a single or multiple pressure channel is not postulated to cause the spurious opening of the pressurizer PORVs. See Calculation XX-E-013 Appendix 1 for additional discussion. Pressurizer pressure indicators are included in the PFSSD design to provide operators with diagnostic capability.

Cable 11BBI16KA associated with pressure transmitter BBPT0455 is run in areas RB-3, RB-4, RB-5, RB-6 and RB-10. Cable 12BBI16LA associated with pressure transmitter BBPT0456 is run in area RB-4. Cable 13BBI16MA associated with pressure transmitter BBPT0457 is run in areas RB-3, RB-4, RB-7 and RB-10. Cable 14BBI16NA associated with pressure transmitter BBPT0458 is run in areas RB-4, RB-8 and RB-10. Based on the cable routing, a fire in certain areas of the reactor building could damage cables for at least two pressurizer pressure transmitters and initiate a spurious SIS. A spurious SIS is discussed in Section 5.1.20.

As stated in the previous paragraph, cables associated with all four pressurizer pressure transmitters are run in this area. Spurious operation of equipment as a result of damage to these cables is not postulated because the Ovation pressure control system uses 4-channel validation logic, which uses the 2nd highest signal as the validated signal and has built-in logic to detect and ignore failed inputs.

Pressurizer pressure indication needs to be available on at least one pressure indicator to provide diagnostic indication of a failed open pressurizer PORV. All four pressurizer pressure transmitters are located in area RB-4. As discussed in Section 1.0, the fire protection features in area RB-4 provide reasonable assurance that only one pressure transmitter will be damaged if the fire is in area RB-4. If the fire is outside area RB-4, then there is reasonable assurance that pressurizer pressure indicator BBPI0456 will be available, since BBPT0456 and associated cable 12BBI16LA are located only in RB-4. Protectowire heat detection zones 203, 204 and 216 run in area RB-4. If a fire is detected in any of these zones as indicated by KC008 fire alarm windows 138, 139 or 148, then Operators should monitor all four pressure indicators to determine which is the faulted indicator and rely on the remaining three.

Based on the above discussion, there is reasonable assurance that at least one pressurizer pressure indicator will be available if a fire occurs in this area.

References: E-15000, XX-E-013, E-13BB16, E-1F9301, E-1F9431, M-12BB02, DCP 13324

5.1.16 Containment Coolers

PFSSD requires containment cooling to maintain the containment environment within EQ limits. Two trains of containment cooling are provided. Train A uses containment coolers SGN01A and SGN01C. Train B uses containment coolers SGN01B and SGN01D. Only one train (2 coolers) is required to supply the needed containment cooling demand for PFSSD.

Power cables for each containment cooler are run in the reactor building. Power cables for Train A coolers are run from containment penetration ZNI268 in the North electrical penetration room (fire area RB-3) to the respective cooler motor. Power cables for Train B coolers are run from containment penetration ZSI219 in the South electrical penetration room (fire area RB-4) to the respective cooler motor. The power cables associated with each train of containment coolers are separated by at least 20 feet of horizontal separation with limited quantities of intervening combustibles. This separation, combined with the overall large volume of the reactor building, provides reasonable assurance that at least one train of containment coolers will be available if a fire occurs in the reactor building.

As stated earlier, ESW control valves to the containment coolers may be affected by a fire in the reactor building. However, based on the cable routing and the location of equipment, a single credible fire will not damage cables and equipment associated with both trains. Therefore, a single credible fire may damage cables and equipment associated with one train of coolers and essential service water, but the opposite train will remain available.

Based on this discussion, there is reasonable assurance that a fire in the reactor building will not cause the loss of containment cooling capability.

References: E-15000, XX-E-013, E-1F9441, E-13GN02, E-13GN02A, E-1R2421, E-1R2422A, E-1R2423, E-1R2512B, E-1R2512C, E-1R2522C, E-1R2522D

5.1.17 Pressurizer PORVs and Associated Block Valves

PFSSD requires that either the pressurizer power operated relief valve (PORV) or its associated block valve be closed. Either PORV BBPCV0455A or its associated block valve BBHV8000A needs to be closed and either PORV BBPCV0456A or its associated block valve BBHV8000B needs to be closed. All four valves are located in the same valve enclosure at elevation 2068’-8” with no suppression and detection or radiant energy shields installed.

The pressurizer PORVs are not considered high/low pressure interfaces. The valves are supplied power by an ungrounded 125 VDC system. Therefore, based on GL 86-10, consideration of multiple proper polarity hot shorts is not required. A single proper polarity hot short still needs to be considered.

Cables 11BBK40AB and 11BBK40AH associated with PORV BBPCV0455A are run in this area. Based on a review of drawing E-13BB40, it would take two concurrent proper polarity hot shorts to cause the PORV to spuriously open. Therefore, a fire in area RB is not postulated to open PORV BBPCV0455A due to damage to the control cables associated with the PORV.

Cables 14BBK40BB and 14BBK40BH associated with PORV BBPCV0456A are run in this area. Based on a review of drawing E-13BB40, it would take two concurrent proper polarity hot shorts to cause the PORV to spuriously open. Therefore, a fire in area RB is not postulated to open PORV BBPCV0456A due to damage to the control cables associated with the PORV.

Based on the above discussion, a fire in the reactor building will not cause PORVs BBPCV0455A or BBPCV0456A to spuriously open as a result of damage to the PORV control cables. However, as discussed in Section 5.1.15, the PORVs could open as a result of a spurious high-pressure signal. See Section 5.1.15 for actions to take if this occurs.

References: E-15000, XX-E-013, E-11NK01, E-13BB39, E-13BB40, E-13GT03, E-13RL05, M-12BB02, E-1R2612, E-1R2512A, E-1R2512B, E-1R2512C, E-1R2512D, E-1R2901, CR 13079, DCP 12944

5.1.18 CCW From RCP Containment Isolation Valves

For PFSSD, the component cooling water (CCW) system is used to provide cooling to the centrifugal charging pump (CCP) oil cooler, the RHR heat exchanger and the RHR pump seal cooler. In addition, the CCW system provides cooling to the RCP thermal barriers and is credited as a backup to RCP seal injection for maintaining seal cooling.

Valves EGHV0060, EGHV0062 and EGHV0132 are included in the PFSSD equipment list to ensure a reliable means of controlling CCW flow to various reactor building components. In certain situations, one or more of these valves is required to be either open or closed to accomplish the PFSSD function.

Valve EGHV0060 is included to ensure availability of CCW to the excess letdown heat exchanger during cold shutdown. For hot standby, the position of this valve (open or closed) will not impact PFSSD.

Valves BBHV0013, BBHV0014, BBHV0015, BBHV0016, EGHV0062 and EGHV0132 are included to evaluate availability of CCW to the RCP thermal barrier heat exchangers. During a loss of seal injection, the thermal barriers provide a redundant means of protecting the RCP seals and preventing a seal LOCA. In this case, the valves are required to remain open to ensure CCW flow to the thermal barrier cooling coils. If a loss of all seal cooling occurs, valves EGHV0062 and EGHV0132 are required to be closed to prevent steam void formation in the CCW piping and possible rupture due to water hammer.

Flow transmitters BBFT0017, BBFT0018, BBFT0019 and BBFT0020 are associated with valves BBHV0013, BBHV0014, BBHV0015 and BBHV0016, respectively. The flow transmitters monitor flow in the CCW piping and shut the valves on high CCW flow. Cables associated with these flow transmitters are run in this area. Damage to these cables could cause a spurious high CCW flow signal and close the valves. Damage to the valve cables could prevent re-opening the valves. Loss of thermal barrier cooling would be indicated in the control room as a reduction in flow on flow indicators EGFI0128 and EGFI0129. Therefore, operators can diagnose a loss of thermal barrier cooling.

A fire in the Reactor Building will not cause a loss of seal injection. All electrically operated components associated with seal injection are located outside the Reactor Building and will be unaffected by a fire in area RB. Therefore, spurious operation of valves BBHV0013,

BBHV0014, BBHV0015, BBHV0016, EGHV0062 and EGHV0132 will not adversely impact PFSSD.

References: E-15000, XX-E-013, E-13BB03, E-13BB28, E-13EG06, E-13EG17A, E-1F9303, M-12EG03

5.1.19 Normal Pressurizer Spray Valves

Pressurizer spray valves BBPCV0455B and BBPCV0455C are analyzed in the PFSSD analysis because spurious operation of the valves could cause a depressurization of the RCS which could lead to boiling in the core.

The pressurizer spray valves are located in fire area RB-10. Cables 15BBI19AB and 15BBI19BB associated with the valves are run in fire areas RB-1, RB-3, RB-6 and RB-10. Damage to the cables in the event of a fire could cause the spurious opening of the spray valves.

The pressurizer normal spray valves operate off a signal from the Ovation pressurizer pressure control system. The operation of the pressure control system is discussed in Calculation XX-E-013.

Instrument cables associated with all four pressurizer pressure transmitters (BBPT0455, BBPT0456, BBPT0457 and BBPT0458) are run in fire area RB. Due to the fire protection features discussed in Section 1.0, at least one pressure transmitter will be available. Damage to pressure transmitter cables could send a spurious high-pressure signal to the pressure control system. However, as discussed in Calculation XX-E-013, Appendix 1, damage to a single or multiple pressure channels will not cause the spurious operation of the pressurizer spray valves due to the Ovation 4-channel validation logic, which uses the 2nd highest signal as the validated signal and has built-in logic to detect and ignore failed inputs. Therefore, spurious opening of the normal pressurizer spray valves due to a spurious high-pressure signal is not postulated.

The pressurizer spray valves are electro/pneumatic operated and loss of air pressure will close the valves. The air supply comes from the compressed air system. Closing valve KAFV0029 using KAHIS0029 on RL024 will isolate compressed air to containment which will cause the pressurizer spray valves to close or prevent them from opening. Based on WCNOC-CP-002, spray flow needs to be stopped within 50 minutes. Since this is a control room action, this can be completed well within 50 minutes.

Based on the above discussion, the pressurizer spray valves could spuriously open if a fire occurs in this area. Pressurizer spray can be stopped by closing valve KAFV0029 from the main control room. Pressurizer pressure indication is available using BBPI0456 unless a fire alarm is indicated on alarm windows 138, 139 or 148. If this is the case, then monitor BBPI0455A, BBPI0456, BBPI0457 and BBPI0458 to determine an accurate pressure reading. At least three of these indicators should trend the same.

References: E-15000, XX-E-013, E-13BB19, E-13KA02, M-12BB02, M-761-02128, M-761-02129, WCNOC-CP-002, CR 25002, DCP 13324

5.1.20 Safety Injection and Containment Spray

Calculation XX-E-013, Appendix 1 (PFSSD Support Section) provides a detailed discussion about the potential PFSSD impact of a spurious safety injection signal (SIS) and spurious containment spray actuation signal (CSAS). This section discusses the specific PFSSD impact if a fire occurs in this area.

A spurious CSAS is not credible if a fire occurs in area RB.

Pressurizer pressure transmitters BBPT0455, BBPT0456, BBPT0457 and BBPT0458 and associated cables are located in area RB. Section 5.1.15 provides a detailed description of where these cables and components are located. Consequently, a fire in area RB can cause a spurious SIS due to low pressurizer pressure.

A spurious SIS starts the charging sequence which starts the CCPs and opens the BIT flowpath valves. For a fire in this area, the BIT flowpath valves are unaffected and would open on a SIS. The RWST valves are unaffected and would open on a SIS. Also, the CCP mini flow valves are unaffected and CCW flow to the seal water heat exchanger is unaffected to ensure cooling of the recirc flow and RCP seal return. The CCW system is also available to provide cooling to the CCP oil coolers. Therefore, the charging pumps will not be affected by a spurious SIS caused by a fire in this area.

A start of the CCW system will not adversely impact the system. Both Trains of ESW are unaffected and will start on a spurious SIS, providing necessary cooling water to the CCW heat exchangers.

A start of the AFW pumps will not adversely impact PFSSD. All three AFW pumps are unaffected by a fire in this area. Suction from the CST to the AFW pumps is unaffected. Discharge flow will either return to the CST or flow to the steam generators through the discharge control valves. Therefore, the AFW pumps are unaffected by a spurious SIS caused by a fire in this area.

A start of the RHR pumps due to a spurious SIS will not adversely impact either pump. The RWST supply to the pumps is not affected and the recirculation valves will remain in the open position. Component cooling water is available to both RHR heat exchangers. Operators will have time to terminate the spurious SIS and stop the pumps.

Based on the above discussion, a spurious SIS can occur if a fire occurs in this area. Credited PFSSD equipment will not be damaged by the spurious SIS. Therefore, a spurious SIS will not adversely impact PFSSD.

References: E-15000, XX-E-013, E-13BB16, E-13EM01, E-13EN03, E-13GN05, E-1F9431, E-1F9432, E-1F9433

5.1.21 Seal Water Return Containment Isolation Valve

Seal water return containment isolation valve BGHV8112 is credited for a fire in area A-16S to prevent seal leakoff flow from entering the CCP suction. This is because a fire in A-16S could cause a loss of CCW cooling flow to the seal water heat exchanger and allow elevated temperature fluid to enter the CCP and possibly damage the pump.

A fire in area RB does not credit valve BGHV8112. Therefore, damage to the valve in the event of a fire will have no adverse impact on PFSSD

References: E-15000, XX-E-013

5.2 PFSSD CABLE EVALUATION

Table RB-8 lists all the PFSSD cables (S. in E-15000) located in fire area RB. The applicable evaluation section is also listed in Table RB-8.

Table RB-7 PFSSD Cables Located in Fire Area RB					
Cable #	**Location**	**Primary PFSSD Equipment**	**Cable Function** (P) Power (C) Control (I) Instrumentation	**Evaluation Section**	**Comments**
11AEI08AA	RB-2, RB-3	AELT0501	I	5.1.9	SG A Wide Range Water Level

5.2.1 Reactor Coolant Pumps

The reactor coolant pumps are not credited in the PFSSD analysis. However, the capability to stop the pumps from the control room in the event of a loss of all seal cooling or spuriously open pressurizer spray is credited. Westinghouse Technical Bulletin TB-04-22, Rev. 1 recommends that if all seal cooling is lost (RCP seal injection and thermal barrier heat exchanger flow), operators need to stop the pumps before a seal LOCA occurs. Calculation WCNOC-CP-002 shows that if pressurizer spray spuriously actuates, the spray flow needs to be stopped within 50 minutes.

One control cable associated with each reactor coolant pump is run in fire area RB. Damage to these cables in the event of a fire could prevent operators from stopping the RCPs from the control room. However, a fire in RB will not cause a loss of all seal cooling because seal injection remains available. As discussed in Section 5.1.19, if pressurizer spray spuriously operates, operators can stop the spray by isolating air to the valve from the control room. Therefore, tripping the RCPs is not required to mitigate spurious pressurizer spray.

Based on the above discussion, the inability to trip the RCPs from the control room will have no adverse impact on PFSSD. If pressurizer spray spuriously actuates, the valves can be closed by isolating air to the valves from the control room. In addition, seal injection is unaffected by a fire in area RB. Therefore, the RCPs do not have to be tripped in the event of a fire in area RB.

1.0 GENERAL AREA DESCRIPTION

The Radwaste Building, excluding the radwaste tunnel, is sub-divided into three fire areas in E-15000 (Setroute). In general, each fire area includes the areas described in Table RW-1. For the radwaste tunnel fire area analysis, see fire area RW-1. For a complete list of rooms in the Radwaste Building, see E-1F9905, Attachment A.

Table RW-1
Fire Areas Located in Fire Area RW

FIRE AREAS	DESCRIPTION
RW A	Radwaste Building 1976' Elevation
RW B	Radwaste Building 2000' Elevation
RW C	Radwaste Building 2022', 2031'-6", 2040'-6", 2047' Elevations

The radwaste building is provided with automatic fire detection throughout most areas. Automatic fire suppression is provided in the dry waste compactor area and in the radwaste storage building. Fire area RW is separated from all adjoining fire areas by minimum 3-hour fire resistance rated construction.

2.0 PRIMARY EQUIPMENT USED FOR PFSSD

Table RW-2 lists each system credited for post-fire safe shutdown and provides a discussion regarding the availability of the system to perform its Post Fire Safe Shutdown (PFSSD) function if a severe fire occurs in this area. For a summary of the potential fire impact on some of the more significant PFSSD equipment, see Section 8.0 of the Fire Area Analysis Narrative section.

Table RW-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area RW

System	System Name	PFSSD Function*	Comments
AB	Main Steam	R, M, H, P, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area RW.
AC	Main Turbine	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area RW.
AE	Main Feedwater	H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area RW.
AL	Aux. Feedwater System	H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area RW.
AP	Condensate Storage System	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area RW.
BB	Reactor Coolant System	R, M, H, P, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area RW.
BG	Chemical and Volume Control System	R, M, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area RW.
BM	Steam Generator Blowdown System	R, M, H	All PFSSD functions associated with the steam generator blowdown system are satisfied. Steam generator blowdown is isolated by closing valves BMHV0001, BMHV0002, BMHV0003 and BMHV0004 using BMHIS0001A, BMHIS0002A, BMHIS0003A and BMHIS0004A, located on the RL024 panel in the main control room.
BN	Borated Refueling Water Storage System	R, M, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area RW.
EF	Essential Service Water System	H, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area RW.
EG	Component Cooling Water System	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area RW.
EJ	Residual Heat Removal System	M, H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area RW.
EM	High Pressure Coolant Injection	R, M	The PFSSD function(s) associated with this system is(are) not affected by a fire in area RW.
EN	Containment Spray	R, M	The PFSSD function(s) associated with this system is(are) not affected by a fire in area RW.

3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD

This section describes operator actions that may need to be performed inside or outside the control room to achieve and maintain hot standby if a fire occurs in area RW. This section also describes cold shutdown repairs that may need to be made to achieve and maintain cold shutdown conditions. Operator actions are proceduralized in OFN KC-016.

3.1 ACTIONS OUTSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

None

3.2 ACTIONS INSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

None

3.3 ACTIONS TO ACHIEVE AND MAINTAIN COLD SHUTDOWN

None

4.0 CONCLUSION

Post-fire safe shutdown is assured if a fire occurs in this area.

5.0 DETAILED ANALYSIS

This section describes the detailed component-by-component and cable-by-cable analysis for a fire in area RW.

5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA RW

PFSSD components (S. in E-15000) located in fire area RW are shown in Table RW-3. An evaluation of each component and associated cables is provided in the sections that follow. The applicable evaluation section is listed in Table RW-3.

Table RW-3 PFSSD Equipment Located in Fire Area RW				
Room #	**PFSSD Equipment**	**Description**	**Evaluation Section**	**Comments**
7209	BM157	Steam Generator Blowdown Control Panel	5.1.1	
7209	BMHIS0001C	BMHV0001 Solenoid Valve Handswitch	5.1.1	
7209	BMHIS0002C	BMHV0002 Solenoid Valve Handswitch	5.1.1	
7209	BMHIS0003C	BMHV0003 Solenoid Valve Handswitch	5.1.1	
7209	BMHIS004C	BMHV0004 Solenoid Valve Handswitch	5.1.1	
7208	RP188A	Auxiliary Relay Rack	5.1.1	

5.1.1 Steam Generator Blowdown to Blowdown Flash Tank Isolation Valves

The reactivity control function requires the steam generator blowdown to blowdown flash tank valves (BMHV0001, BMHV0002, BMHV0003, and BMHV0004) be closed to prevent uncontrolled cooldown. Post-fire safe shutdown credits two methods for isolating blowdown. The first method uses the blowdown control hand switches located in the main control room. The second method uses the blowdown control hand switches located on the blowdown control panel (BM157) in the radwaste control room.

A fire in the radwaste building could damage several cables and components associated with the BM157 panel mounted hand switches for each of the blowdown valves. Damage to these cables and components could impact the ability to close the valves from BM157 in the Radwaste Control Room.

The normal means of closing the blowdown valves, using the RL024 mounted hand switches in the Main Control Room, remains available. Therefore, a fire in area RW will not prevent the closure of valves BMHV0001, BMHV0002, BMHV0003, and BMHV0004.

15BMK06DD	7208, 7209	BMHV0004	C	5.1.1	SG D to Blowdown Flash Tank Isolation Valve
15BMK16AA	7113, 7208, 7209	BM157	P	5.1.1	Steam Generator Blowdown Control Panel
15PGA10BA	7113	PA0106	C	5.2.1	Load Centers PG15, PG17 and PG19 Fdr Bkr
16PGA11AC	7113	PA0207	C	5.2.1	Load Centers PG14, PG18, PG20 and PG24 Fdr Bkr

5.2.1 Load Center Feeder Breakers PA0106 and PA0207

Load center feeder breakers PA0106 and PA0207 are credited for PFSSD because they supply power to credited non-safety related loads. Cables 15PGA10BA, associated with PA0106, and 16PGA11AC, associated with PA0207, run in this area. A fire induced short circuit in these cables will trip the associated breaker.

Breaker PA0106 supplies power to the following PFSSD components:

- PG19GCR217 – MCB Misc. Power Circuits RL023
- PG19GFR3 – Instr. Bus Transformer Alt. Feed XPN07D

PFSSD components supplied power from PG19GCR217 are associated with MSIV downstream components. The MSIVs are unaffected by a fire in this area and can be closed from the control room. Therefore, the MSIV downstream components are not required if a fire occurs in this area.

PG19GFR3 is credited as one source of power to PN07. The redundant source of power from NG01BEF4 is unaffected by a fire in this area.

Based on the above discussion, loss of breaker PA0106 will not adversely affect PFSSD if a fire occurs in this area.

Breaker PA0207 supplies power to the following PFSSD components:

- PG20GBR217 – MCB Misc. Power Circuits RL023
- PG20GER5 – Instr. Bus Transformer Alt. Feed XPN08D

PFSSD components powered from PG20GBR217 are associated with MSIV downstream components. The MSIVs are unaffected by a fire in this area and can be closed from the control room. Therefore, the MSIV downstream components are not required if a fire occurs in this area.

PG20GER5 is credited as one source of power to PN08. The redundant source of power from NG02BBF1 is unaffected by a fire in this area.

Based on the above discussion, loss of breaker PA0207 will not adversely affect PFSSD if a fire occurs in this area.

Damage to cables 15PGA10BA and 16PGA11AC due to a fire in this area will not adversely impact the ability to achieve and maintain PFSSD due to the availability of redundant components that are unaffected by a fire in this area.

1.0 GENERAL AREA DESCRIPTION

Fire area RW-1 is the radwaste tunnel located between the 1976 elevation of the Radwaste Building and the 1974 elevation of the Auxiliary Building and includes the rooms listed in Table RW-1-1.

Table RW-1-1
Rooms Located in Fire Area RW-1

ROOM #	DESCRIPTION
7133	Electrical Chase, Non Radioactive Pipe Tunnel and Personnel Access
7134	Radioactive Pipe Tunnel

Fire area RW-1 is protected with automatic fire detection in room 7133 only. There is no automatic suppression installed. The area is separated from all adjacent areas by minimum 3-hour fire resistant rated construction.

2.0 PRIMARY EQUIPMENT USED FOR PFSSD

Table RW-1-1 lists each system credited for post-fire safe shutdown and provides a discussion regarding the availability of the system to perform its Post Fire Safe Shutdown (PFSSD) function if a severe fire occurs in this area. For a summary of the potential fire impact on some of the more significant PFSSD equipment, see Section 8.0 of the Fire Area Analysis Narrative section.

Table RW-1-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area RW-1

System	System Name	PFSSD Function*	Comments
AB	Main Steam	R, M, H, P, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area RW-1.
AC	Main Turbine	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area RW-1.
AE	Main Feedwater	H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area RW-1.
AL	Aux. Feedwater System	H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area RW-1.
AP	Condensate Storage System	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area RW-1.
BB	Reactor Coolant System	R, M, H, P, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area RW-1.
BG	Chemical and Volume Control System	R, M, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area RW-1.
BM	Steam Generator Blowdown System	R, M, H	All PFSSD functions associated with the steam generator blowdown system are satisfied. Steam generator blowdown is isolated by closing valves BMHV0001, BMHV0002, BMHV0003 and BMHV0004 using BMHIS0001A, BMHIS0002A, BMHIS0003A and BMHIS0004A, located on the RL024 panel in the main control room.
BN	Borated Refueling Water Storage System	R, M, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area RW-1.
EF	Essential Service Water System	H, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area RW-1.

None

3.2 ACTIONS INSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

None

3.3 ACTIONS TO ACHIEVE AND MAINTAIN COLD SHUTDOWN

None

4.0 CONCLUSION

Post-fire safe shutdown is assured if a fire occurs in this area.

5.0 DETAILED ANALYSIS

This section describes the detailed component-by-component and cable-by-cable analysis for a fire in area RW-1.

5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA RW-1

There are no PFSSD components (S. in E-15000) located in fire area RW-1. This fire area only contains PFSSD cables associated with components located in other fire areas.

5.2 PFSSD CABLE EVALUATION

Table RW-1-3 lists all the PFSSD cables (S. in E-15000) located in fire area RW-1. The applicable evaluation section is also listed in Table RW-1-3.

Table RW-1-3
PFSSD Cables Located in Fire Area RW-1

Cable #	Location	Primary PFSSD Equipment	Cable Function (P) Power (C) Control (I) Instrumentation	Evaluation Section	Comments
15BMK06AA	7133	BMHV0001	C	5.2.1	SG A to Blowdown Flash Tank Isolation Valve
15BMK06AB	7133	BMHV0001	C	5.2.1	SG A to Blowdown Flash Tank Isolation Valve
15BMK06AC	7133	BMHV0001	C	5.2.1	SG A to Blowdown Flash Tank Isolation Valve
15BMK06BA	7133	BMHV0002	C	5.2.1	SG B to Blowdown Flash Tank Isolation Valve
15BMK06BB	7133	BMHV0002	C	5.2.1	SG B to Blowdown Flash Tank Isolation Valve
15BMK06BC	7133	BMHV0002	C	5.2.1	SG B to Blowdown Flash Tank Isolation Valve
15BMK06CA	7133	BMHV0003	C	5.2.1	SG C to Blowdown Flash Tank Isolation Valve
15BMK06CB	7133	BMHV0003	C	5.2.1	SG C to Blowdown Flash Tank Isolation Valve
15BMK06CC	7133	BMHV0003	C	5.2.1	SG C to Blowdown Flash Tank Isolation Valve
15BMK06DA	7133	BMHV0004	C	5.2.1	SG D to Blowdown Flash Tank Isolation Valve
15BMK06DB	7133	BMHV0004	C	5.2.1	SG D to Blowdown Flash Tank Isolation Valve
15BMK06DC	7133	BMHV0004	C	5.2.1	SG D to Blowdown Flash Tank Isolation Valve
15BMK16AA	7133	PK5123	P	5.2.1	Power Source for Panel BM157
15PGA10BA	7133	PA0106	C	5.2.2	Load Centers PG15, PG17 and PG19 Fdr Bkr
16PGA11AC	7133	PA0207	C	5.2.2	Load Centers PG14, PG18, PG20 and PG24 Fdr Bkr

5.2.1 Steam Generator Blowdown to Blowdown Flash Tank Isolation Valves

The reactivity control function requires the steam generator blowdown to blowdown flash tank valves (BMHV0001, BMHV0002, BMHV0003, and BMHV0004) be closed to prevent reactivity addition from uncontrolled cooldown.

Several cables associated with the BM157 panel mounted hand switches for each of the valves run through this fire area. Damage to these cables could impact the ability to close the valves from BM157 in the Radwaste Control Room.

The normal means of closing the blowdown valves, using the RL024 mounted hand switches in the Main Control Room, remains available. Therefore, a fire in area RW-1 will not prevent the closure of valves BMHV0001, BMHV0002, BMHV0003, and BMHV0004.

References: E-15000, XX-E-013, E-13BM04, E-13BM06A, E-13BM06B, E-13BM06C, E-13BM06D, E-13BM16, E-1F9101, J-02BM04, M-12BM01

5.2.2 Load Center Feeder Breakers PA0106 and PA0207

Load center feeder breakers PA0106 and PA0207 are credited for PFSSD because they supply power to credited non-safety related loads. Cables 15PGA10BA, associated with PA0106, and 16PGA11AC, associated with PA0207, run in this area. A fire induced short circuit in these cables will trip the associated breaker.

Breaker PA0106 supplies power to the following PFSSD components:

- PG19GCR217 – MCB Misc. Power Circuits RL023
- PG19GFR3 – Instr. Bus Transformer Alt. Feed XPN07D

PFSSD components supplied power from PG19GCR217 are associated with MSIV downstream components. The MSIVs are unaffected by a fire in this area and can be closed from the control room. Therefore, the MSIV downstream components are not required if a fire occurs in this area.

PG19GFR3 is credited as one source of power to PN07. The redundant source of power from NG01BEF4 is unaffected by a fire in this area.

Based on the above discussion, loss of breaker PA0106 will not adversely affect PFSSD if a fire occurs in this area.

Breaker PA0207 supplies power to the following PFSSD components:

- PG20GBR217 – MCB Misc. Power Circuits RL023
- PG20GER5 – Instr. Bus Transformer Alt. Feed XPN08D

PFSSD components powered from PG20GBR217 are associated with MSIV downstream components. The MSIVs are unaffected by a fire in this area and can be closed from the control room. Therefore, the MSIV downstream components are not required if a fire occurs in this area.

PG20GER5 is credited as one source of power to PN08. The redundant source of power from NG02BBF1 is unaffected by a fire in this area.

Based on the above discussion, loss of breaker PA0207 will not adversely affect PFSSD if a fire occurs in this area.

Damage to cables 15PGA10BA and 16PGA11AC due to a fire in this area will not adversely impact the ability to achieve and maintain PFSSD due to the availability of redundant components that are unaffected by a fire in this area.

1.0 GENERAL AREA DESCRIPTION

Fire area RWST is located in the yard area on the West side of the Fuel Building, South of the Hot Machine Shop and includes the rooms listed in Table RWST-1.

Table RWST-1
Rooms Located in Fire Area RWST

ROOM #	DESCRIPTION
9102	RWST Valve House
RWST	Refueling Water Storage Tank

There is no automatic fire detection or suppression in the RWST valve house. Manual fire suppression capabilities are present in the yard area adjacent to the RWST. Based on the Fire Hazards Analysis (E-1F9905), the combustible loading around the RWST is low.

2.0 PRIMARY EQUIPMENT USED FOR PFSSD

Table RWST-2 lists each system credited for post-fire safe shutdown and provides a discussion regarding the availability of the system to perform its Post Fire Safe Shutdown (PFSSD) function if a severe fire occurs in this area. For a summary of the area analysis results, see Section 8.0 of the Fire Area Analysis Narrative section.

Table RWST-2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area RWST

System	System Name	PFSSD Function*	Comments
AB	Main Steam	R, M, H, P, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area RWST.
AC	Main Turbine	R, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area RWST.
AE	Main Feedwater	H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area RWST.
AL	Aux. Feedwater System	H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area RWST.
AP	Condensate Storage System	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area RWST.
BB	Reactor Coolant System	R, M, H, P, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area RWST.
BG	Chemical and Volume Control System	R, M, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area RWST.
BM	Steam Generator Blowdown System	R, M, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in area RWST.
BN	Borated Refueling Water Storage System	R, M, H	All four RWST level transmitters may be affected if a fire occurs in this area. This is acceptable as discussed in Section 5.1.1.
EF	Essential Service Water System	H, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area RWST.
EG	Component Cooling Water System	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area RWST.
EJ	Residual Heat Removal System	M, H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area RWST.
EM	High Pressure Coolant Injection	R, M	The PFSSD function(s) associated with this system is(are) not affected by a fire in area RWST.
EN	Containment Spray	R, M	The PFSSD function(s) associated with this system is(are) not affected by a fire in area RWST.

3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD

This section describes operator actions that may need to be performed inside or outside the control room to achieve and maintain hot standby if a fire occurs in area RWST. This section also describes cold shutdown repairs that may need to be made to achieve and maintain cold shutdown conditions. Operator actions are proceduralized in OFN KC-016.

3.1 ACTIONS OUTSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

None

3.2 ACTIONS INSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

None

3.3 ACTIONS TO ACHIEVE AND MAINTAIN COLD SHUTDOWN

None

4.0 CONCLUSION

Redundant Post-Fire Safe Shutdown capability exists if a severe fire occurs in this area.

5.0 DETAILED ANALYSIS

This section describes the detailed component-by-component and cable-by-cable analysis for a fire in area RWST.

5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA RWST

PFSSD components (S. in E-15000) located in fire area RWST are shown in Table RWST-3. An evaluation of each component and associated cables is provided in the sections that follow. The applicable evaluation section is listed in Table RWST-3.

Table RWST-3 PFSSD Equipment Located in Fire Area RWST				
Room #	**PFSSD Equipment**	**Description**	**Evaluation Section**	**Comments**
9102	BNLT0930	RWST Level Transmitter	5.1.1	
9102	BNLT0931	RWST Level Transmitter	5.1.1	
9102	BNLT0932	RWST Level Transmitter	5.1.1	
9102	BNLT0933	RWST Level Transmitter	5.1.1	
RWST	TBN01	Refueling Water Storage Tank	5.1.1	

5.1.1 Refueling Water Storage Tank

This fire area contains the Refueling Water Storage Tank (RWST) and all four RWST level transmitters. Cables associated with all four level transmitters are run in this area. Loss of the RWST would adversely impact the ability to achieve and maintain PFSSD since the RWST is the only relied on source of boration and reactor makeup. Loss of all four level transmitters would result in loss of RWST level indication in the control room.

A low-low RWST level signal on two out of four level transmitters will provide a permissive for containment sump isolation valves EJHV8811A and EJHV8811B to open. If this occurs coincident with a safety injection signal (SIS), the containment sump isolation valves will open, causing the RWST to drain to the sump. A spurious SIS is not credible for a fire in area RWST. Therefore, the open permissive signal will not occur for valves EJHV8811A and EJHV8811B and the RWST will not drain to the containment sump.

Catastrophic failure of the RWST due to an exposure fire is not considered credible. Administrative controls limit the quantity of combustibles stored in the vicinity of the RWST and normal in-situ combustible loading is low, per E-1F9905. The tank is made of 304 Stainless Steel with a minimum wall thickness of 3/16” at the top and a maximim wall thickness of ½” at the bottom. The administrative controls, low combustible loading, steel tank construction together with the large heat sink provided by the water in the tank provides reasonable assurance that the RWST will remain available in the event of a fire.

A loss of RWST level indication does not impact PFSSD. The tank contains sufficient volume at minimum Tech Spec level to achieve cold shutdown conditions and loss of inventory in the RWST is not a concern.

Based on the above discussion, there is reasonable assurance that the RWST will be available if a postulated fire occurs in the RWST valve house or in the yard area around the RWST.

1.0 GENERAL AREA DESCRIPTION

Fire areas CC-1, T-1, T-2 and TURB consists of all rooms and elevations in the Communications Corridor and Turbine Building, except for the lube oil storage tank room (Fire Area T-4) and the lube oil reservoir room (Fire Area T-10) and include the rooms listed in Table 1. Fire Area CC-1 is the Communication Corridor. Fire Area T-1 is the South stairwell, all levels. Fire Area T-2 includes all levels of the Turbine Building up to 50 feet north of the Auxiliary Building wall. Fire Area TURB includes all remaining areas in the Turbine Building.

Fire area CC-1 has no automatic suppression and partial detection and is separated from the Control Building and Auxiliary Building by minimum 3-hour fire resistant construction and is open to the Turbine Building. Fire Area T-1 is protected with an automatic smoke detector at the top of the stairway. Fire Areas T-2 and TURB are protected with an automatic pre-action sprinkler system and automatic heat detection. The areas are separated from the Auxiliary Building by minimum 3-hour fire resistant construction and are open to the Communication Corridor.

2.0 PRIMARY EQUIPMENT USED FOR PFSSD

Table 2 lists each system credited for post-fire safe shutdown and provides a discussion regarding the availability of the system to perform its Post Fire Safe Shutdown (PFSSD) function if a severe fire occurs in this area. For a summary of the area analysis results, see Section 8.0 of the Fire Area Analysis Narrative section.

Table 2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Areas CC-1, T-1, T-2 and TURB

System	System Name	PFSSD Function*	Comments
AB	Main Steam	R, M, H, P, S	A number of valves located downstream of the main steam isolation valves could be affected. The main steam isolation valves (MSIVs) and MSIV bypass valves are unaffected.
AC	Main Turbine	R, H	All four main turbine stop valves and associated cables and components are located in this area. Damage to this equipment will not adversely impact PFSSD since the MSIVs can be closed from the control room.
AE	Main Feedwater	H, P	Main feedwater pumps, valves and associated cables and components are located in this area. The main feedwater isolation valves are unaffected by a fire in this area and can be closed from the control room to isolate main feedwater flow.
AL	Aux. Feedwater System	H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in areas CC-1, T-1, T-2 and TURB.
AP	Condensate Storage System	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in areas CC-1, T-1, T-2 and TURB.
BB	Reactor Coolant System	R, M, H, P, S	All four reactor coolant pumps could shut down or be prevented from shutting down from the main control room due to damage to the power and control cables. This will not adversely impact PFSSD since natural circulation cooldown can be used if the pumps stop. If the pumps remain on, forced circulation can continue. RCP seal injection is unaffected so continuously operating RCP will not result in a seal LOCA.
BG	Chemical and Volume Control System	R, M, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in areas CC-1, T-1, T-2 and TURB.
BM	Steam Generator Blowdown System	R, M, H	The 125 VDC power supply to Steam Generator Blowdown Control Panel BM157 in the Radwaste Control Room could be affected. This would result in loss of power which would fail the blowdown valves closed, which is the desired position. The main control room hand switches associated with the blowdown valves are unaffected.
BN	Borated Refueling Water Storage System	R, M, H	The PFSSD function(s) associated with this system is(are) not affected by a fire in areas CC-1, T-1, T-2 and TURB.
EF	Essential Service Water System	H, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in areas CC-1, T-1, T-2 and TURB.
EG	Component Cooling Water System	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in areas CC-1, T-1, T-2 and TURB.

Table 2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Areas CC-1, T-1, T-2 and TURB

System	System Name	PFSSD Function*	Comments
EJ	Residual Heat Removal System	M, H, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in areas CC-1, T-1, T-2 and TURB.
EM	High Pressure Coolant Injection	R, M	Power to EMHV8882 could be lost. This valve fails closed on loss of power which is the desired PFSSD position.
EN	Containment Spray	R, M	The PFSSD function(s) associated with this system is(are) not affected by a fire in areas CC-1, T-1, T-2 and TURB.
EP	Safety Injection Accumulators	H	The PFSSD function(s) associated with this system is(are) not affected by a fire in areas CC-1, T-1, T-2 and TURB.
FB	Auxiliary Steam	R, H	Valves FBHV0080 and FBHV0081 and associated cables could be affected. This will not prevent PFSSD since the MSIVs can be isolated from the control room.
FC	Auxiliary Turbines	R, H, P	A number of cables and components associated with this system are located in this area. These cables and components are associated with MSIV downstream components. Damage to these cables and components will not adversely impact PFSSD since the MSIVs are unaffected.
GD	ESW Pump House HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in areas CC-1, T-1, T-2 and TURB.
GF	AFW Pump Room Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in areas CC-1, T-1, T-2 and TURB.
GK	Control Room and Class 1E Switchgear Room Coolers	S	A fire in this area could cause both Class 1E Electrical Equipment Room A/C units (SGK05A and SGK05B) to shut down due to a spurious fire isolation signal or loss of power to the fire isolation relay. The units can be started using bypass hand switches GKHS0101 (SGK05A) and GKHS0104 (GKHS0104) on panel RP068 in the main control room.
GL	Auxiliary Building HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in areas CC-1, T-1, T-2 and TURB.
GM	Emergency Diesel Generator Room HVAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in areas CC-1, T-1, T-2 and TURB.
GN	Containment Coolers	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in areas CC-1, T-1, T-2 and TURB.
JE	Diesel Fuel Oil	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in areas CC-1, T-1, T-2 and TURB.

Table 2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Areas CC-1, T-1, T-2 and TURB

System	System Name	PFSSD Function*	Comments
KA	Instrument Air	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in areas CC-1, T-1, T-2 and TURB.
KC	Fire Protection	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in areas CC-1, T-1, T-2 and TURB.
KH	Service Gas	S	Hydrogen valve KHV0096 is located in this area. Damage to this valve will not adversely impact PFSSD since the valve is not credited for a fire in this area.
KJ	Standby Diesel Engine	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in areas CC-1, T-1, T-2 and TURB.
MA	Main Generation	S	Transformer protection cabinets MA104D, MA104E and MA104F and Site Intreface Panel MA152A could be affected, causing a loss of off-site power on NB01 and NB02. This will not adversely impact PFSSD since on-site power is available from emergency diesel generators A and B.
MR	Startup Transformer	S	Startup transformer protection cabinets and associated cables are located in this area. This will not adversely impact PFSSD since on-site power is available from emergency diesel generators A and B.
NB	4.16 kV System	S	Off-site power to NB01 and NB02 could be affected. On-site power to NB01 and NB02 is unaffected.
NE	Standby Diesel Generator	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in areas CC-1, T-1, T-2 and TURB.
NF	Load Shed and Emergency Load Sequencing	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in areas CC-1, T-1, T-2 and TURB.
NG	480V Load Centers and MCCs	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in areas CC-1, T-1, T-2 and TURB.
NK	125VDC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in areas CC-1, T-1, T-2 and TURB.
NN	120VAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in areas CC-1, T-1, T-2 and TURB.
PA	13.8kV	S	The PA buses are located in this area. Consequently, they could be affected. This will not affect PFSSD since on-site power remains available to NB02 and other loads fed from the PA bus are not required for PFSSD in the event of a fire in this area.

Table 2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Areas CC-1, T-1, T-2 and TURB

System	System Name	PFSSD Function*	Comments
PB	4.16kV	H, S	Bus PB04 control power could be affected. The PFSSD function of PB04 is to ensure the motor driven feedwater pump can be stopped or prevented from starting to prevent steam generator overfill. As stated in the AE system comments, the main feedwater isolation valves are unaffected and can be closed from the control room.
PG	480V Load Centers and MCCs	S	A number of cables and components associated with non-safety related 480 VAC load centers and MCCs are located in this area. None of these components are required for PFSSD in the event of a fire in this area.
PK	125VDC	S	Several cables and components associated with non-safety related 125 VDC system are located in this area. Redundant PFSSD capability is available.
PL	Local Instrument Panels	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in areas CC-1, T-1, T-2 and TURB.
PN	120VAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in areas CC-1, T-1, T-2 and TURB.
QB	Standby AC Lighting	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in areas CC-1, T-1, T-2 and TURB.
QD	Emergency Lighting	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in areas CC-1, T-1, T-2 and TURB.
RL	Control Room MCB	S	120 VAC non-class 1E power to RL023 could be affected. This would affect components located downstream of the MSIVs. The MSIVs are unaffected by a fire in this area. 125 VDC non-class 1E power to RL001/RL002 could be affected. This would affect the letdown isolation valves and letdown orifice isolation valves. Loss of power will fail the valves closed which is the desired PFSSD position. 125 VDC non-class 1E power to RL013/RL014 could be affected. This would affect off-site power to NB01 and NB02. On-site power to NB01 and NB02 remains available. 125 VDC non-class 1E power to RL017/RL018 could be affected. This would affect valve EMHV8882 which fails closed on loss of power, which is the desired PFSSD position.
RP	Miscellaneous Control Panels	R, M, H, P, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in areas CC-1, T-1, T-2 and TURB.
SA	ESFAS	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in areas CC-1, T-1, T-2 and TURB.

Table 2
Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Areas CC-1, T-1, T-2 and TURB

System	System Name	PFSSD Function*	Comments
SB	Reactor Protection System	R, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in areas CC-1, T-1, T-2 and TURB.
SC	Reactor Instrumentation	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in areas CC-1, T-1, T-2 and TURB.
SE	Ex-Core Neutron Monitoring	R, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in areas CC-1, T-1, T-2 and TURB.
SY	Switchyard	S	A control cable associated with switchyard breaker 13-48 is run in this area. Damage to this cable could cause the breaker to open which would affect off-site power to NB01. On-site power to NB01 remains available.
UU	Supervisory System	S	A control cable associated with switchyard breaker 13-8 is run in this area. Damage to this cable could cause the breaker to open which would affect off-site power to NB01. On-site power to NB01 remains available.

* R - Reactivity Control; M - Reactor Coolant Makeup; H - Decay Heat Removal; P - Process Monitoring; S - Support Function

3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD

This section describes operator actions that may need to be performed inside or outside the control room to achieve and maintain hot standby if a fire occurs in fire areas CC-1, T-1, T-2 and TURB. This section also describes cold shutdown repairs that may need to be made to achieve and maintain cold shutdown conditions. Operator actions are proceduralized in OFN KC-016.

3.1 ACTIONS OUTSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

None

3.2 ACTIONS INSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

3.2.1 SGK05A and SGK05B

SGK05A and SGK05B could shut down or fail to start due to a spurious fire isolation signal or loss of power to the fire isolation relay. SGK05A can be re-started by placing GKHS0101 on panel RP068 in bypass position and SGK05B can be re-started by placing GKHS0104 on panel RP068 in bypass position.

3.3 ACTIONS TO ACHIEVE AND MAINTAIN COLD SHUTDOWN

None

4.0 CONCLUSION

Post Fire Safe Shutdown is assured if a fire occurs in fire areas CC-1, T-1, T-2 and TURB.

5.0 DETAILED ANALYSIS

This section describes the detailed component-by-component and cable-by-cable analysis for a fire in areas CC-1, T-1, T-2 and TURB.

5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREAS CC-1, T-1, T-2 AND TURB

PFSSD components (S. in E-15000) located in fire areas CC-1, T-1, T-2 and TURB are shown in Table 3. An evaluation of each component and associated cables is provided in the sections that follow. The applicable evaluation section is listed in Table 3.

5.1.1 Class 1E Electrical Equipment Room A/C Units

Class 1E electrical equipment room cooling is required for PFSSD to maintain the room temperature within operable limits for the equipment. Room cooling for the credited train of PFSSD equipment is required.

Cables 15GKK31CA and 15GKK31CB are associated with the fire isolation signal on SGK05A. Cables 16GKK31DA and 16GKK31DB are associated with the fire isolation signal on SGK05B. An open circuit within these cables will cause the associated unit to shut down. A short circuit within these cables will prevent the associated unit from shutting down in the event of a fire isolation signal. The fire isolation signal on SGK05A is initiated when a fire occurs in the Train A ESF switchgear room or the Train A switchboard rooms to prevent dilution of Halon fire extinguishing agent in the rooms. The fire isolation signal on SGK05B is initiated when a fire occurs in the Train B ESF switchgear room or the Train B switchboard rooms to prevent dilution of Halon fire extinguishing agent in the rooms. A fire in the turbine building or communication corridor does not require shutdown of SGK05A or SGK05B and, therefore, a hot short that prevents shutdown will have no adverse impact on PFSSD.

Smoke detectors installed in the Train A and Train B ESF switchgear rooms and the Train A and Train B switchboard rooms are wired to fire protection panel KC275A, which is located in the communication corridor room 3619. Smoke detection signals are processed in KC275A and, upon receipt of the proper signals for the room, a normally open contact in KC275A closes and initiates a release of Halon into the room and shuts down the associated air conditioning unit. Cables 16KCQ13SA, 16KCQ21DA, 16KCQ21EA, 16KCQ21FA, 16KCQ21HA and 16KCQ21JA carry the short circuit signal from fire protection panel KC275A to the respective Halon releasing panel (KC222 for ESF switchgear rooms and KC230 for the switchboard rooms). An open circuit in these cables due to a fire will prevent Halon release to the associated room. However, since the postulated fire is in the turbine building and communication corridor, this will have no adverse impact on PFSSD. A short circuit in these cables will cause a Halon release and will shut down SGK05A and or SGK05B.

If SGK05A is required for PFSSD, the fire isolation signal can be bypassed in the control room by placing hand switch GKHS0101 in Bypass position. This will bypass the fire isolation signal and allow the unit to operate. GKHS0101 is located on panel RP068.

If SGK05B is required for PFSSD, the fire isolation signal can be bypassed in the control room by placing hand switch GKHS0101 in Bypass position. This will bypass the fire isolation signal and allow the unit to operate. GKHS0104 is located on panel RP068.

Based on the above discussion, a fire in this area could cause one or both Class 1E electrical equipment room A/C units to shut down but the units can be re-started from the control room. Therefore, Class 1E electrical equipment room air conditioning is available if a fire occurs in this area.

5.1.2 Deleted

5.1.3 Hydrogen Supply to VCT and Generator System Isolation Valve

Valve KHV0096 is included in the PFSSD analysis to provide a method to de-pressurize the VCT if a fire occurs in fire area A-8. This action may be necessary to prevent hydrogen gas intrusion into the charging pump suction if the VCT outlet valves do not close and makeup to the VCT is isolated.

A fire in this area will not prevent isolating the VCT outlet valves. Therefore, access to this valve would not be required.

References: XX-E-013, E-15000, M-12BG03, M-12KH02

5.1.4 Main Steam Isolation Valve Downstream Components

PFSSD requires isolation of main steam flow to prevent uncontrolled cooldown and potential return to criticality. There are two methods credited in the PFSSD analysis to isolate main steam. These methods include either isolation of the main steam isolation valves (MSIVs) and MSIV bypass valves or isolation of valves located downstream of the MSIVs.

Cables and components associated with a number of MSIV downstream valves are located in this area. Damage to these cables and components could prevent isolation of the downstream valves. Cables associated with all four MSIVs and bypass valves are unaffected. Therefore, in the event of a fire in this area, main steam flow can be isolated using all close hand switches ABHS0079 or ABHS0080 in the main control room.

Based on the above discussion, damage to cables associated with MSIV downstream components will have no adverse impact on PFSSD.

References: XX-E-013, E-15000, E-13AB02A, E-13AB02B, E-13AB04, E-13AB08, E-13AB11A, E-13AB11B, E-13AB11C, E-13AB18, E-13AB22, E-13AC07, E-13AC15, E-13AC16, E-13FB12, E-13FC08A, E-13FC29A, E-13FC29B, E-13FC35, E-1F9103, M-12AB03, M-12FB01

5.1.5 4.16 kV Class 1E Power

At least one source of 4.16 kV Class 1E power is required to be available to energize required PFSSD equipment. The PFSSD methodology uses Class 1E power from either the off-site or on-site sources.

On-site power originates from the respective train emergency diesel generator. Train A off-site power originates from the switchyard and supplies transformer XNB01 which feeds bus NB01. Train B off-site power originates from the switchyard and supplies startup transformer XMR01 which supplies power to bus PA02. Bus PA02 supplies power to ESF transformer XNB02, through breaker PA0201, which supplies bus NB02.

Transformer protection relay panels MA104D, MA104E and MA104F are located in room 4401W. Relay panels MA104D and MA104E contain relays 286/T1 and 486/T1 associated with startup transformer XMR01 and XNB02 feeder breaker PA0201. Damage to these panels could cause a loss of off-site power from XMR01 and therefore a loss of off-site power to NB02. Relay panel MA104F contains multiple relays associated with off-site power feed to XNB01. Site interface panel MA152A contains circuits associated with off-site power feed to XNB01. Damage to these panels and associated circuits could cause a loss of power to NB01.

A number of off-site power related cables associated with Train A and B are run in this area. Damage to these cables could prevent off-site power feed to NB01 and NB02. Based on Calculation XX-E-013, Appendix 2, off-site power can be lost to both safety-related buses NB01 and NB02. Both trains of emergency diesel generators are available.

Based on the above discussion, off-site power to NB01 and NB02 could be lost if a fire occurs in this area. The Train A and Train B emergency diesel generators remain available to energize NB01 and NB02.

References: XX-E-013, E-15000, E-13MR10, E-13NB03, E-13NB05, E-13NB06, E-13NB10, E-13NB11, E-13PG01, E-1F9423, KD-7496

5.1.6 13.8 and 4.16 kV Non-Class 1E Power

Non-class 1E power is credited to supply certain non-safety related PFSSD equipment.

13.8 kV bus PA01 is credited to supply breakers PA0105, PA0106, PA0107 and PA0108. The impact on loss of these breakers is described below.

Breaker PA0105 supplies power to the following PFSSD components via PG11:

- PG11JFR2 – Main Steam Supply to 2nd Stage Reheat Valve ABHV0031
- PG11KBR3 – Auxiliary Steam System Control Valve FBHV0081

Loss of power to these components will not adversely impact PFSSD. These components are associated with MSIV downstream components. The MSIVs are unaffected by a fire in this area and can be closed from the control room. Therefore, the MSIV downstream components are not required if a fire occurs in this area.

Breaker PA0106 supplies power to the following PFSSD components via PG19:

- PG19GCR217 – MCB Misc. Power Circuits RL023
- PG19GFR3 – Instr. Bus Transformer Alt. Feed XPN07D

PFSSD components supplied power from PG19GCR217 are associated with MSIV downstream components. The MSIVs are unaffected by a fire in this area and can be closed from the control room. Therefore, the MSIV downstream components are not required if a fire occurs in this area.

PG19GFR3 is credited as one source of power to PN07. The redundant source of power is unaffected by a fire in this area.

Breaker PA0107 supplies power to the following PFSSD component:

- Reactor Coolant Pump A Motor DPBB01A

Loss of power to the reactor coolant pump motor will have no adverse impact on PFSSD. If the RCP trips, cooldown can be achieved using natural circulation.

Breaker PA0108 supplies power to the following PFSSD component:

- Reactor Coolant Pump B Motor DPBB01B

Loss of power to the reactor coolant pump motor will have no adverse impact on PFSSD. If the RCP trips, cooldown can be achieved using natural circulation.

13.8 kV bus PA02 is credited to supply breakers PA0204, PA0205, PA0206 and PA0207. The impact on loss of these breakers is described below.

Breaker PA0206 supplies power to the following PFSSD components via PG12:

- PG12KAF4 – Main Steam Supply to 2nd Stage Reheat Valve ABHV0032
- PG12KAF5 – Main Steam Supply to Steam Seals Valve ABHV0046
- PG12KEF3 – Auxiliary Steam System Control Valve FBHV0080

Loss of power to these components will not adversely impact PFSSD. These components are associated with MSIV downstream components. The MSIVs are unaffected by a fire in this area and can be closed from the control room. Therefore, the MSIV downstream components are not required if a fire occurs in this area.

Breaker PA0207 supplies power to the following PFSSD components via PG20:

- PG20GBR217 – MCB Misc. Power Circuits RL023
- PG20GER5 – Instr. Bus Transformer Alt. Feed XPN08D

PFSSD components supplied power from PG20GBR217 are associated with MSIV downstream components. The MSIVs are unaffected by a fire in this area and can be closed from the control room. Therefore, the MSIV downstream components are not required if a fire occurs in this area.

PG20GER5 is credited as one source of power to PN08. The redundant source of power is unaffected by a fire in this area.

Breaker PA0204 supplies power to the following PFSSD component:

- Reactor Coolant Pump D Motor DPBB01D

Loss of power to the reactor coolant pump motor will have no adverse impact on PFSSD. If the RCP trips, cooldown can be achieved using natural circulation.

Breaker PA0205 supplies power to the following PFSSD component:

- Reactor Coolant Pump C Motor DPBB01C

Loss of power to the reactor coolant pump motor will have no adverse impact on PFSSD. If the RCP trips, cooldown can be achieved using natural circulation.

Based on the above discussion, loss of 13.8 and 4.16 kV non-class 1E power will have no adverse impact on PFSSD.

References: XX-E-013, E-15000, E-11PG20, E-11PG21, E-11PK01, E-13BG10, E-13PA14, E-13PG01, E-13PG02, E-13PG03, E-13PG04, E-13PG10, E-13PG11, E-13PG13, E-13RL02, E-13RL07, E-1F9103, E-1F9421, E-1F9424E, KD-7496, M-761-02169, DCP 13324

5.1.7 125 VDC Non-Class 1E Power

Non-Class 1E 125 VDC power is required to energize certain PFSSD components. A fire in this area could result in a loss of non-Class 1E 125 VDC power to PK01, PK02 and PK04. The effects of a loss of power to these buses is discussed below.

The PFSSD components supplied by PK01 are as follows:

- PK0105 - 10 kVA Inverter and Bypass Transformer (PN03)
- PK4103 – PA01 Breaker Control Power (Outgoing Breakers)
- PK4114 – Main Turbine Stop Valves Manual Trip (AC119D)
- PK5113 – Master Supervisory Station (RP060)
- PK5117 – RC & Support Systems Control Panel (RL001 & RL002)
- PK5123 – Steam Generator Blowdown Control Panel (BM157)
- PK5126 – Auxiliary Relay Rack (RP330)
- PK5129 – Auxiliary Relay Rack (RP211)
- PK6106 – Transformer Protection Relay Panel (MA104E)
- PK6108 – Transformer Protection Relay Panel (MA104F)
- PK6115 – Site Related Control Panel (RL013 & RL014)
- PK6116 – ESF Control Panel (RL017 & RL018)

PK0105 supplies 125 VDC power to inverter PN03, which powers 120 VAC distribution panel PN310. PN310 supplies redundant power to NSSS cabinets RP043 and RP047. Redundant 480 VAC power to inverter PN03 is from PG19GCF3. PN03 and PG19GCF3 are located in fire area A-27 and are not affected by a fire in this area. Therefore, power to PN310 is available if a fire occurs in this area.

Switch PK4103 supplies control power to breakers in PA01. Loss of PA01 breaker control power will prevent operation of PA01 breakers. This would also disable the breaker protection features and prevent the breakers from tripping in the event of a fault. If this occurs, PFSSD is assured because on-site power remains available. In addition, if PA01 breaker control power is lost, RCPs A and B may not trip. This will not adversely impact PFSSD since RCP seal cooling remains available.

Switch PK4114 supplies power to cabinet AC119D. For PFSSD, AC119D is credited for closing the main turbine stop valves in the event the MSIVs cannot be closed. A fire in this area will not affect the MSIVs so damage to this switch will not affect PFSSD.

Switch PK5113 is required to ensure NB01 and NB02 can be de-energized in the event of a fire in areas C-9 and C-10. Loss of PK5113 due to a fire in this area will have no adverse impact on PFSSD.

Switch PK5117 supplies power to several non-safety components on panel RL001/RL002. Some of these components are credited for PFSSD. Those components are BGLCV0459, BGLCV0460, BGHV8149A, BGHV8149B and BGHV8149C. Valves BGLCV0459 and BGLCV0460 are letdown isolation valves. Either valve is required to be closed for PFSSD. Loss of power to PK5117 will de-energize the associated control solenoid and fail the valves closed, which is the desired PFSSD position. Valves BGHV8149A, BGHV8149B and BGHV8149C are letdown orifice isolation valves. Loss of power to PK5117 will de-energize the associated control solenoid and fail the valves closed, which is the desired PFSSD position.

Switch PK5123 supplies power to steam generator blowdown control panel BM157 located in the Radwaste control room. The steam generator blowdown panel (BM157) is used as an alternate means for isolating steam generator blowdown. The normal means uses hand switches located on RL024 in the main control room. Loss of power to BM157 will de-energize solenoid valves associated with BMHV0001, BMHV0002, BMHV0003 and BMHV0004 and will fail the valves closed, which is the desired PFSSD position.

Switch PK5126 supplies power to relay 95XGK07 in relay rack RP330, as well as other non-PFSSD relays. Relay 95XGK07 is the automatic fire signal isolation relay for SGK05A. This

relay is normally energized and, upon loss of power, SGK05A will shut down. If desired, SGK05A can be re-started by placing GKHS0101 on panel RP068 in bypass position.

Switch PK5129 supplies power to auxiliary relay rack RP211. The only PFSSD relay within RP211 is 3XBM46, which is the blowdown and sample process isolation signal relay. This relay is normally de-energized, so loss of power to this relay will not affect PFSSD.

Switch PK6106 supplies power to relay panel MA104E which is associated with NB02 off-site power supply. Switch PK6108 supplies power to relay panel MA104F which is associated with NB01 off-site power supply. Switch PK6115 is associated with Site Related Control Panel (RL013 & RL014) which is associated with NB01 and NB02 off-site power. Loss of off-site power is discussed in Section 5.1.5.

Switch PK6116 supplies power to PFSSD component EMHV8882. Valve EMHV8882 fails closed on loss of power which is the desired PFSSD position.

The PFSSD components supplied by PK02 are as follows:

- PK5213 – Reverse Isolation Relay Rack (RP331)
- PK6204 – PA02 Breaker Control Power
- PK6205 – PB04 Breaker Control Power
- PK6216 – Transformer Protection Relay Panel (MA104D)

Switch PK5213 supplies power to reverse isolation relay rack RP331. This relay rack houses two relays (3XEG08 and 95XGK08) used for PFSSD. Relay 3XEG08 is the CCW heat exchanger B temperature valve (EGTV0030) auxiliary relay. Power to this relay originates from RL019/RL020 and is unaffected by a fire in this area. Relay 95XGK08 is the automatic fire signal isolation relay for SGK05B. This relay is normally energized and, upon loss of power, SGK05B will shut down. If desired, SGK05B can be re-started by placing GKHS0104 on panel RP068 in bypass position. Therefore, loss of 125 VDC power to PK5213 will not affect PFSSD.

Switch PK6204 supplies control power to breakers in PA02. Loss of PA02 breaker control power will prevent operation of PA02 breakers. This would also disable the breaker protection features and prevent the breakers from tripping in the event of a fault. If this occurs, PFSSD is assured because on-site power remains available. In addition, if PA02 breaker control power is lost, RCPs C and D may not trip. This will not adversely impact PFSSD since RCP seal cooling remains available.

Switch PK6205 supplies control power to breakers in PB04. Loss of PB04 breaker control power will prevent operation of PB0402 from the control room, which is the feeder breaker to motor driven feedwater pump motor DPAE02. The motor driven feedwater pump is required to be stopped (or prevented from starting) to prevent overfill of the steam generators. Loss of breaker control power after the pump spuriously starts would prevent the pump from being stopped from the control room. A spurious start of the pump is possible since control circuits for the pump are run in this area. The main feedwater isolation valves (MFIVs) are unaffected by a fire in this area. Therefore, feedwater flow can be prevented by closing the MFIVs from the control room. A loss of PB04 breaker control power would also disable the breaker protection features and prevent the breakers from tripping in the event of a fault. If this occurs, PFSSD is assured because on-site power remains available. Based on the above discussion, loss of 125 VDC power from PK6205 will not affect PFSSD.

Switch PK6216 supplies power to relay panel MA104D which is associated with NB02 off-site power supply. Loss of off-site power is discussed in Section 5.1.5.

The PFSSD components supplied by PK04 are as follows:

- PK0407 – 10 kVA Inverter and Bypass Transformer (PN04)

PK0407 supplies 125 VDC power to inverter PN04, which powers 120 VAC distribution panel PN410. PN410 supplies power to NSSS cabinets RP043 and RP047. 125 VDC bus PK04 is powered from battery charger PK24 which is powered from Class 1E 480 VAC breaker NG0410 and battery set PK14. Cables and equipment associated with the 125 VDC power supply to PN04 could be affected by a fire in this area. Redundant 480 VAC power to inverter PN04 is from PG20GAF4. PN04 and PG20GAF4 are located in fire area A-27 and are not affected by a fire in this area. Therefore, power to PN410 will be available if a fire occurs in this area.

References: XX-E-013, E-15000, E-1005-SY01, E-11NG02, E-11PK01, E-11PK02, E-11PK04, E-13AE20, E-13BG10, E-13BM06D, E-13EM05A, E-13GK13, E-13GK13A, E-13GK31, E-13MR10, E-13PA14, E-13PB02, E-13PK01, E-13PK10, E-13PK11, E-13PK13, E-13RL01, E-13RL02, E-1F9201, E-1F9301, E-1F9421, E-1F9422C, E-1F9426, KD-7496, DCP 13324

5.1.8 Reactor Coolant Pumps

The reactor coolant pumps are not credited in the PFSSD analysis. However, the capability to stop the pumps from the control room in the event of a loss of all seal cooling is credited. Westinghouse Technical Bulletin TB-04-22, Rev. 1 recommends that if all seal cooling is lost (RCP seal injection and thermal barrier heat exchanger flow), operators need to stop the pumps before a seal LOCA occurs.

Several control cables associated with each reactor coolant pump are run in this fire area. Damage to these cables in the event of a fire could prevent operators from stopping the RCPs from the control room. However, a fire in this area will not cause a loss of all seal cooling since thermal barrier cooling and seal injection remain available.

Based on the above discussion, the inability to trip the RCPs from the control room will have no adverse impact on PFSSD. The pumps can continue to operate, providing forced flow circulation. If the pumps spuriously stop, natural circulation cooldown can be used.

5.2 PFSSD CABLE EVALUATION

Table 4 lists all the PFSSD cables (S. in E-15000) located in fire areas CC-1, T-1, T-2 and TURB. The applicable evaluation section is also listed in Table 4.

All PFSSD cables that run in this fire area terminate at their associated PFSSD equipment within this area. Therefore, all cable evaluations are included with the equipment evaluations in Section 5.1.

1.0 GENERAL AREA DESCRIPTION

Fire area T-4 is located on the 2000 elevation of the Turbine Building and includes the room listed in Table T-4-1.

Table T-4-1
Rooms Located in Fire Area T-4

ROOM #	DESCRIPTION
4308	Lube Oil Storage Tank Room

Fire area T-4 is protected with automatic flame detection and an automatic fire suppression system. The area is separated on all sides by minimum 3-hour fire resistance rated barriers.

2.0 PRIMARY EQUIPMENT USED FOR PFSSD

Fire area T-4 contains no post-fire safe shutdown cables or equipment. Therefore, both trains of PFSSD equipment are available if a fire occurs in this area.

3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD

Not applicable to fire area T-4.

4.0 CONCLUSION

Post-fire safe shutdown is assured if a fire occurs in this area.

5.0 DETAILED ANALYSIS

A detailed analysis is not required since this area contains no PFSSD cables or components.

NG	480V Load Centers and MCCs	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area YARD
NK	125VDC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area YARD
NN	120VAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area YARD
PA	13.8kV	S	Offsite power to PA01 and PA02 could be lost. PFSSD is assured using onsite power to feed essential PFSSD equipment using NB01 and/or NB02.
PB	4.16kV	H, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area YARD
PG	480V Load Centers and MCCs	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area YARD
PK	125VDC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area YARD
PL	Local Instrument Panels	S	Switchyard supervisory panel 0PL09J could be affected. This will not affect PFSSD since on-site power remains available.
PN	120VAC	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area YARD
QB	Standby AC Lighting	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area YARD
QD	Emergency Lighting	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area YARD
RL	Control Room MCB	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area YARD
RP	Miscellaneous Control Panels	R, M, H, P, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area YARD

Table YARD-2 Summary of Post Fire Safe Shutdown (PFSSD) Capability for Fire Area YARD			
System	**System Name**	**PFSSD Function***	**Comments**
SA	ESFAS	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area YARD
SB	Reactor Protection System	R, S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area YARD
SC	Reactor Instrumentation	S	The PFSSD function(s) associated with this system is(are) not affected by a fire in area YARD
SE	Ex-Core Neutron Monitoring	R, P	The PFSSD function(s) associated with this system is(are) not affected by a fire in area YARD
SY	Switchyard	S	A fire in this area could affect off-site power. On-site power remains available.
UU	Supervisory System	S	The switchyard supervisory system could be affected. This will not affect PFSSD since on-site power remains available.

* R - Reactivity Control; M - Reactor Coolant Makeup; H - Decay Heat Removal; P - Process Monitoring; S - Support Function

3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD

This section describes operator actions that may need to be performed inside or outside the control room to achieve and maintain hot standby if a fire occurs in area YARD. This section also describes cold shutdown repairs that may need to be made to achieve and maintain cold shutdown conditions. Operator actions are proceduralized in OFN KC-016.

3.1 ACTIONS OUTSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

None

3.2 ACTIONS INSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

None

3.3 ACTIONS TO ACHIEVE AND MAINTAIN COLD SHUTDOWN

None

4.0 CONCLUSION

Post-fire safe shutdown is assured if a fire occurs in this fire area.

5.0 DETAILED ANALYSIS

This section describes the detailed component-by-component and cable-by-cable analysis for a fire in area YARD.

5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA YARD

PFSSD components (S. in E-15000) located in fire area YARD are shown in Table YARD-3. An evaluation of each component and associated cables is provided in the sections that follow. The applicable evaluation section is listed in Table YARD-3.

Table YARD-3
PFSSD Equipment Located in Fire Area YARD

Room #	PFSSD Equipment	Description	Evaluation Section	Comments
YARD	0PL09J	Swyd Remote Supervisory Cabinet	5.1.1	
YARD	TBC04	13.8 KV Swyd Breaker 13-48 Control	5.1.1	
YARD	TBSY01	13.8 KV Swyd Breaker 13-48 Control	5.1.1	Interposing Terminal Box for cables 15SY124 & 15SY135

5.1.1 Main Switchyard

Switchyard supervisory panel 0PL09J and terminal box TBC04 are included in the PFSSD design to ensure the ability to isolate off-site power in the event of a fire in areas C-9 and C-10 (ESF Switchgear Rooms). Cables 15SY124, 15SY135, and 15UU003 are also included in the PFSSD design for the same purpose.

Cables 15SY124 & 15SY135 are associated with the run from 1HSSY0022 on panel RL014 to TBC04. Hand switch 1HSSY0022 is the control switch for switchyard breaker 13-48. Breaker 13-48 is one of two redundant off-site power feeders to bus NB01. Damage to these cables could cause breaker 13-48 to trip or prevent the breaker from being closed, causing a loss of this power source to NB01.

Cable 15UU003 runs from panel RP060 (1PM01J) to 0PL09J. This cable is associated with handswitch 1HSSY0018, which is the control switch for switchyard breaker 13-8. Breaker 13-8 is one of two redundant off-site power feeders to bus NB01. Damage to this cable could cause breaker 13-8 to trip or prevent the breaker from being closed, causing a loss of this power source to NB01.

Based on the above discussion, a fire in the switchyard could cause a loss of off-site power to NB01 due to damage to these cables and components. For the purpose of this analysis, bus NB02 off-site power is assumed lost since cables and components associated with NB02 off-site power supply are not analyzed. If off-site power is lost to NB01 and NB02, the on-site power supply from the emergency diesel generators remains available. Therefore, a switchyard fire will not adversely impact the ability to achieve and maintain safe shutdown.

3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD

This section describes operator actions that may need to be performed inside or outside the control room to achieve and maintain hot standby if a fire occurs in area YARD1. This section also describes cold shutdown repairs that may need to be made to achieve and maintain cold shutdown conditions. Operator actions are proceduralized in OFN KC-016.

3.1 ACTIONS OUTSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

None

3.2 ACTIONS INSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

None

3.3 ACTIONS TO ACHIEVE AND MAINTAIN COLD SHUTDOWN

None

4.0 CONCLUSION

Post-fire safe shutdown is assured if a fire occurs in this fire area.

5.0 DETAILED ANALYSIS

This section describes the detailed analysis for a fire in area YARD1.

5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA YARD1

PFSSD components (S. in E-15000) located in fire area YARD1 are shown in Table YARD1-3. An evaluation of each component and associated cables is provided in the sections that follow. The applicable evaluation section is listed in Table YARD1-3.

Table YARD1-3 PFSSD Equipment Located in Fire Area YARD1				
Room #	**PFSSD Equipment**	**Description**	**Evaluation Section**	**Comments**
EXFMR	XNB01	Train A ESF Transformer	5.1.1	
EXFMR	XNB02	Train B ESF Transformer	5.1.1	

5.1.1 ESF Transformer Area

ESF transformers XNB01 and XNB02 supply off-site power to safety related buses NB01 and NB02. The ESF transformers are located in this area. Power and control cables identified in Table YARD1-4 are associated with NB01 and NB02. Damage to these cables or the transformers could cause a loss of offsite power to NB01 and NB02.

If a fire in this area causes a loss of offsite power to NB01 and NB02, on-site power from both emergency diesel generators remains available to supply power to both safety related buses. Therefore, a fire in this area will not adversely impact post-fire safe shutdown.

1.0 GENERAL AREA DESCRIPTION

Fire area YARD2 is located on the north side of the Turbine Building and includes the area listed in Table YARD2-1.

Table YARD2-1
Rooms Located in Fire Area YARD2

ROOM #	DESCRIPTION
MXFMR	Main Transformer Area

Each main transformer is protected with automatic heat detection and an automatic fire suppression system.

2.0 PRIMARY EQUIPMENT USED FOR PFSSD

Fire area YARD2 contains no post-fire safe shutdown cables or equipment. Therefore, both trains of PFSSD equipment are available if a fire occurs in this area.

3.0 ACTIONS TO ACHIEVE AND MAINTAIN PFSSD

Not applicable to fire area YARD2.

4.0 CONCLUSION

Post-fire safe shutdown is assured if a fire occurs in this area.

5.0 DETAILED ANALYSIS

A detailed analysis is not required since this area contains no PFSSD cables or components.

None

3.2 ACTIONS INSIDE THE MCR TO ACHIEVE AND MAINTAIN HOT STANDBY

None

3.3 ACTIONS TO ACHIEVE AND MAINTAIN COLD SHUTDOWN

None

4.0 CONCLUSION

Post-fire safe shutdown is assured if a fire occurs in this fire area.

5.0 DETAILED ANALYSIS

This section describes the detailed component-by-component and cable-by-cable analysis for a fire in area YARD3.

5.1 PFSSD EQUIPMENT LOCATED IN FIRE AREA YARD3

PFSSD components (S. in E-15000) located in fire area YARD3 are shown in Table YARD3-3. An evaluation of each component and associated cables is provided in the sections that follow. The applicable evaluation section is listed in Table YARD3-3.

Table YARD3-3 PFSSD Equipment Located in Fire Area YARD3				
Room #	**PFSSD Equipment**	**Description**	**Evaluation Section**	**Comments**
YARD2	XMR01	Startup Transformer	5.1.1	

5.1.1 Startup Transformer Area

A fire in this area could affect the startup transformer. The startup transformer supplies off-site power to Train B Class 1E transformer XNB02. If a fire affects the startup transformer, the Train B emergency diesel generator is available to provide power to NB02. Therefore, post-fire safe shutdown is assured if a fire occurs in fire area YARD3.

References: E-15000, XX-E-013, KD-7496

5.2 PFSSD CABLE EVALUATION

There are no post-fire safe shutdown cables in fire area YARD3. The cables associated with the startup transformer are evaluated for impact on off-site power availability but are not considered essential to perform a PFSSD function.

SUBJECT: Loss of CCW Cooling to CCP Lube Oil Heat Exchangers

Reference:
1. SA-92-048 Rev. 0, "Human Reliability Analysis for WCGS PRA
2. CKL ZL-001 Rev. 33, "Auxiliary Building Reading Sheets"

The PRA model, as currently configured, contains a dependency between the CCPs and the availability of CCW cooling to the CCP lube oil system. Upon a loss of CCW cooling, it is assumed that the operator must trip the CCPs within 30 minutes to avoid overheating the lube oil and consequentially failing the pumps. This best estimate analysis was performed to determine the amount of time actually available before the lube oil overheats to a level which could cause pump failure.

The following assumptions were used:

1. A lube oil temperature of 180°F at the outlet of the outboard bearing is assumed to cause bearing, and hence pump, failure. This value comes from the Aux Building Reading Sheets, wherein the watchstander is required to notify the control room if the bearing oil outlet temperature is equal to or greater than 180°F.

2. Typically, based on discussions with the CCP System Engineer, the temperature of the outboard bearing oil is about 15 degrees F higher than the oil temperature at the outlet of the heat exchanger.

3. A typical initial condition for the outlet temperature of the lube oil at the heat exchanger is 80°F. This value is based on a conservative average value for measurements taken by the System Engineer in December (64.5°F) and July (90°F). For example, (64.5+90) / 2 = 77.25. Therefore, 80°F is a realistic approximation.

4. The typical CCW delta-T across the lube oil heat exchanger is about 2 degrees F. Again, this is based on System Engineer readings. Based on a typical CCW flow of 30,000 lbm/hr, this equates to a heat transfer into the CCW water of 60,000 BTU/hr. This number is reasonable, considering the heat exchanger is designed to transfer up to 75,000 BTU/hr.

5. The specific heat of the lube oil is 0.47.

IMAGED 11/17/2005

Page 2
January 10, 1996

6. The amount of lube oil in the system is 595 lb based on 85 gallons of oil and an estimated weight of 7 lb/gal.

If the CCW flow is lost to the lube oil heat exchanger, the 60,000 BTU/hr that would have been removed from the lube oil via CCW flow is now assumed to remain entirely in the lube oil. Using the following equation, the temperature rise of the lube oil can be determined:

Q = (m) (Cp) (delta-T), where

Q = heat in BTU added to the lube oil
m = mass of lube oil in the system in lbm
Cp = the specific heat of the lube oil, 0.47
delta-T = the change in the oil temperature in degrees F

delta-T = (Q) / (m) (Cp), or
= 60,000 / (0.47) (595)
= 215 degrees F / hour

The maximum allowed temperature at the outboard thrust bearing is 180°F and the assumed initial temperature is 80°F, so a temperature difference of 100 degrees F is the maximum allowed. The time to reach 180°F is (100 / 215) * 60 minutes = 28 minutes. This 28 minutes assumes that the entire heat normally transferred to the CCW water stays in the lube oil. In actuality, as the lube oil temperature rises above its normal temperature, an increasing amount of heat energy will be transferred to the surrounding air through the piping, reservoir walls, etc. Therefore, it appears the 30 minutes previously allowed for the operator action was a reasonable estimate.

Embedded Conduit Evaluation

TABLE OF CONTENTS

SHEET

1.0 PURPOSE 3
2.0 SCOPE 3
3.0 ASSUMPTIONS 3
4.0 REFERENCES 3
5.0 EVALUATION 4
6.0 CONCLUSIONS 6

1.0 PURPOSE

The purpose of this Attachment is to evaluate embedded conduit that contains Post-Fire Safe Shutdown (PFSSD) related cables.

2.0 SCOPE

All embedded conduit containing PFSSD cables will be evaluated in this attachment, regardless of whether the cable is required for PFSSD in the event of a fire in an adjacent fire area.

3.0 ASSUMPTIONS

The heat sink effect of the concrete is ignored. In reality, the heat transfer through the wall or floor will be much slower than the indicated fire resistance ratings due to the thermal mass of the walls and floors. Therefore, this assumption is conservative.

5.0 EVALUATION

This section provides an analysis of embedded conduit at Wolf Creek to determine if the depth of concrete embedment provides sufficient protection against a design basis exposure fire for embedded conduits carrying PFSSD cables.

Fire rating of reinforced concrete was researched to determine the minimum embedment depth required to achieve the desired fire resistance rating. Fire resistance of concrete walls and ceilings is evaluated using the testing methods specified in ASTM E-119 (Reference 4.1.3). The acceptance criteria in ASTM E-119 states that the temperature rise on the unexposed side of the fire barrier cannot exceed 250 F when averaged among all thermocouples. Table 1 identifies the minimum concrete thickness required to ensure a temperature rise equal to or below 250 F for various types of aggregate and different fire ratings.

NRC Generic Letter 86-10 (Reference 4.2.1) provides acceptance criteria for fire barriers used to separate redundant PFSSD cables. The acceptance criteria requires that the maximum temperature rise does not exceed 250 F, which is the same as that used for fire barriers in ASTM E-119. Generic Letter 86-10 also states that if the temperature rise does not exceed 250 F, then cables on the unexposed side of the barrier are considered free of fire damage.

ACI 216.1-07 (Reference 4.1.2) provides hourly fire resistance ratings for concrete based on barrier thickness and aggregate type used. Table 1 is taken from Reference 4.1.2, Table 2.1, and summarizes the concrete thickness required to meet desired fire resistance ratings.

Wolf Creek specification C-101 (Reference 4.4.1) identifies the aggregate used at Wolf Creek is consistent with siliceous. This aggregate type also results in the most conservative fire resistance rating identified in Table 1. Therefore, to meet the 1 hour fire rating requirements a minimum embedment of 3.5 inches is required and to meet the 3 hour fire rating requirements a minimum embedment of 6.2 inches is required.

Table 1 – Fire Resistance of Single Layer Concrete Walls, Floors and Roofs (Reference 4.1.2, Table 2.1)					
Aggregate Type	**Minimum equivalent thickness for fire-resistance rating, inches**				
	1 hour	**1-1/2 hours**	**2-hours**	**3 hours**	**4 hours**
Siliceous	3.5	4.3	5.0	6.2	7.0
Carbonate	3.2	4.0	4.6	5.7	6.6
Semi-lightweight	2.7	3.3	3.8	4.6	5.4
Lightweight	2.5	3.1	3.6	4.4	5.1

Table 2 identifies each embedded conduit that carries PFSSD cables and identifies some key attributes of those conduits. Those key attributes are described as follows:

Conduit # - The embedded conduit under consideration.

PFSSD Cables Included – The PFSSD related cables that are run in the embedded conduit under consideration.

From Room (Fire Area) – The room and fire area at one of the endpoints for the embedded conduit under consideration.

To Room (Fire Area) – The room and fire area at one of the endpoints for the embedded conduit under consideration.

Cable Function – The function of the PFSSD cable included in the embedded conduit under consideration.

Conduit OD (inches) – The outside diameter of the embedded conduit under consideration.

Adjacent Fire Areas – Fire areas that the embedded conduit passes without terminating in the area.

Required Rating – This is the hourly fire rating required if the embedded conduit contains redundant circuits to those in the adjacent fire areas. If the adjacent fire area contains automatic fire suppression and detection, then the required rating is 1 hour. If the adjacent fire area does not contain automatic fire suppression and detection, then the required rating is 3 hours.

Required Concrete Cover – This is the required depth of coverage to the outer most edge of the conduit based on the required rating and Table 1.

Min Actual Concrete Cover – This is the minimum embedment depth along the length of the embedded conduit based on reference drawings.

The embedded conduit drawings identify the bury depth to the centerline of each embedded conduit. Using the conduit OD and the bury depth, the distance from the face of the wall to the outside edge of the conduit can be determined. This distance must be equal to or greater than the minimum depth indicated in Table 1. Table 2 provides a summary of the results of this evaluation.

6.0 CONCLUSIONS

Based on the information contained in Table 2, the depth of concrete embedment for each conduit carrying PFSSD cables provides sufficient fire resistance for the desired hourly fire rating. Therefore, the cables will remain free of fire damage in the event of a fire in any of the adjacent fire areas.

3.0 ASSUMPTIONS 3
4.0 METHODOLOGY 3
5.0 EVALUATION 3
6.0 CONCLUSIONS 14
7.0 REFERENCES 14

1.0 PURPOSE

The purpose of this evaluation is to determine if fire exposure to instrument tubing associated with post-fire safe shutdown (PFSSD) equipment will adversely impact the ability to achieve and maintain safe shutdown after a fire.

2.0 SCOPE

The scope of this review includes any type of tubing (i.e., copper, brass, stainless steel or capillary) that is directly connected to a transmitter required for PFSSD and that transmitter either provides a signal to an indicator in the control room or provides an actuation signal that can adversely impact PFSSD or both. This evaluation does not look at instrument air, since loss of instrument air will have no adverse impact on the PFSSD analysis. The instrument air system is not analyzed in the PFSSD analysis and is assumed to fail in the worse possible configuration.

3.0 ASSUMPTIONS

3.1 A fire in an area containing instrument tubing associated with PFSSD equipment is assumed to fail the associated transmitter to the worse possible state.

4.0 METHODOLOGY

The location of the instrument tubing was compared with the cable routing and the transmitter location to determine if the PFSSD analysis is potentially affected. If the tubing is located only in areas where the cables are run, then the effects of fire exposure to the tubing will not adversely impact the PFSSD analysis because the analysis already assumes worse case effects in the event the cable is damaged. If the tubing runs in areas where the cables are not located, then the PFSSD analysis will be reviewed to determine the impact on the analysis assuming worse case effect of fire exposure on the tubing.

5.0 EVALUATION

Fire exposure to instrument tubing can have the same effect as fire exposure to cables, where the transmitter can provide a spurious reading that results in spurious operation or mal-operation of required PFSSD equipment. Fire exposure can also result in false readings on indicators in the control room, preventing operators from accurately diagnosing plant conditions.

The difference between fire exposure to cables and fire exposure to instrument tubing is that cable damage will occur if the fire reaches approximately 700°F and the damage will need to be repaired before the associated equipment can be returned to operation. Instrument tubing at Wolf Creek is stainless steel which has a melting point of 2,750°F. The design basis ASTM E-119 fire exposure reaches a temperature of 1,925°F. Therefore, fire exposure to instrument tubing would not cause failure of the tubing and may have a short term effect on the instrument readings but will return to normal whenever the fire is extinguished.

NEI 00-01, Section 3.2.2.3 states the following regarding instrument tubing:

> *Identify instrument tubing that may cause subsequent effects on instrument readings or signals as a result of fire. Determine and consider the fire area location of the instrument tubing when evaluating the effects of fire damage to circuits and equipment in the fire area.*

NEI 00-01, Section 3.4.1.9 states the following regarding instrument tubing:

> *Consider the effects of the fire on the density of the fluid in instrument tubing and any subsequent effects on instrument readings or signals associated with the protected safe*

shutdown path in evaluating post-fire safe shutdown capability. This can be done systematically or via procedures such as Emergency Operating Procedures.

Table 1 lists all PFSSD credited transmitters. This list was developed from XX-E-013, Rev. 2, Appendix 3. The table also provides a description of the transmitter, the room and fire area where the transmitter is located, the instrument cable associated with the transmitter, the fire areas where the cable is located and the fire areas where the instrument tubing is located. In addition, the table indicates whether there are any potential adverse impacts that have not been analyzed in the PFSSD analysis, comments related to the instrument and references.

Notes

1. Cable listed is within containment. Other cable for this instrument runs outside containment. However, since the instrument tubing is only in containment, the other cables are not listed.
2. Deleted
3. All instrument tubing is run in areas where cables are located. Therefore, the PFSSD analysis in E-1F9910 is not affected.
4. ABPT0001 supplies the signal for ARV ABPV0001. ARV ABPV0001 is in fire area A-23W and has been analyzed in the PFSSD analysis assuming worse case spurious operation. The effects of fire exposure to the instrument tubing for ABPT0001 in fire area A-23 is bounded by the A-23 fire area analysis.
5. ABPT0002 supplies the signal for ARV ABPV0002. ARV ABPV0002 is in fire area A-23E and has been analyzed in the PFSSD analysis assuming worse case spurious operation. The effects of fire exposure to the instrument tubing for ABPT0002 in fire area A-23 is bounded by the A-23 fire area analysis.
6. ABPT0003 supplies the signal for ARV ABPV0003. ARV ABPV0003 is in fire area A-23E and has been analyzed in the PFSSD analysis assuming worse case spurious operation. The effects of fire exposure to the instrument tubing for ABPT0003 in fire area A-23 is bounded by the A-23 fire area analysis.
7. ABPT0004 supplies the signal for ARV ABPV0004. ARV ABPV0004 is in fire area A-23W and has been analyzed in the PFSSD analysis assuming worse case spurious operation. The effects of fire exposure to the instrument tubing for ABPT0004 in fire area A-23 is bounded by the A-23 fire area analysis.

<u>Evaluation 1</u>

At least one pressurizer level transmitter is required to be operable to provide operators with pressurizer level indication. Based on E-1F9910, at least one pressurizer level transmitter will remain operable when considering fire damage to the transmitters and/or associated cables. E-1F9910 did not consider fire effects on instrument tubing associated with the transmitters.

The PFSSD analysis credits pressurizer level transmitters BBLT0459 and BBLT0460. The fire area RB analysis in E-1F9910 also analyzes BBLT0461 and BBLT0462 because of the close proximity of all the pressurizer level transmitters.

A fire in the Reactor Building, areas RB-1, RB-4 and RB-10 could affect the instrument tubing for pressurizer level transmitters BBLT0459, BBLT0460, BBLT0461 and BBLT0462.

If the fire is in area RB-4 (South Electrical Penetration Area) the fire protection features provided (automatic fire detection and a manually charged closed head fire suppression system) meet the intent of the requirements of 10 CFR 50 Appendix R, Section III.G.2.e as discussed in the Wolf Creek SER. This protection coupled with the low fixed combustible loading and the strict control of transient combustibles in the containment during power operations provides reasonable assurance that a fire of sufficient magnitude to affect all four pressurizer level transmitters will not occur.

The instrument tubing for all four pressurizer level transmitters also runs in the pressurizer compartment which is part of fire areas RB-1 and RB-10. The only significant combustible loading within the pressurizer compartment are the heater cables. There are no significant ignition sources within the pressurizer compartment other than the energized heater cables. The heater elements are located inside the pressurizer and do not pose an ignition hazard within the pressurizer compartment. At the 2026-0 elevation around the pressurizer, cable trays carrying the pressurizer heater cables are provided with line-type heat detection. In the event of a fire, the heat detection will alarm in the control room on Window 139 (zone 203), prompting operator response. This protection coupled with the low fixed combustible loading and the strict control of transient combustibles in the containment during power operations provides reasonable assurance that a fire of sufficient magnitude to affect all four pressurizer level transmitters will not occur.

Level transmitters BBLT0459, 0460 and 0461 are Barton Model 764 Electronic Transmitters. Level transmitter BBLT0462 is a Barton Model 752 Electronic Transmitter. All four transmitters have built-in temperature compensation to adjust for changes in ambient temperature. The transmitters themselves are designed to operate for a limited period of time when subjected to adverse design-basis accident conditions within the containment, including high pressure, temperature and humidity. If the instrument tubing were exposed to a design basis fire with temperatures reaching 2000°F, the transmitter would likely fail to provide accurate level readings.

As stated earlier, the fire protection features provided in containment, the low fixed combustible loading, the lack of ignition sources in the areas where the instrument tubing runs and the strict control of transient combustible materials inside the containment provides reasonable assurance that a design basis fire will not occur. Any fire that does occur in containment will be limited in size and will likely not affect the accuracy of the pressurizer level transmitters. Therefore, the locations of the instrument tubing for the pressurizer level transmitters is acceptable.

<u>Evaluation 2</u>

Reactor coolant system (RCS) pressure indication is required for PFSSD to provide operators with indication of RCS pressure. Alternatively, pressurizer pressure indication will provide the required diagnostic indication. At least one pressure indicator needs to be available following a fire anywhere in the plant. Each pressure instrument is discussed in the following paragraphs.

BBPT0403

Instrument tubing for BBPT0403 runs in areas A-1, A-25, RB-1, RB-2 and RB-11. The transmitter is located in fire area A-1 so the cables do not run in containment. Instrument cable has been analyzed for PFSSD in areas A-1 and A-25 but not RB-1, RB-2 or RB-11.

The two instrument tubes for BBPT0403 enter containment in the South pipe penetration area on 2000-0. The tubing runs north along the west wall until it reaches the far north portion of containment in area RB-2. The tubing then runs south through the bioshield wall into RB-1 where one tube runs to the top of the reactor vessel and the other tube runs to the seal table. From the seal table, a tube runs to the bottom of the reactor vessel in area RB-11.

BBPT0405

Instrument tubing for BBPT0405 runs in areas A-8, A-24, RB-1, RB-2 and RB-11. The transmitter is located in fire area A-8 so the cables do not run in containment. Instrument cable has been analyzed for PFSSD in area A-8 but not A-24, RB-1, RB-2 or RB-11. If a fire occurs in A-24 and affects the BBPT0405 transmitter, then the remaining pressurizer and RCS pressure transmitters are available to provide pressure indication.

The two instrument tubes for BBPT0405 enter containment in the North pipe penetration area on 2000-0. The tubing runs north along the west wall until it reaches the far north portion of containment in area RB-2. The tubing then runs south through the bioshield wall into RB-1 where one tube runs to the top of the reactor vessel and the other tube runs to the seal table. From the seal table, a tube runs to the bottom of the reactor vessel in area RB-11.

BBPT0406

Instrument tubing for BBPT0406 runs in areas A-1, A-25, RB-1, RB-2 and RB-11. The transmitter is located in fire area A-1 so the cables do not run in containment. Instrument cable has been analyzed for PFSSD in area A-1 but not A-25, RB-1, RB-2 or RB-11. A fire in A-25 could also affect BBPT0403. If a fire occurs in A-25 and affects BBPT0403 and BBPT0406, then the remaining pressurizer and RCS pressure transmitters are available to provide pressure indication.

The two instrument tubes for BBPT0406 are the same as those for BBPT0403. See the discussion for BBPT0403 for the routing.

BBPT0455, 456, 457, 458

BBPT0455 and BBPT0456 are located in area RB-4 in the south electrical penetration area. BBPT0457 and BBPT0458 are located in area RB-10 on the southwest end. Instrument tubing for all four transmitters runs in areas RB-4 and RB-10 (within the pressurizer compartment). Instrument cable has been analyzed for PFSSD in areas RB-4 and RB-10 (outside the pressurizer compartment).

Based on Evaluation 1, a fire in RB-4 will not affect the instrument tubing for the four pressure transmitters. In addition, based on Evaluation 1, a fire in RB-10 in the pressurizer compartment is not likely to affect the instrument tubing in a manner that will affect the accuracy of the pressure transmitters.

In the unlikely event a fire does occur in the pressurizer compartment and affect all four pressurizer pressure transmitters, RCS pressure transmitters BBPT0403, BBPT0405 and BBPT0406 remain unaffected because of the physical separation between their instrument tubes and the pressurizer pressure instrument tubes.

Evaluation 2 Conclusion

A fire in containment will not affect all seven credited pressure transmitters. A fire in the area of the pressurizer will not affect RCS pressure transmitters BBPT0403, BBPT0405 and BBPT0406. A fire in the north or west portions of containment will not affect the four pressurizer pressure transmitters. Therefore, pressure indication is available in the event of a fire anywhere in the plant.

Evaluation 3

Containment pressure transmitters GNPT0935 and GNPT0937 are located in fire area A-18. Instrument tube for these transmitters runs into containment and terminates in the north electrical penetration area (RB-3). Containment pressure transmitters GNPT0934 and GNPT0936 are located in fire area A-17. Instrument tube for these transmitters runs into containment and terminates in the south electrical penetration area (RB-4). Cables for these transmitters have been evaluated in the A-17 and A-18 analysis. There are no cables for these transmitters in containment.

The fire protection features provided in areas RB-3 and RB-4 (automatic fire detection and a manually charged closed head fire suppression system) meet the intent of the requirements of 10 CFR 50 Appendix R, Section III.G.2.e as discussed in the Wolf Creek SER. This protection coupled with the low fixed combustible loading and the strict control of transient combustibles in the containment during power operations provides reasonable assurance that a fire of sufficient magnitude to affect all four containment pressure transmitters will not occur.

Since there is significant physical separation between RB-3 and RB-4, a single fire will not affect all four containment pressure transmitters. In the unlikely event a fire does occur and affect two containment pressure transmitters, the only adverse effect will be to actuate a spurious SIS and/or CISB. These spurious signals can be mitigated from the control room. Since line type heat detection is provided in RB-3 and RB-4, operators will have indication of a fire and can rely on the unaffected pressure transmitters to diagnose the condition. A spurious SIS is discussed in the RB area analysis in E-1F9910.

Evaluation 4

EGFT0062 is located in area A-6. Instrument tubes are run in A-6 and A-24. The cable is run in A-6 but not A-24. Therefore, the effects of a fire in A-24 on EGFT0062 have not been analyzed in E-1F9910.

Fire effects on the EGFT0062 instrument tubes could produce a false high flow signal and close valve EGHV0062, stopping CCW return flow from the thermal barriers. If this occurs, operators can open EGHV0132 to re-establish CCW flow to the RCP thermal barriers. EGHV0132 is unaffected by a fire in A-24. RCP seal injection is unaffected by a fire in area A-24.

Based on the above discussion, a fire in A-24 that causes a high flow signal on EGFT0062 will not adversely affect PFSSD.

Evaluation 5

A minimum of two steam generators are required for decay heat removal. At least one level transmitter on two steam generators is required to be operable to provide operators with diagnostic indication of steam generator level.

Instrument tubing associated with steam generator level transmitters on all four steam generators is run in the vicinity of the associated steam generator. The transmitters are located outside the bioshield wall near the associated steam generator. Steam generators A and D are located less than 20 feet apart and steam generators B and C are located less than 20 feet apart. The separation distance between steam generators A/D and B/C is approximately 45 feet. The minimum separation distance between instrument tubing for steam generators A/D and B/C is approximately 35 feet. Intervening combustibles consist of a limited number of cable trays that are provided with automatic fire detection. Some intervening cable trays are enclosed on all sides with sheet metal covers. The cable trays are not continuous. Based on this discussion, separation in accordance with 10CFR50, Appendix R, Section III.G.2.d exists within containment so that level indication on at least two steam generators will be available.

Based on the above discussion, there is reasonable assurance that level indication on at least two steam generators will be available if a single design basis fire occurs in containment when considering damage to instrument tubing. In some cases, operators may need to monitor level on all four steam generators to determine if erratic readings are present. Operator training covers identification and response to erratic indication.

Evaluation 6

Flow transmitters EGFT0128 and EGFT0129 are used to diagnose availability of CCW flow to the RCP thermal barriers. Instrument tubing for these transmiters runs in fire areas A-8 and A-24. Cables for these transmitters runs in fire area A-8 but not A-24. Therefore, the fire area analysis for area A-24 has not addressed the possibility of a loss of these transmitters in the event of a fire in area A-24.

Based on the fire area analysis for fire area A-24 in E-1F9910, thermal barrier cooling and RCP seal injection are unaffected by a fire in area A-24. Loss of flow transmitters EGFT0128 and EGFT0129 in the event of a fire in area A-24 will not adversly impact PFSSD because flow to the thermal barriers is unaffected. Therefore, the configuration is acceptable.

Evaluation 7

Flow indicating switches EJFIS0610 and EJFIS0611 are used to control RHR mini flow valves EJFCV0610 and EJFCV0611, respectively. Low flow in the respective RHR system causes the associated mini flow valve to open to provide protection for the pump. High flow demand causes the respective mini flow valve to close, ensuring maximum flow in the system.

Instrument sensing lines run from the pump discharge piping in fire areas A-9 and A-10 to the associated switch. The cable runs in the same fire areas as the tubing except in fire areas A-9 and A-10. Fire area A-9 contains the heat exchanger for Train B RHR and fire area A-10 contains the heat exchanger for Train A RHR. The fire area analysis for these areas assumes loss of the associated RHR system in the event of a fire. Therefore, the presence of instrument sensing lines for the associated flow indicating switch in these areas does not impact the conclusions in E-1F9910. Therefore, the configuration is acceptable.

6.0 CONCLUSIONS

Based on the evaluation presented herein, fire exposure to the instrument tubing associated with PFSSD equipment will not adversely impact the ability to achieve and maintain safe shutdown.

1.0 PURPOSE

The purpose of this Attachment is to evaluate the Wolf Creek site specific list of MSOs to determine if any of the scenarios could potentially impact the ability to achieve and maintain Post-Fire Safe Shutdown (PFSSD).

2.0 SCOPE

The scope of this evaluation includes all the MSO scenarios on the Wolf Creek MSO list developed from the expert panel on February 17 – 18, 2009. Generic MSO scenarios are identified by the prefix PWROG. Scenarios developed by the Wolf Creek expert panel are identified by the prefix Expert Panel. In addition, MSO scenarios that were developed following completion of the expert panel are identified by the prefix WCNOC. The MSO scenarios are shown on the attached table.

5.0 EVALUATION

For an evaluation of each MSO scenario, see the table on the following pages.

6.0 CONCLUSIONS

Sixty-two (62) generic and 15 site specific MSO scenarios have been evaluated. Of these 77 scenarios, 24 required further evaluation. Based on the evaluation in following table, 10 MSO scenarios are being addressed by plant modifications. The remaining MSO scenarios that required further evaluation are being addressed by adding components/cables to the PFSSD analysis and/or by requesting deviations via license amendments.

All MSO scenarios have been evaluated and, for those requiring further action, corrective actions have been completed per the action plan in CR 25002.

Scenario ID	Scenario	Scenario Description	Notes	Included Equipment	Applicable Fire Areas at WCNOC?	Comments
RCS Inventory Control						
PWROG 1	Loss of all RCP Seal Cooling	Spurious isolation of seal injection header flow AND Spurious isolation of CCW flow to thermal barrier heat exchanger	Scenario causes loss of all RCP seal cooling and subsequent RCP seal LOCA, challenging the RCS Inventory Control Function.	BBHV8351A, BBHV8351B, BBHV8351C and/or BBHV8351D AND BBHV0013 (BBFT0017), BBHV0014 (BBFT0018), BBHV0015 (BBFT0019), and/or BBHV0016 (BBFT0020) OR EGHV0058, EGHV0061, EGHV0062 (EGFT0062) or EGHV0071	A-21, C-22, C-30, C-33	The RCP seal injection valves (BBHV8351A, BBHV8351B, BBHV8351C and BBHV8351D) are maintained open and de-energized. The valves are not high/low pressure interfaces so consideration of 3-phase hot shorts is not required. Therefore, a fire will not cause the valves to close in the event of damage to power and control cables associated with these valves. In the four applicable fire areas, at least one charging pump will be available to provide seal cooling through the open seal injection valves. License Amendment 190 was issued by the NRC on November 3, 2010. This amendment approved the Technical Specification change to operate with the RCP seal injection valves open and de-energized. Based on the above discussion, a loss of all RCP seal cooling, as a result of this MSO scenario, will not occur in any fire area at Wolf Creek.

Scenario ID	Scenario	Scenario Description	Notes	Included Equipment	Applicable Fire Areas at WCNOC?	Comments
RCS Inventory Control						
PWROG 2	Loss of all RCP Seal Cooling	Spurious opening of charging injection valve(s) causing diversion flow away from seals, AND Spurious isolation of CCW flow to thermal barrier heat exchanger	Scenario causes loss of all RCP seal cooling and subsequent RCP seal LOCA, challenging the RCS Inventory Control Function.	EMHV8801A or EMHV8801B AND EMHV8803A or EMHV8803B AND BBHV0013 (BBFT0017), BBHV0014 (BBFT0018), BBHV0015 (BBFT0019), and/or BBHV0016 (BBFT0020) OR EGHV0058, EGHV0061, EGHV0062 (EGFT0062) or EGHV0071	A-8, A-11, A-18, A-21, C-18, C-22, C-24, C-30, C-33	Calculation change notice (CCN) SA-91-016-000-CN002 calculates the charging flow to the RCP seals and RCS injection points at various RCS pressures. Page 155 of this CCN shows the values at an RCS pressure of 2235 psi. The results show a total flow rate of 23.23 gpm to the seals, which is 5.8 gpm per pump. This flow rate is sufficient to maintain the RCP seals cool. Procedure OFN BB-005 Section 2.0, Symptoms or Entry Conditions, requires entry whenever seal flow is less than 6 gpm. Minimum seal flow is from M-712-00068. As the RCP pressure drops, flow to the seals will increase as shown in this calculation. The calculation reduced the centrifugal charging pump curve by 10% for conservatism. Removing this conservatism would yield higher seal injection flow. In all applicable fire areas, at least one charging pump remains available. Based on the above discussion, spurious opening of the charging injection lines will not adversely impact RCP seal injection. Therefore, this MSO scenario is not an issue at Wolf Creek.

Scenario ID	Scenario	Scenario Description	Notes	Included Equipment	Applicable Fire Areas at WCNOC?	Comments
RCS Inventory Control						
PWROG 3	Thermal Shock of RCP Seals	Loss of all Seal Cooling to any RCP(s). See Scenarios 1 & 2, AND Spurious re-initiation of seal cooling (i.e., seal injection or CCW to TBHX)	Thermal shock of seals causes catastrophic RCP seal failure and subsequent RCP seal LOCA, challenging the RCS Inventory Control Function.	Same as PWROG 1 or 2 AND EGHV0058 AND EGHV0071 or EGHV0126 AND EGHV0127 AND EGHV0062 or EGHV0132 AND EGHV0061 or EGHV0133	A-21, C-22, C-30, C-33	Based on the response to scenarios PWROG 1 and PWROG 2, this MSO scenario is not credible because RCP seal injection will not be lost as a result of these scenarios. Based on the above discussion, thermal shock of the RCP seals, as a result of this MSO scenario, will not occur in any fire area at Wolf Creek.
PWROG 4	Catastrophic RCP Seal Failure	Loss of all Seal Cooling to any RCP(s). See Scenarios 1 & 2, AND Fire prevents tripping, or spuriously starts, RCP(s)	Scenario causes catastrophic RCP seal failure and subsequent RCP seal LOCA, challenging the RCS Inventory Control Function.	Same as PWROG 1 or 2 AND PBB01A, PBB01B, PBB01C or PBB01D	C-22	Based on the response to scenarios PWROG 1 and PWROG 2, this MSO scenario is not credible because RCP seal injection will not be lost as a result of these scenarios. Based on the above discussion, catastrophic RCP seal failure, as a result of this MSO scenario, will not occur in any fire area at Wolf Creek.

Scenario ID	Scenario	Scenario Description	Notes	Included Equipment	Applicable Fire Areas at WCNOC?	Comments
RCS Inventory Control						
PWROG 5	RCP Seal No. 2 Failure	Loss of all Seal Cooling to any RCP(s). See Scenarios 1 & 2, AND Spurious isolation of No. 1 seal leakoff valve(s)	Isolation of the No. 1 seal leakoff line during a loss of all seal cooling event would force the No. 2 RCP seal into a high pressure mode of operation at high temperature, which is beyond the design basis of the No. 2 seal. This could cause catastrophic failure of the No. 2 seal and increase RCS leakage.	Same as PWROG 1 or 2 AND BBHV8141A, BBHV8141B, BBHV8141C or BBHV8141D	A-21, C-22, C-30, C-33	Valves BBHV8141A – D are not PFSSD. Valves are fail open, energize to close. No credible intracable hot short scenarios exist for these valves. An intercable hot short of the correct polarity would be required to close the valves. Cables are run in raceway where this is possible. Therefore, assume valves BBHV8141A – D can spuriously close. Based on the response to scenarios PWROG 1 and PWROG 2, this MSO scenario is not credible because RCP seal injection will not be lost as a result of these scenarios. Based on the above discussion, RCP seal No. 2 failure, as a result of this MSO scenario, will not occur in any fire area at Wolf Creek.
PWROG 6	Letdown Fails to Isolate and Inventory Lost to CVCS	Spurious opening of (or failure to close) letdown isolation valve(s), AND Spurious opening of (or failure to close) letdown orifice valve(s)	Letdown Fails to Isolate and Inventory Lost to CVCS causes loss of RCS inventory, challenging the RCS Inventory Control Function.	BGLCV0459 and BGLCV0460 AND BGHV0149A, BGHV0149B or BGHV0149C	A-1, A-11, A-18, C-7, C-12, C-18, C-21, C-24, RB	In all the applicable fire areas except C-21, the letdown isolation valves can be failed closed by isolating KAFV0029 using KAHIS0029 in the control room. In fire area C-21, License Amendment 191, issued on December 16, 2010, allows the use of operator manual action to close KAV0201 to fail close the letdown isolation valves. Based on the above discussion, this MSO scenario is not an issue at Wolf Creek.

Scenario ID	Scenario	Scenario Description	Notes	Included Equipment	Applicable Fire Areas at WCNOC?	Comments
RCS Inventory Control						
PWROG 7	Letdown Fails to Isolate and Inventory Lost to PRT	Letdown fails to isolate (see Scenario 6), AND Spurious closure of downstream containment isolation valve	Scenario causes letdown flow to PRT through relief valve. This letdown flow is assumed unavailable for RCS makeup.	Same as PWROG 6 AND BGHV8152, BGHV8160, or BGPCV0131	A-1, A-11, A-18, C-7, C-12, C-18, C-21, C-24, RB	BGHV8152, BGHV8160 and BGPCV0131 are not analyzed in the PFSSD analysis. Therefore, the circuits are not evaluated. Assume this MSO scenario can occur anywhere scenario PWROG 6 can occur. Based on the evaluation for scenario PWROG 6, letdown can be isolated in the event of a fire in any area of the plant. Therefore, this MSO scenario is not an issue at Wolf Creek.
PWROG 8	Excess Letdown Fails to Isolate	Spurious opening of (or failure to close) multiple series excess letdown isolation valves	Scenario causes loss of RCS inventory to the CVCS system, challenging the RCS Inventory Control Function. The RCS inventory (letdown) is assumed lost and unavailable for makeup. In reality, additional failures downstream of the excess letdown isolation valves would have to occur for this RCS inventory to be unavailable for makeup.	BGHV8153A and BGHV8154A OR BGHV8153B and BGHV8154B AND BBHV8157A, BBHV8157B or BGHCV0123	RB	Inventory lost through the excess letdown line would normally be returned to the VCT through the RCP seal return path. This pathway is isolated during an SI which could cause loss of RCS inventory to the PRT through the RCP seal return line relief valve. Thermal hydraulic analysis (Calc WCNOC-CP-002) shows that the excess letdown valves can remain open with no adverse impact on PFSSD, as long as letdown is isolated. Based on the above discussion, this MSO scenario is not an issue at Wolf Creek.

Scenario ID	Scenario	Scenario Description	Notes	Included Equipment	Applicable Fire Areas at WCNOC?	Comments
RCS Inventory Control						
PWROG 9	RCS Makeup Isolation	Spurious isolation of seal injection flow path, AND/OR Spurious isolation of normal charging flow path, AND/OR Spurious isolation of charging injection flow path	Scenario isolates all high head RCS makeup flow paths, challenging the RCS Inventory Control Function.	BGFCV0462, BGHCV0182, BGHV8105 or BGHV8106 AND BGFCV0121 or BBHV8351A, BBHV8351B, BBHV8351C and/or BBHV8351D AND BGHV8357A or BGHV8357B	A-21, C-22, C-30, C-33	Valves BGFCV0462, BGHCV0182 and BGFCV0121 are not analyzed in the PFSSD analysis. This scenario is considered wherever cables for BGHV8105 or BGHV8106 and BBHV8351A, BBHV8351B, BBHV8351C and/or BBHV8351D are located. The NCP is not analyzed in the PFSSD analysis, therefore, the normal charging flow path is assumed lost in all fire areas. In all of the applicable fire areas, the A Train CCP is available to provide makeup to the RCS through the BIT. Also, see scenario PWROG 1 for discussion about the seal injection valves. Since the BIT flowpath is available and the seal injection flowpath remains available based on the discussion in PWROG 1, this MSO scenario is not an issue at Wolf Creek.

Scenario ID	Scenario	Scenario Description	Notes	Included Equipment	Applicable Fire Areas at WCNOC?	Comments
RCS Inventory Control						
PWROG 10	Charging Pump Inoperability	Initial condition is charging pump running with normal lineup taking suction from VCT. Spurious isolation of suction from VCT to running charging pump, AND Spurious isolation of (or failure to open) suction from RWST to running charging pump	Scenario causes charging pump inoperability, challenging the RCS Inventory Control Function. This is especially challenging if the credited charging pump is running at the time of the fire.	BGLCV112B (BGLT0112) or BGLCV112C (BGLT0185) AND BNLCV112D (BGLT0112) and BNLCV112E (BGLT0185)	<u>BGLCV112B</u> C-9, C-12, C-18, C-21, C-24 <u>BGLCV112C</u> C-10, C-11, C-17, C-22, C-23, C-30, C-33 <u>BNLCV112D</u> A-2, A-8, C-9, C-12, C-18, C-21 <u>BNLCV112E</u> A-1, A-4, C-1, C-10, C-11, C-17, C-22, C-23, C-30, C-33	Either VCT outlet valve BGLCV112B or BGLCV112C can spuriously close if a fire occurs in any of the applicable fire areas listed. At least one RWST to charging header valve (BNLCV112D or BNLCV112E) is unaffected. However, the RWST valves do not automatically open when one of the VCT valves closes. The RWST to charging valves automatically open on a SIS or low-low VCT level. Therefore, if one VCT valve spuriously closes, an operator in the control room would have to open the available RWST valve. The NCP is the normally operating charging pump and is assumed to be running at the time of the fire. The NCP is not credited for PFSSD. If the MSO occurs, the NCP could be damaged but the credited charging pump will not be affected because it is assumed to be in standby mode. In addition, procedure SYS BG-120 establishes compensatory measures in the applicable fire areas when either CCP is started. Based on the above discussion, this MSO scenario is not an issue at Wolf Creek because at least one RWST valve is unaffected in those areas where the VCT valve could spuriously close.

Scenario ID	Scenario	Scenario Description	Notes	Included Equipment	Applicable Fire Areas at WCNOC?	Comments
RCS Inventory Control						
PWROG 11	Charging Pump Inoperability	Initial condition is charging pump running and drawing suction from RWST. Spurious isolation of two parallel RWST outlet valves.	Scenario causes loss of charging pump suction, causing subsequent pump cavitation and inoperability. This challenges the RCS Inventory Control Function.	BNLCV112D and BNLCV112E	None	There are no III.G.2 fire areas where cables for both RWST to CCP suction valves are run. Therefore, this MSO scenario is not an issue at Wolf Creek.

Scenario ID	Scenario	Scenario Description	Notes	Included Equipment	Applicable Fire Areas at WCNOC?	Comments
RCS Inventory Control						
PWROG 12	Charging Pump Inoperability	Spurious opening (or failure to close) of multiple series VCT outlet valves	Scenario causes VCT drain down and hydrogen cover gas entrainment into charging pump suction, ultimately causing charging pump inoperability and challenging the RCS Inventory Control Function. This is especially challenging if the credited charging pump is running at the time of the fire. Note this scenario assumes that VCT makeup has been isolated (i.e., letdown isolated).	BGLCV112B and BGLCV112C	A-8	Fire area A-8 contains both VCT valves as well as power cables for these valves. Therefore, a fire in this area could prevent closing one of the valves. Fire would also have to affect makeup to the VCT from letdown. Since the letdown flowpath is not fully analyzed, it is assumed that makeup to the VCT is affected. The Train B CCP is the credited charging pump for a fire in area A-8. The NCP is the normally operating charging pump and is assumed to be running at the time of the fire. The NCP is not credited for PFSSD. If the MSO occurs, the NCP could be damaged but the credited charging pump will not be affected because it is assumed to be in standby mode. A spurious SIS coincident with this MSO will start both charging pumps. License Amendment 205 was issued on August 23, 2013 and allows a deviation from the separation requirements of 10 CFR 50, Appendix R for the VCT outlet valves. Based on the Safety Evaluation for Amendment 205, the fire protection features as well as the low combustible loading in fire area A-8 provides reasonable assurance that at least one VCT outlet valve will respond to a close signal from the control room following a fire. Procedure OFN KC-016 has been revised to direct operators to close both VCT outlet valves in the event of a fire in area A-8. Therefore, this MSO issue is considered resolved.

Scenario ID	Scenario	Scenario Description	Notes	Included Equipment	Applicable Fire Areas at WCNOC?	Comments
RCS Inventory Control						
PWROG 13	Charging Pump Inoperability	Letdown fails to isolate (see Scenario 6), AND Spurious isolation of CCW cooling to the letdown heat exchanger	Scenario causes elevated charging pump suction temperature and subsequent pump inoperability. Charging pump inoperability challenges the RCS Inventory Control Function. This is especially challenging if the credited charging pump is running at the time of the fire.	PWROG 6 AND BGTV0130	A-1, A-11, A-18, C-7, C-12, C-18, C-21, C-24, RB	BGTV0130 is not included in the PFSSD analysis. Therefore, assume the valve closes in all fire areas. Water returning to the VCT would be cooled slightly by the regenerative heat exchanger to about 280 degrees F. The letdown heat exchanger further reduces the temperature to around 109 degrees F. Without cooling to the letdown heat exchanger, the 280 degree water would enter the CCP suction and would flash to steam, causing damage to the pump. At least one of the VCT outlet valves can be closed in the event of a fire in any of these areas, preventing hot water from entering the CCP suction. One of the RWST valves can be opened to provide suction to the CCP. Therefore, this MSO can be mitigated from the control room. Isolation of the VCT outlet valves without isolation of letdown would cause RCS water to overflow the VCT and flow to the waste gas compressor or the boron recycle holdup tank, which is not desired. Based on scenario PWROG 6, letdown can be isolated in the event of a fire in any area. Therefore, this concern can be mitigated. Based on the above discussion, this MSO scenario is not an issue at Wolf Creek.

Scenario ID	Scenario	Scenario Description	Notes	Included Equipment	Applicable Fire Areas at WCNOC?	Comments
RCS Inventory Control						
PWROG 14	Charging Pump Inoperability	Charging pump runout when RCS is depressurized	Scenario causes charging pump runout and failure. Pump(s) must be running when RCS is at a depressurized condition. RCS depressurization could occur due to spurious opening of pressurizer PORV(s), for example.	PBG05A PBG05B AND BBPCV0455A And/or BBPCV0456A	None	This scenario is not postulated to occur at Wolf Creek because the credited charging pump is unaffected by a fire in any area and can be stopped if the RCS is completely depressurized. Furthermore, there are no credible scenarios that would lead to a complete depressurization of the RCS. One or both pressurizer PORVs could open if the fire is in certain areas. See PWROG 18 for discussion about the PORVS. See PWROG 36 for discussion about RCS pressure decrease. Based on the above discussion, this MSO scenario is not an issue at Wolf Creek.
PWROG 15	RWST Drain Down via Containment Sump	Spurious opening of multiple series containment sump valves	Scenario causes RWST drain down to the containment sump. Since typical PFSS analyses do not credit alignment of containment sump, the RWST inventory becomes unavailable for RCS makeup, challenging the RCS Inventory Control Function.	BNHV8812A and EJHV8811A OR BNHV8812B and EJHV8811B	A-11, A-16S, A-17, A-18, A-19, A-21, A-22, A-26, A-27	Scenario for Wolf Creek requires spurious opening of EJHV8811A (B) and failure of BNHV8812A (B) to automatically close. Some cables associated with these valves have been re-routed in DCP 12307. The re-routing ensures the redundant valves are not affected by a single fire. In the fire areas listed, manual action in the control room is necessary to close the BN valve if the EJ valve spuriously opens. Since the action is in the control room, the regulatory requirements are met. Based on the above discussion, no further actions are needed to address this MSO scenario.

Scenario ID	Scenario	Scenario Description	Notes	Included Equipment	Applicable Fire Areas at WCNOC?	Comments
RCS Inventory Control						
PWROG 16	RWST Drain Down via Containment Spray	Spurious opening of containment spray header valve(s), AND Spurious starting of containment spray pump(s) and/or RHR pump(s).	Scenario causes a pumped RWST draindown via the containment spray ring. The RWST inventory ultimately settles to the containment sump. Since typical PFSS analyses do not credit alignment of the containment sump, the RWST inventory is assumed unavailable for RCS makeup, challenging the RCS Inventory Control Function.	ENHV0006 AND PEN01A OR ENHV0012 AND PEN01B	C-18, C-21, C-22, C-23, C-24, C-30, C-33	Actuation of Containment Spray (CS) due to spurious containment spray actuation signals (CSAS) is addressed in scenario PWROG 56d. This MSO scenario addresses spurious opening of the valve coincident with spurious start of the pump not caused by a spurious CSAS. For a fire in each of these areas, only one flowpath will spuriously actuate. Therefore, RWST draindown will be limited to the flow from a single CS pump. License Amendment 191, issued on December 16, 2010, allows use of operator manual actions to mitigate spurious CS actuation in these fire areas. Wolf Creek document E-1F9900 demonstrates that feasible and reliable manual actions are available to stop CS prior to the RWST reaching levels below that required to achieve cold shutdown. Based on the above discussion, no further actions are needed to address this MSO scenario.

Scenario ID	Scenario	Scenario Description	Notes	Included Equipment	Applicable Fire Areas at WCNOC?	Comments
RCS Inventory Control						
PWROG 17	Interfacing System LOCA	Spurious opening of multiple series RHR suction valves from RCS	Scenario causes interfacing system LOCA, challenging the RCS Inventory Control Function.	BBPV8702A and EJHV8701A OR BBPV8702B and EJHV8701B	None	All four valves are normally de-energized. Therefore this scenario would require proper polarity hot short of power cables plus damage to control cables. These valves are considered high-low pressure interface components, so consideration of these circuit failures is required. Power cables for the BB valves are run in separate areas from power cables for the EJ valves outside containment. Inside containment, the power cables for the valves do not run in raceway with other 3 phase 480 VAC power cables so a proper polarity hot short is not credible and the valves will not open. For details, see E-1F9910. Based on the above discussion, no further actions are needed to address this MSO scenario.

Scenario ID	Scenario	Scenario Description	Notes	Included Equipment	Applicable Fire Areas at WCNOC?	Comments
RCS Inventory Control						
PWROG 18	Multiple Pressurizer PORVs	Spurious opening of multiple (two or three) Pressurizer PORVs with corresponding block valves in normal, open position	Scenario causes loss of RCS inventory through the pressurizer PORVs, challenging the RCS Inventory Control Function. Scenario also causes pressurizer depressurization, challenging the RCS Pressure Control Function.	BBPCV0455A and BBHV8000A AND BBPCV0456A and BBHV8000B	A-27, RB	License Amendment 193 was issued on March 9, 2011. This amendment changed the classification of the pressurizer PORVs from high/low to non-high/low pressure interface. Therefore, Wolf Creek can use the circuit failure criteria for non-high/low pressure interface components when evaluating the pressurizer PORVs. Change package 12944 was implemented during RF18. This change package re-wired the PORV control circuits so that a spurious PORV opening due to a single proper polarity hot short can be mitigated from the control room. Based on the above discussion, spurious opening of two PORVs due to a fire in areas A-27 and RB can be mitigated from the control room. Therefore, no further actions are needed to address this MSO scenario.
PWROG 19	Pressurizer PORV and Block Valve	Spurious opening of Pressurizer PORV(s), AND Spurious opening of block valve(s) after it has been closed.	Scenario causes loss of RCS inventory through the pressurizer PORV(s), challenging the RCS Inventory Control Function. Scenario also causes pressurizer depressurization, challenging the RCS Pressure Control Function.	BBPCV0455A AND BBHV8000A OR BBPCV0456A AND BBHV8000B	None	There are no fire areas where the PORV can open and the block valve can be credited as closing. The PORV and redundant block valve cables are run in the same fire areas. So, if the PORV is postulated to spuriously open, then the same fire is postulated to prevent the block valve from closing. Therefore, since the block valve cannot be credited to close, it cannot be postulated that it closes then re-opens. See PWROG 18 for discussion of multiple PORVs opening Based on the above discussion, this MSO scenario is not an issue at Wolf Creek.

Scenario ID	Scenario	Scenario Description	Notes	Included Equipment	Applicable Fire Areas at WCNOC?	Comments
RCS Inventory Control						
PWROG 20	Reactor Head Vent Valves	Spurious opening of multiple series reactor head vent valves	Scenario causes loss of RCS inventory through open reactor head vent flowpath(s), challenging the RCS Inventory Control Function.	BBHV8001A and BBHV8002A OR BBHV8001B and BBHV8002B	None	There are no fire areas where both redundant reactor head vent valve flow paths will spuriously open. Therefore, this MSO scenario is not an issue at Wolf Creek.
PWROG 21	Excess RCS Makeup	Spurious starting of additional high head charging pump(s), AND Spurious opening of additional RCS makeup flow paths (i.e., charging injection)	Scenario causes increasing RCS inventory, leading to a water solid pressurizer and PORV or safety valve opening. This scenario challenges both RCS Inventory and RCS Pressure Control Functions.	PBG04, PBG05A or PBG05B AND EMHV8801A or EMHV8801B AND EMHV8803A or EMHV8803B	C-18, C-21, C-22, C-24, C-30, C-33	This scenario addresses spurious opening of the BIT valves and start of the charging pumps without a spurious SIS. Spurious SIS is discussed in scenario PWROG 56. The NCP is not analyzed and is assumed to be running during this scenario, except as discussed below. Normal charging valve BGHV8105 or BGHV8106 can be isolated from the control room for a fire in all fire areas except A-24, where the valves are located. There are no cables for the NCP in A-24, so there is reasonable assurance that the NCP can be stopped from the control room if the fire is in A-24. Pressurizer level indication is available to diagnose excess RCS makeup. CCP status could be affected and valve position indication could be affected. Only one CCP would spuriously run in this scenario. Based on the pump curve (M-721-00439) and normal operating pressure at 2235 psig, the pump will discharge approximately 275 gpm. The pressurizer is normally maintained at approximately 60 % which is 8,109 gallons per WCRE-03. 100% indicated level is 13,090 gallons.

Scenario ID	Scenario	Scenario Description	Notes	Included Equipment	Applicable Fire Areas at WCNOC?	Comments
RCS Inventory Control						
						Therefore, 4,981 gallons is available before going solid. Therefore it would take about 18 minutes to fill the pressurizer. The flow rate does not consider friction loss and elevation differences in the pipe. This calc would need to be formalized if it is to be used to justify timing. Since a spurious SI does not cause this MSO, EMG E-0 would not be entered. DCP 13614 was implemented to address this MSO scenario. The DCP used a combination of fire resistive cables and cable re-routing to ensure a fire will not spuriously open the BIT valves in the applicable fire areas. Therefore, there is reasonable assurance that the postulated MSO scenario will not occur at Wolf Creek.

RCS Inventory Control						
PWROG 22	Primary Sample System	Spurious opening of RCS sample valve(s) (i.e., hot leg, PZR liquid space, PZR steam space, etc.), AND Spurious opening of inside containment isolation valve, AND Spurious opening of outside containment isolation valve, AND Spurious opening of downstream sample valve(s)	Scenario causes loss of reactor coolant through the primary sample system, challenging the RCS Inventory Control Function.	SJHV0003 SJHV0004 SJHV0005 SJHV0006 SJHV0012 SJHV0013 SJHV0020 SJHV0127 SJHV0128 SJHV0129 SJHV0130 SJHV0133	None	None of the SJ valves are PFSSD. Therefore, they are all assumed to fail open in a fire. Sample lines are isolated by a normally closed manual isolation valve downstream of the sample coolers. (M-12SJ01) Based on the above discussion, no actions are needed to address this MSO.

Scenario ID	Scenario	Scenario Description	Notes	Included Equipment	Applicable Fire Areas at WCNOC?	Comments
RCS Inventory Control						
Expert Panel 1	Letdown Fails to Isolate and Inventory Lost to RHT	Letdown fails to isolate (see Scenario 6), AND Spurious diversion of letdown flow to recycle hold-up tank	Scenario causes letdown flow to RHT through divert valve. This letdown flow is assumed unavailable for RCS makeup.	Same as PWROG 6 AND BGLCV0112A (BGLT0149)	None	Divert valve BGLCV0112A is not analyzed in the PFSSD analysis and is assumed failed in the worse position. The signal from BGLT0149 is used to control the divert valve. BGLT0149 is not PFSSD. Damage to BGLT0185 or failure of BGLCV0112C and BNLCV0112E to operate would be required to prevent re-alignment of CCP suction to the RWST. See PWROG 6 discussion for resolution of letdown isolation concern. Based on the above discussion, no actions are needed to address this MSO.
Expert Panel 2	Injection Flow Diverted to RWST or RHT	Scenario assumes high head injection is in operation. BIT test line opens to divert injection flow to the RWST or RHT	Scenario causes diversion of high head injection and loss of RCS makeup.	EMHV8843 or EMHV8882 AND EMHV8871 AND EMHV8964	None	The PFSSD analysis (E-1F9910) shows that this MSO cannot occur due to a fire in any fire area. Therefore, no actions are needed to address this MSO.

Scenario ID	Scenario	Scenario Description	Notes	Included Equipment	Applicable Fire Areas at WCNOC?	Comments
RCS Inventory Control						
Expert Panel 3	Isolation of Charging Pump Miniflow	Spurious closure of normal charging isolation valve AND Spurious closure of pump miniflow valve	Scenario causes overheating and eventual failure of affected pump.	BGFCV0462 and BGHV8109 OR BGFCV0121 and BGHV8110 or BGHV8111	<u>BGHV8110</u> A-1, A-2, A-8, C-9, C-12, C-18, C-21, C-24 <u>BGHV8111</u> A-1, A-4, C-1, C-10, C-11, C-17, C-22, C-23, C-30, C-33 <u>Spurious SI</u> A-8, A-13, A-15, A-16N/S, A-17, A-18, A-23, A-27, C-21, RB	The NCP is not credited for PFSSD. Damage to it will not affect PFSSD. BGHV8109 is not analyzed in the PFSSD analysis and is assumed failed in all fire areas. BGFCV0121 is not analyzed in the PFSSD analysis and is assumed failed in all fire areas. In fire area A-1, cables for BGHV8110 are protected. The PFSSD analysis (E-1F9910) shows that for each fire area, one of the two CCPs will be available and the associated miniflow valve is unaffected. A spurious SIS will cause both CCPs to start. If this occurs and the associated miniflow valve is also affected by the fire or the BIT injection flowpath is affected, then damage to the CCP could occur due to low flow. A fire in areas A-8 and C-21 could cause a spurious SIS coincident with BGHV8110 valve closure. There are no fire areas where a SIS can occur coincident with failure of BGHV8111. In A-8 and C-21, Train B CCP is credited with miniflow through BGHV8111. Based on the above discussion, no actions are needed to address this MSO scenario.
Expert Panel 4	Loss of Low Head SI Pump Suction	Spurious RWST Low Level indication resulting in:	Scenario causes failure of low head SI pumps when required for recirculation.	2/4 Low-Low on BNLT0930, BNLT0931, BNLT0932, and BNLT0933	A-19, A-20, A-22, A-27, C-21, F-1, F-2, F-5, F-7, RWST	This scenario is discussed further in PWROG 56a where a SIS occurs coincident with a spurious low RWST level. If a spurious low RWST level occurs without a SIS,

RCS Inventory Control						
Expert Panel 5	Failure of ECCS Sump Alignment	Spurious RWST High Level indication resulting in: Exhaustion of RWST inventory AND Failure of automatic transfer to ECCS Sump suction source.	Scenario causes damage to CCPs and/or low head SI pumps due to loss of suction source.	SIS AND BNLT0930, BNLT0931, BNLT0932, and BNLT0933	None	Scenario assumes SI flow is in progress due to spurious SI and/or Bleed and Feed operation. Scenario also assumes high water loss rate from the RWST, causing the RWST to empty faster than expected, but the level indicators are reading normal. This would not be the case since the assumption is that no other design basis events occur with the fire. Therefore RWST water usage would be that needed to maintain RCS inventory during hot standby and cold shutdown. RWST draindown caused by the fire is addressed in other MSO scenarios. In all fire areas at Wolf Creek where a SIS can occur, there is at least one RWST level indicator that is unaffected by the fire. Therefore, operators will have RWST level indication available. Based on the above discussion, no actions are needed to address this MSO scenario.

Scenario ID	Scenario	Scenario Description	Notes	Included Equipment	Applicable Fire Areas at WCNOC?	Comments
RCS Inventory Control						
Expert Panel 6	RCP Seal Return Diverted to PRT	Spurious closure of RCP seal return line isolation valve.	Scenario causes loss of RCS inventory to the PRT challenging the RCS Inventory Control function.	BGHV8100 OR BGHV8112	All	This is actually a single spurious scenario that is documented in XX-E-013. BGHV8100 is not included in the PFSSD analysis and is assumed to close in the event of a fire in all fire areas. BGHV8112 is included in the PFSSD analysis because it is needed for a fire in area A-16S. For PFSSD following this scenario, the position of these valves will not affect safe shutdown. If the valves fail closed and seal leakoff is diverted to the PRT, the maximum loss would be 84 gpm (21 gpm per pump). Based on XX-E-013, 214,260 gallons can be lost from the RWST and still have enough for cold shutdown. Therefore, it would take 42 hours to challenge cold shutdown. Cold shutdown manual actions can be taken prior to 42 hours to stop the loss. Based on the above discussion, no actions are needed to address this MSO scenario.
Expert Panel 7	Loss of all RCP Seal Cooling	Loss of Letdown Flow to VCT AND Failure of RWST supply to high head pumps AND Spurious isolation of CCW flow to thermal barrier heat exchanger	Scenario causes loss of all charging pumps due to loss of suction sources, loss of RCP Thermal Barrier cooling and subsequent RCP seal LOCA, challenging the RCS Inventory Control Function.	BGLCV0459, BGLCV0460, BGHV8152, BGHV8160, BGPCV0131, or BGLCV0112A OR BGHV0149A, BGHV0149B and BGHV0149C AND	<u>BNLCV112D</u> A-2, A-8, C-9, C-12, C-18, C-21 <u>BNLCV112E</u> A-1, A-4, C-1, C-10, C-11, C-17, C-22, C-23, C-30, C-33 <u>TBC Valves</u> A-8, A-11, A-18, A-19, A-22, C-18, C-21, C-24, C-31, RB	Spurious isolation of letdown was not addressed in PFSSD analysis. Letdown was only analyzed for isolation capability, not availability. PWROG 10 addresses availability of RWST to CCP suction valves. At least one valve will be available to open in all fire areas. Therefore, CCP suction is available from the RWST and, per License Amendment 190, the RCP seal injection valves are de-energized open (See scenario PWROG 1). Thermal barrier cooling can be lost in fire areas A-6, A-8, A-11, A-16N/S, A-17, A-18, A-19, A-21, A-

Decay Heat Removal						
PWROG 26	Inadvertent Steam Dumping	Spurious operation of main steam header drain valve(s)	Scenario may cause RCS over-cooling. Also, the overcooling can cause RCS shrinkage, causing low pressurizer level, and challenging the RCS Inventory Control Function.	ABLV0007, ABLV0008, ABLV0009 ABLV0010, ABLV0050, ABLV0051, ABLV0052 or ABLV0053	None	ABLV0007, ABLV0008, ABLV0009 and ABLV0010 are not analyzed in the PFSSD analysis. These valves are on 1 inch drain lines upstream of the MSIVs and spurious opening will not challenge RCS cooldown function based on WCNOC-CP-002 which shows that 3 steam generator ARVs (8 inch valves) can fail open with no adverse impact on PFSSD. Based on E-1F9910 and XX-E-013, in fire areas where the MSIVs may be affected, valves ABLV0050, ABLV0051, ABLV0052 and ABLV0053 are unaffected. Based on the above discussion, no actions are needed to address this MSO scenario.
PWROG 27	Turbine Driven AFW Pump Inoperability	Spurious isolation of redundant steam supply valves to turbine driven AFW pump	Scenario causes turbine driven AFW pump inoperability, which challenges the Decay Heat Removal Function.	ABHV0005 and ABHV0006	A-13, A-15, A-16N, A-18, A-23E, A-24, A-27, A-28S, C-10, C-20, C-22, C-25, C-30, C-32, C-34	Based on E-1F9910, in fire areas where the TDAFP is inoperable one of the motor driven AFW pumps is available. Calculation WCNOC-CP-002 shows PFSSD is assured using one MDAFP and 2 steam generators. Therefore, no actions are needed to address this MSO scenario.

Scenario ID	Scenario	Scenario Description	Notes	Included Equipment	Applicable Fire Areas at WCNOC?	Comments
Decay Heat Removal						
PWROG 28	AFW Flow Isolation	Spurious closure of multiple valves in AFW pump discharge flow path(s)	Scenario isolates AFW flow to the steam generator(s), challenging the Decay Heat Removal Function.	ALHV0005 (ALFT0001), ALHV0007 (ALFT0007), ALHV0009 (ALFT0009) and/or ALHV0011 (ALFT0011) OR ALHV0006, ALHV0008, ALHV0010 and/or ALHV0012	Various	E-1F9910 shows that failure of multiple valves in the AFW pump discharge lines will not adversely impact PFSSD because redundant AFW flowpaths are available. In most cases, the available AFW flowpaths will supply steam generators whose ARVs are unaffected and, where this is not the case, calculation WCNOC-CP-002 and E-1F9915 provide justification for acceptability. Based on the above discussion, no actions are needed to address this MSO scenario.
PWROG 29	AFW Flow Isolation	Spurious closure of steam supply valve(s) to turbine driven AFW pump, AND Spurious isolation of AFW pump discharge flow path(s)	Scenario isolates AFW flow to the steam generator(s) and causes turbine driven AFW pump inoperability, challenging the Decay Heat Removal Function.	ABHV0005 and ABHV0006 AND ALHV0005 (ALFT0001), ALHV0007 (ALFT0007), ALHV0009 (ALFT0009) and/or ALHV0011 (ALFT0011)	A-13, A-15, A-16N, A-18, A-24, A-28S, C-10, C-22, C-30	The fire areas listed are those where the steam supplies to the TDAFP can be lost coincident with a loss of at least one MDAFP supply to a steam generator. Based on E-1F9910, there are no fire areas where a loss of steam supply to the TDAFP can occur coincident with a loss of both motor driven AFW pump discharge flow paths to the steam generators. In most cases, the available AFW flowpaths will supply steam generators whose ARVs are unaffected and, where this is not the case, calculation WCNOC-CP-002 and E-1F9915 provide justification for acceptability. Based on the above discussion, no actions are needed to address this MSO scenario.

Scenario ID	Scenario	Scenario Description	Notes	Included Equipment	Applicable Fire Areas at WCNOC?	Comments
Decay Heat Removal						
PWROG 30	AFW Flow Diversion	Combination of spurious valve operations in the AFW pump discharge flowpaths to the steam generators	Scenario causes AFW flow diversion to a non-credited steam generator(s), challenging the Decay Heat Removal Function. A steam generator may be "non-credited" by the SSA for a number of reasons including unavailability of instrumentation, inoperability of steam dumps on that loop, etc.	ALHV0005 (ALFT0001), ALHV0007 (ALFT0007), ALHV0009 (ALFT0009) and/or ALHV0011 (ALFT0011) OR ALHV0006, ALHV0008, ALHV0010 and/or ALHV0012	Various	The feedwater check valves were re-located in RF17 and they are now upstream of the AFW tap. Therefore, the AFW flow will not divert to another steam generator. Calculation WCNOC-CP-002 analyzes possible scenarios that could lead to overcooling. The calculation, along with E-1F9910, shows that operators can mitigate an overcooling event from the control room. In particular, scenarios 2 and 3 in WCNOC-CP-002 investigate the effects of 2 ARVs failed open, pressurizer heaters off, pressurizer spray operating and maximum AFW flow. Based on the results, overcooling and return to criticality did not occur based on operator actions in the control room. Based on the above discussion, no actions are needed to address this MSO scenario.

Decay Heat Removal						
PWROG 31	AFW Pump Run Out	Spurious full opening of multiple AFW flow control and/or isolation valves	Scenario may cause AFW pump runout and inoperability, challenging the Decay Heat Removal Function. Note that this scenario may occur even without spurious operations if the fail-safe position of relevant valves is full open.	ALHV0005 (ALFT0001), ALHV0007 (ALFT0007), ALHV0009 (ALFT0009) and/or ALHV0011 (ALFT0011) OR ALHV0006, ALHV0008, ALHV0010 and/or ALHV0012	Various	See PWROG 30 comments, which are applicable to this scenario. E-1F9910 has analyzed the availability of AFW for fires in any fire area. There are no fire areas where a fire could cause runout of the credited AFW pump. At worse, runout may occur on the non-credited pump which is a commercial concern only. The credited pump and valves can be fully controlled from the control room. Restriction orifices are located in the pump discharge lines. Per discussion with the system engineer and review of system description M-00AL, these orifices are designed to limit AFW flow to 250 gpm and will prevent runout in the event the control valve fully opens. Based on the above discussion, no actions are needed to address this MSO scenario.

Decay Heat Removal						
PWROG 33	Excess Feed Flow to Steam Generator	Scenario can occur due to various combinations of spurious AFW pump starts, spurious opening (or failure to close) of valves in AFW pump discharge flowpaths, and spurious opening of MFW isolation valves with MFW pump(s) running.	Scenario causes RCS over-cooling and/or steam generator overfill, both challenging the Decay Heat Removal Function. RCS over-cooling can cause RCS shrinkage and low PZR level. Steam generator overfill can affect operability of turbine-driven AFW pump. Note that the spurious pump starting can occur for several reasons, including fire damage to control circuitry or a spurious ESFAS signal.	Same as PWROG 27 and 30 Plus PAL01A, PAL01B or PAL02 OR PAE01A or PAE01B fail to trip OR PAE02 spuriously starts and AEHV0102 and AEHV0103 spuriously open AND AEFCV0510 or AEFCV0550 and AEFV0039 or AEFCV0520 or AEFCV0560 and AEFV0040 or AEFCV0530 or AEFCV0570 and AEFV0041 or AEFCV0540 or AEFCV0580 and AEFV0042	A-15, A-23	Main feedwater is stopped by closing the main steam isolation valves (MSIVs) and stopping steam flow to the main feedwater pump (MFP) turbines. In fire areas A-15 and A-23, the MSIVs may not close and steam will continue to be delivered to the MFP turbines. A fire in A-15 and A-23 will not prevent closing the turbine driven main feed pump stop valves (FCFV0005 and FCFV0105). Therefore, main feedwater can be isolated if a fire occurs in any fire area. The main feedwater isolation valves (MFIVs) are included in the PFSSD design. Currently, they are included to evaluate and prevent AFW flow diversion. However, feedwater check valves have been moved and will prevent flow diversion from AFW so the MFIVs are not needed for this purpose. The MFIVs are still credited to prevent excessive feedwater flow. Main feedwater flow control valves and bypass valves are not included in the PFSSD analysis. If PAE02 spuriously starts and AEHV0102 and AEHV0103 open, then feedwater can be stopped by closing the MFIVs. All four MFIVs can be isolated in the event of a fire in all areas except A-15 and A-23. In these areas, PAE02 can be stopped from the control room. Since main feedwater can be isolated in the event of a single fire in all fire areas, this scenario is the same as PWROG 30. Therefore, no actions are needed to address this MSO scenario.

Scenario ID	Scenario	Scenario Description	Notes	Included Equipment	Applicable Fire Areas at WCNOC?	Comments
Decay Heat Removal						
PWROG 34	Steam Generator Blowdown	Spurious opening of, or failure to close, multiple series steam generator blowdown valves	Scenario causes drain down of steam generator inventory through the blowdown system, challenging the Decay Heat Removal Function. Scenario may screen if available AFW mass flow rate exceeds steam generator inventory mass loss rate through blowdown.	BMHV0001, BMHV0002, BMHV0003 or BMHV0004	A-6, A-13, A-15, A-16N, A-16S, A-21, A-23, A-27, C-22, C-23, C-30, C-33	Thermal Hydraulic analysis (WCNOC-CP-002) performed for PFSSD shows insignificant impact on SG inventory even with all 4 blowdown valves open. Therefore, no actions are needed to address this MSO scenario.
PWROG 35	Secondary Sample System	Spurious opening of steam generator sample valve(s) inside containment, AND Spurious opening of isolation valve(s) outside containment, AND Spurious opening of downstream sample valve(s)	Scenario causes drain down of steam generator inventory through the sample system, challenging the Decay Heat Removal Function.	N/A	None	Sample lines are isolated by a normally closed manual isolation valve downstream of the sample coolers. Therefore, this MSO scenario is not an issue at Wolf Creek.

Scenario ID	Scenario	Scenario Description	Notes	Included Equipment	Applicable Fire Areas at WCNOC?	Comments
Decay Heat Removal						
Expert Panel 8	AFW Flow Diversion	1/2 MDAFW Pumps Fails to Start AND MFW Isolation Fails	Scenario results in loss of decay heat removal capability due to flow imbalances created by attempting to feed all 4 SGs with a single MDAFW Pump.	PAL01A or PAL01B AND AEFV0039, AEFV0040, AEFV0042 or AEFV0042 AND AEFCV0510 or AEFCV550, AEFCV0520 or AEFCV0560, AEFCV0530 or AEFCV0570, AEFCV0540 or AEFCV0580	None	Feedwater check valves were moved in DCP 12792 to a location upstream of the AFW tap. Therefore, AFW flow cannot divert to another steam generator. Based on the that above discussion, no actions are needed to address this MSO scenario.

Scenario ID	Scenario	Scenario Description	Notes	Included Equipment	Applicable Fire Areas at WCNOC?	Comments
RCS Pressure Control						
PWROG 36	RCS Pressure Decrease	Spurious opening of pressurizer spray valve(s), AND Inability to trip, or spurious operation of, RCP, AND Inoperability of PZR Heater(s)	Scenario causes a RCS pressure transient, challenging the RCS Pressure Control Function. Typical PFSS analyses address this issue; PRAs often consider scenario negligible since there is no real threat of core uncovery.	PBB01A AND BBPCV0455B OR PBB01B AND BBPCV0455C OR PBG04, PBG05A, or PBG05B AND BGHV8145 AND Pressurizer Heater Backup Groups A and B and Variable Group C Off	A-1, A-11, A-18, C-7, C-12, C-18, C-21, C-24, RB	The pressurizer heaters are not included in the PFSSD design. Calculation WCNOC-CP-002 shows that spurious operation or maloperation of the heaters will not adversely impact PFSSD. The pressure control system components and cables are included in the PFSSD design for analysis of potential spurious actuation of the pressurizer sprays and PORVs due to spurious actuation of the pressure control system. Based on WCNOC-CP-002, spurious operation of pressurizer sprays will not adversely impact PFSSD as long as the spray is stopped in 50 minutes. The pressurizer spray valves are air operated. Isolation of instrument air to containment will fail the spray valves closed. Valve KAFV0029, control room hand switch KAHIS0029 and associated cables are included in the PFSSD design to evaluate whether this valve is affected by a fire. This valve is unaffected by a fire in all areas listed except C-21. If a fire occurs in area C-21, valve KAV0201 can be manually closed within 50 minutes as documented in E-1F9900. Based on the above discussion, the pressurizer spray valves can be closed within 50 minutes in the event of a fire in any of the areas listed. Therefore, no further actions are required to address this MSO scenario.

Scenario ID	Scenario	Scenario Description	Notes	Included Equipment	Applicable Fire Areas at WCNOC?	Comments
RCS Pressure Control						
PWROG 37	RCS Pressure Increase	Spurious operation of multiple PZR heaters, AND Inoperability of pressurizer spray or auxiliary spray, AND Failure to open pressurizer PORVs	Scenario causes a RCS pressure transient, challenging the RCS Pressure Control Function. RCS pressure increase could cause PORV(s) and/or safety valve(s) to open.	Same as PWROG 36 Plus BBPCV0455A and/or BBPCV0456A fail to open	Various	Failure to open PORVs will cause this transient to challenge the pressurizer safety valves. Pressurizer heaters are not included in the PFSSD analysis, so they are assumed to fail in the worse condition. Pressurizer PORV failure to open is not analyzed in E-1F9910 because the desired position is closed. If overpressure occurs, the mechanical safety valves will cycle to prevent overpressure in the pressurizer. The safeties are not affected by a fire. See MSO scenario WCNOC 1 for discussion of RCS pressure increase combined with pressurizer overfill. Based on the above discussion, no actions are needed to address this MSO scenario.

Scenario ID	Scenario	Scenario Description	Notes	Included Equipment	Applicable Fire Areas at WCNOC?	Comments
RCS Pressure Control						
Expert Panel 9	RCS Pressure Decrease	Spurious operation of pressurizer pressure master controller	Scenario causes an RCS pressure transient resulting in spurious SI actuation.	BBPC0455A (BBPT0455)	Various	This could be considered a single spurious scenario, but it was not addressed earlier and, therefore, is included here. Controller failing high would cause Pressurizer Heaters to turn off, Spray Valves to open, and PORV BBPCV0455A to open. The pressurizer pressure control system has been analyzed in E-1F9910. All potential spurious actuations have been evaluated. Calculation WCNOC-CP-002 evaluates spurious operation of the pressurizer sprays and heaters. Based on this calculation, pressurizer spray needs to be stopped within 50 minutes to prevent saturation conditions. See scenario PWROG 36 for a discussion about pressurizer sprays. Implementation of DCP 12944 along with License Amendment 193 ensures the pressurizer PORVs can be closed from the control room in the event of a fire in any area of the plant except the control room. Based on the above discussion, no further actions are needed to address this MSO scenario.

Scenario ID	Scenario	Scenario Description	Notes	Included Equipment	Applicable Fire Areas at WCNOC?	Comments
Reactivity Control						
PWROG 38	Inadvertent Boron Dilution	Unborated water supply to the RCS can occur due to combinations of the following: -Spurious start of reactor makeup pump(s) (supplies unborated water to the VCT), -Spurious opening of valves between reactor makeup pump(s) and VCT, -Spurious full opening of the reactor makeup flow control valve, -Spurious closure of the boric acid flow control valve	Scenario decreases RCS boron concentration, potentially causing reactivity increase, and challenging the Reactivity Control Function.	BGFCV0111A and BGFCV0110B or BGFCV0111B WITH PBL01A or PBL01B OR BGFCV0110A fails closed during auto makeup	A-8	The components listed are not included in the PFSSD analysis and have not been analyzed. The PFSSD lineup uses the borated RWST to provide makeup to the RCS. The reactor makeup pumps supply unborated water to the VCT through valve BGFCV0111A or BGFCV0110B. Both inlets are upstream of the VCT outlet valves. Therefore, closure of one of the VCT outlet valves (BGLCV0112B or BGLCV0112C) will prevent boron dilution per this MSO. Fire area A-8 is the only area where one of the VCT outlet valves may not close. With the reactor at full power, USAR Section 15.4.6.3 indicates approximately 1 hour is available between the time the reactor would trip due to reactivity insertion and the time re-criticality would occur. Therefore, there is a sufficient amount of time for operator action to mitigate this transient. CP 12316 addressed this MSO scenario. E-15000 (Setroute) was revised to add notes to control cables associated with pumps PBL01A and PBL01B to ensure that a fire in area A-8 will not prevent stopping these pumps from the control room. Therefore, there are no fire areas where this scenario would challenge PFSSD. Based on the above discussion, no further actions are needed to address this MSO scenario.

Scenario ID	Scenario	Scenario Description	Notes	Included Equipment	Applicable Fire Areas at WCNOC?	Comments
Reactivity Control						
PWROG 39	Fire Prevents Reactor Trip	Fire damage to RPS may prevent reactor trip. For example, hot shorts may prevent tripping of RPS MG sets.	Scenario results in insufficient shutdown margin and potential need for emergency boration. Note that this review may have already been performed for the disposition of Information Notice 2007-07.	SB102A and SB102B AND PG01902 OR PG02002 and PA0207 Fail to Open AND Failure of Manual Rod Insertion (SFHS0002) AND Failure of Emergency Boration (PBG04, PBG05A, PBG05B, PBG02A, PBG02B, and BGHV8104)	A-27	SB102A is for Bypass Breakers and SB102B is for Main Trip Breakers. IN 2007-07 is applicable to BWRs only. Wolf Creek did not evaluate this IN. Fire area A-27 contains both sets of reactor trip switchgear. A fire in this area may prevent a reactor trip using the reactor trip switches in the control room. If a fire occurs in area A-27, the reactor can be tripped by de-energizing the motor generator sets. This is done by opening breakers PA0106 and PA0207 using PGHIS0002 and PGHIS0003 in the control room. E-1F9910 documents the capability to open these breakers from the control room and shows there is no adverse impact by removing power from the loads supplied by these breakers. Based on the above discussion, no additional actions are needed to address this MSO scenario.

Scenario ID	Scenario	Scenario Description	Notes	Included Equipment	Applicable Fire Areas at WCNOC?	Comments
Reactivity Control						
Expert Panel 10	Malfunction of SGLCS	Spurious operation of SG Water Level control resulting in overfeed of SG	Scenario could cause reactor trip due to positive reactivity insertion.	AEFC0510 (AELC0519), AEFC0520 (AELC0529), AEFC0530 (AELC0539), and AEFC0540 (AELC0549)	A-15, A-23	The MFIVs are included in the PFSSD analysis and can be closed to prevent steam generator overfill. The AFW system has been fully analyzed in E-1F9910 and steam generator level instruments are available so operators can determine SG level. Fire in fire areas A-15 and A-23 could prevent closing the MFIVs. See PWROG 33 for further discussion. Based on the above discussion and the discussion in scenario PWROG 33, no actions are needed to address this MSO scenario.

Support Functions						
PWROG 40	CCW Header Isolation	CCW flow can be isolated via several combinations of spurious valve closures. Pertinent valves include: -pump discharge valves, -pump crosstie valves, -CCW heat exchanger inlet valves, -CCW heat exchanger outlet valves, -CCW heat exchanger crosstie valves, -Etc.	Scenarios cause failure of CCW function to provide cooling to safe shutdown loads.	EGHV0053 and EGHV0054 OR EGHV0015 and EGHV0016	A-16S <u>EGHV53</u> A-8, A-16S, A-19, A-22, C-9, C-12, C-18, C-21, C-24, C-31 <u>EGHV54</u> A-16S, A-21, C-10, C-11, C-17, C-22, C-23, C-30, C-33 <u>EGHV15</u> A-8, A-16N, A-19, A-22, C-18, C-21, C-24, C-31 <u>EGHV16</u> A-16S, A-21, C-22, C-23, C-30, C-33	Spurious closure of both valves on supply or return would impact RCP Thermal Barrier cooling. This loop also cools seal water heat exchanger which could affect charging pumps. Scenarios involving failures of the CCW surge tank makeup valves were discussed by the expert panel, but no scenarios could be identified which would result in loss of CCW flow. CCW has been fully analyzed in E-1F9910. Since one train of CCW is always operating, it may be necessary to swap to the opposite train if a fire occurs because the running train may be the affected train. DCP 12418 addressed this MSO scenario for a fire in A-27 that could have caused a loss of EGHV0016 and EGHV0054. Control room operator actions are available to mitigate loss of EGHV0053 in the event of a fire in A-16S. See E-1F9910. Based on the above discussion, no additional actions are needed to address this MSO scenario.

Scenario ID	Scenario	Scenario Description	Notes	Included Equipment	Applicable Fire Areas at WCNOC?	Comments
Support Functions						
PWROG 41	CCW to Redundant Loads	Spurious isolation of CCW cooling to redundant loads (including lube oil coolers, RHR heat exchangers, etc.)	Scenario isolates CCW cooling to redundant loads causing safe shutdown equipment inoperability of redundant trains. All credited CCW loads should be reviewed.	Loss of CCW to redundant RHR Heat Exchangers: EGHV0101 AND EGHV0102	None	The CCW system has been fully evaluated in E-1F9910. See PWROG 40 discussion. Based on E-1F9910, a fire in any area of the plant will have at least one train of CCW available to redundant loads. Therefore, no actions are needed to address this MSO scenario.
PWROG 42	CCW Flow Diversion to Non-Credited Loop	Flow diversion can occur via several combinations of spurious valve operations in the CCW pump discharge and CCW loop crosstie flowpaths. Review P&IDs to identify relevant combinations.	Scenario causes CCW flow to be diverted to the non-credited loop. This ultimately prevents CCW cooling of credited safe shutdown loads.	Potential failure to close of non-safety loop isolation EGHV0069A, EGHV0069B, EGHV0070A and/or EGHV0070B Spurious opening of SFP HX supply ECHV0011 or ECHV0012	Various	These valves are not included in the PFSSD analysis. Therefore, they are assumed to fail in the worse possible position in all fire areas. Potential diversion pathways through the CCW surge tank were discussed by the expert panel. It was decided that makeup valves EGLV0001 and EGLV0002 connect at the top of the tank making loss of CCW pump suction due to a diversion through this path impossible. Each CCW pump (2 per train) is designed to supply 100% of the heat loads in the safety and non-safety loops. The Radwaste loop supply valves close on low surge tank level, SIS or high flow. The containment loop supply valves close on CISB. See USAR Section 9.2.2. A DBA is not assumed concurrent with a fire. Therefore, the position of the Radwaste loop supply valves has no adverse impact on PFSSD. Likewise, spurious opening of the fuel pool cooling heat exchanger CCW valves will have no adverse

Scenario ID	Scenario	Scenario Description	Notes	Included Equipment	Applicable Fire Areas at WCNOC?	Comments
Support Functions						
						impact on PFSSD. Spurious opening of EGHV0015 or EGHV0016 while operating the opposite train will cause CCW flow to be diverted to the non-credited train. Calculation EG-24 shows that if the opposite train of CCW is running and these valves are open, the operating CCW pump will have sufficient NPSH. Therefore, this is acceptable. Based on the above discussion, no actions are needed to address this MSO scenario.

Scenario ID	Scenario	Scenario Description	Notes	Included Equipment	Applicable Fire Areas at WCNOC?	Comments
Support Functions						
PWROG 43	ESW Header Isolation	ESW flow to credited loads can be isolated via several combinations of spurious valve closures. Pertinent valves include: -pump discharge valves, -pump crosstie valves, -ESW heat exchanger inlet valves, -ESW heat exchanger outlet valves, -ESW heat exchanger crosstie valves, -Etc. Review P&IDs to identify relevant combinations.	Scenario causes isolation of ESW, which can fail cooling to the CCW system and other safe shutdown components directly cooled by ESW (e.g., EDG cooling).	EFHV0037, EFHV0039 and EFHV0041 OR EFHV0038, EFHV0040 and EFHV0042	C-1	EFHV0037 and EFHV0038 are maintained at a minimum of 60% open by limit switch settings. This limit switch contact would have to be bypassed to result in total isolation of flow. Therefore, based on circuit review, two separate shorts would be required to allow full closure of either EFHV0037 or EFHV0038. E-1F9910 analyzes the potential for spurious operation of these components, including MSOs. Based on E-1F9910, at least one train of ESW is available to supply the required cooling flow to credited PFSSD equipment if a fire occurs in any fire area. The ESW system has been analyzed in E-1F9910 to ensure at least one train is available to supply PFSSD loads. There are no fire areas where a fire could affect both trains of ESW. These valves are all located in fire area C-1. Based on E-1F9910, the valves and cables are separated by 20 feet with no intervening combustibles and a suppression and detection system is installed in the area. This configuration meets Wolf Creek's licensing requirements. Based on the above discussion, no actions are needed to address this MSO scenario.

Scenario ID	Scenario	Scenario Description	Notes	Included Equipment	Applicable Fire Areas at WCNOC?	Comments
Support Functions						
PWROG 44	ESW to Redundant Loads	Spurious isolation of ESW cooling to redundant loads (including CCW heat exchangers, EDG cooling, etc.)	Scenario isolates ESW cooling to redundant loads causing safe shutdown equipment inoperability of redundant trains. All credited ESW loads should be reviewed.	Component Cooling Water: EFHV0051 or EFHV0059 AND EFHV0052 or EFHV0060 Instrument Air: EFHV0043 AND EFHV0044 Containment Coolers: EFHV0031, EFHV0032, EFHV0033, EFHV0034, EFHV0045, EFHV0046, EFHV0049 and/or EFHV0050	None	The ESW system has been analyzed in E-1F9910 to ensure at least one train is available to supply PFSSD loads. There are no fire areas where a fire could affect both trains of ESW, considering MSOs. Instrument air compressors are not credited for PFSSD. Therefore, spurious closure of EFHV0043 and EFHV0044 will not adversely impact PFSSD. Based on the above discussion, no actions are needed to address this MSO scenario.

Scenario ID	Scenario	Scenario Description	Notes	Included Equipment	Applicable Fire Areas at WCNOC?	Comments
Support Functions						
PWROG 45	ESW Flow Diversion to Non-Credited Loops/Systems	Flow diversion can occur via several combinations of spurious valve operations in the ESW pump discharge and loop crosstie flowpaths. Review P&IDs to identify relevant combinations.	Scenario causes ESW flow to be diverted to a non-credited loop or system. This ultimately prevents ESW cooling of credited loads.	SW Isolation Failure: EFHV0023 and EFHV0025 OR EFHV0024 and EFHV0026 CCW HX Supply Full Open: EFHV0051, EFHV0052, EFHV0059 or EFHV0060	A-19, C-1	Failure to isolate SW path can result in insufficient flow to the diesel generators in LOSP. Full opening of ESW supply to CCW HX can result in flow imbalances resulting in insufficient cooling. ESW diversion to the Spent Fuel Pool makeup line was discussed by the expert panel, but was excluded because it is isolated by manual valves. The ESW system has been analyzed in E-1F9910 to ensure at least one train is available to supply PFSSD loads. There are no fire areas where a fire could affect both trains of ESW, considering MSOs. Fire area A-19 has cables for EFHV0051, EFHV0052, EFHV0059 and EFHV0060. Train B ESW is credited. The cable damage to EFHV0060 (Train B) will not cause the valve to open. The cable damage to EFHV0052 (Train B) will not cause the valve to close. Therefore, this configuration is acceptable. Valves EFHV0023, 24, 25 and 26 are located in fire area C-1. Based on E-1F9910, the redundant valves and cables are separated by 20 feet with no intervening combustibles and a suppression and detection system is installed in the area. This configuration meets Wolf Creek's licensing requirements. Furthermore, check valves EFV0470 (Train A) and EFV0471 (Train B) are installed on the service water/ESW cross connect piping. The check valves will prevent ESW from diverting to service water.

PWROG 47	Emergency Power	Diesel generator overloading	Scenario causes diesel generator overloading and inoperability. Note: Scenario very site specific. Interlocks may prevent this from occurring. In addition to Scenario 46, overloading may also occur if proper load sequencing is bypassed via hot shorts, causing simultaneous loading of multiple components onto the EDG.	NF039A and NF039B	A-27 (A&B) C-5 (B) C-6 (A) C-9 (B) C-10 (A) C-11 (A) C-15 (A) C-17 (A) C-23 (A) CC-1 (A&B) T-2 (A&B) TURB (A or B) YARD (A or B)	Failure of load shed and/or bypass of load sequence can result in overload condition. The fire areas listed are those where one or both trains of EDGs are credited. The letters in parentheses indicate the EDG train that is required to be in service. In those areas where the diesel generator is credited, the associated train of PFSSD equipment is unaffected by a fire as documented in E-1F9910. Therefore, the credited equipment will not spuriously load to the bus and cause overloading of the EDG. E-1F9910 evaluates the load shedder/sequencer. In the areas where one diesel generator train is credited, the associated train load shedder/sequencer is unaffected. Therefore, the credited train EDG will not be affected by this MSO. Based on the above discussion, no actions are needed to address this MSO scenario.

Scenario ID	Scenario	Scenario Description	Notes	Included Equipment	Applicable Fire Areas at WCNOC?	Comments
Support Functions						
PWROG 48	Emergency Power	Diesel generator spuriously starts without service water cooling.	The fire causes the startup of the Emergency Diesel Generator and spurious isolation of ESW cooling (See Scenarios 42 & 44). Running the Emergency Diesel Generator with a loss of cooling water could trip and/or damage the diesel on high temperature.	KKJ01A and PEF01A OR KKJ01B and PEF01B	A-27 (A&B) C-5 (B) C-6 (A) C-9 (B) C-10 (A) C-11 (A) C-17 (A) C-23 (A) TURB (A or B) YARD (A or B)	Diesels can run for 30 minutes unloaded or 3 minutes loaded with no cooling. If diesel starts with no LOSP, cooling flow would initially be provided from the NSW system. Isolation of NSW is initiated by diesel output breaker closure. The fire areas listed are those that credit the emergency diesel generators because of a loss of off-site power. The letters in parentheses indicate the EDG train that is required to be in service. Calculation XX-E-013, Appendix 2 provides the loss of offsite power evaluation. Based on E-1F9910, the ESW train required to be operable to supply cooling to the diesel generator will not be affected by a fire in these areas. Based on the above discussion, no actions are needed to address this MSO scenario.
PWROG 49	Emergency Power	Non-synchronous paralleling of EDG with on-site and off-site sources through spurious breaker operations	Scenario causes damage to diesel generator by closing into a live bus out-of-phase. Note: Scenario very site specific. Interlocks may prevent this from occurring.	NB0109, NB0111 and NB0112 Or NB0209, NB0211 and NB0212	A-27 (A&B) C-5 (B) C-6 (A) C-9 (B) C-10 (A) C-11 (A) C-17 (A) C-23 (A) TURB (A or B) YARD (A or B)	Synch-check relay would have to be bypassed by the hot short to close a breaker out of phase. The fire areas listed are those that credit the emergency diesel generators because of a loss of off-site power. The letters in parentheses indicate the EDG train that is required to be in service. Calculation XX-E-013, Appendix 2 provides the loss of offsite power evaluation. In the fire areas listed, E-1F9910 has evaluated the availability of the credited EDG and found that cables that would cause non-synchronous paralleling of the credited EDG are not affected by

Scenario ID	Scenario	Scenario Description	Notes	Included Equipment	Applicable Fire Areas at WCNOC?	Comments
Support Functions						
						the fire. Therefore, in the areas where one of the EDGs is credited, non-synchronous paralleling of the credited train is not credible. Another postulated spurious actuation could occur in areas where the EDGs are not credited but they spuriously start due to cable damage or a spurious SIS or undervoltage then another cable failure causes the EDG output breaker to close out of phase. The Train A EDG output breaker synch check relay contact can be bypassed by a hot short occurring within cable 11NEB10AB or a cable to cable hot short between cables 11NEB10AA and 11NEB10AD. This can occur in the following fire areas: C-9, C-12, C-18, C-21, C-24 and D-1. In all of these areas, Train B bus NB02 is unaffected. Therefore, if the Train A EDG spuriously starts and the output breaker closes out of sync, PFSSD is assured using Train B PFSSD equipment. The Train B EDG output breaker synch check relay contact can be bypassed by a hot short occurring within cable 14NEB11AB or a cable to cable hot short between cables 14NEB11AA and 14NEB11AD. This can occur in the following fire areas: C-10, C-11, C-17, C-22, C-30, C-33 and D-2. In all of these areas, Train A bus NB01 is unaffected. Therefore, if the Train B EDG spuriously starts and the output breaker closes out of sync, PFSSD is assured using Train A PFSSD equipment. Based on the above discussion, no actions are

Other						
PWROG 50	Generic - Loss of Pump Suction	Spurious isolation of various valves in pump suction flow path	Suction flow paths for all credited pumps should be reviewed for MSO scenarios causing loss of suction and pump inoperability. An example of a pump suction MSO was previously identified in which both the VCT outlets valve(s) and RWST outlet valve(s) spuriously close. Another example involves pump suction cross-connect valves. Three pumps may be supplied from a common suction header that includes several cross-connect valves. If two valves spuriously isolate, the pump drawing suction from the common header between the two isolated valves can	SI Pumps: EMHV8923A, and EMHV8807A and EMHV8807B, or EMHV8924, or EJHV8804A AND EMHV8923B and EJHV8804B Charging Pumps: See PWROG 10 AFW Pumps: LSP, and ALHV0030, ALHV0031, ALHV0032, and/or ALHV0033 OR LSP, and ESW Unavailable	Various	<u>SI Pumps</u> The SI pumps are not credited for PFSSD. Loss of suction to a running SI pump will not adversely impact PFSSD. <u>RHR Pumps</u> This is discussed in MSO Scenario Expert Panel 4. <u>AFW Pumps</u> A spurious LSP with ESW unavailable could cause a loss of suction to the AFW pumps. Also, any spurious closure of the CST to AFW valves will cause a loss of suction to the AFW pumps unless ESW is available and the ESW valve can be opened. All of the AFW components, including the LSP signals, are included in PFSSD. The potential for loss of suction to the pumps has been evaluated in E-1F9910 and there is no possibility that a fire will cause a loss of suction to the credited AFW pump. Therefore, this scenario is not an issue for the AFW pumps. <u>Charging Pumps</u> See MSO Scenario PWROG 10 <u>ESW Pumps</u> The ESW pumps take suction directly from the lake. There are no fire-induced scenarios that would cause a loss of ESW pump suction.

Scenario ID	Scenario	Scenario Description	Notes	Included Equipment	Applicable Fire Areas at WCNOC?	Comments
Other						
			lose suction and become inoperable. The spurious operation of idle pumps after suction has been spuriously isolated should also be considered. Spurious pump starting can occur for several reasons, including fire damage to control circuitry or a spurious ESAFAS signal.			<u>CCW Pumps</u> The CCW system is a closed loop system with a surge tank maintaining NPSH on the pumps. Except for the CCW supply to the RHR heat exchanger, there are no motor operated valves in the safety loop that could spuriously close in the event of a fire. Also, the line from the pump suction to the surge tanks has no valve. Therefore, a fire will not cause a loss of suction to the CCW pumps. Also see PWROG 42 for discussion on CCW flow diversion to non-credited loop. Based on the above discussion, no actions are needed to address this MSO scenario.
PWROG 51	Generic - Pump Shutoff Head	Spurious isolation of pump discharge flow, AND Spurious isolation of recirculation valve(s)	Scenario causes pump operation at shutoff head and subsequent inoperability. All credited pumps should be reviewed for this scenario. Note that spurious starting of idle pump(s), in combination with isolation of discharge flow and recirculation, may cause inoperability of additional pumps.	RHR Pumps: Spurious SIS or Spurious start of pumps AND EJFCV0610 or EJFCV0611	A-8, A-27, C-21 <u>SIS</u> A-8, A-13, A-15, A-16 (N/S), A-17, A-18, A-23, A-27, C-21, RB <u>EJFCV0610 Close</u> A-8, C-9, C-12, C-18, C-21, C-24 <u>EJFCV0611 Close</u> A-8, A-16S, A-27, C-10, C-11, C-17, C-22, C-23,	<u>SI Pumps</u> The SI pumps are not credited for PFSSD. Therefore, failure of these pumps due to loss of recirc flow will not adversely impact PFSSD. <u>RHR Pumps</u> A spurious pump start at normal temperature and pressure will cause the pump to dead head against reactor pressure. Flow will re-circulate through the re-circ line unless the fire affects this path. Fire in A-8 and A-27 could challenge this scenario. In fire area A-8, both recirculation valves could be affected due to the flow switches being in this area. Therefore, the recirculation valves could go closed.

			Spurious pump starting can occur for several reasons, including fire damage to control circuitry or a spurious ESAFAS signal.		C-30, C-33 <u>A RHR Pump Start</u> C-9, C-12, C-18, C-21, C-24 <u>B RHR Pump Start</u> C-10, C-11, C-17, C-22, C-23, C-30, C-33	If the SIS is spurious, the RHR pumps would be pumping against RCS pressure, in which case there would be no flow. Flow would re-circulate through the RHR heat exchanger and back to the RHR pump suction through the associated flow control valve. In A-27, Train B RHR is credited because Train A CCW is lost. EJFIS0611 could be affected, causing EJFCV0611 to close. Therefore, a fire in A-27 that results in this MSO could cause damage to both RHR pumps. In C-21, the Train B RHR system is unaffected. The Train A RHR pump could be damaged by this scenario but the Train B RHR pump would flow through the recirc line to maintain pump operability. <u>AFW Pumps</u> The AFW pumps re-circulate to the CST through normally open manual valves. There are no electrically operated valves in this flowpath so a fire will not cause damage to the AFW pumps due to isolation of the discharge valves. <u>Charging Pumps</u> See MSO Scenario Expert Panel 3 for discussion of loss of charging pump miniflow. Based on that discussion, this scenario is not an issue at Wolf Creek. <u>ESW Pumps</u> There are no valves in the ESW discharge flowpath that are susceptible to fire induced spurious

Scenario ID	Scenario	Scenario Description	Notes	Included Equipment	Applicable Fire Areas at WCNOC?	Comments
Other						
						operation. Electrically operated valves in the ESW system are discussed in other scenarios. If the ESW pumps start, the only way for the system to operate at no flow is if the return valves (EFHV0037 or EFHV0038) close. These valves are discussed in PWROG 43. At least one train of ESW is available for a fire in any area per E-1F9910. Screen wash valves EFHV0091 and EFHV0092 are included in the PFSSD design. These valves open when the ESW pump runs, providing flow in the system to protect the pump and to keep the screens clean. The credited train valve will open as required in the event of a fire in any area. <u>CCW Pumps</u> The CCW system is a closed loop. There are no possible failures that would prevent discharge flow to the safety loop. Therefore, this scenario is not applicable to the CCW Pumps. DCP 13615 was implemented to correct this MSO issue related to the RHR pumps. The DCP re-located EJFIS0611 from fire area A-8 to fire area A-4 and re-routed the cable and instrument tubing to avoid these areas. Consequently, a fire in A-8 or A-27 will not cause the spurious closure of EJFCV0611 and the B Train RHR pump will be unaffected.

PWROG 52	Generic – Pump Outside Design Flow	Pump damage from operation outside design flow either at shutoff head or pump run-out conditions.	Scenario causes pump failure. Operation at shutoff head can occur, for example, if pump discharge flow spuriously isolates with the recirculation valves closed. Run-out can occur, for example, if the discharge header is at reduced pressure conditions. Note that spurious starting of idle pump(s), in combination with isolation of discharge flow and recirculation, may cause failure of additional pumps. Spurious pump starting can occur for several reasons, including fire damage to control circuitry or an inadvertent ESFAS signal.	All credited pumps.	None	Loss of discharge flow on all credited pumps is analyzed in MSO Scenario Expert Panel 13. Pump run-out for the AFW pumps is discussed in MSO Scenario PWROG 31. Charging pump run-out is not expected to occur because throttle valves on the BIT injection line will provide adequate back pressure. CCW pump run-out is not a concern because the CCW system is a closed loop system. RHR pump run-out will not occur due to flow orifices installed in the discharge line. ESW pump runout is not a concern because flow orifices and manual valve throttling provide necessary flow balance and backpressure in the system to prevent run-out. Based on the above discussion, this MSO scenario is not a concern at Wolf Creek.

PWROG 53	Generic – Flow Diversion	Spurious operation of various valves causing flow diversion.	All credited flow paths should be reviewed for MSO scenarios that can divert flow away from desired location.	Various	Various	Flow diversion is addressed in other MSO scenarios. E-1F9910 analyzes all flow diversion paths for impact on PFSSD. Therefore, no actions are needed to address this MSO scenario.
Expert Panel 13	Generic - Pump Discharge Flow Path Isolation	Spurious isolation of various valves in pump discharge flow path	Discharge flow paths for all credited pumps should be reviewed for MSO scenarios that isolate those flow paths. One example is spurious isolation of two parallel charging injection valves. Another example involves pump discharge cross-connect valves. For example, three pumps may feed a common discharge header that includes several cross-connect valves. If two valves spuriously isolate, pump flow feeding	SI Pumps: EMHV8821A and EMHV8802A fails to open AND EMHV8821B and EMHV8802B fails to open	Various	<u>SI Pumps</u> The SI pumps are not credited for PFSSD. <u>RHR Pumps</u> A single spurious operation would cause a loss of RHR pump discharge flow. This is evaluated in E-1F9910. <u>AFW Pumps</u> AFW pump discharge flowpath MSOs are discussed in MSO Scenario PWROG 28. <u>Charging Pumps</u> Charging flow to the RCS is through the RCP seals or the BIT. MSOs would need to occur to impact both of these flow paths. E-1F9910 fully analyzes charging flow to ensure at least one RCS makeup path is available. There are no fire areas where charging flow is unavailable.

Scenario ID	Scenario	Scenario Description	Notes	Included Equipment	Applicable Fire Areas at WCNOC?	Comments
Other						
			the common header between the two isolated valves will isolate.			<u>ESW Pumps</u> There are no valves in the ESW discharge flowpath that are susceptible to fire induced spurious operation. Electrically operated valves in the ESW system are discussed in other MSO scenarios. <u>CCW Pumps</u> CCW flow to the safety loop has no motor operated valves that could fail closed. CCW flow to the reactor auxiliaries could be affected by spurious closure of one valve and failure to open of another valve. This has been evaluated in E-1F9910 and in areas where CCW flow to the reactor auxiliaries is required, there are no areas where this can occur. Based on the above discussion, no actions are needed to address this MSO scenario.
PWROG 54	Loss of HVAC	Spurious isolation of HVAC to credited loads	Perform review to identify spurious failures that could cause isolation of HVAC to credited loads. Credited loads may include pump rooms, switchgear rooms, and rooms containing solid state control systems. Examples of spurious failures include spurious damper isolation	ESW: GDTZ0001A AND GDTZ0001C OR GDTZ0011A AND GDTZ0011C Diesels: GMTZ0001A AND GMHZ0009 OR		Diesel cooling is not required with outside air temperatures less than 78 degrees. However, since cooling is required for approximately 20% of the year, this scenario is applicable. The internal events PRA model only considers GMHZ0009 and GMHZ0019 for loss of combustion air, not loss of room cooling. E-1F9910 fully analyzes HVAC to credited PFSSD equipment. In all cases, room cooling is available to the credited equipment for fires in areas outside the control room. Based on the above discussion, no actions are needed to address this MSO scenario.

			and spurious isolation of cooling flow to chillers.	GMTZ0011A AND GMHZ0019		
PWROG 55	Valve Inoperability	Spurious motor-operated valve operation, AND Wire-to-wire short(s) bypass torque and limit switches	General scenario is that fire damage to motor-operated valve circuitry causes spurious operation. If the same fire causes wire-to-wire short(s) such that the valve torque and limit switches are bypassed, then the valve motor may stall at the end of the valve cycle. This can cause excess current in the valve motor windings as well as valve mechanical damage. This mechanical damage may be sufficient to prevent manual operation of the			This scenario has been addressed for all valves credited for Control Room fire. For other valves, the PFSSD analysis (E-1F9910) considers prevention of damage to redundant trains. E-1F9910 considers multiple hot shorts with respect to motor operated valve control circuits. IN 92-18 has been analyzed for control room fires and modifications have been completed. For fires outside the control room, the credited train MOVs are either unaffected by the fire or are being modified as discussed in other MSO scenarios. Based on the above discussion, no actions are needed to address this MSO scenario.

Other						
						27 and C-21 a spurious SIS with one RWST to RHR valve closure can occur. The other RWST valve would remain open except in the case of a spurious lo-lo RWST level as discussed in the previous paragraph. <u>Charging Pumps</u> Based on PWROG 10, there are no fire areas where a fire will cause a loss of all suction sources to the CCPs. A SIS will cause the RWST supply to the CCP header valves to open. At least one of these valves is unaffected by a fire anywhere in the plant. The SIS causes the VCT outlet valves to automatically close when the RWST valve is fully open so they are assumed closed in this scenario. DCPs 13612 and 13613 were implemented to address this MSO scenario. DCP 13612 re-routed the BNLT0932 cable to avoid fire areas A-27 and C-21 and prevent a spurious lo-lo RWST level in these areas. DCP 13613 installed fire resistive cable to protect the control circuit for valve BNHV8812B in fire area A-8. These modifications provide reasonable assurance that the MSO scenario will not occur at Wolf Creek.
PWROG 56b	Loss of All Seal Cooling	Spurious containment isolation signal isolates CCW to the thermal barrier heat exchangers for all RCPs, AND	Scenario causes loss of all RCP seal cooling and subsequent RCP Seal LOCA.	2/4 Containment Pressure HI-3 from GNPT0934, GNPT0935, GNPT0936, and GNPT0937 AND	A-16N, A-17, A-18, A-27, C-21	Fire areas listed are those where a fire could cause a spurious CSAS and spurious CISB which would isolate the CCW flow to the RCPs, including the thermal barriers. A review of E-1F9910 for each of these areas shows that RCP seal injection is not affected if a fire occurs. Therefore, a fire cannot cause a simultaneous CISB and failure of seal injection.

		Spurious isolation of seal injection header flow		BGFCV0462 and BGFCV0121 OR BBHV8351A, BBHV8351B, BBHV8351C and/or BBHV8351D		Based on the above discussion, no actions are needed to address this MSO scenario.
PWROG 56c	Loss of All Seal Cooling	Spurious containment isolation signal isolates CCW to the thermal barrier heat exchangers for all RCPs, AND Spurious opening of charging injection valve(s) causing insufficient flow to seals	Scenario causes loss of all RCP seal cooling and subsequent RCP Seal LOCA.	2/4 Containment Pressure HI-3 (CISB) from GNPT0934, GNPT0935, GNPT0936, and GNPT0937 AND EMHV8801A or EMHV8801B AND EMHV8803A or EMHV8803B	<u>CISB</u> A-16N, A-17, A-18, A-27, C-21 <u>SIS</u> A-8, A-13, A-15, A-16 (N/S), A-17, A-18, A-23, A-27, C-21, RB <u>EMHV8801A</u> A-8, A-11, A-18, C-18, C-21, C-24 <u>EMHV8801B</u> A-21, C-22, C-30, C-33 <u>EMHV8803A</u> A-8, A-11, A-18, C-18, C-21, C-24 <u>EMHV8803B</u> A-21, C-22, C-30, C-33	See MSO Scenario PWROG 2 for discussion about flow diversion in the event of spurious opening of the BIT flowpath. Per this discussion, there will be sufficient flow to the RCP seals if the BIT flowpath opens. A CISB will close the CCW valves that supply cooling to the thermal barriers. A SIS will open the BIT flowpath valves and start the CCPs. Damage to certain cables for the EM valves will cause the valves to open. The BIT flowpath will open if either EMHV8801A or EMHV8801B open and EMHV8803A when operating Train A CCP or EMHV8803B when operating Train B CCP. A fire in the following areas could open the BIT flowpath and close the CCW to RCP flowpath due to a simultaneous SIS and CISB:

Scenario ID	Scenario	Scenario Description	Notes	Included Equipment	Applicable Fire Areas at WCNOC?	Comments
Other						
						A-16N, A-17, A-18, A-27, C-21 A fire induced SIS coincident with a CISB could cause this scenario to occur. A fire in some of these areas could prevent stopping the RCPs from the control room. If all seal cooling is lost and the RCPs continue to run, a seal LOCA can occur. However, as discussed in PWROG 2, there will be sufficient flow to the RCP seals to maintain seal cooling. Another possibility for this scenario is a CISB with the fire damaging the control circuits for the BIT valves. A fire in the following areas could cause a spurious CISB with opening of a BIT flowpath due to valve cable damage: A-18, C-21 In both of these areas, the A Train BIT flowpath opens coincident with a CISB. Based on E-1F9910, a fire in these areas credits the B Train CCP. The B Train BIT flowpath valves will not spuriously open and CCP flow will be directed to the RCP seals. Therefore, if the fire causes a CISB and damages cables for the BIT valves, causing the valves to open, PFSSD is assured and seal flow is maintained. Based on the above discussion, no actions are needed to address this MSO scenario.

Expert Panel 14	Loss of Containment Isolation	Various combinations of spurious operation of valves credited for containment isolation.	Scenario could cause uncontrolled release of fission products following core damage.	Penetration 32: LFFV0095 AND LFFV0096 Penetration 65: GSHV0020 AND GSHV0021 Penetration 160: GTHZ0011 AND GTHZ0012 Penetration 161: GTHZ0004 AND GTHZ0005	None	These valves are not included in the PFSSD analysis. Failure of the containment isolation function does not adversely impact PFSSD since a DBA is not assumed concurrent with a fire. Based on the above discussion, no actions are needed to address this MSO scenario.
WCNOC 1	RCS Pressure Increase AND Pressurizer Overfill	Spurious operation of multiple PZR heaters, AND Inoperability of pressurizer spray or auxiliary spray, AND Failure to open pressurizer PORVs, AND	Scenario could cause pressurizer overfill and overpressure, causing the mechanical safetys to open and pass water.	Spurious operation of multiple PZR heaters AND Inoperability of pressurizer spray or auxiliary spray AND Failure to open pressurizer PORVs	Various	Scenario causes an increase in RCS pressure that causes the mechanical safetys to open due to the failure of both pressurizer PORVs to open. In addition, the scenario causes pressurizer overfill due to letdown and excess letdown failing closed. This would cause water to pass through the safetys which they are not designed for. NEI 00-01, Rev. 2, Section 4.4.3.4 states that when evaluating combinations of MSO scenarios, consideration of more than four component failures is beyond the required design basis for MSO scenarios. Furthermore, NRC RG 1.189, Rev. 2, Section 5.3.1.1 states that the approach outlined in Chapter 4 of NEI 00-01 provides an acceptable methodology for the identification of multiple

Scenario ID	Scenario	Scenario Description	Notes	Included Equipment	Applicable Fire Areas at WCNOC?	Comments
Other						
		Letdown spuriously isolates, AND Excess Letdown spuriously isolates.		AND BGLCV0459 or BGLCV0460 AND BGHV8153A or BGHV8154A AND BGHV8153B or BGHV8154B AND BBHV8157A or BBHV8157B		spurious actuations. The scenario identified here requires a number of equipment malfunctions, categorized as follows: 1. Pressurizer heaters fail on 2. Pressurizer spray fails off 3. Pressurizer PORVs (2) fail closed 4. Letdown isolation valve (1) fails closed 5. Excess letdown valves (2) fail closed In this scenario, RCS makeup is approximately 32 gpm through the RCP seals. No other makeup flowpaths are functioning. Two steam generator ARVs are available for cooldown. Calculation AN-96-016 shows that the RCS can be cooled using only one S/G and one ARV following a reactor trip. Decay heat following a reactor trip is approximately 150 MW. The pressurizer heaters total approximately 1.8 MW but are not modeled in this calculation. Since one ARV can cool the RCS considering decay heat only, two ARVs can cool the RCS considering all three heater banks operating. In addition, if letdown or excess letdown are available, the 32 gpm makeup can be offset to prevent an overfill condition. Based on the above discussion, any combination of four individual component failures for this scenario can be mitigated using available PFSSD equipment as described above. Therefore, no actions are needed to address this MSO scenario.
