Table D-18. TDS Near Upgradient Background Data Set, Distribution Summary

Parameter	Distribution Type (tested)	Coefficient of Variation	Studentized Range Test	Coefficient of Skewness (-1 to 1)	Shapiro-Wilk Test	Filliben's Statistic	Histogram	Probability Plot	Number of Samples	Distribution Type (determined)
TDS	Normal	Pass	Pass	Pass	Fail	Fail	X	?	331	Nonparametric
TDS	Lognormal	Pass	NA	Pass	Fail	Fail		?	331	

NA - not applicable
? - Results of graphical test were inconclusive.

Table D-19. T_n Statistic Analysis for TDS Near Upgradient Background Data Set

Parameter	Distribution	Maximum Observation	Mean	Standard Deviation	T_n Statistic	N	Upper 5% Critical Value	Pass or Fail T_n Statistic
TDS	Lognormal	8.354674262	7.52	0.27	3.060	331	3.34+	Pass

N - number of samples

Table D-20. 95th Percentile for Near Upgradient TDS Background Data Set

Parameter	Distribution	Censored?	95th Percentile (mg/L)	Sample #
TDS	Nonparametric	No	3060	331

SD = standard deviation

Table D-21. Summary Table for Near Upgradient TDS Background Data Set

Parameter	Distribution	Mean	SD	95th Percentile (mg/L)	Range (normal)	Sample #
TDS	Nonparametric	1923.02	546.89	3060	4250 to 954	331

SD = standard deviation
ND = non-detect, concentration reported as the minimum detecatable activity (MDA)

Table D-40. TDS Upgradient Background Data, Comparison Statistics Results

Comparison of Medians

Median of Sample 1: 2388.0
Median of Sample 2: 1840.0

Mann-Whitney (Wilcoxon) W test to compare medians

Null hypothesis: median1 = median2
Alt. Hhpothesis: median1 NE median2

Average rank of sample 1: 184.298
Average rank of sample 2: 190.239

w = 8023.0 P-value = 0.72776

The StatAdvisor

This option runs the Mann-Whitney W test to compare the medians of the two samples. This test is constructed by combining the two samples, sorting the data from the smallest to the largest, and comparing the average ranks of the two samples in the combined data. Since the P-value greater than or equal to 0.05, there is not a statistically significant difference between the medians at the 95.0% confidence level.

EXCUTIVE SUMMARY

Molybdenum, selenium, and uranium are key contaminants introduced into the shallow groundwater as a result of the processing of uranium ore at the Homestake site, located near Grants, New Mexico. However, a natural source of these same constituents exists upgradient which influences natural background groundwater quality. The purpose of this report is to statistically characterize upgradient concentrations of molybdenum, selenium, and uranium in the alluvial aquifer and to propose statistical methods for determining whether alluvial wells located downgradient of the site have been impacted by contamination originating at the site.

Samples were collected at near and far upgradient wells from 1976 to 1998. Fifteen wells provided the upgradient well data while data from six far upgradient wells were used to construct that data set. Close examination of the groundwater database provided justification for elimination of select samples. Samples were eliminated based upon high detection limits, reported zero concentrations, and extreme maximum concentrations. Only a minor percentage of samples were eliminated; the completeness of the data set was not compromised.

Statistical analyses were preformed on the individual data sets (constituent and location specific) to determine distribution, statistical similarities between near and far upgradient data, and upper tolerance limits. Results of the distribution analysis indicated that all data sets were nonparametrically distributed. The molybdenum and uranium near and far upgradient background data sets were shown to be statistically similar and so analyses on the combined data set was performed.

The 95th percentile was calculated as the non-parametric upper tolerance limit for all analyzed data sets. The 95th percentile should be used to compare to downgradient well concentrations to determine if "above expected background concentrations" exist. If the downgradient concentration is greater than the 95th percentile, contamination may be indicated. However, it should be noted that since the 95th percentile was calculated as the upper tolerance limit, statistically 5% of the time one would expect the upper tolerance limit to be exceeded. Because the molybdenum and uranium near and far upgradient data sets were statistically similar, the combined data set 95th percentile should be representative of upgradient background concentrations. Because the selenium near and far upgradient data sets were not statistically similar, it is advised to use the near upgradient 95th percentile for downgradient well concentration comparisons. A summary table of the parameter, data set, distribution, 95th percentile, range, arithmetic mean and sample number is provided as Table ES-1.

Table ES-1. Summary Table for Upgradient Wells, Statistical Analysis

Parameter	Data Set	Distribution	95th Percentile	Range	Arithmetic Mean	Samples
Molybdenum	Near Upgradient	Nonparametric	0.054	<0.001 to 0.2	0.019	366
	Far Upgradient	Nonparametric	0.04	<0.01 to 0.07	0.018	42
	Combined	Nonparametric	0.05	<0.001 to 0.2	0.019	408
Selenium	Near Upgradient	Nonparametric	0.27	0.009 to 0.755	0.13	365
	Far Upgradient	Nonparametric	0.72	<0.005 to 0.79	0.3	42
Uranium	Near Upgradient	Nonparametric	0.147	0.003392 to 0.7208	0.05	366
	Far Upgradient	Nonparametric	0.18	0.001 to 0.192	0.07	42
	Combined	Nonparametric	0.16	0.001 to 0.7208	0.05	408

1.0 INTRODUCTION

Molybdenum, selenium, and uranium are key contaminants introduced into the shallow groundwater as a result of the processing of uranium ore at the Homestake site, located near Grants, New Mexico. Because of their mobility, these constituents are used to track contaminant plume migration downgradient of the site. However, extensive mineralized areas upgradient of the site serve as a natural source of these same constituents in the alluvial groundwater. The purpose of this report is to statistically characterize upgradient concentrations of molybdenum, selenium, and uranium in the alluvial aquifer and to propose statistical methods for determining whether alluvial wells located downgradient of the site have been impacted by contamination originating at the site.

This report was prepared at the request of Homestake Mining Company. Homestake Mining Company provided the chemical analysis data, and George Hoffman from Hydro-Engineering, a contractor for the Homestake site, provided the well location map presented in this report as well as other valuable information, both printed and verbal, used in this assessment.

1.1 Monitor well network

Figure 1 shows the location of the fifteen upgradient monitor wells for which ground water quality data were provided. Alluvial wells DD, ND, P, P1, P2, P3, P4, Q, and R are located within approximately one mile of the site and are referred to in this report as near upgradient background wells, four of these wells (DD, P, Q, and R) have been sampled since 1976, data from well ND extends back to 1983, wells P1 and P2 have been sampled since 1992 and wells P3 and P4 were sampled for the first time in 1998. The sampling frequency varies by well and over time, but generally most of the near upgradient wells were sampled at least twice per year through 1998. These data were combined into a statistical set of data based upon geochemical similarities and knowledge of completion interval (Hoffman 1999).

Data from six additional wells farther upgradient of the site were also provided for this analysis. Wells 914, 916, 920, 921, 922, and 950 are located approximately two to three miles upgradient of the Homestake site and are collectively referred to in this report as far upgradient background wells. In addition to being located farther from the site, these wells were not installed by Homestake. Because completion logs are not available (personal communication, G. Hoffman) it cannot be determined whether these wells access alluvial groundwater, water from a deeper water bearing unit, or some combination from both groundwater sources. These wells have been sampled less frequently than the near upgradient wells. These data were combined into a statistical data set based upon upgradient placement in relation to the Homestake site and lack of completion interval knowledge.

A statistical comparison analyses between well sets was performed and the two data sets were combined into a single data set when statistically defensible.

1.2 Data preparation

The database provided for analysis consisted of six fields describing, well identification number, sample date, measured parameter, laboratory identification where the sample was processed, remark code (qualifiers) and concentration (mg/L).

Examination of the database revealed isolated problems with individual data values. For example, two molybdenum values reported as <0.1 mg/L were omitted as uninformative because typically molybdenum analyses were performed using a detection limit of 0.01 or 0.03 mg/L, and most upgradient molybdenum levels lie well below 0.1 mg/L. This data was from well P in November 1982 and from Well R in September 1992. A reported selenium concentration of 12 mg/L for well P on 2/27/91 was determined to be an error and was removed from the database. This concentration was determined to be the result of laboratory error. Two uranium measurements of exactly 0.00 mg/L were omitted (one was from Well P the other from Well R in September 1979). None of the removed data appears on any table in this report.

The laboratory code field entries in the database indicate that the majority of water samples were analyzed on-site (lab code Homestake), with frequent verification analyses provided by independent laboratories. When the dates reported for the on-site and verification results differed by only one or two days, the data were assumed to represent the same sampling round and one of the dates was changed to agree with the other. The database also includes rare cases of what appear to be replicate analyses of a water sample by the same laboratory. Replicate measurements were removed and replaced by a single data value equal to their arithmetic average. Master data tables and corrected data tables are provided for each constituent so all changes to the original set of data can be tracked.

Multiple measurements of constituent concentrations made by different laboratories on split or replicate samples of a well can be expected to be correlated, which violates the assumption of independence required by most statistical procedures. Therefore, as a last step before processing, the on-site and any verification lab results for a sampling round were averaged together to produce one value for the concentration of a constituent in each well on that date. This process equates the number of data to the number of sampling rounds for a well, and should produce more stable data with less noise.

The data used for statistical evaluation are presented for each constituent in tabular form in the back of this report.

2.0 METHODS

2.1 Distribution Analyses

A distribution analysis was performed to determine if a particular data set was parametric or non-parametric. The data first were subjected to an *a priori* screen (Section 2.1.1). The number of non-detects was then evaluated for the data set (Section 2.1.2). If greater than 15% non-detects existed, the data set was considered non-parametric and the distribution analysis was concluded. If fewer than 15% non-detects existed, the data were subjected to six numerical and two graphical procedures to determine the distribution type. The numerical procedures included the coefficient of variation (Section 2.1.3), the Studentized range test (Section 2.1.4), Geary's test (Section 2.1.5), the coefficient of skewness (Section 2.1.6), the Shapiro-Wilk Test of Normality if the sample size was less than or equal to 50 or the Shapiro-Francia test if the sample size was greater than 50 (Section 2.1.7), and Filliben's statistic (Section 2.1.8). The graphical procedures used were the histogram (Section 2.1.9) and the probability plot (Section 2.1.10). The results of the procedures were compared and the distribution was determined (Section 2.1.11). The T_n statistic was then calculated for the parametric data sets as a second screening mechanism for outliers (Section 2.1.12). If a data set contained fewer than 15% non-detects but failed the numerical and graphical procedures for a parametric distribution, the data set was often carried through to the T_n statistic procedure to determine if outliers were present. In some instances, outliers are identified and removed during the T_n statistic procedure causing a data set that had initially failed to pass the parametric numerical and graphical tests. If outliers were identified during the T_n statistical test, the outliers were removed and the mean and standard deviation were recalculated for the data set, and the distribution analysis was performed again.

2.1.1 Rejection of Outliers: *A Priori* Test

The *a priori* test is a screening test used to eliminate outliers before the distribution analysis is performed. This test is applied to all data whether parametric or non-parametric. An observation that is 4 or 5 times as large as the rest of the data is generally considered suspect (EPA 1989). Conservatively, for this *a priori* test, outliers are defined as maximum values greater than three times the next highest value. Non-transformed data are used for this screening test. If a data value fails the *a priori* test, it is removed from the data set for all following statistical analyses. The data point, however, must be explained as either potential sampling error, laboratory error, an anomalously high value, or some other factor contributing to an unexpectedly "high concentration".

2.1.2 Determination of Percent Non-detects

If the percentage of non-detects was less than 15%, the non-detect was replaced by the detection limit divided by two. A parametric distribution analyses was then performed on the modified data set. If the percentage of non-detects was greater than 15%, the distribution was considered non-parametric and a distribution analysis was not performed (EPA 1989, 1992).

2.1.3 Coefficient of Variation

The coefficient of variation (CV) is a unitless measure that determines dispersion for a set of data. The CV is commonly used in environmental statistical analyses because variability (expressed as a standard deviation) is often proportional to the mean. The CV may be used to determine whether or not the data follow a normal curve by comparing the sample CV to 1. EPA guidance (EPA 1998) suggests that the use of the CV is most valid if the data is non-negative. If the CV was greater than 1, the normality of the data was considered suspect. However, this method cannot be used to conclude the opposite, i.e. the distribution is normal if the CV is less than 1 (EPA 1998). This test was used as a preliminary screening test in conjunction with other more powerful distribution determining tests. The CV was calculated by dividing the standard deviation by the mean. Further information is provided in Guidance for Data Quality Assessment, Practical Methods for Data Analysis (EPA 1998).

The following formula is used to calculate CV:

$$CV = \frac{s}{\bar{X}}$$

where,

CV = coefficient of variation
s = standard deviation, and

$\bar{X}$ = sample mean

2.1.4 Studentized Range Test

Almost 100% of the area of a normal curve lies within +/-5 standard deviations from the mean. The Studentized range test for normality was developed based on this fact. This test compares the range of the sample (w) divided by the sample standard deviation (s) to a critical value range. If (w/s) exists outside of the critical value range, the data set fails the test. The Studentized range test does not perform well if the data are asymmetric. If the data appear to be lognormally distributed the test should not be applied (EPA 1998).

The following formula is used to perform the Studentized Range Test:

$$\frac{w}{s} = \frac{X_n - X_1}{s}$$

where,

w/s = sample range divided by the sample standard deviation
X_n = the maximum value of the data set
X_1 = the minimum value of the data set, and
s = the sample standard deviation

2.1.5 Geary's Test

Another numerical test utilized for normality testing was Geary's test. Geary's test uses the ratio of the mean deviation of the sample to the sample standard deviation. This ratio is then adjusted to approximate a standard normal distribution (EPA 1998). A "Z" value is calculated from the sample mean, the sample sum of squares, and the sum of absolute deviations. The "Z" value is then compared to a critical value such that if the absolute value of "Z" is greater than the critical value, the test indicates that the data do not follow a normal distribution.

The following formulas are used in Geary's Test. The first procedure is to calculate the sample mean:

$$\bar{X} = \frac{1}{n}\sum_{i=1}^{n} X_i$$

where,

$\bar{X}$ = the sample mean
X_i = the individual sample within the data set, and
n = the number of samples within the data set

The second procedure is to calculate the sample sum of squares:

$$SSS = \sum_{i=1}^{n} X_i^2 - \frac{\left(\sum_{i=1}^{n} X_i\right)^2}{n}$$

where,

SSS = sample sum of squares
X_i = the individual sample within the data set, and
n = the number of samples within the data set

The third procedure is to calculate the sum of absolute deviations:

$$SAD = \sum_{i=1}^{n} \left| X_i - \bar{X} \right|$$

where,

SAD = sum of the absolute deviations
$\bar{X}$ = the sample mean
X_i = the individual sample within the data set, and
n = the number of samples within the data set

The fourth procedure is to calculate Geary's test statistic:

$$a = \frac{SAD}{\sqrt{n(SSS)}}$$

where,

a = Geary's test statistic
SAD = sum of the absolute deviations
SSS = sample sum of squares, and
n = the number of samples within the data set

The final step in performing Geary's test is to test "a" for significance by computing:

$$Z = \frac{a - 0.7979}{0.2123/\sqrt{n}}$$

where,

Z = test of "a" for significance
a = Geary's test statistic, and
n = the number of samples within the data set

2.1.6 Coefficient of Skewness

The coefficient of skewness indicates to what degree a data set is skewed or asymmetric with respect to the mean. Data from a perfectly shaped normal distribution have a coefficient of skewness of zero, while asymmetric data have either positive or negative skewness depending on whether the right- or left-hand tail of the distribution is longer and "skinnier" than the opposite tail. A small degree of skewness (between -1 and +1) is not likely to affect the results of statistical tests based on an assumption of normality. However, if the coefficient of skewness is larger than 1 (in absolute value) and the sample size is small (e.g., n<25), statistical research has shown that standard normal theory-based tests are much less powerful than when the absolute skewness is less than 1 (Gayen, 1949). Therefore, it is considered a failure of the test for normality if the coefficient of skewness exceeds 1. The formula

for the coefficient of skewness γ_i is shown below, where n is the number of data points, x_i is an individual sample observation, $\bar{x}$ is the mean of the data set, and σ is the standard deviation.

$$\gamma_i = \frac{\frac{1}{n}\sum_{i=1}^{n}(x_i - \bar{x})^3}{\left(\frac{n-1}{n}\right)^{\frac{3}{2}}(\sigma)^3}$$

The Coefficient of Skewness can also be used to evaluate whether the distribution of a data set is more normal or lognormal, based on the closeness of γ_i to zero.

2.1.7 Shapiro-Wilk (n<50) or Shapiro-Francia (n≥50) Test of Normality

The Shapiro-Wilk Test of Normality is based on the premise that, if a set of data is normally distributed, the ordered values should be highly correlative with corresponding quantiles taken from a normal distribution (Shapiro and Wilk, 1965). In particular, the Shapiro-Wilk Test of Normality gives substantial weight to evidence of non-normality in the tails of a distribution, where the robustness of statistical tests based on the normality assumption is the most severely affected (EPA, 1992).

The Shapiro-Wilk test statistic (W) will tend to be large (close to 1) when the data is normally distributed. Only when the plotted data show significant bends or curves will the test statistic be small. The Shapiro-Wilk Test of Normality is considered to be one of the best available tests of normality (Miller, 1986; Madansky, 1988).

The following formula is used to calculate W:

$$W = \left[\frac{b}{\sigma\sqrt{n-1}}\right]^2$$

where,

$$b = \sum_{i=1}^{k} b_i = \sum_{i=1}^{k} a_{n-i+1}\left(x_{(n-i+1)} - x_i\right)$$

and σ = standard deviation,
n = number of data points,
a_{n-i+1} = coefficients determined from Table A-1in EPA (1992) for $3 \leq n \leq 50$
K = greatest integer less than or equal to n/2

Normality of the data should be rejected if the Shapiro-Wilk statistic is too low when compared to the critical values provided in Table A-2 (EPA, 1992). Otherwise, the data are assumed to be approximately normal for purposes of further statistical analysis.

The Shapiro-Francia Test of Normality is also based on the premise that, if a set of data is normally distributed, the ordered values should be highly correlative with corresponding quantiles taken from a normal distribution (Shapiro and Francia 1972).

The Shapiro-Francia test statistic (W') will tend to be large (close to 1) when the data is normally distributed. Only when the plotted data show significant bends or curves will the test statistic be small. Normality of the data should be rejected if the Shapiro-Francia statistic is below calculated critical values (EPA 1992). Otherwise, the data are assumed to be approximately normal for purposes of further statistical analysis.

The following formula is used to calculate W':

$$W' = \frac{\left[\Sigma_i m_i x_i\right]^2}{(n-1)SD^2 \Sigma_i m_i^2}$$

where,

W' = test statistic

x_i = represents the ith ordered value of the sample

n = the number of samples within the data set

SD = the sample standard deviation

m_i = the approximated expected value of the ith ordered Normal quantile.

The values for m_i can be approximately computed as

$$m_i = \Phi^{-1}\left(\frac{i}{n+1}\right)$$

where,

m_i = the approximated expected value of the ith ordered Normal quantile

Φ^{-1} = the inverse of the standard Normal distribution with zero mean and unit variance

n = the number of samples within the data set

2.1.8 Filliben's Statistic

Filliben's statistic is approximately equivalent to the Shapiro-Wilk and Shapiro-Francia tests as described by Filliben (1975). This test correlates well with the use of probability plots, because the essence of the test is to compute the common correlation coefficient for points on a probability plot (EPA 1992). Since the correlation coefficient is a measure of the linearity of the points on a scatterplot, Filliben's statistic will be high when the plotted points fall along a straight line and low when there are significant bends and curves in the probability plot. Comparison of the Shapiro-Wilk and Filliben's statistic has indicated very similar statistical power for detecting non-normality (Ryan and Joiner, 1976). Critical values for the correlation coefficient have been derived in EPA 1992. If the calculated value is less than the critical value, there is significant evidence of non-normality.

Filliben's statistic may be computed as:

$$r = \frac{\Sigma_{i=1}^{n} X_i M_i}{\left(\sqrt{\Sigma_i M_i^2}\right)(SD)\left(\sqrt{n-1}\right)}$$

where,

r = Filliben's statistic

X_i = represents the ith smallest ordered concentration value

n = the number of samples within the data set

SD = the sample standard deviation

M_i = the median of the ith order statistic from a standard Normal distribution.

The ith Normal order statistic median may be approximated as $M_i = \Phi^{-1}(m_i)$, where as before Φ^{-1} is the inverse of the standard Normal cumulative distribution and m_i can be can be computed as follows (given sample size n):

$$m_i = 1 - \left(0.5^{1/n}\right) \text{ for i = 1}$$

$$m_i = (i - 0.3175)/(n + 0.365) \text{ for 1<i<n}$$

$$m_i = 0.5^{1/n} \text{ for i = n}$$

2.1.9 Histograms

Histograms are useful for visually determining whether the data sets are skewed, and if so, in what direction. Histograms are created by determining the range of sample concentrations, then dividing the concentration range into equal intervals. Samples are then placed into the appropriate concentration intervals. The concentration range forms the x-axis. Calculating the percentage of samples per concentration interval compared to the total number of samples, or simply plotting the number of data values that fall within an interval, provides the y-axis in terms of percent frequency or frequency, respectively, of a particular concentration interval.

2.1.10 Probability Plots

Another simple and useful graphical test for determining normality is to plot the data on probability paper. The y-axis is scaled to represent probabilities according to the normal distribution, and the data are arranged in increasing order. An observed value is plotted on the x-axis, and the proportion of observations less than or equal to each observed value is plotted as the y-coordinate. The scale is constructed so that, if the data are normal, the points when plotted will approximate a straight line. Visually apparent curves or bends indicate that the data do not follow a normal distribution (EPA, 1992).

Probability plots are particularly useful for spotting irregularities within the data when compared to a specific distributional model such as the normal distribution. It is easy to determine whether departures from normality are occurring more or less in the middle ranges of the data or in the extreme tails. Probability plots can also indicate the presence of possible outlier values that do not follow the basic pattern of the data and can show the presence of significant positive or negative skewness.

The probability for a particular data value x is calculated as

$$\text{Probability} = 100*((i-3/8)/(n+1/4))$$

where,

i = ranked order of x_i from i to n
n = number of samples

2.1.11 Determination of Distribution

Upon completion of the *a priori* screen, percent non-detect determination, and graphical and numerical distribution analysis, a determination of the distribution was made (EPA, 1992).

2.1.12 The T_n Statistic Test

The T_n Statistic test was performed on the near and far upgradient background data after the *a priori* screen and initial distribution analysis had been completed. The test was run iteratively until the largest remaining value in the

data set passed. If a particular data set had fewer than 15% non-detects but failed the parametric distribution tests, it was often carried over to the T_n Statistic and analyzed using the parametric distribution that it most closely resembled. In some instances, identification and removal of outliers during the T_n Statistic procedure allows for the previously failed data set to pass the parametric numerical and graphical tests. If failures were reported during the T_n statistical test, the values were removed and the mean and standard deviation were recalculated on the censored data set. Failures of the T_n Statistic are defined as T_n calculated values that exceed the critical value (EPA, 1989). The censored data set was then used for all additional statistical tests. (Removed data points are considered either potential sampling error, laboratory error, an anomalously high value, or some other factor contributing to an unexpectedly large concentration).

To calculate the T_n statistic, the following formula is used:

$$T_n = \frac{(x_n - \bar{x})}{\sigma}$$

where

T_n = T_n statistic,
x_n = individual sample,
$\bar{x}$ = mean of sample set, and
σ = standard deviation.

2.1.13 Determination of Upper Tolerance Limit

This section describes two methods, one for parametric data and the other for non-parametric data that establish the maximum expected background concentration using a 95 percent confidence limit. A parametric upper tolerance limit (Section 2.1.13.1) is calculated for parametric data sets, while a 95th percentile (considered a non-parametric upper tolerance limit)(Section 2.1.13.2) is calculated for non-parametric data sets.

2.1.13.1 Parametric Upper Tolerance Limit

A tolerance interval establishes a concentration range that is constructed to contain a specified proportion (P%) of the population with a specified confidence coefficient, Y. The proportion of the population included, P, is referred to as the coverage. The probability with which the tolerance interval includes the proportion P% of the population is referred to as the tolerance coefficient.

A coverage of 95% was used as recommended by EPA (1989). By using this coverage, random observations from the same distribution would exceed the upper tolerance limit less than 5% of the time. Similarly, a tolerance coefficient of 95% was used. This means that there is a confidence level of 95% that the upper 95% tolerance limit would contain at least 95% of the distribution of observations from background groundwater data. These values were chosen to be consistent with the performance standards described in Section 2 of EPA 1989.

Tolerance intervals were constructed assuming that the data or the transformed data were normally distributed.

The formula for the UTL is as follows:

$$UTL = \bar{x} + t_{.05(n-1)} \cdot \sigma$$

where

$\bar{x}$ = the mean of the population,
$t_{.05(n-1)}$ is one-sided tolerance factor for n (Table 5, Appendix B, EPA 1989), and
σ = the standard deviation

2.1.13.2 95th Percentile

For non-parametric data sets, the 95th percentile value was used for expressing the upper range of background. The 95th percentile indicated that 95 percent of the data would be expected to be below that value, while 5 percent would be above the value. The calculated background was therefore insensitive to the magnitude of the largest 5 percent of the data points.

Percentiles can be calculated in several similar manners. EPA 1998 provides one method of calculating percentiles. The 95th percentile presented in this report was calculated electronically by the Microsoft Excel software program (Microsoft 1992).

2.2 Comparison Test

2.2.1 Introduction

A comparison test was performed between near upgradient and far upgradient data sets to determine if the two data sets were statistically similar. If the data sets were similar, then the data sets were combined to determine the upper tolerance limit for the larger data set. If the near and far upgradient data sets did not compare statistically, the data sets were not combined.

Comparison tests are of two basic types: parametric and non-parametric. Only a non-parametric test was applied to the Homestake background data. This test was the Wilcoxon Rank-sum test.

2.2.2. Wilcoxon Rank Sum Test

The Wilcoxon-Rank Sum (WRS) Test is a powerful nonparametric test to determine if data sets are statistically similar (EPA 1992). As a general rule, the WRS test should be used with caution if more than about 40% of the measurements are non-detects. All data were subjected to the WRS test in this analysis with the knowledge that the test power was greatly reduced when the non-detect percent was greater than 40.

In general the WRS test is performed by combining two data sets and ranking that set from highest to lowest. The ranked sum of each set is compared to determine if one set is statistically different than the other. A statistical software package (STATGRAPHICS) (Manugistics 1998) was used to perform this two-way procedure.

3.0 MOLYBDENUM

3.1 Introduction

Molybdenum concentration data for near upgradient wells are characterized by a high frequency of nondetects at laboratory detection limits of 0.03, 0.01, and 0.001 mg/L. Approximately 16 percent of measurements from these wells exceed the NRC site standard of 0.03 mg/L, with exceedences ranging from 0.03 to 0.2 mg/L. Only two of 408 (0.5 percent) measurements exceed 0.10 mg/L.

Molybdenum concentration data for far upgradient wells are also characterized by a high percentage of nondetects at laboratory detection limits of 0.03 and 0.01 mg/L. Approximately 14 percent of measurements from these wells exceed the NRC site standard of 0.03 mg/L, with exceedences ranging from 0.03 to 0.07 mg/L. No measurements from the far upgradient wells exceeded 0.10 mg/L.

Table 1 summarizes data for both near upgradient and far upgradient background wells.

3.2 Molybdenum Near Upgradient

Table 2 presents the molybdenum near upgradient background data set with the data not corrected for non-detects or duplicates. Tables 3 through 10 present the sampling date and the final data set (corrected for non-detects and duplicates for the near upgradient background wells. Finally, Table 11 is a summary table of all the final data sets for the near upgradient wells used in the statistical analyses. A distribution analysis was first performed for the molybdenum data. Then the 95th upper tolerance limit was calculated.

3.2.1 Distribution Analysis Results

3.2.1.1 Rejection of Outliers: *A Priori* Test

Results of the *a priori* test are presented in Table 12. No outliers were determined or eliminated from the molybdenum near upgradient background data set.

3.2.1.2 Determination of Percent Non-detects

Because the near upgradient molybdenum data had 40% non-detects, the data were considered to be nonparametric (EPA 1989)(Table 1). Thus, no more distribution tests were applied to the data.

3.2.2. Determination of Upper Tolerance Limit

3.2.2.1 95th Percentile

Because the data was determined to be nonparametrically distributed (due to greater than 15% non-detects), the 95th percentile of the data was calculated. The 95th percentile was determined to be 0.054 mg/L (Table 13). The molybdenum near upgradient background data set summary table is presented as Table 14.

3.3 Molybdenum Far Upgradient Distribution Analysis Results

Table 15 presents the molybdenum far upgradient background data set with the data not corrected for non-detects or duplicates. Tables 16 through 21 present the sampling date and the final data set (corrected for non-detects and duplicates for the far upgradient background wells. Finally, Table 22 is a summary table of all the final data sets for the far upgradient wells used in the statistical analyses. A distribution analysis was first performed for the molybdenum data. Then the 95th upper tolerance limit was calculated.

3.3.1 Distribution Analysis Results

3.3.1.1 Rejection of Outliers: *A Priori* Test

Results of the *a priori* test are presented in Table 23. No outliers were determined or eliminated from the molybdenum far upgradient background data set.

3.3.1.2 Determination of Percent Non-detects

Because the far upgradient molybdenum data had 86% non-detects, the data were considered to be nonparametric (EPA 1989) (Table 1). Thus, no more distribution tests were applied to the data.

3.3.2 Determination of Upper Tolerance Limit

3.3.2.1 95th Percentile

Because the data was determined to be nonparametrically distributed (due to greater than 15% non-detects), the 95th percentile of the data was calculated. The 95th percentile was determined to be 0.040 mg/L (Table 24). The molybdenum far upgradient background data set summary table is presented as Table 25.

3.4 Molybdenum Near and Far Upgradient Comparison Statistics Results

The molybdenum near upgradient background data set was statistically similar to the molybdenum far upgradient background data set (Table 26). Thus, distribution fitting and an upper tolerance limit calculation was performed on the combined data set.

3.5 Molybdenum Combined Distribution Analysis Results

Table 27 is a summary table of all the final data sets for the combined upgradient wells used in the statistical analyses. A distribution analysis was first performed for the molybdenum data. Then the 95th upper tolerance limit was calculated.

3.5.1 Distribution Analysis Results

3.5.1.1 Rejection of Outliers: *A Priori* Test

Results of the *a priori* test are presented in Table 28. No outliers were determined or eliminated from the molybdenum combined upgradient background data set.

3.5.1.2 Determination of Percent Non-detects

Because the combined upgradient molybdenum data had over 40% non-detects, the data were considered to be nonparametric (EPA 1989) (Table 1). Thus, no more distribution tests were applied to the data.

3.5.2 Determination of Upper Tolerance Limit

3.5.2.1 95th Percentile

Because the data was determined to be nonparametrically distributed (due to greater than 15% non-detects), the 95th percentile of the data was calculated. The 95th percentile was determined to be 0.05 mg/L (Table 29). The molybdenum combined upgradient background data set summary table is presented as Table 30.

4.0 SELENIUM

4.1 Introduction

Selenium concentrations measured in near upgradient wells range from 0.009 mg/L to 0.755 mg/L. Less than five percent of measurements are below detection, and slightly above half of all measurements from the near upgradient wells lie above the NRC site standard of 0.10 mg/L with exceedances ranging from 0.1 to 0.755. Table 31 provides a statistical summary of the data by well for both near upgradient and far upgradient wells.

Selenium concentrations measured in far upgradient wells range from <0.005 to 0.79 mg/L. Approximately 16% of the data for the far upgradient wells are nondetect. Approximately 60 percent of measurements from these wells exceed the NRC site standard of 0.10 mg/L, with exceedences ranging from 0.276 to 0.79 mg/L. Though typically when non-detects exceed 15% of the data set only non-parametric statistics are applied, because the percent non-detect was so close to 15, parametric distribution analyses were still performed.

4.2 Selenium Near Upgradient

Table 32 presents the selenium near upgradient background data set with the data not corrected for non-detects or duplicates. Tables 33 through 40 present the sampling date and the final data set (corrected for non-detects and duplicates for the near upgradient background wells. Finally, Table 41 is a summary table of all the final data sets for the near upgradient wells used in the statistical analyses. A distribution analysis was first performed for the molybdenum data. Then the 95th upper tolerance limit was calculated.

4.2.1 Distribution Analysis Results

4.2.1.1 Rejection of Outliers: *A Priori* Test

Results of the *a priori* test are presented in Table 42. No outliers were determined or eliminated from the selenium near upgradient background data set.

4.2.1.2 Determination of Percent Non-detects

Because the near upgradient selenium data set had less than 15% non-detects, distribution tests were applied to the data (Table 31).

4.2.1.3 Coefficient of Variation

Both the normal and log-transformed data sets passed the CV screen (Table 43). The CV value was 0.73 for the normal data and –0.41 for the log-transformed data compared to the critical value of 1. According to EPA 1998, if the CV is less than 1, the data may be, but does not necessarily have to be normal.

4.2.1.4 Studentized Range Test

The normal data set failed the Studentized range test (Table 44). The range (w) divided by the standard deviation (s) produced a result of 8.05. The critical value range was 5.47 to 6.94. When (w/s) falls outside the critical range, it implies that the data are not well modeled by a normal curve (EPA 1998).

4.2.1.5 Geary's Test

Both the normal and log-transformed data sets failed Geary's test (Table 45). The calculated "Z" values were –2.0 and –2.9 respectively, while the critical value is 1.645. Because the absolute value of "Z" was

4.2.1.6 Coefficient of Skewness

Both the normal and log-transformed data sets failed the coefficient of skewness test (Table 46). The calculated coefficient of skewness was 1.7 for the normal set and −1.1 for the log-transformed data set compared to an acceptable range of −1 to 1. Because the coefficient of skewness is greater than 1, the normal distribution may provide a poor approximation to the data set (EPA 1992).

4.2.1.7 Shapiro-Francia (n≥50) Test of Normality

Both data sets failed the Shapiro-Francia test (Table 47). Though the critical value for the test could not be precisely determined, it is evident from comparison of tabulated critical values to n that the critical value approaches 1 as n increases. The critical value for n=99 is 0.975 for 95% confidence. The calculated W' for the normal data was 0.88, for the log-transformed data it was 0.90. Therefore, normality of the data was rejected (EPA 1992).

4.2.1.8 Filliben's Statistic

Both data sets failed Filliben's Statistic (Table 48). Though the critical value for the test could not be precisely determined, it is also evident from comparison of tabulated critical values to n that the critical value approaches 1 as n increases. The critical value for n=100 is 0.987 for 95% confidence. The calculated test statistic for the normal data was 0.937, for the log-transformed data it was 0.950. Therefore, normality of the data was rejected (EPA 1992).

4.2.1.9 Histograms

Figure 2 depicts the histogram for the normal data set. The figure depicts a fair distribution "fit" with right skewness implying that the normal distribution could provide a poor approximation to the data set. Figure 3 depicts the histogram for the log-transformed data set. This figure also depicts a fair distribution "fit" with left skewness implying that the normal distribution could provide a poor approximation to the data set

4.2.1.10 Probability Plots

Figure 4 shows the probability plot for the normal data set. There are two sharp breaks in the plot, one near the detection limit, the other near 0.4 mg/l. This probability plot depicts a poor normal distribution "fit", implying the normal distribution will provide a poor approximation to the data set. Figure 5 is the probability plot for the log-transformed data set. There are at least four breaks in the plot. This probability plot also depicts a poor normal distribution "fit", with the same implication as above.

4.2.1.11 Determination of Distribution

Based on the distribution analysis results, the selenium near upgradient background data set is non-parametric (Table 49).

4.2.1.12 The T_n Statistic Test

Though the data set was determined to be nonparametric, the T_n statistic outlier test was applied to the log-transformed data set. The log-transformed data set was selected because it approximated normality better than the non-transformed data set. No outliers were detected using the T_n statistic (Table 50).

4.2.2. Determination of Upper Tolerance Limit

4.2.2.1 95th Percentile

Because the data was determined to be non-parametrically distributed, the 95th percentile of the data was calculated. The 95th percentile was determined to be 0.27 mg/L (Table 51). The selenium near upgradient background data set summary table is presented as Table 52.

4.3 Selenium Far Upgradient Distribution Analysis Results

Table 53 presents the selenium far upgradient background data set with the data not corrected for non-detects or duplicates. Tables 54 through 59 present the sampling date and the final data set (corrected for non-detects and duplicates for the far upgradient background wells. Finally, Table 60 is a summary table of all the final data sets for the far upgradient wells used in the statistical analyses. A distribution analysis was first performed for the selenium data. Then the 95th upper tolerance limit was calculated.

4.3.1 Distribution Analysis Results

4.3.1.1 Rejection of Outliers: *A Priori* Test

Results of the *a priori* test are presented in Table 61. No outliers were determined or eliminated from the selenium far upgradient background data set.

4.3.1.2 Determination of Percent Non-detects

Because the far upgradient selenium data set had only slightly more than 15% non-detects, distribution tests were applied to the data (Table 31).

4.3.1.3 Coefficient of Variation

Both the normal and log-transformed data sets passed the CV screen (Table 62). The CV value was 0.88 for the normal data and –0.88 for the log-transformed data compared to the critical value of 1. According to EPA 1998, if the CV is less than 1, the data may be, but does not necessarily have to be normal.

4.3.1.4 Studentized Range Test

The normal data set failed the Studentized range test (Table 63). The range (w) divided by the standard deviation (s) produced a result of 3.03. The critical value range was 3.75 to 5.26. When (w/s) falls outside the critical range, it implies that the data are not well modeled by a normal curve (EPA 1998).

4.3.1.5 Geary's Test

Both the normal and log-transformed data sets failed Geary's test (Table 64). The calculated "Z" values were 3.2 and 4.5 respectively, while the critical value is 1.645. Because the absolute value of "Z" was greater than the associated critical value, it implies that the data are not well modeled by a normal curve (EPA 1998).

4.3.1.6 Coefficient of Skewness

Both the normal and log-transformed data sets passed the coefficient of skewness test (Table 65). The calculated coefficient of skewness was 0.1 for the normal set and –0.5 for the log-transformed data set compared to an acceptable range of –1 to 1. Because the coefficient of skewness was less than 1, the normal distribution may accurately approximate the data set (EPA 1992).

4.3.1.7 Shapiro-Wilk (n<50)

Both data sets failed the Shapiro-Wilk test (Table 66). The calculated W for the normal data was 0.85, for the log-transformed data it was 0.77 compared to a critical value of 0.942. Therefore, normality of the data was rejected (EPA 1992).

4.3.1.8 Filliben's Statistic

Both data sets failed Filliben's Statistic (Table 67). The calculated test statistic for the normal data was 0.934, for the log-transformed data it was 0.893 compared to a critical value of 0.973. Therefore, normality of the data was rejected (EPA 1992).

4.3.1.9 Histograms

Figure 6 depicts the histogram for the normal data set. The figure depicts a poor distribution "fit" implying that the normal distribution could provide a poor approximation to the data set. Figure 7 depicts the histogram for the log-transformed data set. This figure also depicts a poor distribution "fit" also implying that the normal distribution could provide a poor approximation to the data set

4.3.1.10 Probability Plots

Figure 8 shows the probability plot for the normal data set. There is at least two sharp breaks in the plot. This probability plot depicts a poor normal distribution "fit", implying the normal distribution will provide a poor approximation to the data set. Figure 9 is the probability plot for the log-transformed data set. There are at least four breaks in the plot. This probability plot also depicts a poor normal distribution "fit", with the same implicatic as above.

4.3.1.11 Determination of Distribution

Based on the distribution analysis results, the selenium far upgradient background data set is non-parametric (Table 68).

4.3.1.12 The T_n Statistic Test

Though the data set was determined to be nonparametric, the T_n statistic outlier test was applied to the normal data set. The normal data set was selected because it approximated normality better than the log-transformed data set. No outliers were detected using the T_n statistic (Table 69).

4.3.2 Determination of Upper Tolerance Limit

4.3.2.1 95th Percentile

Because the data was determined to be non-parametrically distributed, the 95th percentile of the data was calculated. The 95th percentile was determined to be 0.72 mg/L (Table 70). The selenium far upgradient background data set summary table is presented as Table 71.

4.4 Selenium Near and Far Upgradient Comparison Statistics Results

The selenium near upgradient background data set was not statistically similar to the selenium far upgradient background data set (Table 72). Thus, distribution fitting and an upper tolerance limit calculation was not performed on the combined data set.

5.0 URANIUM

5.1 Introduction

Uranium concentrations measured in the near upgradient wells range from 0.003392 to 0.7208 mg/L. The highest uranium concentrations are found in samples from well DD, where 96 percent of measurements exceed the NRC site standard of 0.04 mg/L. Other wells also show exceedences of the standard, and overall 46 percent of measurements in near upgradient wells are above the 0.04 mg/L NRC standard.

Uranium concentrations measured in the far upgradient wells range from 0.001 to 0.192 mg/L. The highest uranium concentrations are found in samples from wells 920 , 921 and 950, where over 80 percent of measurements exceed the NRC site standard of 0.04 mg/L. No other wells show exceedences of the standard, and overall approximately 53 percent of measurements in the far upgradient wells are above the 0.04 mg/L NRC standard.

Table 73 provides a statistical summary of the uranium data by well for both near upgradient and far upgradient wells.

5.2 Uranium Near Upgradient

Table 74 presents the uranium near upgradient background data set with the data not corrected for non-detects or duplicates. Tables 75 through 82 present the sampling date and the final data set (corrected for non-detects and duplicates for the near upgradient background wells. Finally, Table 83 is a summary table of all the final data sets for the near upgradient wells used in the statistical analyses. A distribution analysis was first performed for the uranium data. Then the 95th upper tolerance limit was calculated.

5.2.1 Distribution Analysis Results

5.2.1.1 Rejection of Outliers: *A Priori* Test

Results of the *a priori* test are presented in Table 84. No outliers were determined or eliminated from the uranium near upgradient background data set.

5.2.1.2 Determination of Percent Non-detects

Because the near upgradient uranium data less than 15% non-detects, distribution tests were applied to the data (Table 73).

5.2.1.3 Coefficient of Variation

The log-transformed data set passed the CV screen (Table 85). The normal data set failed the CV test. The CV value was 1.09 for the normal data and –0.29 for the log-transformed data compared to the critical value of 1. According to EPA 1998, if the CV is less than 1, the data may be, but does not necessarily have to be normal.

5.2.1.4 Studentized Range Test

The normal data set failed the Studentized range test (Table 86). The range (w) divided by the standard deviation (s) produced a result of 12.72. The critical value range was 5.47 to 6.94. When (w/s) falls outside the critical range, it implies that the data are not well modeled by a normal curve (EPA 1998).

5.2.1.5 Geary's Test

Both the normal and log-transformed data sets failed Geary's test (Table 87). The calculated "Z" values were –16.6 and –3.9 respectively, while the critical value is 1.645. Because the absolute value of "Z" was greater than the associated critical value, it implies that the data are not well modeled by a normal curve (EPA 1998).

5.2.1.6 Coefficient of Skewness

The normal data set failed the coefficient or skewness test while the log-transformed data set passed (Table 88). The calculated coefficient of skewness was 5.4 for the normal set and –0.4 for the log-transformed data set compared to an acceptable range of –1 to 1. Because the coefficient of skewness was less than 1 for the log-transformed data set, the normal distribution may accurately approximate the data set (EPA 1992).

5.2.1.7 Shapiro-Francia (n≥50) Test of Normality

Both data sets failed the Shapiro-Francia test (Table 89). Though the critical value for the test could not be precisely determined, it is evident from comparison of tabulated critical values to n that the critical value approaches 1 as n increases. The critical value for n=99 is 0.975 for 95% confidence. The calculated W' for the normal data was 0.62, for the log-transformed data it was 0.96. Therefore, normality of the data was rejected (EPA 1992).

5.2.1.8 Filliben's Statistic

Both data sets failed Filliben's Statistic (Table 90). Though the critical value for the test could not be precisely determined, it is also evident from comparison of tabulated critical values to n that the critical value approaches 1 as n increases. The critical value for n=100 is 0.987 for 95% confidence. The calculated test statistic for the normal data was 0.790, for the log-transformed data it was 0.982. Therefore, normality of the data was rejected (EPA 1992).

5.2.1.9 Histograms

Figure 10 depicts the histogram for the normal data set. The figure depicts a poor distribution "fit" implying that the normal distribution could provide a poor approximation to the data set. Figure 11 depicts the histogram for the log-transformed data set. This figure depicts a good distribution "fit" implying that the normal distribution could provide a representative approximation to the data set

5.2.1.10 Probability Plots

Figure 12 shows the probability plot for the normal data set. There is at least three sharp breaks in the plot. This probability plot depicts a poor normal distribution "fit", implying the normal distribution will provide a poor approximation to the data set. Figure 13 is the probability plot for the log-transformed data set. There are at least two breaks in the plot. This probability plot depicts a fair to poor normal distribution "fit", with the same implication as above.

5.2.1.11 Determination of Distribution

Based on the distribution analysis results, the uranium near upgradient background data set is non-parametric (Table 91).

5.2.1.12 The T_n Statistic Test

Though the data set was determined to be nonparametric, the T_n statistic outlier test was applied to the log-transformed data set. The log-transformed data set was selected because it approximated normality better than the normal data set. No outliers were detected using the T_n statistic (Table 92).

5.2.2 Determination of Upper Tolerance Limit

5.2.2.1 95th Percentile

Because the data was determined to be non-parametrically distributed, the 95th percentile of the data was calculated. The 95th percentile was determined to be 0.147 mg/L (Table 93). The uranium near upgradient background data set summary table is presented as Table 94.

5.3 Uranium Far Upgradient Distribution Analysis Results

Table 95 presents the uranium far upgradient background data set with the data not corrected for non-detects or duplicates. Tables 96 through 101 present the sampling date and the final data set (corrected for non-detects and duplicates for the near upgradient background wells. Finally, Table 102 is a summary table of all the final data sets for the near upgradient wells used in the statistical analyses. A distribution analysis was first performed for the uranium data. Then the 95th upper tolerance limit was calculated.

5.3.1 Distribution Analysis Results

5.3.1.1 Rejection of Outliers: *A Priori* Test

Results of the *a priori* test are presented in Table 103. No outliers were determined or eliminated from the uranium far upgradient background data set.

5.3.1.2 Determination of Percent Non-detects

Because the far upgradient uranium data set had only slightly more than 15% non-detects, distribution tests were applied to the data (Table 73).

5.3.1.3 Coefficient of Variation

Both the normal and log-transformed data sets passed the CV screen (Table 104). The CV value was 0.99 for the normal data and –0.45 for the log-transformed data compared to the critical value of 1. According to EPA 1998, if the CV is less than 1, the data may be, but does not necessarily have to be normal.

5.3.1.4 Studentized Range Test

The normal data set failed the Studentized range test (Table 105). The range (w) divided by the standard deviation (s) produced a result of 2.83. The critical value range was 3.75 to 5.26. When (w/s) falls outside the critical range, it implies that the data are not well modeled by a normal curve (EPA 1998).

5.3.1.5 Geary's Test

Both the normal and log-transformed data sets failed Geary's test (Table 106). The calculated "Z" values were 3.1 and 3.6 respectively, while the critical value is 1.645. Because the absolute value of "Z" was greater than the associated critical value, it implies that the data are not well modeled by a normal curve (EPA 1998).

5.3.1.6 Coefficient of Skewness

Both the normal and log-transformed data sets passed the coefficient of skewness test (Table 107). The calculated coefficient of skewness was 0.5 for the normal set and –0.3 for the log-transformed data set compared to an acceptable range of –1 to 1. Because the coefficient of skewness was less than 1, the normal distribution may accurately approximate the data set (EPA 1992).

5.3.1.7 Shapiro-Wilk (n<50) Test of Normality

Both data sets failed the Shapiro-Wilk test (Table 108). The calculated W for the normal data was 0.83, for the log-transformed data it was 0.88 compared to a critical value of 0.942. Therefore, normality of the data was rejected (EPA 1992).

5.3.1.8 Filliben's Statistic

Both data sets failed Filliben's Statistic (Table 109). The calculated test statistic for the normal data was 0.924, for the log-transformed data it was 0.951 compared to a critical value of 0.973. Therefore, normality of the data was rejected (EPA 1992).

5.3.1.9 Histograms

Figure 14 depicts the histogram for the normal data set. The figure depicts a poor distribution "fit" implying that the normal distribution could provide a poor approximation to the data set. Figure 15 depicts the histogram for the log-transformed data set. This figure also depicts a poor distribution "fit" also implying that the normal distribution could provide a poor approximation to the data set

5.3.1.10 Probability Plots

Figure 16 shows the probability plot for the normal data set. There is at least two sharp breaks in the plot. This probability plot depicts a fair to poor normal distribution "fit", implying the normal distribution will provide a poor approximation to the data set. Figure 17 is the probability plot for the log-transformed data set. There are at least two breaks in the plot. This probability plot also depicts a poor normal distribution "fit", with the same implication as above.

5.3.1.11 Determination of Distribution

Based on the distribution analysis results, the uranium far upgradient background data set is non-parametric (Table 110).

5.3.1.12 The T_n Statistic Test

Though the data set was determined to be nonparametric, the T_n statistic outlier test was applied to the log-transformed data set. The log-transformed data set was selected because it approximated normality better than the normal data set. No outliers were detected using the T_n statistic (Table 111).

5.3.2 Determination of Upper Tolerance Limit

5.3.2.1 95th Percentile

Because the data was determined to be non-parametrically distributed, the 95th percentile of the data was calculated The 95th percentile was determined to be 0.18 mg/L (Table 112). The uranium far upgradient background data set summary table is presented as Table 113.

5.4 Uranium Near and Far Upgradient Comparison Statistics Results

The uranium near upgradient background data set was statistically similar to the uranium far upgradient background data set (Table 114). Thus, distribution fitting and an upper tolerance limit calculation was performed on the combined data set.

5.5 Uranium Combined

Table 115 is a summary table of all the final data sets for the near upgradient wells used in the statistical analyses. A distribution analysis was first performed for the uranium data. Then the 95th upper tolerance limit was calculated.

5.5.1 Distribution Analysis Results

5.5.1.1 Rejection of Outliers: *A Priori* Test

Results of the *a priori* test are presented in Table 116. No outliers were determined or eliminated from the uranium combined upgradient background data set.

5.5.1.2 Determination of Percent Non-detects

Because the combined upgradient uranium data had less than 15% non-detects, distribution tests were applied to the data (Table 73).

5.5.1.3 Coefficient of Variation

The normal data set failed the CV screen while the log-transformed data set passed (Table 117). The CV value was 1.08 for the normal data and –0.31 for the log-transformed data compared to the critical value of 1. According to EPA 1998, if the CV is less than 1, the data may be, but does not necessarily have to be normal.

5.5.1.4 Studentized Range Test

The data set failed the Studentized range test (Table 118). The range (w) divided by the standard deviation (s) produced a result of 12.46. The critical value range was 5.47 to 6.94. When (w/s) falls outside the critical range, it implies that the data are not well modeled by a normal curve (EPA 1998).

5.5.1.5 Geary's Test

Both the normal and log-transformed data sets failed Geary's test (Table 119). The calculated "Z" values were -13.8 and –2.9 respectively, while the critical value is 1.645. Because the absolute value of "Z" was greater than the associated critical value, it implies that the data are not well modeled by a normal curve (EPA 1998).

5.5.1.6 Coefficient of Skewness

The normal data set failed the coefficient of skewness test while the log-transformed data set passed (Table 120). The calculated coefficient of skewness was 4.6 for the normal set and –0.5 for the log-transformed data set compared to an acceptable range of –1 to 1. Because the coefficient of skewness was less than 1 for the log-transformed data set, the normal distribution may accurately approximate that data set (EPA 1992).

5.5.1.7 Shapiro-Francia (n≥50) Test of Normality

Both data sets failed the Shapiro-Francia test (Table 121). Though the critical value for the test could not be precisely determined, it is evident from comparison of tabulated critical values to n that the critical value approaches 1 as n increases. The critical value for n=99 is 0.975 for 95% confidence. The calculated W' for the normal data was 0.67, for the log-transformed data it was 0.966. Therefore, normality of the data was rejected (EPA 1992).

5.5.1.8 Filliben's Statistic

Both data sets failed Filliben's Statistic (Table 122). Though the critical value for the test could not be precisely determined, it is also evident from comparison of tabulated critical values to n that the critical value approaches 1 as n increases. The critical value for n=100 is 0.987 for 95% confidence. The calculated test statistic for the normal data was 0.818, for the log-transformed data it was 0.983. Therefore, normality of the data was rejected (EPA 1992).

5.5.1.9 Histograms

Figure 18 depicts the histogram for the normal data set. The figure depicts a poor distribution "fit" implying that the normal distribution could provide a poor approximation to the data set. Figure 19 depicts the histogram for the log-transformed data set. This figure also depicts a good distribution "fit" implying that the normal distribution could provide a good approximation to the data set.

5.5.1.10 Probability Plots

Figure 20 shows the probability plot for the normal data set. There is at least four breaks in the plot. This probability plot depicts a poor normal distribution "fit", implying the normal distribution will provide a poor approximation to the data set. Figure 21 is the probability plot for the log-transformed data set. There are also at least four breaks in this plot. This probability plot also depicts a poor normal distribution "fit", with the same implication as above.

5.5.1.11 Determination of Distribution

Based on the distribution analysis results, the uranium combined upgradient background data set is non-parametric (Table 123).

5.5.1.12 The T_n Statistic Test

Though the data set was determined to be nonparametric, the T_n statistic outlier test was applied to the log-transformed data set. The log-transformed data set was selected because it approximated normality better than the normal data set. No outliers were detected using the T_n statistic (Table 124).

5.5.2 Determination of Upper Tolerance Limit

5.5.2.1 95th Percentile

Because the data was determined to be non-parametrically distributed, the 95th percentile of the data was calculated. The 95th percentile was determined to be 0.16 mg/L (Table 125). The uranium combined upgradient background data set summary table is presented as Table 126.

6.0 SUMMARY

Samples were collected at near and far upgradient wells from 1976 to 1998. Fifteen wells provided the upgradient well data while data from six far upgradient wells were used to construct that data set. Close examination of the groundwater database provided justification for elimination of select samples. Samples were eliminated based upon high detection limits, reported zero concentrations, and extreme maximum concentrations.

Statistical analyses were preformed on the individual data sets to determine distribution, statistical similarities between near and far upgradient data, and upper tolerance limits. Results of the distribution analysis indicated that all data sets were nonparametrically distributed. The molybdenum and uranium near and far upgradient background data sets were shown to be statistically similar and so analyses on the combined data set was performed.

The 95th percentile was calculated as the non-parametric upper tolerance limit for all analyzed data sets. The 95th percentile should be used to compare to downgradient well concentrations to determine if "above expected background concentrations" exist. If the downgradient concentration is greater than the 95th percentile, contamination may be indicated. However, it should be noted that since the 95th percentile was calculated as the upper tolerance limit, statistically 5% of the time one would expect the upper tolerance limit to be exceeded. Because the molybdenum and uranium near and far upgradient data sets were statistically similar, the combined data set 95th percentile should be representative of upgradient background concentrations. Because the selenium near and far upgradient data sets were not statistically similar, it is advised to use the near upgradient 95th percentile for downgradient well concentration comparisons. A summary table of the parameter, data set, distribution, 95th percentile, range, and sample number is provided as Table 127.

Table 26. Molybdenum Upgradient Background Data, Comparison Statistics Results

Comparison of Medians

Median of sample 1: 0.015
Median of sample 2: 0.015

Mann-Whitney (Wilcoxon) W test to compare medians

Null hypothesis: median1 = median2
Alt. hypothesis: median1 NE median2

Average rank of sample 1: 213.417
Average rank of sample 2: 203.477

W = 7311.5
P-value = 0.598284

The StatAdvisor

This option runs a Mann-Whitney W test option to compare the medians of the two samples. This test is constructed by combining the two samples, sorting the data from smallest to largest, and comparing the average ranks of the two samples in the combined data. Since the P-value is greater than or equal to 0.05, there is not a statistically significant difference between the medians at the 95.0% confidence level.

Table 28. Molybdenum Combined Upgradient Background Data Set, A Priori Screening

Parameter	Maximum Value	Next Maximum Value	Multiplicative Factor	Results
Molybdenum	0.2	0.16	1.3	**PASS**

Table 29. Molybdenum Combined Upgradient Background Data Set, 95th Percentile Calculation

Parameter	Distribution	95th Percentile (mg/L)	Sample #
Molybdenum	Nonparametric	0.05	408

Table 30. Molybdenum Combined Upgradient Background Data Set, Summary Table

Parameter	Distribution	95th Percentile (mg/L)	Range	Sample #
Molybdenum	Nonparametric	0.05	<0.001 to 0.2	408

Table 31. Selenium concentrations in alluvial ground water samples upgradient of the Homestake Site, Grants, New Mexico, March 1976 to November 1998

Normal

9.661	=sum X(i)*M(i)
38.622	=sum M(i)^2
0.26	= standard deviation
6.2147	= square root of sum Mi^2
0.934	= Fillibens's Statistic

Lognormal

76.064	=sum X(i)*M(i)
38.622	=sum M(i)^2
2.14	= standard deviation
6.2147	= square root of sum Mi^2
0.893	= Fillibens's Statistic

.973 is acceptable value

Normal - Fail
Lognormal - Fail

Table 68. Selenium Far Upgradient Background Data Set, Distribution Summary

Parameter	Distribution Type (tested)	Coefficient of Variation	Studentized Range Test	Geary's Test	Coefficient of Skewness (-1 to 1)	Shapiro-Wilk Test	Filliben's Statistic	Histogram	Probability Plot	Number of Samples	Distribution Type (determined)
Selenium	Normal	Pass	Fail	Fail	Pass	Fail	Fail	Nonparametric	Nonparametric	42	Nonparametric
Selenium	Lognormal	Pass	NA	Fail	Pass	Fail	Fail	Nonparametric	Nonparametric	42	

NA - not applicable

Table 69. Selenium Far Upgradient Background Data Set, T_n Statisitic Analysis

Parameter	Distribution	Maximum Observation	Mean	Standard Deviation	T_n Statistic	N	Upper 5% Critical Value	Pass or Fail T_n Statistic
Selenium	Normal	0.79	0.295238095	0.259811781	1.904	42	2.887	Pass

ND - concentration was non-detect
N - number of samples

Table 70. Selenium Far Upgradient Background Data Set, 95th Percentile Calculation

Parameter	Distribution	95th Percentile (pCi/g)	Sample #
Selenium	Nonparmetric	0.72	42

SD = standard deviation

Table 71. Selenium Far Upgradient Background Data Set, Summary Table

Parameter	Distribution	Mean	SD	95th Percentile (pCi/g)	Range (normal)	Sample #
Selenium	Nonparmetric	0.295238095	0.259811781	0.72	<0.005 to 0.79	42

SD = standard deviation
ND = non-detect, concentration reported as the minimum detecatable activity (MDA)

Table 72. Selenium Upgradient Background Data, Comparison Statistics Results

Comparison of Medians

Median of sample 1: 0.34125
Median of sample 2: 0.104

Mann-Whitney (Wilcoxon) W test to compare medians

Null hypothesis: median1 = median2
Alt. hypothesis: median1 NE median2

Average rank of sample 1: 243.119
Average rank of sample 2: 199.499

W = 6022.0
P-value = 0.0228734

The StatAdvisor

This option runs a Mann-Whitney W test option to compare the medians of the two samples. This test is constructed by combining the two samples, sorting the data from smallest to largest, and comparing the average ranks of the two samples in the combined data. Since the P-value is less than 0.05, there is a statistically significant difference between the medians at the 95.0% confidence level.
