Millstone Nuclear Power Station, Unit No. 3 First Response to a Request for Additional Information Technical Specifications Change Request 3-11-00 Reactor Coolant System Heatup and Cooldown Curves

In a letter dated April 23, 2001,⁽¹⁾ Dominion Nuclear Connecticut, Inc. (DNC), requested a change to the Millstone Unit No. 3 Technical Specifications. The proposed changes were primarily associated with revised Reactor Coolant System pressure/temperature limit curves and cold overpressure protection limit curves. In a facsimile received on June 7, 2001,⁽²⁾ the Nuclear Regulatory Commission provided questions for discussion during a conference call conducted on June 14, 2001. The purpose of this letter is to transmit the responses to those questions, correct information contained in the original submittal, and provide additional information supporting the license amendment request. Attachment 1 contains this information. Attachment 2 contains requested calculations supporting the proposed changes to the Reactor Coolant System pressure/temperature limit curves and cold overpressure protection limit curves.

There are no regulatory commitments contained within this letter.

⁽¹⁾ E. S. Grecheck letter to U.S. Nuclear Regulatory Commission, "Millstone Nuclear Power Station, Unit No. 3, Technical Specifications Change Request 3-11-00, Reactor Coolant System Heatup and Cooldown Curves," dated April 23, 2001.

⁽²⁾ U.S. Nuclear Regulatory Commission letter to Dominion Nuclear Connecticut, Inc., "Millstone Nuclear Power Station, Unit 3, Facsimile Transmission, Draft Request for Additional Information (RAI) to be Discussed in an Upcoming Conference Call (TAC No. MA1785)," dated June 7, 2001.

First Response to a Request for Additional Information Technical Specifications Change Request 3-11-00 Reactor Coolant System Heatup and Cooldown Curves Supplemental Information

First Response to a Request for Additional Information Technical Specifications Change Request 3-11-00 Reactor Coolant System Heatup and Cooldown Curves <u>Supplemental Information</u>

In a letter dated April 23, 2001,⁽¹⁾ Dominion Nuclear Connecticut, Inc. (DNC), requested a change to the Millstone Unit No. 3 Technical Specifications. The proposed changes were primarily associated with revised Reactor Coolant System pressure/temperature limit curves and cold overpressure protection limit curves. In a letter dated June 7, 2001,⁽²⁾ the Nuclear Regulatory Commission provided questions for discussion during a conference call conducted on June 14, 2001. The questions and associated responses are presented below. In addition, this letter will also correct information contained in the original submittal.

Question 1

In addition to the fluence values, did you also use other information from the surveillance report for capsule X (such as the chemistry factor of 25.1 and a reduced margin of 17°F for the limiting material) in your proposed pressure-temperature (P-T) limits calculations?

<u>Response</u>

The Westinghouse analysis of Capsule X (WCAP-15405, Rev. 0,⁽³⁾) was reviewed to evaluate the potential use of additional information beyond the fluence values. To date, the data provided by the surveillance capsule results show that the Regulatory Guide methods are over predicting the mean shift in RT_{NDT}. Therefore, DNC has chosen to use the more conservative Regulatory Guide 1.99, Rev. 2, Position 1.1 method to calculate the chemistry factor instead of deriving a plant specific chemistry factor.

⁽¹⁾ E. S. Grecheck letter to U.S. Nuclear Regulatory Commission, "Millstone Nuclear Power Station, Unit No. 3, Technical Specifications Change Request 3-11-00, Reactor Coolant System Heatup and Cooldown Curves," dated April 23, 2001.

⁽²⁾ U.S. Nuclear Regulatory Commission letter to Dominion Nuclear Connecticut, Inc., "Millstone Nuclear Power Station, Unit 3, Facsimile Transmission, Draft Request for Additional Information (RAI) to be Discussed in an Upcoming Conference Call (TAC No. MA1785)," dated June 7, 2001.

⁽³⁾ WCAP-15405, Rev. 0, "Analysis of Capsule X from the Northeast Nuclear Energy Company Millstone Unit 3 Reactor Vessel Radiation Surveillance Program," May 2000.

U.S. Nuclear Regulatory Commission B18428/Attachment 1/Page 2

Question 2

In the current P-T limit curves, you considered (1) indicator uncertainties, 22°F for temperature and 129 psia for pressure, (2) a pressure drop of 28.3 psi between the pressure transmitter and the reactor vessel beltline for one pump operation and a pressure drop of 74 psi for four pump operation, (3) the conservative portions of the P-T limits at a cooldown rate of 0°F/hr and the P-T limits at a cooldown rate of 80°F/hr to 160°F and 40°F/hr to 60°F, and (4) pressure in "psia", with a value of 10 added to the gage pressure to account for the primary containment pressure. Point out any deviations in the proposed P-T curves from the previous approach.

Response

The general methodology used to calculate the P-T curves is unchanged from the previous approach with the exception of using K_{IC} in place of K_{IR} . An administrative change has been made to allow a maximum of one reactor coolant pump (RCP) operation during cooldown from 160°F down to the minimum bolt up temperature. The previous cooldown curve was based on a maximum of one RCP in operation from 160°F to 120°F, and no RCPs in operation below 120°F.

The proposed P-T limit curves include the following adjustments, with the specific values clarified to indicate any changes.

- 1. The instrument uncertainty value for pressure has been revised from 129 psi to 115.5 psi. The instrument uncertainty value for temperature has been revised from 22°F to 25.3°F.
- 2. The pressure drop of 28.3 psi between the pressure transmitter and the reactor vessel beltline for one RCP operation and the pressure drop of 74 psi for four RCP operation remain unchanged from previous approach.
- 3. The curves shown are composite curves derived from the most restrictive pressure value considering the specified rates and isothermal conditions. This method remains unchanged from the previous approach.
- 4. The adjustment from gage pressure to an absolute containment pressure remains unchanged at 10 psi.

The development of the P-T curves is documented in DNC Calculation M3-LOE-284-EM, Rev. 4, which is contained in Attachment 2.

U.S. Nuclear Regulatory Commission B18428/Attachment 1/Page 3

Question 3

Provide detailed explanation and calculations for the indented portion of the P-T limit curves between 160°F and 186°F.

Response

The "indent" or reduction in allowable pressure between 160°F and 186°F is due to different dynamic pressure correction factors for one and four RCP operation when applied to the calculation of the 20 percent preservice hydrostatic test pressure defined by ASME Code NB-6221. With one RCP in operation at or below 160°F, a dynamic correction of 28.3 psi is applied. Above 160°F, a factor of 74.0 psi is applied. These calculations are also included in DNC Calculation M3-LOE-284-EM, Rev. 4 (Attachment 2). The current Technical Specification P-T curves were administratively smoothed to hide this step.

Correction to Original Submittal

The following two corrections to the information contained in the original submittal should be made.

1. Attachment 1 Page 3 and Attachment 5 Page 2

The following sentence should be replaced on the two identified pages.

- Original: The proposed COPPS setpoint curves have been established to protect the 32 EFPY isothermal reactor vessel beltline P/T curve and the power operated relief valve (PORV) discharge piping design pressure of 800 psia.
- Revised: The proposed COPPS setpoint curves have been established to protect the 32 EFPY isothermal reactor vessel beltline P/T curve and limit pressurizer pressure to 800 psia consistent with the current design analysis associated with the PORV discharge piping.
- 2. Attachment 1 Page 21

The reference to the criteria contained in 10 CFR 50.36 for items required to be in Technical Specifications should be 10 CFR 50.36(c)(2)(ii). The parenthesis around the letter c were inadvertently omitted.

Docket No. 50-423 B18428

1.0 OBJECTIVE

The purpose of this calculation is to develop revised pressure/temperature (P/T) limits for the Millstone Unit 3 reactor coolant pressure boundary ferritic materials through 32 effective full power years (EFPY) of operation.

The P/T curves will be developed for incorporation in to the Technical Specifications and address normal heatup, cooldown and hydrostatic test conditions. These curves will be adjusted to reflect indicated pressurizer pressure and indicated cold leg temperature which will include elevation and flow induced pressure differences and instrumentation uncertainties. The permissible heatup and cooldown rates (used to develop the curves) will be maintained consistent with the previous revision of this calculation.

This calculation will also develop cold overpressure protection system (COPS) enable temperature using the guidance provided by ASME Boiler and Pressure Vessel Code Section XI, Appendix G.

The Unit 3 surveillance capsule withdrawal schedule will be developed based upon the guidance of ASTM E 185-82 for the purpose of updating the Technical Specifications in accordance with 10 CFR 50 Appendix H. Consideration will be given to commercial issues and timing of the recommended withdrawal dates within the ASTM guidance.

Note, this revision is major and therefore revision bars have not been incorporated.

2.0 ASSUMPTIONS

2.1 Reactor coolant pump (RCP) operation will be assumed based upon the indicated cold leg temperature (T_c) :

During heatup, one RCP will be permitted to operate with $T_C \le 160^{\circ}F$. When $T_C > 160^{\circ}F$, up to four RCP's may be operated.

During cooldown, up to four RCP's can be operated while $T_C > 160^{\circ}F$, and one RCP may be operated while $T_C \le 160^{\circ}F$.

Note: these pump restrictions affect the dynamic pressure losses between the vessel and the pressure instrument. These values affect the final P/T values.

2.2 During heatup, the radial thermal gradients generate a compressive stress at the 1/4t location. As the thermal stresses are compressive, they would tend to resist crack growth. This calculation will conservatively treat the compressive stress intensity factor due to this stress as zero.

2.3 The yield stresses for the reactor vessel material will be taken from the reactor vessel design code of record in an unirradiated condition. The actual material has been irradiated which increases the yield stress. Treating the material as unirradiated produces a conservative stress intensity factor.

2.4 The reactor vessel beltline is the controlling location for the develop RCS P/T limits. This assumption is appropriate because the beltline materials are subjected to neutron irradiation which degrades the materials fracture toughness.

3.0 DESIGN INPUTS

- 3.1 Reactor Vessel Beltline Material Base metal material: SA-533 Grade B Class 1 Ref. 4.1, page A-35 Clad Material: Type 304 Stainless Steel Ref. 4.22
- 3.2 Reactor Vessel Beltline Geometry

Inside Radius to Clad Wetted Surface = 86.656 in Ref. 4.1, page A-11 Clad thickness = 0.156 in. Ref. 4.1, page A-11 Base metal thickness = 8.625 in Ref. 4.1, page A-35

3.3 Reactor Vessel Beltline Material Properties

The reactor vessel was designed and fabricated to the rules of ASME Boiler and Pressure Vessel Code, Section III, 1971 Edition with Addenda through 1973 (Reference 4.4)as identified by the ASME N-1 Certification (Reference 4.5). The previous revisions of this calculation utilize material properties obtained from the 1989 Edition of the ASME Boiler and Pressure Vessel Code, Section III (Reference 4.6) to perform the heat transfer analysis. Justification for use of this Code year was previously documented in Reference 4.22. A summary is provided for completeness.

Review ASME Boiler and Pressure Vessel Code, Section II, Material Specification for SA 533 Grade B Class 1 Vacuum Forged Plated for the 1971 Edition through Summer 1973 Addenda and 1989 Edition (References 4.7 And 4.8, respectively) demonstrate that the chemical composition between the code years is essentially the same. As the thermal properties should be controlled by the chemical composition of this plate material, using the 1989 Edition of Section III is acceptable. In addition, it should be noted that use of the later code edition provides a better representation of this information as this information provided by the 1971 Edition through Summer 1973 Addenda was developed to cover a broader range of materials with more specific information in the 1989 Edition.

550	23.2	0.354	0.1337

¹ Note: Specific Heat (Cp) = Thermal Conductivity / (Density * Thermal Diffusivity). The information was obtained from Reference 4.6. The thermal analysis used the properties from the 1989 Edition of Section XI and was demonstrated to have no impact.

Density = 490 lb/ft^3 (Ref. 4.9)

(489 lb/ft^3 actually used which has no affect.)

Adjusted Reference Temperature at $1/4 t (32 \text{ EFPY}) = 123.6^{\circ}\text{F}$ (Ref. 4.11) Adjusted Reference Temperature at $3/4 t (32 \text{ EFPY}) = 105.8^{\circ} \text{ F}$ (Ref. 4.11)

Temperature, °F	Yield Strength, ksi
100	50.00
200	47.10
300	45.20
400	44.50

Yield Strength (Reference 4.4)

3.4 Thermal Hydraulic Pressure Correction

The maximum dynamic pressure differential between the mid-plane of the reactor vessel down comer region and the wide range pressure transmitter (located on the RHR piping) is:

One RCP Operation $\Delta P = 28.3 \text{ psi}$ (Reference 4.10) Four RCP Operation $\Delta P = 74 \text{ psi}$ (Reference 4.12)

It has been demonstrated that the static elevation head can be ignored due to the location of the pressure sensor and the limiting reactor vessel material. This has been documented in Reference 4.22.

3.5 Pressure and Temperature Indicator Uncertainties (Reference 4.13)

Wide range temperature and pressure indication instrumentation probable error (uncertainty) will be applied to the RCS Pressure/Temperature limits. These values will provide the worst case information and is based upon a 24 month fuel cycle. These values were obtained from the calculation of record, Reference 4.13.

The instrument uncertainty associated with wide range temperature indication loops 3RCS*TI413A/B and 3RCS*TI423A/B will be applied.

Temperature Uncertainty: 25.3 °F

The instrument uncertainty associated with wide range pressure indication loops 3RCS*PI403 and 3RCS*PI405 will be applied.

Pressure Uncertainty: 115.5 psia

3.6 Adjustment of Gage Pressure to Absolute Pressure

The primary containment pressure is maintained below atmospheric pressure to minimize radioactive release in the event of an emergency. Containment pressure is maintained greater than or equal to 10.6 psia and less than or equal to 14.0 psia (Reference 4.24, page 3/4 6-7. The computations of allowable beltline pressure are based upon a differential or gage pressure. To adjust the resultant pressure, the minimum containment pressure permitted by Technical Specifications (10.6 psia) will be bound by 10 psia in lieu of adding normal atmospheric pressure of 14.7 psia. Consequently, an additional 10 psi will be added to the pressures to obtain an absolute pressure.

5.0 METHOD OF ANALYSIS

5.1 Beltline Pressure/Temperature Limits

Development of P/T limits is based upon the requirements provided by 10 CFR 50 Appendix G. 10 CFR 50 Appendix G mandates the use of ASME Boiler and Pressure Vessel Code (referred to as ASME Code), Section XI, Appendix G. In addition to ASME Code, Appendix G, Code Case N-640 (Reference 4.14) has published by ASME Section XI which permits the reference fracture toughness curve, K_{IC} , as found in Appendix A of Section XI, in lieu of K_{IR} , Figure G-2210-1 in Appendix G. It is important to recognize that 10 CFR 50.55a acknowledges Regulatory Guide 1.84 (Reference 4.15) contains those Code Cases which are approved for use. In this instance, Code Case is not approved for use and requires specific approval by the Office of Nuclear Reactor Regulation. Following submittal and upon issuance of an SER from the NRC, the results of this calculation will be acceptable to utilize in normal plant operation. In addition, 10 CFR 50.55(b)(2) permits the use of Section XI including editions through 1995 Edition and addenda through 1996 (subject to the limitations defined of which none apply).

To evaluate the vessel beltline, the requirements of ASME Code, Appendix G, 1995 Edition (Reference 4.2) were followed as augmented by Code Case N-640.A summary of the requirements/process follows. The P/T limits developed as part of this calculation apply to the ferritic components of the RCS as specified by 10 CFR 50 Appendix G.

To evaluate the beltline region, a defect one-fourth the section thickness is postulated (Ref. 4.16, G-2120). This flaw is commonly referred to as the 1/4 t and 3/4 t locations referring to inside and outside surface defects, respectively.

The beltline region is remote from structural discontinuities and the provision of G-2210 (Ref. 4.16) apply. Paragraph G-2212.1 recommends the use of K_{IA} or K_{IR} as the critical reference stress intensity factor. This is a lower bound fracture toughness for materials tested which include dynamic effects and the basis is described by WRC-175 (Reference 4.17). In lieu of K_{IA} , Code Case N-640 provides the recommendation of using K_{IC} , as provided by ASME Code Appendix A. K_{IC} can be expressed by the following equation:

 $K_{IC} = 33.2 + 20.734 \exp[0.02(T-RT_{NDT})] \text{ ksi}\sqrt{\text{in}}$ (Ref. 4.16, A-4200)

(Note: K_{IR} values will be calculated for information only and will not be used in the calculation of the allowable pressure.)

The RT_{NDT} is the reference nil ductility temperature (°F), and needs to account for irradiation effects (G-2212.2) Irradiation effects are accounted for using the procedures contained in Regulatory Guide 1.99, Revision 2. This has been documented in calculation 95-SDS-1008MG, Rev. 4 (Reference 4.11). The irradiation damage has considered 32 effective full power years (EFPY) of operation using the most recent surveillance capsule evaluation (Reference 4.18). The terminology used for the irradiated

 RT_{NDT} is the adjusted reference temperature (ART) which is the summation of the initial RT_{NDT} , the shift in the 30 ft-lb transition temperature and the uncertainty term. The 1/4 t ART and 3/4 t ART are used in place of RT_{NDT} in the computation of K_{IC} .

To compute the applied stress intensity factor, the methods of linear elastic fracture mechanics are used. The loading condition required to be considered are those due to membrane tension (Ref. 4.16, G-2214.1), bending (Ref. 4.16, G-2214.2) and radial thermal gradients (Ref. 4.16, G-2214.3). In the case of the beltline of the reactor vessel, there are no loads due to bending.

To compute the allowable pressure for normal operation (Ref. 4.16, G-2215), a factor of two is required to be applied to the stress intensity factor due to primary stresses. In the case of the beltline, the only significant loading is general primary membrane stresses due to internal pressure and thermal stresses due to the radial thermal gradient developed in the vessel wall due to either heatup or cooldown evolutions. Algebraically, the expression required is as follows for normal operation:

 $K_{IC} < 2K_{IM} + K_{IT}$

In the case of hydrostatic testing, the factor of safety is reduced to 1.5 on the primary membrane stress and can be depicted as follows:

 $K_{IC} < 1.5 K_{IM} + K_{IT}$

In the case of hydrostatic testing, the curve will be based upon an isothermal condition (< 10 °F/hr).

When performing the heatup evaluation, the 1/4 t and 3/4 t locations will be evaluated. During heatup, the stresses at the 1/4 t location are compressive and the 3/4 t location are tensile. However, the neutron damage is a function of wall thickness, greater at the inside and decreasing through the walls thickness. Consequently, it is necessary to evaluate both locations to ensure the controlling location is determined. To determine the composite heatup limit, the limiting heatup location (1/4 t or 3/4 t) is compared to an isothermal limits and the controlling pressure is used.

To perform the cooldown evaluation, only the 1/4 t location needs to be evaluated because the thermal gradients produce a tensile stress at the inside surface combined with the greater embrittlement provide the limiting location.

The evaluation is performed by first computing K_{IT} . This is performed by first performing a thermal transient heat transfer analysis using the ABAQUS general purpose finite element analysis code. The analysis is performed for the particular rates and temperature ranges of interest. The heat transfer analysis is performed using one dimensional two noded heat transfer element to provide the radial temperature distributions as a function of time. The ability of this code to accurately predict the through wall temperatures as a function of time has been verified using the VISA code as documented in Revision 0 of this calculation. It should be noted that the stainless steel cladding is modeled in the heat transfer analysis but no credit is taken for the cladding in the structural analysis.

The boundary conditions imposed on the model consist of a convective boundary layer on the inside surface to represent an effectively infinite heat transfer coefficient, h (assumed h = 10000 Btu/hr ft² °F). The outside of the vessel is assumed to be insulated.

$$K_{rT} = M_t * \Delta T_w \text{ ksi} \sqrt{\text{in}}$$
 (Ref. 4.16, G-2214.3)

where:
$$\Delta T_w =$$
 the temperature difference through the wall, °F $M_t =$ is as shown in Ref. 4.16, Fig. G-2214-2.

Then using the 1/4 t and 3/4 t crack tip temperatures, a reference critical stress intensity can be computed using the following equation:

 $K_{IC} = 33.2 + 20.734 \exp(0.02[T-RT_{NDT}])$ ksi \sqrt{in}

Determining the maximum permissible stress intensity due to membrane stress can be accomplished by solving for K_{IM} .

 $K_{IM} = (K_{IR} - K_{IT})/2$ ksi \sqrt{in}

From Ref. 4.12, G-2214.1, K_{IM} can be expressed by the following equation:

 $K_{IM} = M_m * \sigma_m$ ksi \sqrt{in} , where:

 σ_m = the membrane stress due to internal pressure, ksi M_m = factor defined by Ref. 4.16, Figure G-2214-1

Note that $\sigma_m = K_{IM}/M_m$ and based upon thick wall vessel theory can be expressed as a function of pressure by the following expression:

 $\sigma_{\rm m} = [a^{2*}p/(b^{2}-a^{2})]^{*}[1+(b^{2}/r^{2})] \qquad (\text{Reference 4.19, page 142})$

where: a = vessel inside radius, in. (clad/base metal interface)

b = vessel outside radius, in.

r = radial distance to point being analyzed, in. (i.e., 1/4 t and 3/4 t)

p = internal pressure, ksi (gage)

Consequently, the calculation of allowable pressure for the temperature of interest can be computed by knowing the allowable membrane stress intensity and the vessel geometry by algebraically manipulating the previous two equations. These values will be adjusted with pressure and temperature correction factors which account for indication uncertainty along with static and dynamic pressure differences between the beltline and indicator.

5.2 Additional P/T Requirements

10 CFR 50 Appendix G provides additional limitations on the ferritic materials of the reactor coolant pressure boundary. The following provides a summary of the requirements.

Hydrostatic pressure and leak tests (Core not critical)

1a. With fuel in the vessel, the pressure must not exceed 20% of the preservice hydrostatic test pressure until the vessel closure flange (treated as the cold leg temperature) is equal to or greater than the highest reference temperature (RT_{NDT}) of the material in the closure flange region that is highly stressed by the bolt preload. Note, the beltline limits developed in accordance with ASME Appendix G may be more limiting and would therefore control pressure.

1b. With fuel in the vessel, the temperature of the material in the closure flange region that is highly stressed by the bolt preload must be equal to the reference temperature plus 90°F (RT_{NDT} + 90°F) for the pressure to exceed 20% of the preservice hydrostatic test pressure. Note, the beltline limits developed in accordance with ASME Appendix G may be more limiting and would therefore control pressure.

Normal Operation (including heatup and cooldown), including anticipated operational occurrences

2.a With the core not critical, the pressure must not exceed 20% of the preservice hydrostatic test pressure until the vessel closure flange temperature (treated as the cold leg temperature) is equal to or greater than the highest reference temperature (RT_{NDT}) of the material in the closure flange region that is highly stressed by the bolt preload. Note, the beltline limits developed in accordance with ASME Appendix G may be more limiting and would therefore control pressure.

2.b With the core not critical, the temperature of the material in the closure flange region that is highly stressed by the bolt preload must be equal to the reference temperature plus $120^{\circ}F(RT_{NDT} + 120^{\circ}F)$ for the pressure to exceed 20% of the preservice hydrostatic test pressure. Note, the beltline limits developed in accordance with ASME Appendix G may be more limiting and would therefore control pressure.

2.c With the core critical, the pressure must not exceed 20% of the preservice hydrostatic test pressure when the larger of the vessel closure flange temperature

(treated as the cold leg temperature) is equal to or greater than the highest reference temperature plus 40°F (RT_{NDT} + 40°F) of the material in the closure flange region that is highly stressed by the bolt preload or the minimum permissible temperature for inservice system hydrostatic pressure test. In addition, the beltline limits developed in accordance with ASME Appendix G + 40°F must be considered and may be more limiting and would therefore control pressure. Note that these limits are solely to establish margins against non-ductile failure and are not intended to establish temperatures at which the core can be brought critical.

2.d With the core critical, to exceed 20% of the preservice hydrostatic test pressure, the larger of either the vessel closure flange temperature (treated as the cold leg temperature) is equal to or greater than the highest reference temperature plus 160°F (RT_{NDT} + 160°F) of the material in the closure flange region that is highly stressed by the bolt preload or the minimum permissible temperature for inservice system hydrostatic pressure test. In addition, the beltline limits developed in accordance with ASME Appendix G + 40°F must be considered and may be more limiting and would therefore control pressure. Note that these limits are solely to establish margins against non-ductile failure and are not intended to establish temperatures at which the core can be brought critical.

Minimum Boltup Temperature

ASME Boiler and Pressure Vessel Code, Section XI, Appendix G, G-2222(c), recommends that when the vessel flange and shell region are stressed by the full intended bolt preload and by pressure not exceeding 20% of the preservice system hydrostatic test pressure, the minimum metal temperature of the stressed region be at least the initial RT_{NDT} for the material in the stressed region plus any effects of irradiation.

Lowest Service Temperature

ASME Boiler Pressure Vessel Code Section III, NB 2332(b) (Reference 4.4) requires that for piping, pumps and valves, (excluding bolting) with nominal wall thickness greater than 2.5 inches, the lowest service temperature shall not be less than $RT_{NDT} + 100^{\circ}F$.

These values will be adjusted with the appropriate pressure or temperature correction factors which account for indication uncertainty along with static and dynamic pressure differences between the beltline and indicator.

5.3 COPS Enable Temperatures

The Cold Overpressure Protection System (COPS) is used to ensure that the P/T limits are not exceeded due to inadvertent mass and energy addition transients. This system is

synonymous with Low Temperature Overpressure Protection (LTOP). The temperature ranges which the system shall be aligned and operational are called COPS Enable temperatures. Determination of these temperatures for heatup and cooldown were based upon ASME Code Section XI G-2215 (Ref. 4.16). The minimum COPS enable temperature is when coolant temperatures are less than 200°F or at coolant temperatures corresponding to a reactor vessel metal temperature less than $RT_{NDT} + 50$ °F, whichever is greater. The reactor coolant temperature is defined as the reactor coolant inlet temperature. The RT_{NDT} is the highest ART in the beltline at the 1/4 t location. The vessel metal temperature is the temperature used in this calculation is the 1/4 t from the clad/base metal interface. This will result in a slightly more conservative [higher] coolant temperature.) These values are determined and then corrected for instrument uncertainty with the cold leg instrumentation.

5.3 Surveillance Capsule Withdrawal Schedule

10 CFR 50 Appendix H provides the requirements relative to the reactor vessel material surveillance program. The requirements associated with the design of the program and the withdrawal schedule must meet the requirements of the edition of ASTM E 185 that is current on the issue date of the ASME Code to which the reactor vessel was purchased. Later editions may be used but only up to and including those editions through 1982. Development of the revised withdrawal schedule will be based upon the ASTM E 185-82 (Reference 4.20).

There has been two surveillance capsule removed and evaluated from Unit 3 to date. Capsule U and Capsule X have been removed and are documented in References 4.18 and 4.21. The most recent capsule evaluation, Capsule X, provides a proposed schedule which will be reviewed as part of the process.

Hydrotest: Summary of Results for a 1/4t Flaw

Heatup at 40 °F/hr TO 160°F and 80°F/hr to 560°F: Adjusted Values for use in TS Figure Development

j := 1.. 15

 P_{hu} is taken as the lesser value of pressure from the 1/4t, 3/4t, and 0°F/hr calculations. The following table reflects the composite heatup limit for these rates without correction for pressure differences due to flow or elevation and instrumentation uncertainties. These values will be corrected for use in the composite TS figure and the COPS curve.

j =	T _{huj} :=	= P _{hu} :=
1	60	674.4
2	68	684.9
3	76	697.2
4	84	692.2
5	92	695.5
6	100	708.5
7	116	761.9
8	132	853.0
0	134.7	875.6
9	134.8	876.5
10	148	987.0
11	168	1169
12	200	1505
13	232	2150
14	264	3553
15	† L	I I

Temperatures will be adjusted by 25.3°F to account for instrument uncertainty and represent indicated cold leg temperature.

$$T_{hu_i} := T_{hu_i} + 25.3$$

Calculated values of pressure will be corrected for the instrument uncertainty for pressure (115.5 psi), the pressure drop across the core (28.3 psi for single pump operation at or below 160°F, and 74 psi for four pump operation above 160°F), and 10 psi to convert to absolute pressure. The temperatures noted above are treated as indicated temperatures after the instrument uncertainties are applied.

k := 1...9 l := 10...15

 $P_{hu_k} := P_{hu_k} - 115.5 - 28.3 + 10$ For indicated T $\le 160^{\circ}$ F $P_{hu_i} := P_{hu_i} - 115.5 - 74 + 10$ For indicated T $> 160^{\circ}$ F

Thus, for heatup at 40°F/hr to 160°F and 80°F/hr to 560°F:

$T_{hu_j} =$	$P_{hu_j} =$

The following table reflects the hydrostatic limit for these rates without correction for flow or instrument uncertainties. These values will be corrected for use in the composite TS figure.

Temperatures will be adjusted by 25.3° F to account for instrument uncertainty and represent indicated cold leg temperature. Calculated values of pressure will be corrected for the instrument uncertainty for pressure (115.5 psi) and the pressure drop across the core of 74 psi for four pump operation, and 10 psi to convert to absolute pressure. The temperatures noted above are treated as indicated temperatures after the instrumentation uncertainties are applied.

$$P_{hydro_i} := P_{hydro_i} - 115.5 - 74 + 10$$

6.2 Additional P/T Requirements

Preservice hydrostatic test pressure is defined by ASME Code NB-6221(Reference 4.4) to be at least 1.25 times the design pressure. The design pressure of the reactor vessel is 2500 psia (Reference 4.5). Therefore, 20% of preservice hydrostatic test pressure is:

0.2*1.25*2500 psia = 625 psia (20% preservice hydro)

Heatup

In consideration of heatup, the pressure correction consider the effects of static and dynamic pressure difference and instrument uncertainty.

For indicated temperatures less than or equal to 160°F (one RCP operating), the corrected value for consideration in Technical Specifications would be:

625 psia - 28.3 psi - 115.5 psi = 481.2 psia

For indicated temperatures greater than 160°F (four RCP's operating), the corrected value for consideration in Technical Specifications would be:

625 psia - 74.0 psi - 115.5 psi = 435.5 psia

Cooldown

Similarly for cooldown, the pressure correction shall consider the effects of static and dynamic pressure difference and instrument uncertainty.

For indicated temperatures less than or equal to 160°F (one RCP operating), the corrected value for consideration in Technical Specifications would be:

625 psia - 28.3 psi - 115.5 psi = 481.2 psia

For indicated temperatures greater than 160°F (four RCP's operating), the corrected value for consideration in Technical Specifications would be:

625 psia - 74.0 psi - 115.5 psi = 435.5 psia

The temperatures associated with the 20% of preservice hydrostatic test pressure are due to temperature requirements provided by 10 CFR 50 Appendix G and ASME Boiler and Pressure Vessel Code. Each of these conditions are reviewed below for consideration in the development of the Technical Specification Figures. Note that these temperature are corrected for wide range instrument uncertainty associated with sensing cold leg temperature.

1.a Hydrostatic Pressure and leak tests (core not critical), $P \le 20\%$ Preservice Hydro

To pressurize the vessel while not exceeding 20% of the preservice hydrostatic test pressure, the temperature of the vessel closure flange is equal to the highest RT_{NDT} that is highly stressed by the bolt preload.

The RT_{NDT} for this region has been previously established in this calculation as 40°F. This requirement is equivalent to the minimum boltup temperature provided by the ASME Boiler and Pressure Vessel Code.

Therefore, the minimum boltup temperature including instrumentation uncertainty is:

Minimum boltup temperature = $40^{\circ}F + 25.3^{\circ}F = 65.3^{\circ}F$

1.b Hydrostatic Pressure and leak tests (core not critical), P > 20 % Preservice Hydro

To exceed 20% of the preservice hydrostatic test pressure, the minimum temperature of the vessel closure flange is equal to the highest RT_{NDT} + 90°F that is highly stressed by the bolt preload.

Again, the RT_{NDT} for this region has been previously established in this calculation as 40°F.

Therefore, the temperature including instrumentation uncertainty is:

Minimum temperature = $40^{\circ}F + 90^{\circ}F + 25.3^{\circ}F = 155.3^{\circ}F$

2.a Normal Operation (core not critical), $P \le 20\%$ Preservice Hydro

As previously calculated for hydrostatic and leak tests (1.a), to pressurize the vessel while not exceeding 20% of the preservice hydrostatic test pressure until the temperature of the vessel closure flange is equal to the highest RT_{NDT} that is highly stressed by the bolt preload.

The RT_{NDT} for this region has been previously established in this calculation as 40°F. This requirement is equivalent to the minimum boltup temperature provided by the ASME Boiler and Pressure Vessel Code.

Therefore, the minimum boltup temperature including instrumentation uncertainty is:

K:\DEPTDATA\Comp Perf\STEWART\UNIT3\PT Curves\u3PT1.doc

Minimum boltup temperature = $40^{\circ}F + 25.3^{\circ}F = 65.3^{\circ}F$

2.b Normal Operation (core not critical), P > 20% Preservice Hydro

To exceed 20% of the preservice hydrostatic test pressure, the minimum temperature of the vessel closure flange is equal to the highest RT_{NDT} + 120°F that is highly stressed by the bolt preload.

Again, the RT_{NDT} for this region has been previously established in this calculation as 40°F.

Therefore, the temperature including instrumentation uncertainty is:

Minimum temperature = $40^{\circ}F + 120^{\circ}F + 25.3^{\circ}F = 185.3^{\circ}F$

2.c Normal Operation (core critical), $P \le 20\%$ Preservice Hydro

To pressurize the vessel while not exceeding 20% of the preservice hydrostatic test pressure with the core critical the minimum temperature of the vessel closure flange is equal to the highest $RT_{NDT} + 40^{\circ}F$ that is highly stressed by the bolt preload or the minimum permissible temperature required for inservice system hydrostatic pressure test.

The RT_{NDT} for this region has been previously established in this calculation as 40°F.

Minimum temperature = $40^{\circ}F + 40^{\circ}F + 25.3^{\circ}F = 105.3^{\circ}F$

The minimum temperature for inservice system hydrostatic testing is defined by ASME Section XI Article IWB-5000 (Reference 4.) A minimum test pressure of nominal operating pressure is required. Nominal operating pressure is 2250 psia based upon Reference . To achieve this pressure, a temperature in excess of 200°F is require based upon the beltline hydrostatic P/T limits developed previously. Conservatively using a value of 1.08*normal operating pressure provides and test pressure of 2430 psia. Based upon the indicated beltline inservice hydrostatic P/T limits (adjusted for TS), a minimum indicated temperature of 219.2°F was developed based upon linear interpolation.

Consequently, the minimum temperature at which the core can be brought critical while not exceeding the required pressure is 219.2°F.

2.d Normal Operation (core critical), P > 20% Preservice Hydro

To pressurize the vessel to pressures exceeding 20% of the preservice hydrostatic test pressure with the core critical, the larger of a minimum temperature of the vessel closure flange is equal to the highest RT_{NDT} + 160°F that is highly stressed by the bolt preload or the minimum permissible temperature required for inservice system hydrostatic pressure test.

The RT_{NDT} for this region has been previously established in this calculation as 40°F.

Minimum temperature = $40^{\circ}F + 160^{\circ}F + 25.3^{\circ}F = 225.3^{\circ}F$

The minimum temperature for inservice system hydrostatic testing is defined by ASME Section XI Article IWB-5000 (Reference 4.) This was determined conservatively to be 216.9°F.

Consequently, the minimum permissible temperature required to exceed 20% of preservice hydrostatic pressure is 225.3°F.

6.3 COPS Enable Temperatures

The minimum COPS enable temperature is when coolant temperatures are less than 200° F or at coolant temperatures corresponding to a reactor vessel metal temperature less than $RT_{NDT} + 50^{\circ}$ F, whichever is greater.

The ART for the 1/4 t location was determined to be 124.8°F at 32 EFPY.

The metal temperature corresponding to RT_{NDT} + 50°F is as follows:

 $1/4 t ART + 50^{\circ}F = 124.8^{\circ}F + 50^{\circ}F = 174.8^{\circ}F$

Cooldown

In the case of cooldown, the COPS enable temperature should be based upon the isothermal profile or just ART + 50°F for the 1/4 t location. The basis for this statement is hat the technical Specifications permit a range of cooldown rates ranging from isothermal to the specified maximum values and the most restrictive enable temperature would be due to the isothermal condition. If you consider the through-wall temperature distributions for linear cooldown scenarios, the fully developed profile would exponentially decay from the reactor vessel OD to ID. As such, if you were to compute a coolant temperature for the applicable rate the resulting temperature would be below the isothermal condition. Therefore, an uncorrected value of 174.8°F was calculated. Adding 25.3°F which represent the instrument uncertainty for the wide range indication loops (3RCS*) provides a value of 200.1°F.

A minimum value of 200°F is required by the ASME Code. Consequently, the controlling value is 200.1°F. It is interpreted that this is the minimum value and instrumentation uncertainty would need to be added to ensure that the system was aligned at this temperature. Therefore, the enable temperature for cooldown is 225.4°F (200.1°F + 25.3°F). Note, higher values can be conservatively used without further justification if additional administrative margin is desired.

Heatup

The heat transfer results for the two heatup scenarios are summarized previously in the calculation. The most conservative enable temperature will be established using the heat transfer output.

Using the tables for each of the heatup evaluated previously, coolant temperatures corresponding to $RT_{NDT} + 50^{\circ}F$ (174.8°F).

 $(40^{\circ}\text{F/hr} \le 160^{\circ}\text{F} \text{ and } 80^{\circ}\text{F/hr} > 160^{\circ}\text{F})$

The coolant temperature corresponding to a 1/4 t metal temperature was developed based upon linear interpolation.

(174.8-153.2)/(179.6-153.2) = (Tc-168)/(200-168) \therefore Tc = 194.2°F

Addition of instrument uncertainty to the coolant temperature provides the enable temperature for heatup of 219.5°F (194.2°F + 25.3°F). Note, higher values can be conservatively used without further justification if additional administrative margin is desired.

6.4 Surveillance Capsule Withdrawal Schedule

The material surveillance capsule withdrawal schedule identifies the number and location of capsules and the approximate withdrawal time and estimated accumulated fluence. This schedule is required to be developed in accordance with ASTM E 185-82 (Reference 4.20).

A withdrawal schedule was developed as part of the most recent capsule evaluation (Capsule X, Reference 4.18). This schedule has been developed to meet the requirements of ASTM E 185-82. However, due to the high lead factors associated with the capsule, the proposed schedule is to remove the third capsule at 12.3 EFPY. Due to the short time duration between capsule withdrawal (the second capsule was removed at 8 EFPY), a review of the requirements is necessary to evaluate a longer time period.

ASTM E 185-82 provides the following guidance of particular interest. Relative to the number of capsule required to be withdrawn and evaluated, the basis is based on the predicted transition temperature shift or possibly the decrease in upper shelf energy.

Based upon review of the current predicted shift in transition temperature at the vessel inside surface of 66°F (Reference 4.23), a minimum of three capsules are required. Note that this transition temperature shift is based on the results the fluence results of the first surveillance capsule which provided significantly higher projected end-of-life (EOL) fluence values.

Withdrawal of the third capsule is to be removed at EOL conditions. Specifically, the requirement is for the capsule to be removed when the capsule has received not less than once or greater than twice the peak EOL fluence. ASTM E 185-82 also identifies that this date may be modified based upon previous tests and this capsule may be held without testing following withdrawal. However, it should be noted that the requirements of 10 CFR 50 Appendix H requires that the capsule be evaluated and a report submitted within one year of withdrawal modifying the standard requirements.

Based upon the Capsule X evaluation, the peak calculated EOL fluence (E > 1.0 MeV, 32 EFPY) is $1.97E+19 \text{ N/cm}^2$ and considering license renewal is projected to be $3.31E+19 \text{ N/cm}^2$ (54 EFPY). Based upon ASTM E 185-82, the desired capsule fluence would be from $1.97E+19 \text{ n/cm}^2$ to $3.94E+19 \text{ n/cm}^2$ (two times projected inside surface fluence). Note that the projected vessel inside surface fluence for 54 EFPY is $3.31E+19 \text{ n/cm}^2$. It would be desirable to have the capsule receive at least $3.31E+19 \text{ n/cm}^2$ which would provide a value of less than twice the vessel surface fluence at EOL yet accumulate a value equivalent to license extension.

An estimate of the fluence capsule can be made based upon linear interpolation from the peak vessel calculated fluence using linear interpolation and the capsule lead factor. The previous capsule was removed from the vessel during refueling outage six (RFO6) and had accumulated 8.0 EFPY. Assuming 18 month fuel cycles along with a 100% capacity factor and permitting the third capsule to remain in the vessel for three additional cycles would equate to an additional 4.5 EFPY. This would result in a total of 12.5 EFPY for capsule W. Using linear interpolation between 12 EFPY and 16 EFPY the peak vessel inside surface can be estimated to be 7.80E+18 n/cm². Multiplying this value by the capsule lead factor (4.32) provides an estimate of the accumulated capsule fluence, 3.37E+19 n/cm². Again, assuming the capsule remained in the vessel for four cycles, the accumulated capsule fluence would be (14.0 EFPY) 3.76E+19 n/cm². (Note that the capsule fluence values provided in Table 7-1 of Reference 4.18 are incorrect). Based upon the accumulated capsule fluence estimates, pulling the capsule during RFO 10 (14 EFPY) or allowing the capsule to remain in an additional four cycles (18 month fuel cycles) will provide the most value. This will meet all the ASTM requirements and satisfy our own goals. In summary, removing the capsule at 14 EFPY will provide an estimated capsule fluence of 3.76E+19 n/cm². This will exceed one time the peak end-oflife (32 EFPY) vessel surface fluence of 1.97E+19 n/cm² yet not exceed two times this value, 3.94E+19 n/cm². In addition, if license renewal is pursued, the capsule will receive at least one times the peak (54 EFPY) vessel surface fluence of 3.31E+19 n/cm².

The following table provides the proposed withdrawal schedule for the Unit 3 material surveillance program. This table has been produced from Reference 4.18 with corrections to the capsule fluence values. In addition the removal time has been increased to 14.0 EFPY and the appropriate fluence based upon the preceding projection.

Millston	Millstone Unit 3 Reactor Vessel Surveillance Capsule Withdrawal Schedule				
Capsule	Location	Lead Factor ^(a)	Removal Time (EFPY) ^(b)	Fluence $(n/cm^2, E>1.0MeV)^{(a)}$	
U	58.5°	4.31	1.3	$4.49 \times 10^{18} (c)$

(a) Updated in Capsule X dosimetry analysis (Reference 4.18).

(b) Effective Full Power Years (EFPY) from plant startup.

(c) Plant specific evaluation.

(d) This fluence is not less than once or greater than twice the peak end of license EOL fluence, and is approximately equal to the peak vessel fluence at 54 EFPY.

(e) These capsules will be at the approximate 54 EFPY peak surface (i.e. clad/base metal interface) fluence when capsule W is withdrawn and should be removed a placed in storage when capsule W is removed.

7.0 RESULTS

7.1 Composite RCS P/T Limits Figures for Technical Specifications

The RCS P/T limits provided in the following figures apply to Unit 3 considering a reactor vessel beltline fluence of $1.97 \times 10^{19} \text{ n/cm}^2$, E > 1.0 MeV (Reference 4.11) which corresponds to 32 EFPY. These limits are developed to provide protection against non-ductile failure of ferritic materials at low temperatures. The development of these curves considers all of the requirements developed by this calculation and ensures that the controlling values are used. With use of the controlling values a best fit lower bound curve is generated. A tabulation of specific temperature points from the lower bound best fit curve is provided to assist in the development of procedures.

Executive Summary

Calculation 94-ENG-1018-E3, "Millstone Unit 3 COPPS/PORV Loop Uncertainty" Revision 1 provides the Channel statistical allowance for the COPPS/PORV bistable and the RCS wide range pressure and temperature indicators (*PI403,*PI405,*TI413A/B and *TI423A/B). These instrument loops provide support for Overpressue Protection Technical Specification 3/4.9.3, Shutdown Monitoring Instrumentation 3.3.3.5 and Accident Monitoring Instrumentation 3.3.3.6.

Reason for Revision:

•Incorporate Methodology of 24 Month Fuel Cycle Evaluation WCAP 14353 "Westinghouse Setpoint Methodology for Indication, Control and Protection Systems for Millstone Nuclear Power Station Unit 3."

•Revise specific component error allowances.

•Include evaluation for both instrument channels A and B to document the dominant CSA.

•Update Calculation Format

Does this calculation:	
1. Support a DCR, MMOD, an independent review method for a DCR, or confirm test results for an installed DCR? If yes, indicate the DCR, MMOD number and/or Test Procedure number.	Yes 🗌 No 🛛
 Support independent analysis? If yes, indicate the procedure, work control or other reference it supports. WCAP 14353 Rev. 0 	Yes 🖾 No 🗌
3. Revise, supersede, or void existing calculations? If yes, indicate the calculation number and revisions. 94-ENG-1018-E3	Yes 🖾 No 🗋
4. Involve QA or QA-related systems, components or structures?	Yes 🖾 No 🗌
 Impact the Unit licensing basis, including technical specifications, FSAR, procedures or licensing commitments? If yes, identify appropriate change documents. no change 	Yes 🗌 No 🔯

1.0 Purpose

This calculation will determine the total probable error of the Cold Overpressure Protection System (COPPS) Power-operated Relief Valve (PORV) actuation bistable and pressure and temperature indicators in instrument loops 3RCS*PT403, 3RCS*PT405 & 3RCS*TE413,423,433,443B/C. This calculation is based on a 24 month fuel cycle plus an allowance for unscheduled extensions. This calculation is applicable for normal plant heatup and cooldown evolutions and will not address Loss of Coolant Accidents (LOCA's), High Energy Line Breaks (HELB's) and radiation effects

2.0 Summary of Results

INSTRUMENT CHANNEL	CSA % SPAN(SPAN)	CSA ENG UNITS
3RCS*PI403 3RCS*PI405	3.85(3000)	115.5 PSIA
3RCS*TI413A/B 3RCS*TI423A/B	3.62(700)	25.3 °F

Table 1. Summary of results for Heatup/Cooldown Post OBE Curve using Mainboard Indicators.

INSTRUMENT	CSA	CSA
CHANNEL	% SPAN(SPAN)	ENG UNITS
PRESSURE	2.13(1000)	21.3 PSIA
BISTABLE (0-1000)		
TEMPERATURE	2.32(700)	16.2 °F
BISTABLE		

Table 2. Summary of results for COPPS Post OBE Curve.

INSTRUMENT	CSA	CSA
CHANNEL	% SPAN(SPAN)	ENG UNITS
PRESSURE COMPUTER PNT	1.83(3000)	54.9 PSIA
TEMPERATURE COMPUTER PNT	2.33(700)	16.3 °F

4.0 Assumptions

4.1 This calculation is based on the installed instrumentation and does not account for Reactor Coolant Pump dynamic head losses and PORV overshoot.

4.2 The calculation assumes that the pressure readings come from the centerline of the RCS. It is noted that the pressure instrumentation is mounted at an elevation 9' 4" below the centerline of the hot leg. The difference in actual elevation and the elevation assumed in the calculation leads to an approximate 4 psi bias increase on the pressure measurement.

4.3 Only post OBE seismic effects will be included.

4.4 Additional assumptions are stated in Section 6 within the individual sections where they apply.

5.0 Method of Calculation

The calculation utilizes the standards of preparation, reviewing and approving as set forth in the Design Control Manual Chapter 5.

The calculation tabulates the individual CSA terms for each component considering the full span of the instrument channel (0-3000 PSIA, 0-700 °F) for the main control board indicators, computer points and temperature bistables. The full span of the low range transmitter (0-1000 PSIA) was used for the pressure bistables. Sensor CSA tabulations are done for the low range transmitter (0-1000 PSIA), the high range transmitter (800-3000 PSIA), and one Weed RTD since all eight are identical (0-700 °F). Rack CSA terms are done for the bistable strings, the 0-3000 PSIA indicators and the 0-700 °F indicators. The CSA components are then combined taking into account the individual instrument spans in the SRSS method as described in reference 3.3.1. A summary table is provided to clearly indicate the respective CSA channel values.

Instrumentation for PORV Cold Overpressure Protection Trains A/B is described as follows:

Pressure transmitters 3RCS*PT405A/403A and 3RCS*PT405/403 sense wide range Reactor Coolant System (RCS) hot leg pressure and provide 4-20 mA DC signals to signal converters 3RCS*PQY405/403 and 3RCS*PQY405A/403A respectively. The two transmitters are Rosemount split-ranged, one for the low range(0-1000) and one for the high range (800-3000), to provide improved overall accuracy. The 0-10 VDC output signals are processed through summing amplifiers 3RCS*PY405C/403C and 3RCS*PY405G/403G and then combined by summing amplifier 3RCS*PY405D/403D to provide an analog signal to wide range pressure indicator 3RCS*PI405/403 and a plant process computer point. Loop power supply 3RCS*PQ405/403 provides input to signal comparator 3RCS*PB405C/403C.

Resistance temperature detectors (RTDs) 3RCS*TE413C/B, 423C/B, 433C/B and 443C/B are used to monitor the wide range RCS hot/cold leg temperature. Each RTD signal is converted to 0-10 VDC via the associated R/E converters 3RCS*TY413A/B, 423A/B, 433A/B or 443A/B. The output signals of these four R/E converters are auctioneered through summing amplifier 3RCS*TY413J/K to select the lowest indicated temperature. This low selected temperature signal is then processed in function generator 3RCS*TY413M/P where a PORV pressure setpoint is calculated.

R/E converters 3RCS*TY413A/B and 3RCS*TY423A/B also provide analog signals to wide range temperature indicators 3RCS*TI413A/B and 3RCS*TI423A/B at Main Control Board 2. Each temperature indicator 3RCS*TE413C/B, 423C/B, 433C/B, and 443C/B feeds a plant process computer point.

The output signal of function generator 3RCS*TY413M/P is sent to signal comparator 3RCS*PB405C/403C for comparison with an RCS pressure signal from 3RCS*PT405A/403A via loop power supply 3RCS*PQY405/403. If the RCS

pressure is equal to or greater than the PORV pressure setpoint, a bistable output is generated to open Train A PORV (3RCS*PCV455A)/Train B PORV (3RCS*PCV456) via Solid State Protection System (SSPS) Train A/B.

A block diagram of the PORV Cold Overpressure Protection Loop Train A/B is shown in Figure 1.

1

FIGURE 1 BLOCK DIAGRAM - PORV SETPOINT UNCERTAINTIES (Train A Component ID Numbers Shown, Train B Similar)

OPEN 3RCS*PCV455A

NOTES:

- 1. All equipment is prefixed with 3RCS*.
- 2. 3RCS*TI423A is similar to 3RCS*TI413A shown.
- 3. No Main Board indication for 3RCS*TE433C or 3RCS*TE443C .
- 4. Computer indication similar for 3RCS*TE423/433/443C.

6.0 Body of Calculation

References 3.3.1 and 3.3.2 describe the method used to combine instrument uncertainties. The values used for the various components and their sources are described as follows:

6.1 Process Measurement Accuracy (PMA)

This term includes errors in the plant variable measurement up to but not including the sensor.

Per Reference 3.3.2, PMA associated with the low range transmitter is ± 0.0 %.

Per Reference 3.3.2, PMA associated with the high range transmitter is ± 0.0 %.

Per Reference 3.3.2, PMA associated with the Weed RTD is \pm 2.0 %.

6.2 Primary Element Accuracy (PEA)

PEA typically accounts for errors due to metering devices such as elbows, venturis and annubars. There are no effects from elbows, venturis or annubars associated with these instrument strings. Therefore, the PEA term for the sensor strings is 0.0%.

6.3 <u>Sensor Calibration Accuracy (SCA)</u>

This term is the accuracy to which the sensor can be calibrated in the field as indicated by the surveillance procedures used to calibrate these sensors, expressed as a percentage of channel span.

Per Reference 3.6.4, SCA associated with the low range transmitter is \pm 0.25 %.

Per Reference 3.6.5, SCA associated with the high range transmitter is ± 0.25 %.

Per Reference 3.3.2, SCA associated with the Weed RTD is \pm 0.3 %.

note: RTD self-heating effects and RTD lead-balance errors are not available from the manufacturer and will not be included in this calculation.

6.4 <u>Sensor Reference Accuracy (SRA)</u>

This term is the accuracy to which the sensor can acheive in the field per vendor specifications, expressed as a percentage of calibrated span of the channel.

Per Reference 3.6.4, SRA for the low range transmitter is ± 0.25 %.

Per Reference 3.6.5, SRA for the high range transmitter is \pm 0.25 %.

Per Reference 3.3.2, SRA for the Weed RTD is \pm 0.4 %.

6.5 <u>Sensor Drift (SD)</u>

This term accounts for variations in the sensor accuracy over the calibration interval corresponding to a fuel cycle of 24 months plus an extension of 6 months. This term is provided per a statistical evaluation of past plant calibration data contained in reference 3.3.2.

SD for the low range pressure transmitter for 30 months is $\pm 0.6\%$.

SD for the high range pressure transmitter for 30 months is $\pm 0.3\%$.

SD for the wide range RTDs for 30 months is $\pm 0.1\%$

6.6 Sensor Temperature Effects (STE)

This term accounts for the error due to difference in temperature when the instrument is calibrated and the normal ambient temperature at operating conditions. Assumed is a ± 50 °F shift of temperature which is congruent with the design assumption contained in reference 3.3.2.

Per reference 3.6.4, STE for Rosemount 1154 range code 4-9 transmitters (low range transmitter) is defined as:

STE = 0.75% (URL) + 0.50% (SPAN) per 100 °F change STE = [0.0075*(1000) + 0.005*(1000)]*0.50STE = (6.3/1000)*100STE = $\pm 0.63\%$.

Per reference 3.6.5, STE for Rosemount 1154 Series H range code 4-9 transmitters (high range transmitter) is defined as:

STE = 0.25%(URL) +0.50%(SPAN) per 50 °F change STE = [0.0025(3000) + 0.005(2200)]*1.0STE = (18.4/2200)*100STE = $\pm 0.84\%$

RTDs are not affected by temperature affects, therefore, STE for the wide range RTD is ± 0.0 %.

6.7 <u>Sensor Pressure Effects (SPE)</u>

Sensor pressure effect applies to differential pressure devices and accounts for the effect on accuracy due to the differences in static pressure between calibration and operation.

Pressure sensors are not affected by SPE, the SPE for the wide range pressure transmitters is ± 0.0 %.

Per Reference 3.3.2, SPE for the Weed RTDs is \pm 0.0 %.

6.8 Rack Calibration Accuracy (RCA)

The rack calibration is the overall accuracy to which rack-mounted, signal conditioning components are calibrated in the plant as indicated by the surveillance procedures, expressed as a percentage of calibrated span. The following attributes are typically considered for each rack component in determining the overall RCA:

- Reference Accuracy
- Linearity
- Repeatability
- Power supply variation effect

Per reference 3.3.2 the RCA for the pressure signal bistable is \pm 0.4 %.

Per reference 3.3.2 the RCA for the temperature signal bistable is \pm 0.6 %.

Per reference 3.3.2 the RCA for the pressure signal indicator string including the 0-3000 psia main board indication is \pm 1.7 %.

Per reference 3.3.2 the RCA for the temperature signal indicator string including the 0-700°F indicator is \pm 1.5 %.

Per reference 3.3.2 the RCA for the pressure computer point is \pm 0.3 %

Per reference 3.3.2 the RCA for the temperature computer point is $\pm 0.4\%$

6.9 Rack Drift (RD)

This term accounts for variations in the calibration of rack-mounted, signal conditioning components over calibration interval which corresponds to a fuel cycle of 24 months plus an extension of 6 months. The drift data for the individual rack components is expressed as a percentage of calibrated span. This term is provided per a statistical evaluation of past plant calibration data contained in reference 3.3.2 unless otherwise noted.

RD for pressure/temperature signal bistable string is \pm 0.3 %.

RD for pressure signal indicator string including the 0-3000 psia main board indication is \pm 1.5 %.

RD for the wide range temperature indicator string including the 0-700°F main board

RD for the wide range temperature indicator string including the 0-700°F main board indicator is $\pm 2.0\%$.

RD for the wide range pressure computer point is $\pm 0.3\%$.

RD for the wide range temperature computer point is $\pm 0.6\%$.

6.10 Rack Temperature Effects (RTE)

This term accounts for the error due to the difference in temperature when the rack is calibrated versus normal ambient operating temperature. Instrument racks 3RPS*RAKSET1 (Process Cabinet Protection Set 1) and 3RPS*RAKSET2 (Process Cabinet Protection Set 2) are located in the Instrument Rack Room El. 47'-6" of the Control Building which is a controlled environment as described in Reference 3.6.

Per Reference 3.3.2, RTE for pressure/temperature signal bistable / indicator / computer string is \pm 0.5 %.

6.11 Measurement and Test Equipment Allowance (MTE)

MTE is the error introduced by test equipment.

Per Reference 3.3.2, MTE associated with the low range transmitter is \pm 0.3 %.

Per Reference 3.3.2, MTE associated with the high range transmitter is ± 0.3 %.

Per Reference 3.3.2, MTE associated with the Weed RTD is \pm 0.3 %.

Per reference 3.3.2 the MTE for the pressure signal bistable is \pm 0.3 %.

Per reference 3.3.2 the MTE for the temperature signal bistable string is \pm 0.0 %. (Note: This is because component MTE accuracy exceeds a 1:10 ratio).

Per reference 3.3.2 the MTE for the pressure signal indicator string including the 0-3000 psia main board indication is \pm 0.3 %.

Per reference 3.3.2 the MTE for the temperature signal indicator string including the 0-700°F indicator is \pm 0.0 %. (Note: This is because component MTE accuracy exceeds a 1:10 ratio).

Per reference 3.3.2 the MTE for the pressure computer point is \pm 0.3 %

Per reference 3.3.2 the MTE for the temperature computer point is \pm 0.0%. (Note: This is because component MTE accuracy exceeds a 1:10 ratio).

6.12 Radiation Allowance (RA)

The instrumentation is installed in the following environments: (Containment Structure Elevations. 4'- 0" & 18'- 0" and Control Building-El. 47'-6") (Reference 3.1.2). This calculation is based on normal plant heatup and cooldown evolutions and will not include radiation effects.

6.13 LOCA/HELB Effects (DLH)

This term accounts for the effects on accuracy of the sensor during the first 24 hours of the post accident environment. This calculation is based on normal plant heatup and cooldown evolutions and will not include LOCA or HELB effects.

6.14 LOCA/HELB Effects (PLH)

This term accounts for the effects on accuracy of the sensor after the first 24 hours of the post-accident environment, expressed as a percentage of calibrated span.

Since DLH is not included, PLH will not be included in the calculation.

6.15 Indicator Readability (OIA)

This term accounts for the overall accuracy of the indicator (IA) such as accuracy, resolution, drift, temperature effect and a readability allowance (R). The readability allowance accounts for parallax distortion when reading analog indicators. This term shall be equal to the percentage of full scale represented by one-half of the smallest increment on the indicator scale, or one percent of full scale, whichever is smaller.

The smallest increment for the wide range pressure indicator is 100 PSIA and the scale is 0-3000 PSIA. The smaller value is one-half of the minor division which is 50 PSIA.

 $R_{PRESS IND} = (1/2 \text{ of minor division/indicator span})(100\%)$ $R_{PRESS IND} = \pm (50 \text{ PSIA}/3000 \text{ PSIA}) (100\%)$ $R_{PRESS IND} = \pm 1.7 \% \text{ of span}$

The smallest increment for the wide range temperature indicator is 20°F and the scale is 0-700°F. The smaller value is one-half of the minor division which is 10°F.

R TEMP IND = (1/2 of minor division/indicator span)(100%)R TEMP IND = $\pm (10^{\circ} \text{ F}/700_F) (100\%)$ R TEMP IND = $\pm 1.4 \%$ of span

6.16 Overall Computer Accuracy (OCA)

This term accounts for the overall accuracy of computing devices such as the plant process computer input A/D converter.

Per reference 3.3.1, OCA or device accuracy for the plant process computer is 0.2%. However, this inaccuracy is already included in the RCA for the computer loops. Therefore, an OCA of 0.0% is used in the computer point CSA equations.

6.16 Insulation Resistance Effects (IRE)

This term accounts for the effects of degradation in the insulation resistance of cables, terminal blocks & containment penetrations in a post accident environment. The insulation resistance decreases are caused by elevated temperatures and/or the effects of moisture from LOCA's, HELB's or Main Steam Line Break (MSLB)s. Since the COPS does not provide a protective function during an accident, IR losses will not be considered in this calculation.

6.17 Seismic Allowance (SA)

Per Ref. 3.3.2, this term is the effect on accuracy of the sensor due to seismic in the normal and post accident environment expressed as a percentage of span. The term is derived from the qualification test report or manufacturer published data and used to determine SA as a bias error.

Per Ref. 3.6.4 and 3.6.5, the SA for the wide range pressure transmitters after an OBE and Safe Shutdown Earthquake (SSE) is 0.5% URL.

 $SA(low range) = 0.5*(1000/1000) = \pm 0.5 \%$

SA(high range) = $0.5*(3000/2200) = \pm 0.682$ % use ± 0.7 %.

Manufacturer's data for the seismic effects on the Westinghouse 7300 Process Rack signal bistable string are not available. Since the rack components are composed of electronic circuits with no mechanical or pneumatic moving parts, the seismic effects on the signal bistable string are considered negligible and are not included in the calculation. This is reinforced by analysis contained in Ref. 3.3.2.

SA for the Weed RTDs is considered negligible.

6.18 Other Effects

No other effects are considered to be significant for the preparation of this calculation.

6.19 CSA CALCULATIONS

The Channel Statistical allowances (CSA) for the wide range pressure loops per the equation in Reference 3.3.2 is shown below with siesmic effect added as a bias:

 $CSA = \{(PMA)^{2} + (PEA)^{2} + [(SCA + SMTE)^{2} + (SD + SMTE)^{2} + (STE)^{2} + (SPE)^{2} + (SRA)^{2} + (G_{1})^{2} + (RCA + RMTE)^{2} + (RD + RMTE)^{2} + (RTE)^{2} + (O|AP|)^{2} \}^{1/2} + BIAS^{*}(G_{1}) = \% \text{ of span}$

where G_1 is the relative gain associated with the transmitter split ranges.

Note: Because the bistable signals are derived only from the low range transmitters correction to the 3000 psia span is not required.

The plant process computer CSA equations are meant to support a normal heat up/cooldown curve and therefore do not include any seismic effects. Any curve generated with these CSAs is not applicable for all plant conditions. The indicator CSAs do incorporate post seismic effects and and are applicable for all plant conditions.

It should be noted that portions of the rack effects (RCA and RD) used in the pressure bistable CSA equations are a combination of temperature and pressure rack errors. These values are in given terms of the pressure channel and cannot be separated out. These values were developed from historical operating data during the COPPS bistable calibration. This will be treated as a conservatism for the purposes of the calculation.

Pressure Bistable

 $CSA_{BISTABLE} = \{(0.0)^2 + (0.0)^2 + [(0.25 + 0.3)^2 + (0.6 + 0.3)^2 + (0.63)^2 + (0.0)^2 + (0.25)^2]^*(1.0)^2 + (0.4 + 0.3)^2 + (0.3 + 0.3)^2 + (0.5)^2 + (0.0)^2\}^{1/2} + 0.5(1.0)$ = % of span

 $CSA_{BISTABLE} = 2.13$ % of 1000 psi span

Low Range Pressure Indication and Computer

The low range channel summing amplifier 3RCS*PY403C/405C has a gain (G) of (1000/3000) or 0.33. Each sensor term will be compensated for the gain value and is shown below:

 $CSA_{0-3000 \text{ psi IND}} = \{(0.0)^2 + (0.0)^2 + [(0.25 + 0.3)^2 + (0.6 + 0.3)^2 + (0.63)^2 + (0.0)^2 + (0.25)^2] * (0.33)^2 + (1.7 + 0.3)^2 + (1.5 + 0.3)^2 + (0.5)^2 + (1.7)^2\}^{1/2} + 0.5(0.33)^{1/2} = \% \text{ of span}$

 $CSA_{0-3000 \text{ psi IND}} = 3.42 \%$ of 3000 psi span

 $CSA_{COMP IND} = \{(0.0)^{2} + (0.0)^{2} + [(0.25 + 0.3)^{2} + (0.6 + 0.3)^{2} + (0.63)^{2} + (0.0)^{2} + (0.25)^{2}]^{*}(0.33)^{2} + (0.3 + 0.3)^{2} + (0.3 + 0.3)^{2} + (0.5)^{2} + (0.0)^{2}\}^{1/2} + 0.5(0.33)^{2} = \% \text{ of span}$

 $CSA_{COMP IND} = 1.24$ % of 3000 psi span

High Range Pressure Indication and Computer

The high range channel summing amplifier 3RCS*PY403G/405G has a gain (G) of (2200/3000) or 0.733. Each sensor term will be compensated for the gain value and is shown below:

 $CSA_{0-3000 \text{ psi IND}} = \{(0.0)^2 + (0.0)^2 + [(0.25 + 0.3)^2 + (0.3 + 0.3)^2 + (0.84)^2 + (0.0)^2 + (0.25)^2] * (0.733)^2 + (1.7 + 0.3)^2 + (1.5 + 0.3)^2 + (0.5)^2 + (1.7)^2\}^{1/2} + 0.7(0.733) = \% \text{ of span}$

 $CSA_{0.3000 \text{ psi IND}} = 3.85\%$ of 3000 psi span

 $CSA_{COMP IND} = \{(0.0)^{2} + (0.0)^{2} + [(0.25 + 0.3)^{2} + (0.3 + 0.3)^{2} + (0.84)^{2} + (0.0)^{2} + (0.25)^{2}]^{*}(0.733)^{2} + (0.3 + 0.3)^{2} + (0.3 + 0.3)^{2} + (0.5)^{2} + (0.0)^{2}\}^{1/2} + 0.7(0.733)^{2} = \% \text{ of span}$

 $CSA_{COMP IND} = 1.83\%$ of 3000 psi span

Temperature Bistable, Indication and Computer

The CSA for the wide range temperature loops per the equation in Reference 3.3.2 is shown below:

 $CSA = \{(PMA)^{2} + (PEA)^{2} + [(SCA + SMTE)^{2} + (SD + SMTE)^{2} + (STE)^{2} + (SPE)^{2} + (SRA)^{2} + (RCA + RMTE)^{2} + (RD + RMTE)^{2} + (RTE)^{2} + (OIAPI)^{2} \}^{1/2} + BIAS$ = % of span

The sensor wide range temperature terms are low auctioneered in order to select the lowest temperature reading out of four inputs. Since the sensor errors are treated as random errors, it is mathematically plausible to assume that the chance of all four inputs reading high at the same time is a one in sixteen chance (6%). Conversely, 94% of the time the sensor error will be in the conservative direction. However, standard practice dictates that the low auctioneering circuit be ignored and the uncertainty be treated as if it is a single sensor term feeding the loop.

The COPPS bistable is calibrated by selecting a single temperature input value and varying the pressure input. This data was tracked, compiled and used as input for the 95/95 drift analysis. Portions of the rack effects (RCA, RD and RTE) used in the temperature bistable CSA equations are a combination of temperature and pressure rack errors accounted for in

the pressure bistable equation. These effects are accounted for in the COPPS pressure bistable CSA equation and therefore will not be reproduced in the COPPS temperature bistable CSA equation.

 $CSA_{BISTABLE} = \{(2.0)^2 + (0.0)^2 + (0.3 + 0.3)^2 + (0.1 + 0.3)^2 + (0.0)^2 + (0.0)^2 + (0.4)^2 + (0.6 + 0.0)^2 + (0.3 + 0.0)^2 + (0.5)^2 + (0.0)^2 \}^{1/2} + 0.0 = \% \text{ of span}$

CSA_{BISTABLE} = 2.32% of 700 °F span

 $CSA_{0-700 \text{ °F IND}} = \{(2.0)^2 + (0.0)^2 + (0.3 + 0.3)^2 + (0.1 + 0.3)^2 + (0.0)^2 + (0.0)^2 + (0.4)^2 + (1.5 + 0.0)^2 + (2.0 + 0.0)^2 + (0.5)^2 + (1.4)^2 \}^{1/2} + 0.0 = \% \text{ of span}$

CSA _{0-700 °F IND} = 3.62% of 700 °F span

 $CSA_{COMP IND} = \{(2.0)^2 + (0.0)^2 + (0.3 + 0.3)^2 + (0.1 + 0.3)^2 + (0.0)^2 + (0.0)^2 + (0.4)^2 + (0.4 + 0.0)^2 + (0.6 + 0.0)^2 + (0.5)^2 + (0.0)^2 \}^{1/2} + 0.0 = \% \text{ of span}$

CSA _{COMP IND} = 2.33% of 700 °F span

7.0 Design Verification

Design Review is the design verification method used in this calculation to provide assurance that the calculation is correct and satisfactory. Design Reviews were conducted at the discipline level. Concerns have been addressed and resolutions documented on attached DCM Forms (Form 5-1C), in accordance with DCM Chapter 4, Design Inputs and Design Verification, and DCM Chapter 5, Calculations. _____

1.0 OBJECTIVE

The purpose of this calculation is to develop revised power operated relief valve (PORV) setpoint curves for the Millstone Unit 3 cold overpressure protection system (COPS). This revision is made to update the setpoint curves to utilize the revised pressure/temperature (P/T) limits for the Millstone Unit 3 through 32 effective full power years (EFPY) of operation.

This calculation will also document the basis for using the residual heat removal (RHR) system relief values for COPS and calculate a minimum vent size which will ensure the RCS is incapable of being pressurized above a predetermined value satisfying COPS. This calculation will use the most current instrument uncertainties.

Note, this revision is major and therefore revision bars have not been incorporated. CCN 1 through 5 of Revision 3 have been considered and where appropriate incorporated into this revision.

2.0 SCOPE

In general, this calculation ensures that the peak transient pressures due to postulated mass and energy transients which would potentially result in an overpressurization event do not exceed the appropriate limit. This calculation will identify the pressure relief mechanisms (i.e., PORV's, RHR relief valves, vents) and the limits which represent the controlling condition (i.e., reactor vessel beltline P/T limits, PORV discharge piping, etc.).

This calculation summarizes the transient overshoot and undershoot pressures associated with the limiting mass and energy addition transient. This information currently exists and will be used as input to the evaluation. These overshoot pressures are used in conjunction with operational restrictions required to ensure that an appropriate setpoint is established which ensures the applicable P/T limits are not exceeded. The applicable limits have typically already been developed and are design inputs to this calculation. This calculation will clarify operational restrictions necessary to achieve these goals. In addition, the undershoot pressures due to a PORV 2.0 second closure time will be used to review the minimum pressure to assess potential reactor coolant pump seal damage.

3.0 ASSUMPTIONS

3.1 Reactor coolant pump (RCP) operation will be assumed based upon the indicated cold leg temperature (T_c) :

During heatup, one RCP will be permitted to operate with $T_C \le 160^{\circ}F$. When $T_C > 160^{\circ}F$, up to four RCP's may be operated.

During cooldown, up to four RCP's can be operated while $T_C > 160^{\circ}F$, one RCP may be operated with $T_C \le 160^{\circ}F$. (Note: operation of one RCP below 160°F down to the minimum boltup temperature was provided to permit greater flexibility and the intent to assist in cooling the steam generators down further prior to stopping the final RCP.)

Note: these pump restrictions affect the dynamic pressure losses between the vessel and the pressure instrument. This is an operational restriction affecting the final P/T values and needs to be consistent with operation.

3.2 The dynamic and static pressure differences between the pressure transducers in the hot legs and the pressure in the pressurizer PORV piping will be ignored. This is conservative for flow and no-flow conditions as the pressure would be significantly lower due to line losses and elevation head.

3.3 The reactor coolant pump (RCP) configuration (Reference 5.20) was reviewed to assess seal pressure relative to pump discharge pressure. Charging pump flow is normally introduced and travels both up the shaft to the no. 1 seal or down the shaft through the labyrinth seals and exits into the RCS flow region between the impeller and the diffuser. The pressure in the vicinity of the no. 1 seal is not known relative to the RCS discharge pressure. However, the pressure in the impeller discharge region should be higher than the suction side pressure.

This calculation will assume that the seal pressure is equal to pump discharge pressure since the seal region discharges into the RCS flow stream after the impeller. This would be an optimum situation. This would permit the flow induced (velocity head) pressure drop through the reactor vessel to be added to the PORV setpoint curve to represent the pressure at the pump discharge (seals).

To assess a more limiting condition, the pump seal pressure is assumed to be the same as that measured by the hot leg pressure transducer or no correction will be applied to the PORV setpoint curves to assess seal integrity.

Using both these approaches provide assurance to the degree of potential risk to seal integrity.

3.4 It is assumed that the main board indication of RCS Tcold, which may be used to determine when an RCP may be started or maintained in operation, is accurate. No main board indication instrument uncertainties need be included in the COPS setpoint curve. This assumption was previously justified in Rev. 3, CCN 003.

The justification provided was that the automatic actuation circuitry accounts for maximum temperature and pressure uncertainties. Due to the methodology of the setpoint development, the temperature at which the RCP's are started and or maintained in service can affect the PORV opening logic.

When the first RCP is started, a 50 °F temperature correction is added to account for the fact that during a heat injection transient, the RCS temperature indicators could see a higher Steam Generator secondary water side temperature due to the "slug" of primary side water inside the Steam Generator passing by the temperature element. An additional 17 °F was added to account for the PORV actuation loop uncertainty. This bounds the Plant Process Computer (PPC) where RCS temperature could be read. Although the PPC would most likely be used to start an RCP, there is no procedural requirement to do so. The main board indication could also be used for the same purpose.

The time which the plant would remain in this condition would be very limited due to the transient nature. The likely hood of an overpressurization transient occurring during this time frame is very low.

Additional justification was provided by Reference 5.10. It provides these additional points relative to RHR initiation which can be extrapolated to this application:

- 1. Indication of both the hot and cold leg temperature (one each per loop) is provided in the control room via main board indicators, main board recorders, and/or the PPC.
- 2. There are multiple instruments loops measuring the same parameters and the likelihood that they all would be at worst case conditions and all reading low at the same time is unlikely.
- 3. The multiple indications provide the operators with sufficient sources of information to determine if a specific instrument loop is malfunctioning and should be ignored.

This information was used in the previous submittal regarding the COPS setpoint curves in B16845 (Reference 5.26). Specifically, it stated that no main board indication needs to be considered and the assumption that it is accurate.

4.0 DESIGN INPUTS

4.1 Isothermal Reactor Vessel Beltline Pressure/Temperature Limits (Normal Operation), Ref. 5.1. These limits have no corrections applied and represent the isothermal beltline P/T limits developed using K_{lc} and projected material irradiation damage through 32 EFPY (surface fluence = $1.97 \times 10^{19} \text{ n/cm}^2$). Note that in this instance, protection of the actual limits, not indicated limits (TS limits), shall be used as the basis of establishing the setpoint curves.

4.2 Thermal Hydraulic Pressure Correction

The maximum dynamic pressure differential between the mid-plane of the reactor vessel down comer region and the wide range pressure transmitter (located on the RHR piping) is:

One RCP Operation $\Delta P = 28.3$ psi (Reference 5.2) Four RCP Operation $\Delta P = 74$ psi (Reference 5.3)

It has been demonstrated that the static elevation head can be ignored due to the location of the pressure sensor and the limiting reactor vessel material. This has been documented in Reference 5.4.

4.3 Pressure and Temperature Indicator Uncertainties (Reference 5.5)

Wide range temperature and pressure indication instrumentation probable error (uncertainty). These values will provide the worst case information and is based upon a 24 month fuel cycle. These values were obtained from the calculation of record, Reference 5.5.

The instrument uncertainty associated with wide range temperature indication loops 3RCS*TI413A/B and 3RCS*TI423A/B will be applied.

Temperature Uncertainty: 25.3 °F

The instrument uncertainty associated with wide range pressure indication loops 3RCS*PI403, 3RCS*PI403A and 3RCS*PI405, 3RCS*PI405A will be applied.

Pressure Uncertainty: 115.5 psia

4.4 Pressure and Temperature Uncertainties Associated with the PORVs 3RCS*PCV455 and 3RCS*456 (Reference 5.5)

The instrument loop associated with sensing cold/hot leg temperature is used to establish the PORV pressure. The maximum value is selected.

Temperature Uncertainty:	16.2 °F	(Temperature Bistable)
Pressure Uncertainty:	21.3 psia	(Pressure Bistable)
4.5 Plant Process Computer (PPC) Temperature Indication Uncertainties (Reference 5.5)

The uncertainty associated with establishing RCS temperature using the PPC is bounded by the wide range indication instrument uncertainty values. (See Section 4.3.)

PPC Temperature Uncertainty: 16.3 °F

4.6 PORV Overshoot (Reference 5.6)

The most recent predictions of PORV overshoot values due to mass and energy addition transients is provided by Reference 5.6. The overshoot values for the mass injection event are a function of mass injection flow rate and is independent of PORV setpoint. In the case of the heat injection transients, the overshoots are a function of both RCS/SG temperatures. This information is provided for 4 (N) loop and 3 (N-1) loop operation. The following provides a conservative consolidation of this information to be applied in the development of the setpoint curves.

Review of the mass injection event provides a maximum overshoot of 35 psi for the N-1 loop configuration. This value bounds N loop operation and all lower injection rates (< 550 gpm).

Review of the heat injection events provide a maximum overshoot of 49 psi for the N and N-1 loop configuration given a 50 °F temperature differential (SG hotter than the RCS) between the RCS and the steam generator with the RCS at 250 °F. This overshoot values is conservative for lower RCS temperatures where the SG temperature is no more than 50 °F hotter and for both N and N-1 loop configurations.

Based upon the previous information, bounding values were developed by adding the overshoot pressure to the correction and choosing the maximum for the specific defined temperature ranges. Note: the PORV opening time analyzed was 0.85 seconds considering mass and energy addition events.

Therefore, the overshoot values are as follows:

For RCS temperatures, $T \le 250$ °F, ΔP above setpoint pressure = 49 psi For RCS temperatures, T > 250 °F, ΔP above setpoint pressure = 35 psi

4.7 Adjustment of Gage Pressure to Absolute Pressure

The primary containment pressure is maintained below atmospheric pressure to minimize radioactive release in the event of an emergency. Containment pressure is maintained greater than or equal to 10.6 psia and less than or equal to 14.0 psia (Reference 5.7, page 3/4 6-7. The calculation of the allowable beltline pressure are based upon a differential or

gage pressure. To adjust the resultant pressure, the minimum containment pressure permitted by Technical Specifications (10.6 psia) will be bound by 10 psia in lieu of adding normal atmospheric pressure of 14.7 psia. Consequently, an additional 10 psi will be added to the beltline pressures to obtain an absolute pressure.

4.8 PORV Piping Design Pressure (References 5.8 and 5.9)

Maximum Permissible Discharge Piping Pressure = 800 psi

4.9 Summary of Pertinent Energy and Mass Addition Transient Analyses Assumptions (Reference 5.6)

The maximum primary to secondary temperature differential is 50°F for the starting of the first idle reactor coolant pump.

Water solid conditions of the RCS were assumed.

4.10 COPS Enable Temperatures (Reference 5.1)

The development of COPS Enable Temperatures were performed using the guidance of ASME Boiler and Pressure Vessel Code, Section XI, Appendix G. The minimum required values for heatup and cooldown were developed which include the wide range instrument uncertainty. These values are summarized below.

 Unit 3 COPS Enable Temperatures throu	gh 32 EFPY (with instrument Uncertainty)
 Heatup	225.4 °F
Cooldown	219.5 °F

Table 2COPS Enable Temperatures through 32 EFPY

4.11 PORV Undershoot (Reference 5.6)

This calculation will evaluate the impact of a PORV opening on the integrity of the RCP seal. Based upon CCN 05, the PORV closure time which has been justified and analyzed is 2.0 seconds. Previous CCN's (1, 2 and 5) had addressed the impact of the PORV closing time increasing. The significance of the undershoot is that it can challenge RCP seal integrity should a PORV open due to a COPS transient. Therefore, it is prudent to attempt to establish a setpoint which provides low temperature overpressure protection of the reactor vessel (the limiting RCS component) and at the same time minimize the risk to equipment which may be affected.

To do this, one of the most beneficial attributes is to have as high as a setpoint as possible while still providing low temperature overpressure protection. Use of Code Case N-640 will provide the maximum fracture toughness thereby providing the least restrictive

pressures for the selected heatup and cooldown rates. Another method to minimize undershoot are to have high mass input rates which is adverse to low temperature overpressure protection and would provide higher transient pressures and result in a lower setpoint curve and smaller operational window. Closure stroke time is another direct method of controlling the undershoot.

Given the current constraints, the maximum undershoot would be associated with the heat injection event as can be seen from Tables B and D of Reference 5.6. (Note, the maximum undershoot for mass addition would be 165 psi assuming the highest setpoint and full charging pump flow (approx. 550 GPM).) Review of Reference 5.6 provides the results of regression analyses which were performed to provide best estimate values of undershoot. These regression analyses are linear and are for either specific temperatures with the PORV setpoint being the variable or the for a constant PORV setpoint with the temperature being the variable. While the maximum undershoot of 239 psi for bounding conditions could be utilized, an initial evaluation provided unacceptable results. In lieu of the overly conservative and simple approach, the undershoot will be estimated using the results from the linear regression analysis. The approach will be to determine the undershoot due to the heat injection transient based upon the PORV setpoint at the specified temperatures. The N-1 loop configuration is controlling and will be used. Then based on the results at the specified temperatures based upon linear interpolation/extrapolation.

4.12 RCP Seal Integrity Requirements (Reference 5.11) ccn01

The RCP #1 seal pressure requirement is 200 psid (Refer to Westinghouse Product Update S-009, #1 Seal Normal Operating Range). Based on an RCS Pressure of 300 psia and a maximum backseat pressure of 100 psia in the seal return line, which is derived from the set pressure of the relief valve for the Volume Control Tank (VCT), results in an acceptable differential pressure of 200 psid across the seal.

For MP3, the actual set pressure for the VCT relief valve 3CHS*RV8120 is 85 psig (see P&ID 25212-26904, Sheet 1, Rev. 41, Reference 5.12) Thus, the seal integrity pressure is 285 psig or 300 psia. The normal operating pressure of the VCT is 15 to 60 psig (Reference 5.13). Thus, under normal operating conditions, with the VCT at 60 psig, the required RCS pressure can be 25 psia lower or 275 psia instead of 300 psia.

6.0 METHOD OF ANALYSIS

6.1 COPS Setpoint Development

6.1.1 Setpoint Curves Based Upon Beltline Pressure/Temperature Limits

The development of the P/T limits was based ASME Section XI Code Case N-640 (Reference 5.14) which permits the reference fracture toughness curve, K_{IC} , as found in Appendix A of Section XI, in lieu of K_{IR} , Figure G-2210-1 in Appendix G. It is important to recognize that 10 CFR 50.55a acknowledges Regulatory Guide 1.84 (Reference 5.15) which contains those Code Cases which are approved for use. In this instance, Code Case N-640 is not approved for use and requires specific approval by the Office of Nuclear Reactor Regulation. Following submittal and upon issuance of an SER from the NRC, the results of this calculation will be acceptable to utilize in normal plant operation. In addition, 10 CFR 50.55(b)(2) permits the use of Section XI including editions through 1995 Edition and addenda through 1996 (subject to the limitations defined of which none apply).

ASME Section XI, Appendix G (Reference 5.16) recommends LTOP systems limit the pressure in the vessel to 110% of the beltline P/T limits. However, the guidance provided by Code Case N-640 recommends LTOP systems limit the pressure in the vessel to 100% of the beltline P/T limits when K_{Ic} is used. Therefore, the reactor vessel pressures will not be permitted to exceed 100% of the beltline P/T limits. The beltline P/T which will be protected are those associated with the isothermal condition as low temperature overpressure events have historically been isothermal. This approach has been supported by Westinghouse and the NRC as documented in WCAP-14040-NP-A, Reference 5.17.

The approach taken by Westinghouse and previously used in the setpoint development is to have staggered setpoints for each valve (i.e., a low and high setpoint curve). This approach will permit one valve to relieve the transient without excessive undershoot which would occur if both valves were to open simultaneously. It also addresses single failure as if the first valve fails to open the second valve opening setpoint has also been selected to protect the isothermal curve. The primary focus of the PORV setpoint curve is to provide protection from overpressurizing the reactor vessel. That is, the PORV are intended to be overpressure protection for the NSSS components. This is consistent with WCAP-14040-NP-A (Reference 5.17) and the SER which states that the setpoint selection shall provide protection against the upper limit and shall take precedence over the lower limit (minimum RCS pressure associated with the RCP seals).

The COPS is an automatic system which utilizes existing temperature elements to monitor RCS temperature in combination with pressure transmitters to monitor pressure. The COPS setpoint curves provides pressure as a function of temperature. If the system pressure exceeds the setpoint pressure for the specific temperature, a signal is generated to open the PORV. As such no operator action is required to open the valves. A temperature uncertainty of 16.2 °F associated with the temperature bistable as described in Section 4.4 will be considered. Main Board indication and PPC temperature uncertainties are not considered. As discussed in Section 3.4, no instrument uncertainty is necessary to account for the start of an RCP. The pressure uncertainty associated with the instrumentation of 21.3 psia will be applied.

To establish the high setpoint curve consideration of instrument uncertainty, RCP operation to account for dynamic pressure effects, and PORV overshoot will be included. The high setpoint curve will use one times the valve overshoot. The same consideration will be given to the development of the low setpoint curve. However, the development of the low setpoint curve will use two times the valve overshoot to accomplish staggered setpoints.

In addition, since the PORV setpoint circuitry is based upon an automated system, when an RCP is started it is possible for the temperature instrument to read up to 50 °F higher due to the steam generator being permitted to be as much as 50 °F above the RCS temperature (design basis transient). If this were to occur without considering this effect, the PORV setpoint would automatically be adjusted upward without the vessel having an adequate time to respond (increase in temperature). Consequently, the curve will also be adjusted by adding an additional 50 °F to account for this.

6.1.2 PORV Discharge Piping

Review of the loadings for the PORV discharge piping show that the maximum pressurizer pressure assumed was 800 psia (@350°F) for water discharge (Reference 5.9). To ensure that the COPS setpoint curve maintains this piping qualification assumption, the setpoint will be established ensuring that 800 psia pressurizer pressure is not exceeded. Utilizing the maximum overshoot and instrument uncertainty will insure that the pressurizer pressure is not exceeded. Note, due to the location of the pressure sensor (hot legs) it is conservative to ignore the flow induced pressure drop through the vessel and is appropriate for no flow conditions.

6.1.3 Composite COPS Setpoint Curves

Composite curves are generated considering the controlling pressure from the beltline COPS setpoint curve and the PORV discharge piping curve. These curves are plotted as a function of temperature and pressure. Note that these curves are only required at temperature less than or equal to the enable temperature. The maximum enable temperature associated with heatup or cooldown is plotted along with the setpoint curves to depict the PORV setpoint window.

6.2 Minimum Vent Size to Insure Overpressure Protection

Once the RCS is depressurized, an adequate size vent exposed to the containment atmosphere will maintain the RCS at pressures below the Appendix G limits during a

design basis COPS event. To establish this requirement, it is assumed that the one of the PORV's are removed form the line. Since the design basis for the COPS events include the single failure of one PORV to open, it is known that this line is capable of mitigating the design basis transients with the valve in place.

Westinghouse developed the minimum vent area required for COPS in Reference 5.27. This was performed due to the replacement of the PORV block valves under DCR M3-97007 (Reference 5.28). These replacement block valves had a smaller inside diameter than the previously installed valves. Review of Reference 5.27, provided several cases which would satisfy the overpressure protection requirements. The following summary is provided:

- 1) Removal of a PORV with the newly installed valve will limit pressure to 61.2 psig given the maximum charging flow of 560 GPM. The flow area is 3.976 in² and is based upon the block valve flow diameter of 2.25 inches.
- 2) Removal of a PORV with a minimum flow area of 2.0 in² will limit pressure to 139.9 psig given the maximum charging flow of 560 GPM. The flow area 2.0 in² is based upon a postulated block valve flow diameter of 1.596 inches.
- 3) Removal of a PORV with a minimum flow area of 1.022 in² will limit pressure to 500 psig given the maximum charging flow of 560 GPM. The flow area 1.022 in² is based upon a postulated block valve flow diameter of 1.141 inches.

The three cases are based upon a depressurized RCS which is consistent with establishing an RCS vent. The mass addition event was the only COPS transient considered. The energy addition event was deemed incredible as the RCS is depressurized with an open vent and the start of an RCP is governed by procedure.

The minimum vent size selected for Technical Specifications will be the 2.0 in². This will limit the pressure to 139.9 psig which is less than the minimum beltline pressure and is also less than the RHR system relief valve setpoint of 440 psig (Reference 5.25).

6.3 Reactor Coolant Pump Seal Integrity Assessment

The issue of RCP seal damage due to a COPS design basis event was identified due to pressure falling back down below the setpoint value and the PORV taking a finite length of time to stroke closed. During the time it takes the valve to close the pressure continues to decrease. If the RCS pressure drops below 300 psia, it is possible to damage the seal cartridge (References 5.19). While seal damage is not desired, it is important to recognize that the primary purpose of the cold overpressure protection system is to ensure that the brittle fracture limits of the ferritic RCS materials (the reactor vessel is the limiting component) are not exceeded during the limiting design basis transients. RCP seal integrity will be reviewed in this calculation to identify if the seals may be challenged to ensure that proper controls are identified by procedure to minimize this risk.

To assess this event, the undershoot values due to the mass and energy addition events have been provided by Reference 5.6 and summarized in Section 4.11. The specific undershoot values have been calculated assuming a two second closure time and are a function of the PORV setpoint and RCS temperature (Reference 5.6). To assess the impact of the PORV opening, the potential pressures during the event will be conservatively established considering N-1 loop operation and compared to the minimum pressure of 300 psia.

It should be noted that the pressure transducer are on instrument lines which are off two of the hot legs between the reactor vessel and the steam generator. The setpoint curves established to protect the vessel account for the dynamic losses through the vessel. There were no static elevation corrections required due to the location of the pressure transducer relative to the reactor vessel beltline. In the case of the RCP's seals, the primary side pressure is better represented by RCP discharge pressure (See assumption 3.3). The dynamic pressure losses used to protect the reactor vessel while the RCP's are operating are not necessary. However, when there is no flow, the pressure in the vessel is approximately the same pressure at the RCP (neglecting any small elevation differences). Consequently, flow induced corrections are not required to protect the RCP seals. The dynamic pressure differences which were subtracted to develop the setpoint curve to protect the reactor vessel will added back to the setpoint pressure. In addition the effect of the dynamic head will be considered assuming that the pump seal pressure is the same as provided by the hot leg pressure transducer This will be addressed for the low setpoint curve (the most restrictive curve) and resultant pressure will be compared to the minimum RCP seal pressure of 300 psia considering the pressure undershoot.

6.4 Review of RHR Relief Valve Capability for COPS Use

At reduced RCS temperatures, the residual heat removal (RHR) system is aligned to the RCS to continue the cooldown process as cooling the plant through steaming the steam generators becomes less effective. The RHR system contains pressure relief valves which are designed to protect the RHR system from overpressurization. Since alignment of the RHR relief valves to the RCS can be established, these valve provide an additional means of providing low temperature overpressure protection to the RCS. In order to credit use of these valves, it is necessary to establish the relief capacity of the valves, the setpoint of the valves and the valve accumulation. In addition, any differences in pressure between the RHR relief valve and reactor vessel should be considered.

RHR relief valve capacity has been reviewed and established in Reference 5.21. This memo conclude that the relief valve and piping is adequate to mitigate the limiting LTOP transient. Utilizing this information, the maximum pressure will be calculated and compared to the most restrictive isothermal reactor beltline pressure (the limiting RCS component).

7.0 BODY OF CALCALCULATION

7.1 COPS Setpoint Development

7.1.1 Setpoint Curves Based Upon Beltline Pressure/Temperature Limits

Development of the COPS setpoint curve will need to encompass both heatup and cooldown scenarios. Consistent with the assumption regarding reactor coolant pump (RCP) operation, heatup and cooldown usage is the same providing identical flow induced pressure losses. Again for heatup and cooldown, the pump operation is summarized as:

During heatup and cooldown, one RCP will be permitted to operate with $T_C \le 160^{\circ}F$. When $T_C > 160^{\circ}F$, up to four RCP's may be operated.

Based upon the RCP operation, the maximum dynamic pressure differential between the mid-plane of the reactor vessel down comer region and the wide range pressure transmitter (located on the RHR piping) is:

One RCP Operation $\Delta P = 28.3 \text{ psi}$ (Reference 5.2) Four RCP Operation $\Delta P = 74 \text{ psi}$ (Reference 5.3)

To accommodate either 4 loop or 3 loop operation, the more conservative overshoot values associated with 3 and 4 loop operation will be used.

Values to be applied, developed from the combination of 3 and 4 loop values and consideration of both mass and energy transients:

For temperatures, $T \le 250^{\circ}$ F, Δ P above setpoint pressure = 49 psi For temperatures, $T > 250^{\circ}$ F, Δ P above setpoint pressure = 35 psi

Instrumentation uncertainty will also be considered in the establishment of the setpoint curve. The values associated with COPS are as follows:

Temperature Bistable = 16.2 °F Pressure Bistable = 21.3 psia

To accommodate the PORV temperature circuitry (temperature bistable) inaccuracy a bounding value of 17.0 °F will be used. The temperature correction of 17 °F is applied first. The following Table summarizes the pressure corrections to be applied to generate the high and low COPS setpoint curve based upon the beltline P/T limits and the corresponding temperature ranges. Table 3 was generated based upon the preceding input.

Temperature, °F	No. of RCP's	ΔP flow, psi	Overshoot, psi	Pressure Instrument Inaccuracy, psi	Adjustment to Obtain Abs. Pressure, psi
T ≤ 160	1	28.3	49.0	21.3	10
$160 < T \le 250$	4	74	49.0	21.3	10
T > 250	4	74	35.0	21.3	10

 Table 7

 COPS Low Setpoint Curve Determination For Beltline

1 - This value represents the minimum boltup temperature (uncorrected) which lowest temperature the reactor vessel can be tensioned and pressurized.

2 - This value was generated by linear interpolation to accommodate changes in the applied correction factors at the specific temperatures.

7.1.2 PORV Discharge Piping

The PORV discharge piping has been designed for two phase flow with a water solid pressurizer at a maximum pressure of 800 psia. To ensure that this condition is not exceeded, the maximum PORV overshoot of 39 psi and the instrumentation uncertainty of 21.3 psi shall be subtracted to establish the high setpoint curve. The low setpoint curve will be established the same way with two times the PORV overshoot.

High Setpoint

Required PORV Setpoint for PORV Discharge Piping = 800 psia - 21.3 psid - 49 psid = 729.7 psia

Low Setpoint

Required PORV Setpoint for PORV Discharge Piping = 800 psia - 21.3 psid - 2*49 psid = 680.7 psia

Note that this pressure does not include any pressure losses through the upstream piping and the upstream valves nor does it include any elevation differences or dynamic losses. Use of this pressure is conservative to ensure the limiting piping pressure is met. This pressure applies at all temperatures.

7.1.3 Composite COPS Setpoint Curves

Each of the high and low setpoint curves for the beltline are over laid with the PORV discharge piping pressure. The lower bound values of the two curves at temperatures below the enable temperatures (Heatup = $225.4 \,^{\circ}$ F, Cooldown = $219.5 \,^{\circ}$ F) represents the composite setpoint curve. The following figures are a graphical representation of the comparison using the conservative enable temperature of $225.4 \,^{\circ}$ F.

Figure 1 Composite PORV High Setpoint Curve

Figure 2 Composite PORV Low Setpoint Curve

7.2 Minimum Vent Size to Insure Overpressure Protection

The PORV's are located on line 3-RCS-003-69-1 and 3-RCS-003-67-1 (Reference 5.18). These pipes are 3 inch schedule 160 (Reference 5.22). The block valves upstream of the PORV's provide the most restrictive flow area of 3.976 in^2 based upon a block valve flow diameter of 2.25 in (Reference 5.27).

Analysis demonstrate that removal of a PORV with a minimum flow area of 2.0 in² will limit pressure to 139.9 psig at the low core support plate given the maximum charging flow of 560 GPM. The flow area 2.0 in² is based upon a postulated block valve flow diameter of 1.596 inches. (The actual valve configuration will provide a maximum pressure of 61.2 psig.)

The reduced area will provide some flexibility should it be necessary to vent through a different path. Engineering analysis will be necessary to justify the alternate path and the associated peak pressure. This calculation does not provide this justification.

This area also ensures the pressure does not exceed the RHR system relief valve pressure of 440 psig (Reference 5.25 locations A-7 and C-3). This ensures that the pressure does not challenge the RHR system should a COPS event occur.

7.3 Reactor Coolant Pump Seal Integrity

The lower bound composite PORV low setpoint curve was identified in Figure 2. It is represented by the lower portion of the beltline COPS curve and the COPS setpoint curve to protect the PORV piping. To identify the risk associated to the seals, it is necessary to evaluate the undershoot from the PORV setpoint curve.

Based upon linear interpolation, the beltline low setpoint curve is intersected by the PORV piping setpoint curve at 180.6 °F (corrected temperature). Above this point the setpoint is limited by the PORV piping setpoint pressure of 680.7 psia.

Based upon Reference 5.6 (see section 4.11), the undershoot is a function of setpoint pressure, number of operating loops and RCS temperature ($\Delta T = 50$ °F). The maximum undershoot occurs for the N-1 loop configuration and will be used as a bounding condition. Subtracting the value from the setpoint curve will provide the pressurizer pressure. In addition, the dynamic pressure difference is added back to the PORV setpoint curve allowable pressure (Corrected). The dynamic pressure difference values as a function of temperature were identified in Table 5.

To determine the undershoot, a review of Reference 5.6, Tables B and D were performed. This review clarified that the heat addition event provides the controlling conditions. That is the mass injection event will be encompassed by evaluating the heat addition events. To do this, the linear regression results provided by Reference 5.6 page 3 and 4 were used. Again, the N-1 (3) loop configuration provides conservative results relative to N (4)-loop operation. Two formulas are provided, one providing the undershoot as a function of the setpoint for defined temperatures and the second providing the undershoot as a function of temperature for defined setpoint values. The approach chosen to determine the undershoot was to utilize the formula for undershoot as a function of PORV setpoint and the low setpoint curve (temperature versus PORV setpoint pressure). Undershoot was calculated at temperatures enveloping the setpoint temperature. Linear interpolation between the two undershoot values to obtain the specific value at the setpoint temperature.

The following expression was used as provided by Reference 5.6:

Undershoot = M*setpoint +B, where; M = slope and B = intercept

The following table provides the results of the regression analysis to be used for N-1 loop operation, also provided by Reference 5.6.

	A	
RCS Temperature (°F)	Slope (M)	Intercept (B)
70	0.223	81.8
100	0.201	72.7
150	0.163	86.2
200	0.188	69.8
250	0.189	65.0
300	0.156	67.9

Undershoot as a Function of Setpoint: N-1 loop Operation

To assess the impact of the PORV opening, the potential RCS pressures resulting form the undershoot will be conservatively established considering N-1 loop operation and compared to the minimum pressure of 300 psia.

The following example is provided for 118°F and a PORV setpoint of 520.6 psia.

Using the formula, the undershoot will be calculated at 100°F and 150°F for the PORV setpoint of 520.6 psia.

Undershoot (@ 100° F) = 0.201* 520.6 + 72.7 = 177.3 psi Undershoot (@ 150° F) = 0.163* 520.6 + 86.2 = 171.1 psi

Linear interpolation provides an undershoot at 118°F of 175.1 psi.

The resulting RCS pressure can be computed by subtracting the undershoot from the setpoint and adding the flow induced pressure difference.

520.6 psia -175.1 psi + 28.3 psi = 373.8 psia

Since this pressure exceeds the desired pressure of 300 psia, a seal integrity issue is not expected.

Note that the entire setpoint curve was not evaluated as the controlling region is at the lowest temperatures.

Fluid Temperature, °F (Corrected)	PORV Allowable Pressure, psig (Corrected)	Undershoot (psi)	Pressure @ RCP, psig
57	504.3	203.0	329.6 (504.3 - 203.0+ 28.3)
107	504.3	173.3	359.3 (504.3 - 173.3 + 28.3)
118	520.6	175.1	373.8 (520.6 - 175.1+ 28.3)
125	532.9	176.4	384.8 (532.9 - 176.4+ 28.3)
126	534.8	176.6	386.5 (534.8 - 176.6+ 28.3)
127	536.8	176.9	388.2 (536.8 - 176.9 + 28.3)
129	540.8	177.3	391.8 (540.8 - 177.3 + 28.3)
135	553.9	178.8	403.4 (553.9 - 178.8+ 28.3)
142	571.2	180.6	418.9 (571.2 - 180.6+ 28.3)
143	573.9	180.9	421.3 (573.9 - 180.9+ 28.3)
145	579.4	181.5	426.2 (579.4 - 181.5+ 28.3)
151	597.4	183.5	442.2 (597.4 - 183.5+ 28.3)
158	621.3	187.3	462.3 (621.3 - 187.3 + 28.3)
159	625.0	187.9	465.4 (625.0 - 187.9+ 28.3)
160	628.8	188.6	468.5 (628.8 - 188.6+ 28.3)
160.1	583.5	180.9	476.6 (583.5 - 180.9 + 74)
161	586.9	181.5	479.4 (586.9 - 181.5 + 74)

Table 8Pump Pressure @ RCP due to Undershoot

Review of the results show that the predicted pressure at the pump would not be expected to fall below approximately 330 psia. This maintains approximately 30 psi (330 - 300) margin to the minimum RCP seal pressure of 300 psia.

As a second check, if the dynamic head was not accounted for, there would be a reduction in the margin down to 1.3 psi, (the existing margin minus the velocity head or 29.6 psi - 28.3 psi).

In both cases, margin exists between the predicted RCS pressure and the desired RCS pressure of 300 psia. These are both conservative estimates of the available margin. To assure equipment protection, credit could be taken to account for normal operation

pressure of the VCT providing additional margin of approximately 25 psi to assure that the necessary seal differential pressure of 200 psid was maintained.

7.4 Review of RHR Relief Valve Capability for COPS Use

Heat Addition Transient

The design basis heat addition transient for MP3 is the start of an RCP with an RCS temperature as high as 150 °F and the steam generators as high as 200 °F (Reference 5.24, page 13-2). A single RHR relief valve with a capacity of at least 470 GPM would maintain the peak pressure below the valve accumulation pressure (Reference 5.24, page 13-2). Since the flow capacity of an RHR relief valve is 560 GPM (Reference 5.21), the valve accumulation pressure will not be exceeded.

Mass Addition Transient

The design basis mass addition transient for MP3 is the maximum flow from a single charging pump (Reference 5.24, page 13-3). The relief capacity of the RHR relief valve must be greater that the maximum flow from a single charging pump. A charging pump flow has a maximum flow rate of 560 GPM (Reference 5.24, page 3/4 5-6). Since the flow capacity of an RHR relief valve is 560 GPM, the valve accumulation pressure will not be exceeded.

Peak Pressure at the Reactor vessel Beltline

The peak pressure at the reactor vessel beltline is equal to the sum of the accumulation pressure of the RHR relief valve plus the ΔP between the valves and the vessel.

SP = 440 psig	The valve setpoint (Reference 5.25 locations A-7 and C-3)
ACC = SP*10%	The accumulation
ACC = 44 psi	

 $\Delta P = 63$ psi The ΔP between the RHR suction relief valves and the vessel beltline due to elevation head, frictional losses and velocity head (Reference 5.2). Note that this ΔP is for temperatures below 200 °F. For a fixed setpoint relief valve the only temperature of interest is at the lowest temperature (Approx. 70 °F) since, by inspection of the beltline pressure/temperature limits, the allowable pressure increases exponentially with increasing temperature. The controlling allowable pressure from Reference 5.1 is 658.2 psig.

 $P = SP + ACC + \Delta P$

P = 547 psig

Note that the 3% tolerance on valve setpoint is not explicitly accounted for in the calculation of peak pressure at the reactor vessel beltline. This is because Westinghouse analysis models the valve as commencing to open at the setpressure plus the 3% tolerance, and full open at the set pressure plus 10% accumulation (Reference 5.24, page 10-2).

8.0 RESULTS

8.1 COPS Setpoint Figures for Technical Specifications

The PORV setpoint curve for use during COPS operation has been developed using the isothermal beltline P/T limits considering a reactor vessel beltline fluence of 1.97 x 10¹⁹ n/cm^2 , E > 1.0 MeV (Reference 5.1) which corresponds to 32 EFPY. In addition, the setpoint curve also considers the design conditions associated with the PORV discharge piping relative to this mode of operation. These setpoint curves represent the maximum pressure versus temperature for use in the Technical Specifications. These curves have been developed up to the minimum enable temperatures. It should be noted that the pressure resulting from the COPS setpoint curve may be less restrictive than the RCS P/T limits associated with heatup and cooldown while in the COPS region. Administrative controls should be implemented to ensure that the RCS P/T heatup and cooldown limitations are not exceeded. In addition, once above the minimum enable temperatures, the pressure should again be administratively controlled to ensure that the appropriate RCS P/T limits are not exceeded. When establishing the actual setpoint, pressure values which are lower than the setpoint curves are acceptable although the potential for seal damage is increased as the undershoot increases with reduced setpoints and there is currently very little margin.

The COPS enable temperatures for heatup and cooldown were 225.4 °F and 219.5 °F for heatup and cooldown respectively. Note that the Technical Specification figures have considered the bounding value of 225.4 °F for both heatup and cooldown.

Note that the beltline P/T limits were developed using Code Case N-640 which requires an exemption request and NRC approval prior to implementation.

K:\DEPTDATA\Comp Perf\STEWART\UNIT3\PT Curves\u3COPS.doc

8.2 Minimum Vent Size to Insure Overpressure Protection

The minimum vent size shall be 2.0 in^2 and will be established by removing one of the PORV's (valves). This will ensure that the peak pressure does not exceed the isothermal beltline P/T limit.

8.3 Reactor Coolant Pump Seal Integrity

Reactor coolant pump seal integrity was reviewed to assess the potential to have seal damage due to a COPS event and the transient would result in a reduced RCS system pressure given a finite length of time for the PORV to close. It has been concluded that the undershoot pressures resulting from the COPS design basis transient and a 2.0 second closure stroke time pose no challenge to RCP seal integrity. There are no restrictions required to ensure RCP seal integrity during an RCP pump start other than the limitations imposed based upon the design basis transient assumptions.

8.4 Review of RHR Relief Valve Capability for COPS Use

Use of the RHR relief suction valve have been shown capable of providing the requisite protection during the COPS mode of operation. Use of these valves by themselves or in conjunction with the PORV's will provide adequate relief. A combination of two valves must be used at all times.

One constraint regarding the RHR valves currently exists and is summarized by the design basis statement as follows:

The design basis heat addition transient for MP3 is the start of an RCP with an RCS temperature as high as 150 °F and the steam generators as high as 200 °F (Reference 5.24, page 13-2). A single RHR relief valve with a capacity of at least 470 GPM would maintain the peak pressure below the valve accumulation pressure (Reference 5.24, page 13-2). Since the flow capacity of an RHR relief valve is 560 GPM (Reference 5.21), the valve accumulation pressure will not be exceeded.

8.5 Summary of Pertinent Operational Restrictions

The results of this calculation identify the necessary requirements to provide adequate low temperature overpressure protection with the Cold Over Pressurization System at Unit 3. Discussion of RCP seal integrity issues are also provided.

The maximum number of permissible operating reactor coolant pumps as a function of corresponding reactor vessel inlet temperature are as follows for heatup and cooldown:

No. of RCP's Operating	Cold Leg Temperature Range, T _c , °F,
	Indicated
1	$T_c \le 160$
4	$T_c > 160$

Table 9RCP Operation for Normal Heatup and Normal Cooldown

The design basis transients were assumed to be water solid. Adequate relieving capacity will be established in the case of a steam bubble in the pressurizer. It is beneficial to operate with a steam bubble as it provides a cushion and operator action time in comparison to water solid operation.

The PORV stroke time open/close of 0.85/2.0 seconds has been assumed. The open time is critical for ensuring that the peak transient pressure does not exceed the applicable limit. In the case of the closure time, this value is used to review undershoot relative to RCP seal integrity. This stroke time conservatively provides approximately 30 psi margin between the minimum seal pressure of 300 psia and the minimum RCS pressure. An increase in the stroke time will increase the undershoot and may challenge RCP seal integrity. In addition, administratively reducing the setpoint at the low pressures (<503.0 psig, 300 psig required for RCP operation plus 203.0 psi maximum undershoot) will further increase the risk of seal damage. A reduced setpoint will also result in greater undershoot have a cumulative effect on the risk to the RCP seals. Note that the primary purpose of the PORV's is to provide overpressure protection to the ferritic boundary components and this attribute shall receive precedence.

Only one charging pump is permitted while below the COPS enable temperature. The analysis assumption was full or non-throttled charging flow. Reductions in charging flow will result in lower peak transient pressures but will also provide greater setpoint undershoot which may challenge RCP seal integrity.

While the PORV's are being used for low temperature overpressure protection, the maximum temperature for the start of the first idle RCP is 250 °F. The steam generators were assumed to be 50°F hotter than the RCS for the energy addition analysis. In the case when an RHR relief valve is being used for low temperature overpressure protection, the maximum temperature for the start of the first idle RCP is 150 °F. Again, the steam generators were assumed to be 50°F hotter than the RCS for the energy addition analysis

The isothermal beltline P-T limit and the PORV discharge piping form the basis for establishing the PORV setpoint curve. It should be noted that the pressure resulting from the COPS setpoint curve may be less restrictive than the RCS P/T limits associated with heatup and cooldown while in the COPS region. Administrative controls should be implemented to ensure that the RCS P/T heatup and cooldown limitations are not exceeded. In addition, once above the minimum enable temperatures and with no automatic protection from the PORV's, the pressure should again be administratively controlled to ensure that the appropriate RCS P/T limits are not exceeded.

1 2	5 of 35/3.1 14 of 35/6.1.1	Refueling schedulers might want to run RCPs below 120F to facilitate the cool-down. The third paragraph implies that the PORV set-point curves are different to prevent both valves from opening at once. My understanding from the last calculation was that the curves were different to accommodate different instrument uncertainties applied to either loop due to different pressure instrument manufacturers.	PT limit calc. revised to Permit RCP operation down to min. bothisp temp. Cerrit forward into this calc. Per Mike Hess: Don Asay verified that the instruments were changed-out and now have similar instrument uncertainties. No change to the calculation is required.		
3	15 of 35/6.1.1	Second paragraph from the top, first sentence does not appear to be a sentence.	Corrected Sendence		
4	16 of 35/6.2	Second paragraph assumes the pipe size to be the limiting flow area for a pressurizer vent. A subsequent change made the block valves the limiting flow area. Westinghouse Calculation SAE/FSE-C-NEU- 0020 documents that the actual required area is 2.0 square inches. Please change the Technical Specification from 5.4 square inches to 2.0 square inches. Also this calculation needs to be changed from 5.4 square inches to the block valve area, Sections 7.2 and 8.2.	The subject calculation was reviewed. In fact, a rent area of 1.022in ² is adequate for COPS and limits pressure to 500psig. The 2.0 in ² vent size will limit pressure to ~/fopsig satisfying CoPS as well as concern for other aligned systems. Will incorporate 2.0 in2.

5	18 of 35/7.1.1	The last paragraph identified an instrument uncertainty to be applied to the operator's decision for the correct temperature to start an RCP However, section 3.4 states that "the main board indication to RCS T-cold, which may be used to determine when an RCP may be started or maintained in operation, is accurate. It appears the Section 7.1.1 is overly conservative.	(S) Clarification has been added to the text. Instrument Uncertainty due the the operator using the
6	32 of 35/8.3	Add note that seal damage at reduced pressure is an economic concern and not a safety concern.	main board instruments of PPC have not been included. (b) The current TS and Licensing perspective requires that the RCP seals be protected making it a safety assue. This will be addressed as part of the license amendment FPB west and is had to ally

addressed.
