ABSTRACT

This report provides a complete description of calculations and their results estimating potential annual doses, normalized to a unit concentration, to an individual following the clearance of specific materials. These materials are scrap iron and steel, copper, aluminum, and concrete rubble from licensed nuclear facilities. Clearance means the removal of radiological controls by the licensing authority. The estimated potential doses are calculated probabilistically to account for a large number of possible variations in each of the 86 scenarios. These scenarios encompass the full range of realistic situations likely to yield the greatest normalized doses. Each scenario was analyzed with the 115 radionuclides considered most likely to be associated with materials from licensed nuclear facilities. The design basis of the analyses is to realistically model current processes, to identify critical groups on a nuclide-by-nuclide basis, and to enable the conversion of a dose criterion to a concentration.

Material for recycle or disposal was evaluated using material flow models and dose assessment models. Both models are based on probabilistic methods. This resulted in distributions of nuclide-by-nuclide normalized doses from one year of exposure per mass- or surface-based concentrations. The means and the 5th, 50th, 90th, and 95th percentiles are reported. These percentiles can be used to generically evaluate the likelihood that the derived mean concentration would correspond to a particular dose criterion. Additionally, they can be used to quantify the confidence that a safety goal is not exceeded.

F RESULTS OF ASSESSMENTS OF IRON AND STEEL SCRAP

This appendix presents some of the results of the radiological assessments of the recycling and disposal of iron and steel scrap cleared from NRC-licensed facilities. Monte Carlo uncertainty analyses are employed to calculate 5,800 to 10,000 realizations for each radionuclide in each of 37 exposure scenarios. The end points of the analyses are the effective dose equivalent (EDE) and the effective dose from one year of exposure, normalized to an initial unit activity concentration of each separate radionuclide in the scrap metal at the time of clearance. The results are reported as both mass-based and surficial normalized doses (: Sv per Bq/g and : Sv per Bq/cm²).

The mean normalized doses from each radionuclide in 30 of these scenarios are ranked to determine the critical groups for each nuclide. The mean and the 5th, 50th, 90th, and 95th percentile values of the normalized EDEs from 5,800 to 10,000 realizations of these 30 scenarios are tabulated in Appendix F-1. The corresponding effective doses are listed in Appendix F-2. The results from the seven scenarios—describing exposures to iron and steel products produced from the single furnace heat during one year that contains the maximum fraction of cleared scrap—that were not included in the ranking are presented in Appendix M.

Some scenarios involve only one exposure pathway: either external exposure or ingestion of water. In others, doses are delivered by all three principal pathways: external exposure, inhalation, and ingestion. The results of scenarios with multiple pathways are presented in sets of four tables: one table lists the sum of the doses via all three pathways, while the other three list the doses from each individual pathway. When only one pathway is active, a single table of results is presented. The pathways addressed in the analysis of each scenario are presented in Table 3.10 in Volume 1 of this report.

In the interest of a uniform presentation, all 115 radionuclides addressed by the analysis are listed in the dose tables. However, not every nuclide is present in every scenario. When the source of exposure is material produced during the melting and refining of scrap metal, the only nuclides that result in doses to the exposed individuals are those that partition to the given medium: metal product, slag, dust, or gaseous effluent. The doses from all other nuclides are listed as zero.

The doses from certain other nuclides in some scenarios are also listed as zero. In scenarios where external exposure is the only pathway, the dose contributions from three radionuclides—H-3, Ca-41 and Mn-53—are not assessed. H-3 is an extremely weak β -emitter which produces a negligibly small external exposure. Ca-41 and Mn-43 decay by electron capture and emit low-energy x-rays ($E_{\gamma} < 10$ keV) that are below the threshold for external exposure calculations in the present analysis. The dose contributions from external exposure to other nuclides emitting low-energy x- and γ -rays would be negligible in scenarios where shielding between the source and the receptor would essentially absorb such radiation. In the groundwater scenarios, some nuclides would not reach the well during the maximum period of assessment, which is 1,000 years or 20 half-lives of the nuclide in question, whichever is shorter.

Table F1.1 Normalized effective dose equivalents from all pathways: Scrap yard

Radionuclide	Mass-based EDE (: Sv/y per Bq/g)					Surficial EDE (: Sv/y per Bq/cm ²)

G RESULTS OF ASSESSMENTS OF COPPER SCRAP

This appendix presents some of the results of the radiological assessments of the recycling and disposal of copper scrap cleared from NRC-licensed facilities. Monte Carlo uncertainty analyses are employed to calculate 10,000 realizations for each radionuclide in each of 20 exposure scenarios. The end points of the analyses are the effective dose equivalent (EDE) and the effective dose from one year of exposure, normalized to an initial unit activity concentration of each separate radionuclide in the scrap metal at the time of clearance. The results are reported as both mass-based and surficial normalized doses (: Sv per Bq/g and : Sv per Bq/cm²).

The mean and the 5th, 50th, 90th, and 95th percentile values of the normalized EDEs from 10,000 realizations of these 20 scenarios are tabulated in Appendix G-1. The corresponding effective doses are listed in Appendix G-2. Some scenarios involve only one exposure pathway: either external exposure or ingestion of drinking water. In others, doses are delivered by all three principal pathways: external exposure, inhalation, and ingestion. The results of scenarios with multiple pathways are presented in sets of four tables: one table lists the sum of the doses via all three pathways, while the other three list the doses from each individual pathway. When only one pathway is active, a single table of results is presented. The pathways addressed in the analysis of each scenario are presented in Table 4.7 in Volume 1 of this report.

In the interest of a uniform presentation, all 115 radionuclides addressed by the analysis are listed in the dose tables. However, not every nuclide is present in every scenario. When the source of exposure is material produced during the melting and refining of scrap metal, the only nuclides that result in doses to the exposed individuals are those that partition to the given medium: metal product, slag, dust, or gaseous effluent. The doses from all other nuclides are listed as zero.

The doses from certain other nuclides in some scenarios are also listed as zero. In scenarios where external exposure is the only pathway, the dose contributions from three radionuclides—H-3, Ca-41 and Mn-53—are not assessed. H-3 is an extremely weak β -emitter which produces a negligibly small external exposure. Ca-41 and Mn-43 decay by electron capture and emit low-energy x-rays ($E_{\gamma} < 10$ keV) that are below the threshold for external exposure calculations in the present analysis. The dose contributions from external exposure to other nuclides emitting low-energy x- and γ -rays would be negligible in scenarios where shielding between the source and the receptor would essentially absorb such radiation. In the groundwater scenarios, some nuclides would not reach the well during the maximum period of assessment, which is 1,000 years or 20 half-lives of the nuclide in question, whichever is shorter.

Table G1.1 Normalized effective dose equivalents from all pathways: Scrap yard

Radionuclide	Mass-based EDE (: Sv/y per Bq/g)					Surficial EDE (: Sv/y per Bq/cm ²)
