

A SUBSIDIARY OF UNIFIRST CORPORATION

RECEIVED  
REGION 1

2000 APR 14 AM 9:14 BR2  
030-20934

April 12, 2000

Mr. John R. McGrath  
Senior Health Physicist  
United State Nuclear Regulatory Commission  
Division of Nuclear Material Safety  
475 Allendale Road  
King of Prussia, PA 19406-1415

RE: License No. 37-23341-01 - Amendment Request

Dear Mr. McGrath:

The intent of this license amendment request is to modify the uranium bioassay program for UniTech Services Group, Inc. (UniTech). Currently UniTech conducts uranium bioassay quarterly whenever uranium is indicated on incoming shipping papers. UniTech respectfully requests to modify its bioassay program as follows.

- 1) UniTech will implement a program for uranium bioassay only when uranium contaminated clothing is received from customers who would normally be required to implement such a program for their employees; i.e., uranium mills or fuel fabrication facilities.
- 2) When implemented, the bioassay program will involve all employees who work (sort clothing, load/unload washers, load dryers or perform maintenance) in designated contaminated areas as specified in the license.
- 3) When implemented, bioassays will be conducted prior to potential exposures (baseline), every 6 months thereafter while potential occupational exposure continues, and following the final potential occupational exposure.<sup>1</sup>

The basis of the program as outlined below is supported by several years of negative data. Attached is a summary of all data for the past 3 years. Development of specific program elements is based primarily on the following two documents.

*Regulatory Guide 8.11, Application of Bioassay for Uranium*

*Regulatory Guide 8.12, Bioassay at Uranium Mills.*

<sup>1</sup> For terminating employees, failure to participate in the program will be documented in writing with proof of mailing.

NMSS/RGN-002

128009

## BIOASSAY PROGRAM FOR URANIUM

### Criteria for Implementation

Uranium is listed as a nuclide on the shipping papers from numerous customers at nearly all UniTech facilities. However, uranium is usually a very small fraction of the total activity received in laundry shipments, often present only in trace amounts. Typically, the customers indicating uranium on shipping papers are not required, nor do they implement, a bioassay program specific for uranium at their facilities. Urinalysis for uranium is indicated only when significant amounts of loose uranium are being processed. UniTech will implement the proposed uranium bioassay program when processing uranium mill or fuel fabrication customers.

### Action Levels

The UniTech Action Level is 5  $\mu\text{g/L}$ . This action level is conservatively 1/3 of the lowest criteria (15  $\mu\text{g/L}$ ) indicated in Table 1 of the U.S. Nuclear Regulatory Commission Regulatory Guide 8.22, Bioassay at Uranium Mills. If UniTech's Action Level is exceeded, the affected employee will be immediately re-sampled and an investigation into potential causes will be conducted. Corrective actions will be implemented if indicated by the investigation.

### Procedures

Bioassay for uranium will be performed by a qualified vendor. Currently, analysis is performed by Thermo Nutech, TNU (formerly a division of TMA Eberline) in accordance with Method ASTM D5174 modified. The method utilized is Kinetic Phosphorescence Analysis (KPA). (See ANSI/HPS N13.30-1996, A.5.13.2, page 59)

### Frequency/Method Detection Limit

The frequency of urinalysis is based on US NRC Reg. Guide 8.11, Application of Bioassay for Uranium, for the minimum bioassay program. (See Reg. Guide 3.c., Table 2, and Figure 4.) The minimum bioassay program indicates that semi-annual frequency is appropriate. The current analytical detection limit is 0.03  $\mu\text{g/L}$  which is very conservatively consistent with the criteria in Figure 4 of Reg. Guide 8.11.<sup>2</sup> This determination incorporates the most conservative assumptions as identified in the footnote.

### Personnel Participation

Notwithstanding the provisions of Regulatory Guide 8.11, 3.d to limit the number of employees participating in the sample group during each sampling period, UniTech will sample all

---

<sup>2</sup> Figure 4 of Reg Guide 8.11 indicates that a 0.1  $\mu\text{g/L}$  measurement sensitivity is sufficient to detect a 2.7 mg intake of Class "D" natural uranium ( $\text{DAC} = 5\text{E-}10 \mu\text{Ci/cc}$ ) with greater than 210 days between measurements. UniTech calculates the mass of uranium due to the inhalation of the Class "Y" natural uranium ( $\text{DAC} = 2\text{E-}11 \mu\text{Ci/cc}$ ) for an entire year at the DAC to be 676 mg. A corresponding intake at 10% of the DAC for 6 months would result in 33.8 mg. This value would increase to 845 mg for Class D uranium.

personnel conducting work in areas designated as contaminated areas during periods when the Uranium bioassay program is required to be implemented.

### Records

Records of bioassay results are kept at the individual UniTech facilities for 3 years. Thereafter, records may be shipped to a storage facility and may be produced upon request. Records will be reviewed during annual audits conducted by Corporate Health Physics and Engineering personnel. All records are available for inspection.

### Special Circumstances Requiring Bioassay

Bioassay sampling will also be implemented in special circumstances as follows.

- 1) Following an incident such as a fire, spill, equipment malfunction, or other departure from normal operation which caused, or could have caused, abnormally high concentrations of uranium in air. (See Regulatory Guide 8.11, 3.a, paragraph 5.)
- 2) When airborne concentrations have indicated the presence of uranium at or above 10% of the DAC. This evaluation will be based on the results of isotopic analysis at the end of a calendar quarter. Isotopic analysis is conducted on a composite of all samples for a particular sampling location at the end of a calendar quarter when any individual samples has exceeded 10% of the DAC based on a gross alpha (or beta-gamma) analysis for the most restrictive nuclide being processed during the sample period. Isotopic analysis is conducted prior to the end of the quarter if total DAC-hours for the quarter reach or exceed 50. UniTech's Action Level (10% of the DAC, or  $2 \times 10^{-12}$   $\mu\text{Ci/ml}$ ) for additional evaluation is 50 times below the suggested threshold provided in Regulatory Guide 8.22, Section 2.
- 3) Personnel contamination events involving contamination on the face of any individual when uranium contaminated clothing was processed. Note: A chest count designed for Co-60 would also be conducted in this event.
- 4) Whenever an in-vivo chest count indicated any activity above the action limit.
- 5) Upon direction of the Plant Manager/RSO, HP Supervisor, Production Supervisor, or Corporate Health Physics staff. Factors considered by these individuals that would result in such direction include observance of poor work practice(s) that might result in an internal uptake.

## CONSIDERATION OF PRIOR DATA

### Results of Bioassay

The results of all bioassays since early 1997 are included. A few comments are warranted.

The results of 2335 sample during the past 3 years are overwhelmingly negative. The results of 99.57% of the samples were within the range of naturally occurring uranium excreted by reference man; i.e., less than  $0.36 \mu\text{g/L}^3$ . Based on another study, 99.91% of the results were less than the mean of uranium excreted by non-occupationally exposed individuals; i.e., less than or equal to  $1.00 \mu\text{g/L}^4$ . Only 0.09% of the results were greater than  $1.00 \mu\text{g/L}$ .

With reference to the two results greater than  $1.00 \mu\text{g/L}$ , the following discussion is presented. The result of one sample is suspect since this sample was the initial/baseline sample for a new employee who had not yet been potentially exposed to occupational airborne radioactivity at UniTech or any other nuclear facility. Both results are suspect since neither employee worked in contaminated areas where unwashed contaminated clothing is handled. Furthermore, based on a review of 76 other samples collected for the same periods covered by these two results, no other sample was greater than the analytical MDA of  $0.03 \mu\text{g/L}$ , including several samples from employees working in sorting and washroom areas handling unwashed clothing. Additionally, there were no unusual airborne concentrations detected during either period. Based on all of this information, UniTech has determined that neither of the two data points above  $1.00 \mu\text{g/L}$  was due to occupational exposure to airborne radioactivity. Sample contamination, either during collection or in the laboratory, is suspected.

### UniTech's Air Sampling Program

It is important to note that UniTech air sampling program is not conducted to evaluate occupational exposures; that is the data is not used to conduct an ALARA benefit analysis with regard to a respiratory protection program, monitor or assign dose. UniTech's air sampling program is used to collect negative data; that is, data that confirms that employees are not exposed to airborne concentrations of radioactive material, including uranium, greater than or equal to 10% of the Derived Air Concentration (DAC) for any nuclide. Accordingly, no internal dose assignment is required in accordance with the provisions of 10 CFR 20, 1204(g).

Notwithstanding the foregoing, UniTech's long-standing air sampling program is quite well developed. INS facilities typically have 15 to 30 fixed air sample head locations. Air sample heads are located in the breathing zone, typically between 5'6" and 6'6" depending on their

---

<sup>3</sup> ICRP (1975) International Commission on Radiological Protection. Report of the Task Group on Reference Man. ICRP Publication 23, (Pergamon Press, Elmsford, New York). NOTE: ICRP Publication 23 reported a background range of uranium in urine of 0.05 to  $0.5 \mu\text{g/d}$ . Reference Man's given urinary excreta rate of 1.4 L/d results in the indicated upper concentration of  $0.36 \mu\text{g/L}$ .

<sup>4</sup> DRUTMAN, R.D. and MORDASHEVA, V.V. (1985). "Natural uranium content in human organs and excreta," in *Gigiena i Sanit.* 7, 61-64. NOTE: This study involved 483 urine samples (254 women, 229 men) with a mean urinary content of  $1.4 \pm 0.1 \mu\text{g}$ . The mean concentration for women would be approximately  $1.4 \mu\text{g/L}$  since Reference Woman excretes 1.0 L/d.

location (as low as 5'6" if they can be located next to a piece of fixed equipment and as high as 6'6" if located in a more open traffic-area of the facility). Sample filters are exchanged and counted either daily or weekly. Sample filters in areas conservatively designated as contaminated areas are typically exchanged daily and counted after a 48 to 72 hour radon decay period. UniTech has not identified any sample head with concentrations exceeding 10% of the DAC for any nuclide based on isotopic analysis.

#### In-vivo Bioassay

INS conducts in-vivo bioassays for Co-60 activity in the lungs. In-vivo chest counts are conducted quarterly and are designed to detect 2.5% of the ALI due to an acute inhalation exposure at the beginning to the quarter (actually 120 days prior to allow for operational scheduling flexibility). Incorporating these assumptions into the development of the program ensures that any chronic exposures during the quarter would be identified due to airborne concentrations of 10% of the Co-60 DAC.

#### Airborne Radioactivity Controls

The principle means of controlling airborne radioactivity is through engineered controls. Localized exhaust ventilation where unwashed contaminated clothing is sorted and handled draws contaminants away from the personnel breathing zone. Entrained radioactive material then passes through a series of filters, including a large array of HEPA filters, and is sampled prior to being exhausted to the environment.

#### Facility Monitoring

Facility monitoring, other than air sampling, plays another important role in controlling potential levels of airborne radioactivity. Of primary interest in this respect are surveys for loose removable contamination. Daily plant surveys for removable contamination, as well as general area and contact dose rates, are conducted. In addition, removable contamination surveys are conducted between the processing of each customer. Decontamination actions are taken whenever contamination is identified above specified levels (see Appendix D, Section II.E. of the license application). Notwithstanding license requirements for taking action, plants typically take corrective action at levels significantly lower than those specified in the license; as low as the free release criteria of 20 and 200 dpm/100cm<sup>2</sup> alpha and beta-gamma, respectively. In addition, between-customer clean-up efforts, which are similar to decontamination actions, are conducted to minimize the potential spread of contamination from one customer's clothing to another, regardless of identified levels of contamination. These surveys and housekeeping efforts minimize surface contamination and the potential for airborne radioactivity.

Oversight of work activities is conducted in order to ensure that they are consistent with safe radiological practices. Employees are instructed in work practices that minimize the potential for airborne radioactivity. Supervisors continuously monitor work activities and clothing-handling techniques which are inconsistent with the instruction and training which employees receive and take corrective action as necessary. Corporate health physics staff also review clothing-handling techniques during annual corporate audits at all operating INS facilities. Survey records,

including contamination levels and air concentrations, are subject to inspection during the annual corporate health physics audit. During these corporate audits, an annual ALARA program review is conducted and recommendations made as appropriate.

#### Compliance History

All program elements discussed are considered during inspections by regulatory agencies throughout all of UniTech's plants. UniTech's excellent compliance history further documents UniTech's successful and compliant implementation of all of these programs. UniTech's compliance record provides confirmation that programs are in place to sufficiently monitor workplace conditions and detect situations that would invoke appropriate uranium bioassay, as necessary.

#### Conclusion

UniTech believes that the data and program as committed to supports this request in accordance with regulatory guidance documents. UniTech trusts that the information provided is sufficient. However, if you have any questions, please do not hesitate to contact this office.

Sincerely,

Glenn Roberts, CHP  
Health Physicist
