(8:28 a.m.)

CHAIRMAN APOSTOLAKIS: The meeting will now come to order. This is the second day of the 490th Meeting of the Advisory Committee on Reactor Safeguards. During today's meeting, the Committee will consider the following; Phase II, Pre-Application Review of the AP1000 Design, Future ACRS Activities, a Report of the Planning and Procedures Subcommittee, Reconciliation of ACRS Comments and Recommendations and Proposed ACRS Reports.

A portion of the meeting may be closed to discuss Westinghouse proprietary information. This meeting is being conducted in accordance with the provisions of the Federal Advisory Committee Act. Mr. Sam Duraiswamy is the designated federal official for the initial portion of the meeting.

We have received no written comments or requests for time to make oral statements from members of the public regarding today's sessions. A transcript of portions of the meeting is being kept and it is requested that the speakers use one of the microphones, identify themselves and speak with sufficient clarity and volume so that they can be readily heard. I will begin by asking Dr. Kress, a

NEAL R. GROSS

WASHINGTON, D.C. 20005-3701

(202) 234-4433

www.nealrgross.com

1 member in this issue, to lead us through the Phase II
2 Pre-application Review.

3 MEMBER KRESS: Thank you, Mr. Chairman.
4 I remind the members that the application review for
5 AP1000 is being done in three phases. Phase 1 was for
6 Westinghouse and the NRC to identify what would be the
7 key issues in the certification and Phase II was for
8 Westinghouse to ponder those key issues and come to
9 some sort of position on them. There are four of
10 these basically and today that's what we're going to
11 hear about, the four key issues and the staff's
12 position on these.

13 And I think we'll be asked for a letter,
14 of course, on our feelings about these issues. So,
15 with that, I'll turn it over to Jim Lyons.

16 MR. LYONS: Thank you, Dr. Kress. I'm Jim
17 Lyons, Director of the New Reactor Licensing Project
18 Office and we're glad to be here this morning to
19 discuss the completion of our review of the AP1000
20 pre-application review. We are getting ready to start
21 the review of the design certification which
22 Westinghouse is proposing to send in either later this
23 month or, I guess, next month. We are looking forward
24 to receiving your letter and with that, I'll turn it
25 over to Larry Burkhardt, who will make the

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 presentation.

2 MR. BURKHART: Good morning, I'm Larry
3 Burkhart, the AP1000 Project Manager and as has been
4 said already, we're here to discuss the staff's
5 assessment of the pre-application review. Phase II,
6 the end of Phase II brings to a conclusion the end of
7 the pre-application review.

8 Briefly, the agenda, obviously,
9 introduction, what I am doing now, Mike Corletti from
10 Westinghouse will give us an overview of the AP1000
11 design, with some highlights on the differences
12 between the AP600 and that AP1000. We will provide
13 our assessment of the four issues that were decided to
14 be reviewed for the pre-application review. I'll talk
15 about those details in a second.

16 We have staff from NRR and the Office of
17 Research who were involved in that assessment and
18 after our assessment, Westinghouse will give their
19 presentation and their comments.

20 Some background; the AP600 was certified
21 in December of 1999. About that time, Westinghouse
22 expressed interest in applying for basically a larger
23 version of the AP600, the AP1000, based on the AP600
24 design. Early in the year 2000, we discussed a three-
25 phase approach that Dr. Kress mentioned. Pre-

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 application review involved Phases 1 and 2. Phase 1,
2 the scoping review, was completed in July of 2000 and
3 Phase II is to be completed by the end of March,
4 that's what we're talking about right now, and Phase
5 III is the actual design certification review, which
6 could come in as early as March, late March or early
7 April.

8 So getting to the point of what we're here
9 to talk about today, the scope of the Phase II review
10 is limited to four issues; the applicability of the
11 AP600 testing program to the AP1000 design
12 certification review, the applicability of the AP600
13 analysis codes to the AP1000 design, acceptability of
14 using the DAC approach in the INC control room and
15 piping design areas and that's in lieu of providing
16 detailed design, and acceptability of requesting
17 certain exemptions that were granted for AP600. There
18 are three exemptions which I'll talk about later.

19 The staff's assessment on these four
20 issues will be documented in a SECY to the Commission
21 and that would involve discussions of the design
22 acceptance criteria, the DAC, and the other three
23 issues would be documented in a letter directly to
24 Westinghouse and both of these are on tap to be issued
25 by the end of this month.

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 One last introductory slide, interaction
2 we've had with Westinghouse, as you imagine, have been
3 numerous. We had eight correspondences, which
4 involved requests for additional information that
5 actually covered 74 different questions. We issued
6 those RAIs between January and October of 2001 and
7 Westinghouse completed their answers to those RAIs by
8 November of 2001. We've had several public meetings
9 and tele-conferences and our interactions with the
10 ACRS included a briefing on Phase 1 in August of the
11 year 2000 and a couple weeks ago, three weeks ago, we
12 briefed two subcommittees as listed on the slide on
13 our assessments.

14 At that time our assessments were still
15 not completely finalized, as you'll see in the
16 discussion of design acceptance criteria. So moving
17 on, I would like to turn over the mike to Mike
18 Corletti, who will discuss the background of the
19 design, philosophy of design for the AP1000.

20 MR. CORLETTI: Good morning. It's a
21 pleasure to be here in front of you today. My name is
22 Mike Corletti, with AP1000 Project. I have quite a
23 few slides there in that package. I think I'm just
24 going to try to highlight on a few of those, but
25 they're there in case you have questions about the

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 background of the design.

2 As Larry said, we are designing AP1000 to
3 be based extensively on AP600 and to the extent that
4 you see here is a comparison of the general
5 arrangement of both AP600 and AP1000. And you will
6 see, we are maintaining the design within the space
7 constraints, within the general arrangement of the
8 nuclear island. So the system configuration of the
9 passive systems is the same as AP600 I'm going to show
10 and here, we typically say to people, "Can you tell
11 the difference between the two"? I think you'll see
12 that the steam generators are larger but other than
13 that from as far as the structural design here,
14 there's not really much difference on this view.

15 However, when you go to a 70 percent
16 upgrading, there are some changes that you have to
17 make. Here's a good view of the -- a section view of
18 the AP600 compared to the AP1000. The containment has
19 been -- the height of the containment is increased
20 approximately 25 feet basically to accommodate the
21 larger mass and energy releases associated with the
22 design basis accidents, and also to allow for steam
23 generator removal, if necessary.

24 Here's a comparison of some key selected
25 parameters. You'll see the power output, electric

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 power output essentially 1117, which is more than
2 1,000 megawatts and we'd like to say that the 1,000
3 doesn't necessarily stand for 1,000 megawatt. That's
4 \$1,000.00 a kilowatt which is basically what we're
5 designing the installed cost of AP1000 to be.

6 MEMBER POWERS: What is W 3XL?

7 MR. CORLETTI: The 3XL is the Dole and
8 Tihange plants in Belgium. They are 14-foot core
9 plants, 157 fuel assemblies. Pretty much this is the
10 core, the reactor vessel that we've started with for
11 AP1000 and I have comparison to AP600. AP600, if you
12 remember, was a very low power density core. We
13 essentially had a 1,000 megawatt reactor vessel and a
14 1,000 megawatt core and we were running it at 600
15 megawatts.

16 To improve economic competitiveness, we've
17 basically taken the Doel Tihange core and as our basis
18 for AP1000 and we have increased its rating to -- a
19 comparable power rating to our operating three loop
20 plants. You'll see some of the other key parameters.
21 They both, AP600 and AP1000 uses a 17 by 17 fuel. As
22 I said, we've gone to the 14-foot -- 14-foot active
23 fuel length. One difference of AP600 and AP1000
24 compared to most operating Westinghouse PWRs is we use
25 gray rods for load follow, so we don't use boron for

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 load follow, which minimizes waste production.

2 CHAIRMAN APOSTOLAKIS: What did you say
3 about the AP1000, what does 1000 means?

4 MR. CORLETTI: Oh, I'm sorry, that was our
5 marketing. Typically, we started with 1,000 megawatts
6 electro-power rating but you see the -- we've actually
7 gone to 1117 but the driver for going from AP600 to
8 AP1000 was to get a cost competitive product and where
9 our U.S. utilities now are -- the target cost that we
10 need to deliver on an overnight capital cost is
11 essentially \$1,000.00 a kilowatt, installed capital
12 cost. This is our major driver for developing --
13 taking AP600 and developing it to an AP1000.

14 MEMBER KRESS: Tell me, what is it -- what
15 is the need that drives the pressurizer volume
16 increase?

17 MR. CORLETTI: The pressurizer volume
18 increases there, to handle thermal transients,
19 transients that would occur.

20 MEMBER KRESS: So it's thermal capacity.

21 MR. CORLETTI: Yes, and it provides
22 basically a much more forgiving plant. AP600, you'll
23 remember, is designed to the utility requirements
24 document. One of those requirements was to eliminate
25 the PORV function stemming from the Three-Mile Island

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 accident. So the vendors all -- we've incorporated a
2 larger pressurizer to mitigate these transients
3 without opening -- without opening the safety valves,
4 right, without the need for opening the PORVs.

5 MEMBER KRESS: So that's what takes the
6 volume up.

7 MR. CORLETTI: That's what drives the
8 sizing of the pressurizer and for AP1000 it even got
9 larger. So it really provides a good operational
10 benefit for -- to mitigate transients.

11 VICE CHAIRMAN BONACA: A couple of other
12 things; at the surface area, there is a big increase
13 over the hedge.

14 MR. CORLETTI: There's a big increase,
15 right. The steam generator is what we call Delta 125
16 and it is similar to the -- it is based on the
17 replacement steam generator that we had supplied for
18 Arkansas but also essentially a small generator when
19 you compare it to the CE type -- you know, the CE,
20 System 2 type steam generators, where they fix their
21 designs on two loops and with very large steam
22 generators. This generator is within that size.

23 In the development of AP1000 shortly after
24 we started, we had merged with Combustion Engineering
25 and we really had the benefit of working with the

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 Combustion Engineering steam generator designers and
2 the Westinghouse designers in bringing a larger
3 generator within their operating -- it had been within
4 their design experience.

5 VICE CHAIRMAN BONACA: The other thing I
6 notice there, you have very similar core between the
7 Belgium reactors and this but you have much less of
8 reactor cool and pump flow.

9 MR. CUMMINS: Excuse me, this is Ed
10 Cummins. When you compare steam generators and pumps
11 to Tihange, you need to consider that there are three
12 steam generators and three pumps in Tihange and two in
13 AP1000.

14 VICE CHAIRMAN BONACA: Yeah, thank you.

15 MR. CORLETTI: Yeah, see the vessel flow
16 is essentially the same.

17 VICE CHAIRMAN BONACA: Yeah, okay, right.

18 MR. CORLETTI: With AP1000 we have four
19 pumps, four reactor coolant pumps.

20 VICE CHAIRMAN BONACA: The other one has
21 three, all right.

22 MR. CORLETTI: Right.

23 VICE CHAIRMAN BONACA: That makes a
24 difference.

25 MR. CORLETTI: So these are some of the

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 key parameters comparing AP600 and AP1000 in the
2 reference plan.

3 Just quickly here, we see the reactor
4 coolant system. As you'll notice, it is two loops but
5 four reactor coolant pumps which is a different
6 configuration than the previous Westinghouse plants.
7 As I said, the reactor vessel is based on the 3XL.
8 It's the same outside diameter as AP600 but is a
9 longer vessel. The Delta 125 steam generators, the
10 use of canned motor pumps which is based on our naval
11 applications, a very high, reliable canned motor
12 pumps, eliminate seals, no seal injection, no need for
13 seal support.

14 Simplified main loop piping, eliminate the
15 cross-over line. This elimination of the cross-over
16 line improves a small break LOCA performance is one of
17 the inherent features of the AP600 and the AP1000.

18 VICE CHAIRMAN BONACA: How do you deal
19 with the coast down?

20 MR. CORLETTI: For the reactor coolant
21 pump, for the Navy applications, they have a very --
22 do not worry about coast down. For AP600 we designed
23 a high integrity fly wheel, we built it and tested it
24 and we've incorporated that in this design.

25 VICE CHAIRMAN BONACA: Okay, a fly wheel.

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 A VOICE: It's depleted uranium, right?

2 MR. CORLETTI: The -- it is constructed of
3 depleted uranium. It is totally sealed.

4 MEMBER POWERS: Why a 60-year design
5 lifetime and not 80?

6 MR. CORLETTI: Well, the regulations only
7 allow us 40 at this point in time. We've designed it
8 for 60 --

9 MEMBER POWERS: And you're going to go for
10 20.

11 MR. CORLETTI: Perhaps 70 years from now
12 we'll be talking about plant life extension.

13 MEMBER KRESS: And big steam generators
14 let you go to a power upgrade.

15 MR. CORLETTI: Right. You go into high
16 burn-up fuel, I'll tell you that.

17 What you see here is the passive decay
18 heat removal heat exchanger. This is one of the key
19 features of the passive safety systems. It is used to
20 mitigate transients. It replaces essentially the
21 safety grade emergency feed water and ox (phonetic)
22 feedwater. So it's designed for events like a loss of
23 normal feed. The passive heat exchanger is located in
24 the refueling water storage tank, inside containment.
25 It's located above the core on a low steam generator

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 water level. Valves are actuated and by natural
2 circulation, the heat exchanger provides core decay
3 heat to mitigate any of the transients that were
4 designed for.

5 MEMBER KRESS: Does the water boil there
6 in the transient?

7 MR. CORLETTI: Yes, the IRWST, the heat
8 capacity is such that after about an hour and a half
9 of continued operation, the tank would begin to boil,
10 but with the passive containment cooling, where
11 condensate then is condensed on the steel shell and
12 returned to the IRWST, the passive decay heat removal
13 can provide core cooling essentially indefinitely.

14 MEMBER KRESS: Is there a pump that takes
15 that back or is it gravity?

16 MR. CORLETTI: No, it's by gravity. The -
17 - it's got an arrangement on the containment shell
18 that returns the condensate back to the refueling
19 water storage thing.

20 MEMBER KRESS: That's just like the AP600.

21 MR. CORLETTI: Exactly like the AP600.
22 Now, the heat exchanger has been increased in surface
23 area roughly 20 percent. How we've -- we've kept the
24 capacity though in relation to the core power and
25 we've achieved that by making the inlet and outlet

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 piping a larger diameter so that reduces the
2 resistance to the natural circulation driving head and
3 we've been able to maintain a capacity about the same
4 factor as the core power. Because this is designed to
5 remove core decay heat, we had to maintain that sort
6 of a --

7 MEMBER KRESS: These two valves --

8 MR. CORLETTI: Those are fail open air
9 operated valves, yes, and they receive a signal on low
10 steam generator water level. Again, with AP600 and
11 AP1000 with defense in depth, we typically have non-
12 safety active systems which is the first line of
13 defense. You would have a loss of normal feedwater.
14 The start-up feedwater pumps would be actuated to
15 supply feed water to the generators.

16 If they would then fail, then the passive
17 decay removal heat exchanger is actuated.

18 MEMBER KRESS: Now, you indicate that the
19 four-stage ADS comes out of that vertical line. I
20 thought it came out of the hot leg.

21 MR. CORLETTI: It shares a connection.
22 The ADS 4 on that loop is actually -- is t'd off of
23 this inlet line.

24 MEMBER KRESS: T'd off of this line.

25 MR. CORLETTI: Yes. So it is connected to

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 the hot leg, it's very close coupled to the hot leg.

2 MEMBER RANSOM: At one time there was a
3 concern about the ability to model the heat exchange
4 and the vertical heat exchanger tubes. Were any
5 experiments done to verify the --

6 MR. CORLETTI: Yes, as part of AP600, we
7 did a full height, full pressure, full temperature
8 tests of vertical tubes to develop a heat transfer
9 correlation which we then validated our analysis codes
10 to that heat transfer correlation and also
11 demonstrated it with blind tests at the Rosa facility
12 which is one of the test facilities that was conducted
13 by the NRC and we had very good predictions of heat
14 transfer using that correlation.

15 MEMBER KRESS: Now, what's the issue then
16 with thermal plume there?

17 MR. CORLETTI: There is a -- the staff had
18 asked questions in regards to are you able to have
19 steam blanketing on the outside of the tubes. We
20 essentially showed that for the tests that we ran and
21 for the tests at Rosa that really that our heat
22 transfer correlation which is based on a modified
23 Rosenal (phonetic) correlation, was sufficient to
24 predict overall heat transfer.

25 I think the concern they had was could it

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 degrade the heat transfer of the heat exchanger? And
2 I think that we showed that through our tests and
3 through -- we did several sensitivity studies where
4 we --

5 MEMBER KRESS: Well, I recall in one of
6 the presentations or something that I read that if the
7 velocity exceeded a certain level, you had a problem
8 with that.

9 MR. CORLETTI: Okay, that is a -- that
10 question is specific to the no trump code (phonetic),
11 the LOCA Code. There was an issue there that for the
12 correlation that we use in the NOTRUMP code, if the
13 velocity was too high, it could be non-conservative.
14 For AP600 the velocity was not in the non-conservative
15 region but there is an issue, with AP1000 with the
16 higher flow rates, will your correlation --

17 MEMBER KRESS: Will you get into that?

18 MR. CORLETTI: Right, and what we're going
19 to have to do there as part of -- as part of design
20 certification is provide -- is take -- essentially
21 adjust that heat correlation so it is not -- so it is
22 no longer non-conservative with respect to our test
23 data.

24 And I think what the staff is requiring us
25 to do is provide a justification for that modification

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 to that correlation. So we will plan on doing that as
2 part of the --

3 MEMBER KRESS: The correlation is HA times
4 a delta T. My understanding was you're going to
5 adjust the A.

6 MR. CORLETTI: Right.

7 MEMBER KRESS: But since it's a product of
8 HA, it doesn't --

9 MR. CORLETTI: Right, that's right and
10 this is only for the NOTRUMP code.

11 MEMBER KRESS: And under certain --

12 MR. CORLETTI: For the loss of coolant
13 accident which really the passive chart is not a big -
14 - you know, it's not dominate in the loss of coolant
15 accidents. For the transients, there we've used the
16 modified Rosenal correlation that we based on our test
17 data. That's not a concern there.

18 MEMBER KRESS: It's okay, there.

19 MR. CORLETTI: Yes.

20 MEMBER KRESS: And that's in -- what code
21 is that?

22 MR. CORLETTI: That's in the LOFTRAN code.

23 MEMBER KRESS: The LOFTRAN, okay.

24 MR. CORLETTI: Here you see the passive
25 safety injection system for the AP600. I think this

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 is probably familiar to most of you, but the features
2 of passive safety injection, the accumulators, we have
3 two accumulators that are exactly the same for both
4 600 and 1000 and they're really sized to mitigate the
5 large break loss of coolant accident. Their size is
6 consistent with our operating plants today.

7 You have the core makeup tanks which are
8 aligned at very high pressure in case of a leak from
9 the reactor coolant system and they're able to provide
10 high pressure injection. They replace the high head
11 safety injection function in today's plants. They
12 also provide boration capability to mitigate steam
13 line breaks.

14 We also have the refueling water storage
15 tank which is there and we're going to be talking a
16 little bit more later to provide long-term safety
17 injection. As the pressure is reduced following the
18 loss of coolant accident, as the core makeup tanks
19 would drain, automatic depressurization valves
20 connected to the pressurizer designed to reduce the
21 system pressure to allow gravity injection from the
22 refueling water storage tank.

23 The final stage of depressurization is
24 achieved with the four-stage valves which are
25 connected to the hot leg and how we've differed the

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 design from the AP600, essentially the same
2 configuration has been maintained. We've maintained
3 the same elevations. The core makeup tanks are
4 increased approximately 25 percent and the line
5 resistance has been reduced to increase their flow
6 rates about 25 percent.

7 The low pressure portion, low pressure
8 injection portions of the system, including the ADS
9 stage 4, and the IRWST injection lines and the sump
10 injection lines have all been increased to -- in
11 relationship to core power to accommodate the higher
12 core power associated with those.

13 MEMBER KRESS: What does FAI stand for on
14 that?

15 MR. CORLETTI: That's a fail as is valve.

16 MEMBER KRESS: Fail as is.

17 MR. CORLETTI: That's what that means,
18 yes. Those are -- those four-stage valves are Squib
19 valves. They're explosively operated valves that
20 operate one time type operation. When the core --
21 following the loss of coolant accident, after the core
22 makeup tank has essentially been emptied. So you've
23 had a very large loss of coolant accident.

24 MEMBER KRESS: What causes the signal?

25 MR. CORLETTI: On a core makeup tank?

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 MEMBER KRESS: There's a level signal?

2 MR. CORLETTI: Yes, there's a 25 percent
3 level signal, 25 percent level in the core makeup
4 tank.

5 MEMBER KRESS: And it's explosive Squib
6 valve that once it goes, it's opened.

7 MR. CORLETTI: Yes, it opens, it opens.

8 MEMBER KRESS: And the steam just goes
9 into the containment there.

10 MR. CORLETTI: Right, I think my next
11 slide, for all accidents, we use passive containment
12 cooling, so for an accident like a steam line break or
13 a loss of coolant accident where steam is released
14 into containment. Water tanks at the top of
15 containment there we have a line that opens. We pour
16 water on the steel containment shell. There enters
17 these baffles that you see on the shield building and
18 down and pass over the containment shell and by
19 evaporative cooling, provide containment cooling to
20 mitigate all design basis accidents.

21 MEMBER KRESS: That feed line from the
22 water tank, it has a valve in it that's not shown
23 here?

24 MR. CORLETTI: Yes, in fact, for AP1000 we
25 actually have added a third -- there's actually three

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 lines, so as part of our PRA studies, we've added a
2 third diverse line for passive containment cooling.

3 MEMBER KRESS: Wide open so --

4 MR. CORLETTI: Those valves open on high
5 containment pressure or high containment temperature.

6 MEMBER KRESS: Okay, that makes sense.

7 MR. CORLETTI: The tanks on --

8 MEMBER KRESS: And where are those
9 measurements made?

10 MR. CORLETTI: Those are made from
11 instrumentation inside containment.

12 MEMBER KRESS: You mean, you have a bunch
13 of them redundant?

14 MR. CORLETTI: Yes, redundant, redundant,
15 at least, I believe we have four, four containment
16 pressure measurements.

17 The tank is sized for three days of
18 containment cooling flow. After three days we would
19 have water tanks and the dedicated pump to provide
20 water to replenish the tanks to provide core cooling
21 but even after -- on AP600 after three days, our
22 studies showed that air cooling was sufficient. Air
23 cooling is also sufficient to keep containment
24 pressure below the service level cease limits for the
25 containment.

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 MEMBER KRESS: Now, these are based on
2 your separate effects test with the large containment
3 vessel?

4 MR. CORLETTI: Well, yes, we performed a
5 slew of separate effects tests as far as basically to
6 get heat transfer correlations to apply for the
7 passive containment coolant, heat transfer
8 correlations for heat transfer across the containment
9 shell. Essentially, we've used them in a steady state
10 heat transfer correlations.

11 MEMBER KRESS: Right.

12 MEMBER POWERS: Where are those
13 documented?

14 MEMBER KRESS: There was a test basis
15 document that --

16 MR. CORLETTI: Right, for AP1000 we
17 submitted a test applicability -- I mean, our
18 applicability document that went through all of the
19 test programs for AP600 and showed how they were still
20 applicable for 1000. For AP600, we had -- there's
21 several different tests, either test reports or the
22 final validation report for Gothic which the Gothic
23 report showed the validations of the tests.

24 MEMBER KRESS: We got all those when we
25 reviewed AP600.

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 MR. CORLETTI: Right.

2 MEMBER KRESS: I don't know if we still
3 have them or not. I've got --

4 MR. CORLETTI: You know, there were
5 several reports.

6 MEMBER KRESS: They might have just been
7 sent to the Thermal Hydraulics Section.

8 MEMBER POWERS: None of this is very
9 hopeful because there's a mountain of information
10 here. Could somebody point me toward where all this
11 stuff is?

12 MR. CORLETTI: Sure.

13 MEMBER KRESS: Well, we'll get -- these
14 are sort of just for our information now because we'll
15 get a chance to go over all this again when we talk
16 about the recertification. This is just to orient us
17 more or less. I don't think there's any decisions
18 that have to be made regarding these things at this
19 point.

20 MR. CORLETTI: Yes, right. I think during
21 the review the crux of the review from this issue was
22 that were the tests that we performed for AP600, was
23 AP1000 still within the range of those tests that were
24 performed.

25 MEMBER KRESS: Yeah, that's the issue,

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 that's the issue.

2 MR. CORLETTI: And I think the staff's
3 going to report on their findings on that.

4 Just a couple slides just showing some of
5 the performance of the passive systems. You'll see,
6 here's a comparison for a large break LOCA showing the
7 large margins that the passive plants provide for
8 mitigation of a large break.

9 For AP600, peak clad temperature was less
10 than 1640 degrees fahrenheit. For AP1000 it will be
11 higher but we will be well within the regulatory
12 limits for it. Essentially, here the dominate
13 phenomena is not the passive systems, it's really the
14 accumulators and the core-stored energy.

15 This slide here shows a comparison for
16 small breaks, for small break LOCA margin. One of the
17 key features of the passive safety systems was that
18 the improved performance for small break where we
19 would not have core uncovering for these events, for our
20 current PWRs, for two-inch, three-inch sized breaks
21 where they're limited on safety injection flow
22 typically you would have a fairly decent, fairly
23 significant heat-up, still under the regulatory
24 limits.

25 Here you see for the passive plants

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 essentially you have no core uncoverly for the range of
2 small breaks. A couple others I just will real
3 quickly go; this just shows a comparison of our PRA.
4 This is another one of the benefits of the passive
5 systems, you see very low risk margins for AP600. We
6 expect AP1000 to have similar results.

7 MEMBER POWERS: I'm unfamiliar with the
8 requirement for -- NRC requirements. What are you
9 referring to there?

10 PARTICIPANT: The one times tenth to the
11 minus four core damage frequency for initiating
12 events.

13 MEMBER KRESS: It don't think it's a
14 requirement.

15 MR. CORLETTI: Probably it's a guideline,
16 I think. It's probably not a requirement.

17 MEMBER KRESS: Yeah, a guideline is a
18 better word.

19 MR. CORLETTI: Yes, I think that's fair.
20 And this last slide really shows you a comparison of
21 the size of the 600 compared to an evolution style
22 plant, I'm sorry, AP1000, compared to an evolutionary
23 plant. This is Sizewell. And you see with the
24 passive systems, that we've been able to achieve a
25 much simpler design and a much smaller plant footprint

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 because due to the modular construction the plant, the
2 whole plant is designed in modules and very much
3 smaller footprint than those in the past, such as the
4 Sizewell.

5 MEMBER KRESS: What's the power of
6 Sizewell?

7 MR. CORLETTI: Sizewell, yeah, we are
8 cheating a little bit there, about 3800 megawatts
9 thermal, we're 3400 megawatts thermal.

10 MEMBER KRESS: Not that much difference.

11 MR. CORLETTI: Yeah. I think Larry
12 talked about the scope of Phase II of this pre-
13 certification review that we've just finished and I
14 think the four major questions that we were looking to
15 answer in regards to the applicability of our test
16 program that we completed for AP600, as we said, we
17 completed a very thorough test program that was
18 extensively reviewed by ACRS and the staff. We're
19 looking to see the applicability of that test program
20 to AP1000.

21 And also then the AP set of analysis codes
22 that were validated against those tests, we plan on
23 using those codes too, in the design certification for
24 AP1000. And then the other two issues, the one is on
25 the issue of the use of piping design acceptance

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 criteria and the issue of the exemptions approved for
2 AP600.

3 That's all I have. I think I'm going to
4 turn it over to the staff now.

5 MR. BURKHART: Dueling slides. You've
6 seen this slide before. It's not a new one. It
7 reflects what Mike just stated as the scope of review
8 and here we'll start the staff's assessment. I will
9 discuss the applicability of the exemptions and the
10 DAC approach and Steve Bajorek from the Office of
11 Research, will discuss the applicability of the AP600
12 testing program and Ed Throm and Walt Jensen from NRR
13 will discuss the analysis codes.

14 PARTICIPANT: Do you have copies of these
15 slides, sir?

16 MR. BURKHART: Yeah, this was a previous
17 slide I had in my introduction. Okay, exemptions, the
18 applicability of the exemptions; the three exemptions
19 that Westinghouse plans to request for the AP1000,
20 this is a rundown of what the requirements are.
21 Section 50.34 (f)(2)(iv) additional TMI related
22 requirements regarding technical information contained
23 in application requires the safety parameter display
24 console, 50.62, requirements of the reduction of the
25 risk from ATWS requires diverse and automatic

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 initiation of auxiliary feed water, emergency feed
2 water and the third GDC 17 which requires two
3 physically independent offsite power sources.

4 A little more information added on this
5 slide, based on the design, the passive design of the
6 AP600, mostly, these exemptions, the request for
7 exemptions were granted for the AP600 and based on
8 meeting the special circumstance, that application of
9 the regulation is not necessary to achieve the
10 underlying purpose of the rule. And based on our
11 review, we believe that due to the similarity in
12 design between the AP600 and AP1000, that it's
13 appropriate to ask for these exemptions and expect
14 that they will be justifiable and the exemptions are
15 basically applicable. We will do the complete
16 detailed review during Phase III, the design
17 certification review.

18 Design acceptance criteria; I'd just like
19 to go over the requirements and how we've used the
20 design acceptance criteria approach in the past in
21 design certification reviews. The requirement in Part
22 52 is as stated; "An application must contain a level
23 of design information sufficient to enable the
24 Commission to judge the Applicant's proposed means of
25 assuring that construction conforms to the design and

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 to reach a final conclusion on all safety questions
2 associated with the design before the certification is
3 granted".

4 Not a prescriptive requirement, but pretty
5 clear on the intent. And after Part 52 was issued,
6 there were issues that came up on the level of detail
7 that was being provided in the ABWR and the System
8 80+. And where we start to get some clear direction
9 and guidance on the use of the DAC approach was in
10 SECY-92-053 and this is again during the review of the
11 System 80+ ABWR. The staff observed that applicants
12 weren't providing the level of information that we
13 thought we would get and this is where the DAC
14 approach first was discussed.

15 And the DAC, Design Acceptance Criteria,
16 are defined as, "A set of prescribed limits,
17 parameters, procedures, and attributes upon which the
18 NRC realized in a limited number of technical areas
19 that making a final safety determination to support a
20 design certification". And it was conceived that, you
21 know, this concept would enable the staff to make a
22 final safety determination as required by Part 52,
23 subject only to satisfactory design implementation,
24 verification by the combined licensee for appropriate
25 use of inspections, tests, analysis and acceptance

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 criteria.

2 And the staff concluded that you should
3 restrict the use of DAC to two cases where a design
4 area is characterized by rapidly changing technology
5 and thus, if you finalize a design at the design
6 certification phase, it may be obsolete by the time a
7 plant is actually built or design areas for which as-
8 built or as-procured information was not available.

9 And how we use it in design
10 certifications, for the ABWR the System 80+, we
11 approved the DAC approach for the I & C and control
12 room or human factors engineering areas due to the
13 rapidly changing technology aspects. We also, for
14 both of these design certifications, approved the DAC
15 approach for the piping and radiation protection areas
16 based on the lack of as-built or as-procured
17 information being available.

18 MEMBER KRESS: So you were able to approve
19 the piping DAC for ABWR and System 80+ without it
20 being a safety issue apparently.

21 MR. BURKHART: Correct, we were able to
22 come to a conclusion on all safety questions, right,
23 as required by Part 52.

24 MEMBER KRESS: And you feel like you can't
25 do that with AP1000?

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 MR. BURKHART: We're getting to that.

2 MEMBER KRESS: Okay.

3 MR. BURKHART: Our conclusions may be a
4 little bit different than what we discussed back in
5 February.

6 MEMBER KRESS: Okay.

7 MR. BURKHART: Okay, so chronologically
8 moving on to the AP600 design certification review, we
9 allowed the use of DAC in the I & C and control room
10 areas just as we did for the ABWR and System 80+, same
11 reason. However, piping back was not requested and it
12 wasn't used. And even though the as-built or as-
13 procured information wasn't available, Westinghouse
14 completed the piping design and they basically assumed
15 that information.

16 The DAC approach as proposed for the
17 AP1000, a little history here; originally,
18 Westinghouse proposed or it was discussed that DAC,
19 the DAC approach would be used in the I & C, the
20 control room, the piping, the structural and the
21 seismic areas for hard rock and non-hard rock sites.
22 And that was definitely expanding the use of DAC as
23 compared to what we had done before. And we had some
24 discussions with Westinghouse on our ability to come
25 to conclusion on all safety questions due to coupling

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 all of these together, especially the piping
2 structural and seismic areas.

3 We had some conversations and some public
4 meetings and voicing our concerns, and basically on
5 February 13th, Westinghouse revised their proposal for
6 the use of DAC to limit DAC in the I & C, control room
7 and piping areas. They would basically provide
8 sufficient information to preclude the use -- the need
9 to use DAC in the seismic and structural areas and in
10 that same letter, they provided more information
11 supporting why they should be able to use DAC in the
12 piping area.

13 So our assessment, we think the DAC
14 approach is acceptable for the I & C and control room
15 design areas, the same reason as we approved it for
16 the previous three design certifications, rapidly
17 changing technology. In the piping area, we do
18 recognize that Westinghouse completed the piping
19 design in the AP600 and due to the similarity, we
20 think there will -- we will realize the benefits of
21 standardization that they'll carry over from the AP600
22 to the AP1000 due to the similarity.

23 Westinghouse noted in their February 13th
24 letter that it gained very little regulatory benefit
25 by performing a detailed piping design because they

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 were still subject to pretty much the same ITAAC as
2 the ABWR and System 80+. And due to the similarities
3 in design, we find that the completed AP600 piping
4 layout and design provides a sufficient level of
5 detail to assure that the benefits of standardization
6 will be achieved for the AP1000 piping.

7 MEMBER RANSOM: I have one question on the
8 instrumentation and control, are these hard wired
9 plants, or have they gone to fiber optic pipe systems?

10 MR. BURKHART: Mike, do you know the
11 answer to that?

12 MR. CORLETTI: Yes, we do use a digital I
13 & C. We are hard-wired from the sense of to the data
14 highway but we have gone to the digital.

15 MEMBER RANSOM: So you have two
16 independent systems then?

17 MR. CORLETTI: We have three actually. We
18 have a safety related protection monitoring system.
19 We have the plant control system and we have a diverse
20 actuation system which is digital also but is diverse
21 to the protection system and it provides certain
22 protection type functions.

23 MEMBER RANSOM: Thank you.

24 MR. BURKHART: So based on the arguments
25 on the previous slide, we find that the piping DAC

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 approach is acceptable for the AP1000. However, just
2 as with any DAC, it's contingent upon being able to
3 agree with Westinghouse on adequate DAC. Again,
4 that's for any design acceptance criteria used. There
5 will be changes in piping size and we will have to
6 identify areas of concern. We think we can -- we can
7 be able to make -- come to a conclusion on all safety
8 questions but there are some areas where some changes
9 may cause us to focus, again, areas for Phase III,
10 design certification review and some of those areas
11 are listed here.

12 Now, the impacts of using design
13 acceptance criteria; it has a potential to increase
14 the likelihood of post-construction hearing petitions,
15 and to expand the scope of a hearing. Compliance with
16 a DAC can be subject of a hearing just prior to
17 operation, including those DAC that were intended to
18 be verified early in the construction process.

19 MEMBER KRESS: In other words, you're
20 moving towards what you used to do when you had to
21 have a construction permit and an operating permit.

22 MR. BURKHART: A little and I do want to
23 say that we're -- with allowing pipe DAC for
24 Westinghouse, we're not expanding the use of DAC
25 compared to what's been used before.

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 MEMBER KRESS: Because you did it before.

2 MR. BURKHART: Because we did it before.

3 In fact, Westinghouse -- well, ABWR and System 80+
4 used it for radiation protection. They're not using it
5 in this case. So the reason for approving the piping
6 DAC is a bit different than the reason we use for
7 approving the DAC approach for the ABWR and System
8 80+. That was, again, for as-built or as-procured
9 information not being available. We think because of
10 all the work that's been done on the AP600 and the
11 similarity of the design between the 600 and the 1000,
12 which the exact extent of that similarity will be
13 determined in the Phase III review, but because of the
14 work that's been done and the degree of
15 standardization we'll probably get from the AP600
16 design, that's why we're finding it acceptable for the
17 AP1000.

18 Well, that concludes the assessment of the
19 exemptions and the design acceptance criteria. Now,
20 Steve Bajorek from the Office of Research, to discuss
21 the staff's assessment of the applicability of the
22 AP600 testing.

23 MR. BAJOREK: Okay, thank you, Larry.

24 Good morning, my name is Steve Bajorek. I'm from the
25 Office of Research. What I'm going to talk about

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 hopefully over the next 20, 25 minutes or so is the
2 research evaluation of the test programs that
3 Westinghouse is using for the AP1000 and that were
4 done primarily in support of the AP600. As Larry and
5 Mike Corletti mentioned, as part of the AP1000
6 application, Westinghouse has proposed to use the test
7 programs that were used for the AP600 in support of
8 all of the data needs for the AP1000.

9 Their contention is that the data from the
10 AP600 programs is adequate. It's sufficient and it
11 covers the range of conditions that one would expect
12 for accident scenarios in the AP1000. The research
13 role was asked to come in and for those tests that
14 effected the primary system, evaluate those tests,
15 perform an independent evaluation and come up with our
16 own opinion on whether that data is truly acceptable.

17 What we did is we broke our evaluation up
18 into what I would consider three overall segments.
19 One, which I'll refer to as a top down scaling
20 approach which takes a look at the major interactions
21 of the system between other subsystems, how it
22 interacts with safety systems and how the system
23 behaves as a whole. We supplemented that with
24 simplified calculations. You might think of a first
25 principles thermodynamic evaluation looking at the

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 RCS, the flows into and out of the system in order to
2 get a better handle on the transient behavior as the
3 AP600 or AP1000 transitions from its high pressure
4 performance as the ADS 1/2/3 are on all the way
5 through to the IRWST injection phase.

6 Finally, we did another evaluation that
7 has been referred to as a bottom up scaling approach
8 that looks at those individual two-phased processes
9 that you really can't address very well, either with
10 simplified numerical calculations or in the top-down
11 scaling approach which really homogenizes everything
12 that goes on in the system.

13 You could spend a couple of days just
14 going over different top-down scaling methodologies
15 and what they entail. Essentially, what is done in a
16 top down scaling approach is to look at the mass
17 momentum and energy equations for a particular flow
18 circuit in a system and non-dimensionalize those and
19 then you look at those non-dimensional terms which
20 appear in front of each one of the major components of
21 that mass momentum or energy equation. This gives you
22 a set of dimensional groups, what we would refer to
23 as pi groups that you can compare from one facility to
24 the next and make a decision if the important
25 processes in the AP600 or the AP1000 are those same

NEAL R. GROSS

(202) 234-4433

www.nealrgross.com

1 things that occurred in the major integral test
2 facilities.

3 MEMBER KRESS: Let me ask you a question
4 about that. When you take these pi groups, you ratio
5 the -- say from 1000 to the test or to 600 and you say
6 that if that ratio for any one of these umpteen pi
7 groups falls in a range of .5 to 2, then that's an
8 acceptable range so that the phenomena you would
9 expect to be the same. My question is, how did you
10 arrive at that range and why is it -- why is it the
11 same range for every pi group ratio?

12 MR. BAJOREK: It necessarily isn't the
13 same range for every pi group. Let me just briefly
14 describe the overall approach.

15 MEMBER KRESS: Okay.

16 MR. BAJOREK: It's to take a look at these
17 dimensionless groups and if you -- the ratio of those
18 is between .5 and 2. Essentially, if everything is
19 within an order of magnitude it was deemed acceptable.
20 Now, in answer to your question on where I got that,
21 I got that from the AP600 review, used that as an
22 acceptability criteria. It was the tighter of the
23 acceptability criteria that was used. In some cases
24 it was between .3 and 3. Now, we didn't just base our
25 conclusion on all pi groups falling within that range.

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 Indeed, if you take a look at the test,
2 some of them fall without that, outside of that range.
3 We independently evaluate each one of those groups to
4 come up with a determination; one, is it really
5 important to the problem. In the INEL methodology
6 that we applied, one of the nice features is that the
7 pi groups are such that ones with very large values
8 are indicators, these are important. Ones with very
9 small values are effectively unimportant.

10 So when we looked at those --

11 MEMBER KRESS: That's like saying it's a
12 coefficient multiplying something that determines the
13 influence of that something in the equation. And you
14 know, I think it's both the size of the coefficient
15 and the something that determines. I mean, you have
16 to have -- you can't look at the coefficient by
17 itself.

18 MR. BAJOREK: Okay. I guess, you know,
19 the best I can say is we tried to follow what was done
20 in the AP600. We stayed on the tighter side of that
21 criteria. And when we did this we looked at things.
22 If they were outside of the range and distorted, we
23 tried to come up with a rationale, did it really
24 matter? And if it didn't matter, or if they were such
25 that the process in the AP1000 was going to be more

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 benevolent, have more mass in the system, behave
2 better than the tests, then you would assume that that
3 distortion was a conservative one and it would be
4 acceptable.

5 A real concern are those things that we
6 could identify as being very important to how the
7 AP1000 behaves and were not represented well in the
8 experiments. And usually, I think we would fine in
9 these scale groups they were fairly close to 1, 1.2,
10 1.3.

11 MEMBER KRESS: And those things came out
12 of the PIRT?

13 MR. BAJOREK: Yes, yes, or they fell
14 outside of that range. If we changed that range a
15 little bit, we would come up with essentially the same
16 conclusions. So I think that, yes, we did look at the
17 sensitivity to that and things that we will identify
18 as being important we think would fall outside of an
19 acceptability criteria even if you made it much
20 looser.

21 Okay, with respect to the top-down
22 scaling, the news is basically good here, in the use
23 of the AP600 integral tests. We looked at two
24 different scenarios, a one-inch cold leg break, a
25 double-ended guillotine of a DVI line, which tends to

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 be perhaps the most important of the transients,
2 looking at small break processes and we found that for
3 five -- four of the five major periods of the small
4 break and a long term cooling transient, tests that
5 were done in support of AP600 cover what we would
6 expect for the AP1000.

7 I show here on these bullets the five
8 different periods. Early in time, we see that the
9 AP1000 scales very well with SPES. In fact, AP1000
10 scales better with SPES than the AP600 did based on
11 the changes that were made to the system. If you go
12 further out in time, there weren't a tremendous amount
13 of changes that were made effecting the IRWST. The
14 sizes were larger but elevations which effected
15 driving heads didn't change that much, so again we
16 reached the conclusion that AP1000 scales fairly well
17 with APEX, the facility at OSU for the late phases.

18 Now, we do have what I might call a
19 difference of opinion with Westinghouse on the one
20 phase that transitions from high pressure to low
21 pressure. I refer to this as the ADS-4 blowdown.
22 Westinghouse claimed in their submittals that APEX,
23 the OSU facility, was valid and that data was good
24 throughout that period. When we do our scaling
25 evaluation we find that APEX starts to fall just

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 outside of that acceptability range but SPES remains
2 within that range.

3 So with regards to the test programs, we
4 would conclude, yes, the tests are available. During
5 this period we think SPES is probably the better one
6 to base your conclusions on code accuracy as opposed
7 to APEX but once you get down to lower pressure, APEX,
8 again, becomes the facility that you should base your
9 decisions on.

10 MEMBER KRESS: Is this one of your
11 bottoms- up scaling?

12 MR. BAJOREK: No, this is a top down.

13 MEMBER KRESS: This is top down.

14 MR. BAJOREK: This is top down.

15 MEMBER KRESS: So you're dealing with the
16 momentum and energy equations.

17 MR. BAJOREK: Yes, yes.

18 MEMBER KRESS: And what pi groups come out
19 of that? Are they --

20 MR. BAJOREK: Essentially --

21 MEMBER KRESS: Froude number?

22 MR. BAJOREK: Well, in this one it is a --
23 well, there's actually about 65 to 70 scaling groups.

24 MEMBER KRESS: Total, yeah, so they don't
25 all apply to APEX.

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 MR. BAJOREK: Total. They don't all show
2 up in each one of the periods. They change as you go
3 throughout. The Froude number and things like that,
4 that's for bottom up and we'll get to that in just a
5 second.

6 Now, one thing that we do note with the
7 ADS-4 blow-down and this is perhaps more of a critique
8 on the methodology itself, is it does make some
9 assumptions on what goes on in the tests and in the
10 AP1000 and one of those is that you have a certain
11 exit quality leaving the ADS. We stayed consistent
12 with the methodology. We didn't want to invent
13 anything new at this point but we did note that during
14 this period, those assumptions and the scaling groups
15 are relatively sensitive to your assumption in what is
16 that flow quality? How much liquid is leaving during
17 this period. And we thought, well, this is something
18 that means we should look at it in a little bit more
19 detail.

20 We continued with the bottom up --

21 MR. CORLETTI: Steve, could I just make
22 one comment? This is Mike Corletti, Westinghouse. In
23 regards to our code validation, we did validate our
24 codes to both APEX and SPES and typically we wanted to
25 have at least one of the facilities be well-scaled in

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 all of the regimes, so we did actually have acceptable
2 validation for one well-scaled facility for AP1000,
3 even.

4 MR. BURKHART: That's right and that's
5 basically what my conclusions say. Based on top-down,
6 you don't need any more data. It may be how we look
7 at what validation you did that's the determining
8 factor in how good the code is doing. But we went on
9 and we still want to look at the bottom up processes.
10 As part of that we set up a simplified model. It
11 looked that the RCS essentially is one node, takes the
12 mass equation, the energy equation and sets up
13 essentially a thermodynamics problem to look at the
14 shrink and swell of the phases, the flows into and out
15 of the system.

16 The conclusion that we get out of those
17 calculations is that regardless of what we assumed for
18 exit quality out of the ADS, the pressurization of the
19 system didn't change all that much. Now, that's
20 important because it says the delay time between when
21 you have CMT flow and that essentially stops and
22 you're waiting for the IRWST to come into the system,
23 that period of time stays about the same. But what
24 the sensitivity also showed us that we would very
25 drastically reduce the mass in the vessel, in the

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 AP1000 relative to the AP600 or the experimental
2 facilities at a rate at which suggested maybe we're
3 going to see some core uncovering because of this
4 uncertainty in the exit quality through the ADS.

5 That starts to point at things in a bottom
6 up evaluation. It says, well what would contribute to
7 a high amount of flow leaving the system, things like
8 entrainment in the vessel and in the hot leg. So this
9 starts to support some of our conclusions in the
10 bottom up scaling where we look at precisely those
11 phenomena that get missed in a top-down scaling.

12 And these are things in two-phase flow
13 which tend to act as cliffs, flow regime transitions.
14 Are you homogenous or are you stratified or annular?
15 Are you flooding in the surge line or are you not
16 flooding in the surge line? Entrainment is another
17 process by which you have a gas flow, there's no
18 entrainment. Higher gas flow, no entrainment.
19 Suddenly you reach a critical point and you have a
20 great deal of entrainment. So we looked at the bottom
21 up processes for flooding, flow regime transition and
22 again, I think the message should be that the news is
23 really quite good here because when we looked at
24 regime transition, flooding, core level swell and void
25 fractions again, they're not too far off from the

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 ranges that we saw in the AP600 tests.

2 The exceptions, the things that start to
3 stand up as important items to look at in Phase III
4 are two-fold. Both are related to entrainment; one in
5 the hot leg. The other I'll refer to as a pool type
6 entrainment. And this is entrainment that occurs at
7 the top of the core, between the top of the core and
8 the upper plenum.

9 MEMBER KRESS: Now, did any of the tests
10 have a way to determine what that particular
11 entrainment was?

12 MR. BAJOREK: Yes.

13 MEMBER KRESS: You were able to get that
14 out of some --

15 MR. BAJOREK: Yes, I'll jump ahead a
16 couple of overheads, but after the AP600 tests were
17 completed, the NRC ran what they called no reserve
18 tests. Now, these were tests in which you had mass in
19 the upper plenum, they turned on the power, evaporated
20 and swept out that liquid. It showed from the test
21 results that there was an unexpectedly high amount of
22 entrainment from the upper plenum pool.

23 MEMBER KRESS: You could compare the level
24 change with the amount of energy going in and if it
25 wasn't going out as steam --

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 MR. BAJOREK: It was going out as liquid
2 and they used the separator tanks also to catch that.

3 MEMBER KRESS: I was going to ask you, you
4 could catch it.

5 MR. BAJOREK: Yes.

6 MEMBER KRESS: Okay.

7 MR. BAJOREK: Now it wasn't a primary
8 focus in the APEX tests that were run integrally for
9 looking at one-inch cold leg breaks and you can't
10 really get it out of those. There's too many things
11 going on. But in these no reserve tests, they noted,
12 yes, this is a process that was going on and what
13 became bothersome is that RELAP calculations,
14 simulations of those events under-predicted the
15 entrainment, where when they ran the tests they got a
16 lot of entrainment, actually got the level into the
17 core. RELAP couldn't predict that. It was getting
18 too high a level.

19 Now, those tests are not a good indicator
20 of whether you will have core uncovering or not. But
21 they are indicative of the fact that for flows similar
22 to AP600, AP1000, you will have a lot of entrainment.
23 One thing I want to point out, there's two different
24 entrainment processes. We talked about this at the
25 combined subcommittee meeting a couple of weeks ago

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 and I want to make sure that we're clear on the
2 distinction.

3 One is entrainment in the hot leg and
4 we're looking over at this region of the figure where
5 gas that leaves the core goes into the hot leg. The
6 principal view that people have is that there's a
7 stratified level in the hot leg. The high gas
8 velocities entrained droplets from this stratified
9 layer and it gets swept into the ADS. Where we did
10 have some discussion and what I think a better view is
11 called for is, where we really expect the most
12 entrainment is when the levels are fairly high in the
13 hot leg.

14 It's not quite entrainment from a
15 stratified layer but what we've seen or I should say
16 some of us have seen in -- of some flow visualizations
17 that have been done at OSU is that you get entrainment
18 there but you also get most of your entrainment from
19 plugs intermittent flows that occur in the hot leg.
20 Now, trying to predict that, trying to scale that
21 leaves us at a loss. When we take the best
22 correlation that we can find, best we can say at this
23 point is we'd expect a lot more entrainment in AP1000
24 than what we would expect in the tests or in the
25 AP600, but we can't put a good number on that.

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 MEMBER KRESS: In other words, it's kind
2 of self-limiting as the level gets down --

3 MR. BAJOREK: It may well be. I think my
4 point on this is this is something that we cannot say
5 at this point has been well scaled in the tests but
6 keep in mind, when it occurs, there's a lot of water
7 in the system. This is up close to the top of the hot
8 leg.

9 MEMBER KRESS: Yes, so one asks the
10 question, does it really --

11 MR. BAJOREK: It is --

12 MEMBER KRESS: -- from the standpoint of
13 safety?

14 MR. BAJOREK: My point here is, is the
15 data acceptable to evaluate these models in the code?
16 That's one question. Well, even if they aren't, then
17 those models are not doing a great job, the other
18 question that needs to be answered, I think, in Phase
19 III is how safety significant is that? The answer
20 that's still open, okay, and we have our opinions on
21 that at this point is, well, is this really going to
22 be important to the safety of the plant and uncovering
23 of the core if you aren't predicting this properly.

24 My opinion is probably not, but we've got
25 to get --

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 MEMBER KRESS: It's kind of a race.
2 You've got the decay heat driving stuff off and if you
3 -- and it's going down and if you've thrown out too
4 much already, you're starting from lower level, it
5 means you're going to dip farther into the core
6 depending on how much that was.

7 MR. BAJOREK: Right, right. Now, this
8 process goes away when you start to get down into the
9 core and --

10 MEMBER KRESS: Does this -- does the fact
11 that you now have a 14-foot core instead of a 12-foot
12 one impact on this at all?

13 MR. BAJOREK: Not this because the upper
14 plenum hardware has remained the same.

15 MEMBER KRESS: Oh, the same.

16 MR. BAJOREK: Unless I've missed it, Mike.
17 Upper plenum elevations and that hardware is identical
18 to the AP600.

19 MEMBER SIEBER: What's the distance from
20 the top of the core to the bottom of the hot leg?

21 MR. BAJOREK: I estimate it as 1.82 meters
22 based on some numbers that I had, six feet or so.

23 MEMBER SIEBER: Six feet.

24 MR. BAJOREK: Yeah, and that's to the top
25 of the active part of the core. The core plate is a

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 few inches off of that.

2 Now, I think what you were referring to,
3 Dr. Kress, was the other entrainment process that
4 starts to become dominant if you have scenarios that
5 lead to a two-phase level that drops below the top of
6 -- the bottom of the hot leg.

7 MEMBER KRESS: Yeah, that's what I was
8 concerned about.

9 MR. BAJOREK: Now, this gets away from the
10 slugging and stratified entrainment in the hot leg but
11 it's a different physical process by which you have
12 gas bubbling through a pot, in this case liquid
13 trapped in the upper plenum, entrains these droplets
14 and if that gas velocity is high enough, it sweeps
15 those out through the ADS.

16 Now, where this starts to get our
17 attention is in the double-ended guillotine break of
18 the DVI line, where calculations done by both the
19 staff and Westinghouse suggest that that level will
20 drop and reach a minimum, I think it's about a foot
21 above the core, more or less. Our question now is, if
22 you do not predict that adequately, are you looking at
23 a level that remained in the upper plenum or
24 potentially drops into and uncovers the top part of
25 the core?

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 So we focused more of our attention on
2 scaling this process from a bottom up viewpoint. And
3 on page 8, I put a little bit of that -- those numbers
4 and some of the scaling criteria that we used to take
5 a look at this process. First, this is something that
6 does show up being highly ranked in the PIRT. Okay,
7 this is Westinghouse's and what we also believe to be
8 correct it this is a truly important process,
9 especially for this double-ended guillotine break of
10 the DVI line.

11 And as I mentioned just a few minutes ago,
12 tests that were done after the AP600 program, did show
13 what when you had the two-phase level below the bottom
14 of the hot leg, I did have significant amounts of
15 entrainment and that we had a very difficult time
16 trying to determine how much should be entrained in a
17 calculation using RELAP. Now, there's a flock of
18 correlations that have been proposed to take a look at
19 this. The chemical industry very interested in
20 separations processes, so we see an amount of work.

21 Principally, what happens is it depends on
22 one, what's the gas velocity as you bubble through
23 this pool and secondly, how far to you have to entrain
24 a droplet before it goes up and out of your system.
25 So it's basically two parameters which are dominant in

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 these correlations.

2 MEMBER KRESS: E is defined as the ratio
3 of the mass of liquid to the mass of vapor?

4 MR. BAJOREK: Right. It's a mass of the
5 liquid -- it's the liquid flux over the gas flux.
6 Okay, and it's a dimensionalist way of representing
7 the entrainment. Looking at the correlations that we
8 find to be closest to the AP1000 in the test and we
9 did find those to be in the same range, okay, we find
10 that this relative entrainment scales to J_g , the gas
11 velocity to the third, maybe the fourth power.

12 MEMBER KRESS: That's looking at these
13 correlations you say exist.

14 MR. BAJOREK: Yes.

15 MEMBER KRESS: I mean, it doesn't come out
16 of this. It just --

17 MR. BAJOREK: These are correlations that
18 were done. There was some work done in Russia to take
19 a look at this. Ishii had done some work at Argonne.
20 There had been some other work. They all basically
21 suggest that E scales with J_g to the third, fourth or
22 higher power.

23 So I defined a scaling ratio based on
24 those correlations and if you assume, as I think we've
25 just heard, AP600 has the same upper plenum hardware,

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 same geometry but you increase the power by 75, 76
2 percent, you can very quickly estimate that the AP1000
3 should have at least five times the amount of
4 entrainment that occurred in the AP600.

5 MEMBER KRESS: Now, this is decay heat
6 driving this.

7 MR. BAJOREK: This is decay heat driving
8 the --

9 MEMBER KRESS: So you wouldn't quite
10 expect the same ratio of decay heat as due to the
11 power, would you?

12 MR. BAJOREK: Well, no, we did take that
13 into account. Yes.

14 MEMBER KRESS: Oh, the 75 is --

15 MR. BAJOREK: Yeah, the decay heat goes up
16 by 75 percent.

17 MEMBER KRESS: Okay.

18 MR. BAJOREK: So the power -- depending on
19 when you look in the transient, that's scaled power
20 still goes up by 75 percent. Now, there are some
21 differences in pressure and in what that scale power
22 was in the facility and we sharpened our pencil and we
23 looked at those and we found that SPES or AP1000 would
24 have over 100 times the amount of entrainment as the
25 SPES facility, roughly 20 times what you saw in ROSA

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 facility.

2 APEX, only about six, somewhere between --
3 well, I estimated 6.3. APEX is a lot closer. It still
4 is a bit of a concern because the way APEX got closer
5 was not because of the gas velocity being correct for
6 the entrainment but the fact that it was a one-quarter
7 facility. So we're looking at it in -- from the
8 viewpoint that APEX is closest at this point. It's
9 distorted in a non-conservative direction but the one-
10 quarter height may actually save some of those test
11 results so that eventually they may be able to be
12 applied to the AP1000.

13 But our conclusion to date is looking at
14 this process, which was ranked high by Westinghouse,
15 using the best information we have, we find that none
16 of these test facilities were appropriately scaled to
17 capture this phenomena which we think is going to be
18 important in determining whether we have uncoverly or
19 not in the AP1000. So by conclusion --

20 MEMBER KRESS: So your concern, though, is
21 only on this upper plenum entrainment --

22 MR. BAJOREK: That's basically --

23 MEMBER KRESS: -- and not at the ADS-4.

24 MR. BAJOREK: We think we still need to
25 take a look at entrainment in the hot leg. The

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 question is, well, how does this effect other parts of
2 the transient and you may want to use those results to
3 make other decisions, not just on whether you have
4 core uncoverly or not.

5 MEMBER KRESS: So there's two areas of
6 entrainment, the ADS-4 and then the other one is --

7 MR. BAJOREK: The other is the hot leg. In
8 one case, I think it's a lot easier to make the
9 argument it may not be safety significant. And I
10 think that's the distinction. So by conclusion, we
11 should lost sight of the fact that by and large those
12 tests for AP600 are still valuable. They cover --
13 they answer an awful lot of questions for the AP1000.

14 We feel there are a couple of issues, a
15 couple of problems that stand out as exceptions to
16 that. Both involve entrainment. As we looked at the
17 RAIs, information that was submitted to Westinghouse
18 and results of our own independent investigation, at
19 this point we conclude that Westinghouse has not
20 demonstrated that the test data is adequate for
21 validation for these processes and we suggest that
22 they and we need to come up with either alternative
23 data, a different criteria for scaling or some new
24 test results in order to close out these issues and we
25 think this is going to be something that we need to

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 look at in Phase III.

2 MEMBER SIEBER: Has that decision been
3 made yet, which of the three approaches?

4 MR. BAJOREK: No, we've -- in the SECY, I
5 believe the language is such we're leaving this open
6 for discussion. We're not saying you've got to go out
7 and run tests because there may be other entrainment
8 tests that can be used. They may not just be what was
9 done in the original AP600 test.

10 MEMBER SIEBER: But of all the phases,
11 this is the most important because it results in the
12 loss of inventory.

13 MR. BAJOREK: Yes, this one is going to
14 basically show us do you have core uncovering and some
15 clad heat-up or not in the AP1000. Now, again, I
16 think there's -- you can do some other work looking at
17 how quickly you should lose liquid from the upper
18 plenum. Again, you may be able to demonstrate that
19 the uncovering that you expect is not going to be
20 significant or that it's going to take so long to get
21 that last bit of liquid out of the upper plenum,
22 again, your concern may not be justified.

23 But at this point, the data doesn't bound
24 the types of things that we expect in the AP1000.

25 MEMBER KRESS: If more data were needed,

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 can APEX be used to produce that data?

2 MR. BAJOREK: I think so. In fact, I
3 think that a series of tests could be run in the APEX
4 you should do something to the no reserve but you do
5 it under steady state. Okay, they still had
6 complications in the no reserve because they started
7 from a high pressure and flashed a lot of liquid. Run
8 some steady state tests to get the effluent and the
9 exhaust flow rate and bench mark these correlations
10 which we still have questions about. I mean, these --

11 MEMBER KRESS: What would you do about the
12 H difference?

13 MR. BAJOREK: The H difference, I think,
14 can be addressed, although I would not do that in the
15 APEX facility itself. There is a sister facility out
16 at OSU called ATLAS. It has the same diameter vessel.

17 MEMBER KRESS: ATLAS. That's the one we
18 saw.

19 MR. BAJOREK: That's the one we saw but
20 they didn't have anything in their upper plenum, okay,
21 or above the core. But they do have some nice
22 visualizations and working with plexiglass and lower
23 pressure is a lot easier than messing around with
24 APEX, where you have all the instrumentation. I think
25 it would be very feasible to put in upper core plate,

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 simulated upper internals, a couple of DP cells and
2 try to get at some of these same things. There you
3 could, I think, fairly easily change your upper plenum
4 geometry, okay.

5 You could put in what I'd call a donut in
6 the upper plenum to restrict some of the flow and
7 change your gas velocities or change the height of the
8 core plate and get at some of those things. So an
9 answer, yeah, I think APEX would help. I think maybe
10 that sister facility may be a better place of
11 exercising some of these parameters that apparently
12 effect the correlations.

13 MEMBER SIEBER: Just stepping back and get
14 the big pictures. ADS operates to get the pressure
15 down enough so that you can inject from the
16 accumulators. Roughly, what is that period of time
17 from the time that ADS-4 begins to operate until the
18 accumulators inject and I'm sure it's a function of
19 break size.

20 MR. BAJOREK: Yeah, it's -- I believe that
21 what happens in like a double headed guillotine
22 transient is that the accumulators come in while
23 you're still depressurizing. The length of time then
24 between ADS -- or excuse me, accumulator injection and
25 the time you actually get the IRWST is on the order of

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 several hundred seconds. Mike, do you remember that?

2 MR. CORLETTI: Yeah, the core makeup takes
3 time to drain in about 20 minutes and then after that,
4 the ADS-4 is actuated and IRWST injection can occur
5 immediately to some time there's a delay a hundred,
6 couple hundred seconds. It ranges, as I said, based
7 on the break size. But it's not a long duration and
8 essentially once you get the IRWST injection, we're
9 flooding in the vessel in the hot leg and so we're up
10 to, you know, a lot of water, a lot of water in the
11 system.

12 MEMBER SIEBER: Now, once ADS-4 operates,
13 it's there forever, right? It's open.

14 MR. CORLETTI: It's open, yes.

15 MEMBER SIEBER: Open to the containment
16 forever. All right, okay.

17 MR. CUMMINS: This is Ed Cummins. There
18 is actually a black valve that you could close but
19 that's not the intention. The intention is that the
20 steady state safety case remains open.

21 MEMBER SIEBER: Right.

22 MEMBER KRESS: But even then, steam
23 condenses on the walls and goes back to the IRWST.

24 MEMBER SIEBER: Yeah, there's a recipro
25 path that -- yeah.

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 MR. BAJOREK: Okay, well, thank you and I
2 think the next presentation is by Ed Throm and he's
3 going to talk about the containment issues.

4 MR. BURKHART: This is Larry Burkhart just
5 to be clear, our assessment on the codes testing and
6 exemptions issues we documented in a letter to
7 Westinghouse, not in a SECY.

8 MR. THROM: Good morning, my name is
9 Edward Throm and I'm with the Plant Systems Branch and
10 I'll be going over the WGOthic computer program review
11 that was done for the AP1000 Phase II evaluation.
12 WGOthic is the computer program that Westinghouse uses
13 to evaluate the design basis accident response of the
14 containment to double-ended guillotine primary LOCAs
15 and main steam line breaks.

16 The code is described in WCAP 14.407 and
17 basically WGOthic is an extension of the numerical
18 applications incorporated GOTHIC 4.0 computer program
19 and what Westinghouse did was included a model in the
20 code called a Clime which represents the heat transfer
21 modeling to look at the condensation on the inside
22 surface, through the wall and the evaporation of the
23 PCS water flowing down the outside of the vessel.

24 The staff's evaluation was presented in
25 NUREG-1512. It covered the scaling studies, the part

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 studies, the testing program, a description of those
2 parts of GOTHIC that we reviewed, our review of the
3 Clime model and our overall conclusions on the
4 acceptability of what we came to call an evaluation
5 model for doing these types of analysis.

6 The evaluation model basically consists of
7 the use of the lumped parameter modalization process
8 in the WGOTHIC program. We believe that the lumped
9 parameter approach is applicable based on looking at
10 the buoyancy of the jets Froude number scaling, also
11 in looking at international test programs such as the
12 Patel model containment and the HDR which showed that
13 you would get a fairly well-mixed environment for all
14 parts of the transient.

15 One issue that we had to deal with was the
16 large scale test facility. It was not really scaled
17 for transient applications, so there were a lot of
18 questions on the circulation, stratification and
19 mixing of the steam environment within the
20 containment.

21 Westinghouse has addressed these in
22 conservative manners. Two address circulation, for
23 example, after the blow-down period, they don't take
24 any credit for steam that might get into the dead-
25 ended compartments below the deck. So they're not

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 trying to take any credit for any mixing that the code
2 might be calculating because of the uncertainties.
3 Stratification is also a concern with potentially
4 creating an air blanket on the operating deck which
5 will be a relatively large heat structure, so they
6 don't take any credit for the operating deck as a heat
7 structure in the analysis.

8 Also for horizontal surfaces that may get
9 condensing pools on them, they also don't count those
10 as heat structures. The other things that are done in
11 the evaluation model, is the PCS flow and mass and
12 heat transfer models are conservatively used. They
13 use minimum PCS flows in the massive heat transfer
14 models. They apply multipliers onto essentially bound
15 the uncertainty in all the data that went into
16 developing these models.

17 The AP1000 is a little bit different than
18 the AP600 as been noted before. The power level is
19 quite a bit higher, about 75 percent. The vessel
20 itself is about 25 feet higher. It's a slightly
21 larger volume. In looking at the PIRT and looking at
22 the fact that the AP1000 is using the same mechanism
23 for heat removal, we didn't see any changes in the
24 PIRT rankings of the important phenomena. There were
25 a couple of issues that we were concerned with in

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 going up to the AP1000.

2 One of them was whether or not the shell
3 temperature would get above 212 degrees Fahrenheit
4 before the PCS water came on. If that were to occur,
5 then we would have a problem with the model for the
6 film. We'd have to consider boiling of the film and
7 potentially breakup of the film. Westinghouse did
8 calculations that showed that at the time the PCS
9 water would be credited in the calculation. The shell
10 is only going to be about 180 degrees, so we don't
11 have to be concerned with that particular problem.

12 The other one was in looking at the
13 increased power and basically size of the AP1000 and
14 the stored energy and mass is somewhat larger than the
15 AP600. So the question was, are the massive heat
16 transfer correlations still being used within their
17 applicable range. And that was pretty much the focus
18 of the review was to go out and look at the mass and
19 energy, the heat fluxes that had to be addressed in
20 the correlations.

21 Okay, then in summary, no new phenomena
22 were identified in the process and the PIRT rankings
23 remained unchanged. The heat transfer models and
24 correlations are being used within their applicable
25 range. This is based on scoping studies that

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 Westinghouse performed provided to the staff in
2 December of last year in which they looked at most of
3 the dimensionalist groups and found that the expected
4 performance of the AP1000 would fall within the
5 applicable ranges of all the data upon which these
6 correlations were based.

7 So we basically feel that WGOTHIC when
8 used with the evaluation model, is applicable to the
9 AP1000. The lumped parameter, mixing, we expect it to
10 be a well-mixed environment. They're still using the
11 same conservative approaches in addressing circulation
12 stratification and heat transfer. In Phase III there
13 are some things that we need to go back and look at
14 because the scoping analysis were not done completely
15 in accordance with the evaluation model but they're
16 very close.

17 They have not applied what they call their
18 evaporated flow model. And this is just a model that
19 adjusts the PCS flow to only take credit for the
20 amount of water that you could evaporate. The
21 standard review plan has mechanisms or guidelines for
22 calculating the mass and energies from both LOCA and
23 steam line releases. The LOCA analysis that was in
24 the scoping analysis is not quite in conformance with
25 what we expect to see in the design certification

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 analysis but we don't believe that that's a problem.
2 Also in the scoping analysis that Westinghouse did,
3 they looked at the ADS-4, IRWST and sump flows based
4 on the AP600. There's going to be some changes to
5 those in the long term and defining the mass and
6 energies that you have to account for in the process.

7 So during Phase III we will go back and
8 look at those evaluations again and we will --
9 Westinghouse, I believe, is committed to providing us
10 with similar evaluations to demonstrate that the codes
11 are still being applied within the applicable ranges.

12 I don't see any particular problem with
13 the expected changes in those but we reserve the right
14 to assure ourselves that we haven't gone outside the
15 applicability of the code. We have done Contain 2.0
16 audit calculations for the scoping analysis. We got
17 a very good comparison for the steam line break where
18 the passive containment cooling system is not really
19 a contributor to the peak pressure calculation.

20 We did do the large break LOCA
21 calculation. We did not do it for a licensing case
22 but we did it for the one of the reference cases that
23 Westinghouse provided us back in December 2000 we
24 calculated a peak pressure of about 54 psia compared
25 to that calculation which would have calculated about

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 60 psia. The contained two code is designed to be a
2 best estimate code for all practical purposes.

3 We did to a sensitivity study that tried
4 to mimic the penalties or multipliers that
5 Westinghouse applies to the heat transfer correlations
6 and we got about a two psi increase which we would
7 expect. We've not yet attempted to model or remove
8 any of the other heat structures from the contained
9 code to see if we could actually predict all of the
10 conservative features that are in the evaluation model
11 that Westinghouse uses with WGOTHIC. We do plan to
12 perform audit calculations as part of the Phase III
13 review once the mass and energies are finalized and
14 Westinghouse provides us with the detailed information
15 to make sure we've got all the volumes and heat
16 structures that we do apply in the code properly
17 marked.

18 So we believe that the WGOTHIC code is
19 applicable to the AP1000. That it will be used within
20 its range of applicability in terms of the mass and
21 heat transfer models that Westinghouse developed for
22 the PCS. That's all I really wanted to say this
23 morning.

24 MR. BURKHART: Great. Now, we'll turn it
25 over to Walt Jensen to discuss the applicability of

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 the reactor codes.

2 MR. THROM: Thank you.

3 CHAIRMAN APOSTOLAKIS: No, if he wants to
4 stand, he can stand. Do you want the mobile
5 microphone?

6 MR. JENSEN: I'm Walt Jensen of the
7 Reactor Systems Branch of NRR and I was responsible
8 for the review of the LOFTRAN, NOTRUMP codes that will
9 be used by Westinghouse for analysis of AP1000. The
10 LOFTRAN code is used by Westinghouse for non-LOCA
11 transients, including steam generator tube rupture and
12 it's used with other codes to assess the maximum
13 reactor system pressure, fuel temperature and the DNBR
14 that might be obtained.

15 The NOTRUMP code is used for small break
16 LOCA but in the time between a break occurs and stable
17 flow is established from the IRWST. After that the
18 WCOBRA track code is used for long term cooling
19 evaluation. And the staff did detailed reviews of
20 both these codes for operating plants in the mid-
21 1980's and again for AP600 and wrote an SER in 1998.

22 The review process that we took just these
23 codes that have already been reviewed in some detail
24 in the past. We looked at the differences that might
25 effect the analysis between the AP600 and the AP1000

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 plants. In particular the PRHR heat exchanger carries
2 a greater heat exchanger carries a greater heat load.
3 Steam generators are larger and the ADS-4 is larger
4 and carries more flow and has a greater role in small
5 break LOCA mitigation than it did for AP600.

6 We looked at the scaling, which you've
7 just heard about, of the tests that were used to
8 qualify the codes for AP600 to see if they would still
9 be qualified for AP1000. We obtained the Westinghouse
10 standards for generating input to the codes and this
11 is important because both codes are very versatile and
12 allow many user options. And Westinghouse has
13 established the set of options that should be used to
14 analyze the passive plants and we reviewed those.

15 And then we performed independent audit
16 calculations using RELAP5. We looked at a main steam
17 line break, small break LOCA. We got similar results
18 as Westinghouse for small break LOCA, but we did get
19 a very minimal amount of core uncover for the double-
20 ended DVI injection line break. We took a look at the
21 limits in NOTRUMP and analyzing the PRHR heat
22 exchanger and we looked at the hot leg velocity and
23 how it might effect the entrainment going out of ADS-
24 4.

25 First, conclusions with LOFTRAN, we found

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 LOFTRAN was capable of analyzing the anticipated
2 transients and accidents, non-LOCA, for AP1000.
3 However, the steam line break is still open.
4 Westinghouse has not performed the steam line break
5 for AP1000 and we are concerned that the voiding in
6 the reactor system might extend beyond the capability
7 of the LOFTRAN code, though they have done one
8 preliminary calculation of steam line break that shows
9 there to be very low voiding.

10 The NOTRUMP code, we also found that to be
11 acceptable with the following exceptions that are
12 still open, and number one is the liquid entrainment
13 out of the -- which began in the core into the upper
14 plenum and out of ADS-4. Westinghouse has proposed to
15 bench mark the NOTRUMP code which has a very
16 rudimentary entrainment model against the WCOBRA tract
17 that they've modified with correlations to predict
18 entrainment and then they will bench mark that WCOBRA
19 tract code against experimental data which is still
20 under discussion with the staff.

21 Perhaps we will do some sensitivity
22 studies with RELAP to see the effect of entrainment on
23 the core. The conservatism of the PRHR heat exchanger
24 model is still under review. There's a limitation in
25 NOTRUMP to limit the code to flow rates in the primary

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 side of the PRHR heat exchangers to less than 1.5 feet
2 per second and this is based on a limit in the heat
3 flux comparisons with the experimental data by the
4 time correlations that's used in NOTRUMP that was
5 found to be non-conservative in comparison to the
6 experimental data for high heat flows.

7 So we'll be looking at that but
8 preliminary studies here show that the PRHR heat
9 exchanger flow has a very small effect on the course
10 of a small LOCA. And finally, we only looked at a few
11 breaks with either RELAP or NOTRUMP and the
12 entrainment issue is still open and this will effect
13 the results. So if core uncovering is calculated, we
14 will have to take up the review of the core uncovering
15 models in NOTRUMP and in the SBLOCTA code that's used
16 to evaluate the final core temperature when the core
17 is uncovered.

18 So that's where we stand at the end of
19 Phase II and we will be continuing the review in Phase
20 III. Thank you.

21 MR. BURKHART: Thanks, Walt. Just a quick
22 summary, again, the scope of Phase II was limited to
23 four issues. You've seen this slide before, this was
24 from my introductory slides. As you've heard in
25 general, the AP600 testing program and analysis codes

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 are applicable to the AP1000 design. We've noted some
2 exceptions and where we will focus our efforts on the
3 review during the design certification review.

4 We've also shared that the staff finds the
5 DAC approach in the I & C, human factors, control room
6 design and piping areas acceptable and also that the
7 three exemptions that are proposed for AP1000 are
8 applicable. And that concludes our presentation of
9 the staff's assessment. I'll turn it over to Mike for
10 Westinghouse's presentation.

11 MR. CORLETTI: We'll have Bill Brown, will
12 be our next presenter, will be presenting some of the
13 issues in regards to the applicability of the tests in
14 response to Steve Bajorek's presentation.

15 MR. BROWN: Okay. PIRT scaling and
16 entrainments assessment; Steve's already covered a lot
17 of this which we pretty much agree on most points, and
18 that is that there is no new phenomena expected for
19 AP1000 and we've already submitted our scaling
20 analysis to demonstrate that our 5600 test facilities
21 are applicable to AP1000. We previously presented
22 this work to both the NRC and the ACRS subcommittee.

23 Obviously, there were some issues
24 discussed here with respect to entrainment, especially
25 in the upper plenum and because of that, we went back

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 and did some additional evaluation and some scaling
2 which I'll present here in a moment. Before I do
3 that, though, I thought it was maybe a little bit
4 helpful in that I tried to come up with a -- sort of
5 an integral effect type of a slide to put this
6 entrainment a little bit in a system level
7 perspective. I know we kind of have focused on this
8 a lot from a very separate effect level and it
9 certainly is something that is considered to be high
10 ranked or important during the ADS to IRWST transition
11 phase of the transient but I think we need to keep in
12 mind a couple of things that are going out during this
13 time frame as well as not only do we have stuff going
14 out but we've also got potentially a lot of stuff
15 going in.

16 And one of the biggest things to always
17 keep in mind is that we've got roughly a 600,000
18 gallon tank sitting up here after the core make-up
19 tank, which is continuing to drain through the ADS-4
20 as well, that is certainly willing to sit there and
21 feed whatever entrainment that might be going along,
22 but based on our testing and a lot of the analysis
23 that we had done on the AP600, what we would expect to
24 see here which we had seen in AP600, is more of a
25 situation where you might start off in a phase where

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 you've got the ADS-4 is on and been actuated and is in
2 here venting steam to reduce the RCS pressure.

3 We've got injection from a core makeup
4 tank and then later here with a significant amount of
5 water from the IRWST potentially available here to
6 inject. We've got liquid perhaps in a first phase
7 being entrained from the upper plenum due to the high
8 steam flow associated with the AP1000. We would
9 expect some amount of phase separation in the hot
10 legs.

11 Some of the de-entrained liquid here would
12 initially start to accumulate somewhat in the hot leg.
13 We would expect that this process would continue. As
14 Steve mentioned earlier, we probably wouldn't
15 initially get a significant amount of entrainment
16 through the ADS-4 at this point until we reach a
17 critical inception level within the tanks so that the
18 velocity is high enough and to draw it, sort of a
19 Bernoulli effect, sort of sucking the water out of the
20 hot leg, so that we continue replenishment here in the
21 IRWST.

22 The ADS-4 would still be venting and
23 eventually we hit this point where we begin to hit an
24 inception point we now begin to entrain the liquid up
25 into the vents. At that point, then, as we would draw

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 the liquid up into the vents at this point, now you've
2 got the vents now that were predominately venting
3 steam out probably got to clear this liquid out, so at
4 that rate we'd probably see a bit of a reduction in
5 the amount of injection but on the other hand, now you
6 don't have a nice path for the steam to go out any
7 more, so now you've temporarily got a lower velocity
8 of steam and so you've got an entrainments reducing.

9 So the system is kind of correcting itself
10 here a bit and it's clearing itself purging the liquid
11 out. So eventually you clear out, so again you get
12 the pressure back down, you've vented the steam here,
13 so now you can resume to inject more water and entrain
14 more liquid out here and the process would then repeat
15 and we would see this going on through the long-term
16 cooling phase.

17 So that just sort of sets up a little bit
18 of the, I think, more of a system level effect to put
19 the local entrainment into context for you.

20 MEMBER SIEBER: If I look at the slide 9
21 and compare it to your drawing, it looks like ADS-4
22 comes off the line at the next ER of EST to the hot
23 leg, instead of as you show it there where it comes
24 in.

25 MR. BROWN: The ADS-4 here?

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 MEMBER SIEBER: Yeah.

2 MR. BROWN: The ADS-4 comes off the top of
3 the hot leg.

4 MEMBER SIEBER: Now, the IRWST line comes
5 in the same place, right?

6 MR. CUMMINS: This is Ed Cummins. I think
7 the thing that you're looking at is the PRHR heat
8 exchanger.

9 MEMBER SIEBER: Okay.

10 MR. CUMMINS: The PRHR heat exchanger is
11 a tank within the IRWST. It is connected to one of
12 those two ADS four lines.

13 MR. BROWN: Off the top of this line right
14 here, you would have a connection from PRHR off of one
15 of these ADS-4s that continues up and then that comes
16 up into here which is the exchanger sitting in the
17 tank here.

18 MEMBER SIEBER: All right.

19 MR. CUMMINS: If you look at slide 10, in
20 your presentation, all the injection from the core
21 makeup tanks to the accumulators and the IRWST for
22 make up to the reactor vessel, is through two direct
23 vessel injection lines which are basically independent
24 of other lines.

25 MEMBER SIEBER: Okay, I see that. Thank

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 you.

2 MR. BROWN: In fact, we finally see in the
3 tests that the PRHR actually helps to provide
4 fissional depressurization because it does condense
5 more steam.

6 MEMBER POWERS: Can you give me a feeling
7 for during this period where you have entrainment what
8 the superficial gas velocity through the core region
9 is?

10 MR. BROWN: Through the core region
11 itself? Well, obviously not as -- I think really the
12 highest velocity you could get is through the upper
13 core plate. That's really the highest velocity that
14 you get. It's pretty substantial. I'm trying to
15 remember what that was off-hand. Steve, do you
16 remember? Is it 100 feet a second or something like
17 that? I think it's pretty high. And it's moving up
18 through there, yeah, yeah, to the core plate and then
19 you would expand into the upper plenum where you --

20 MR. BAJOREK: This is Steve Bajorek for
21 Research. I don't exactly remember the velocity at
22 the core plate. However, in the AP1000 your
23 superficial velocity through the upper plenum, the
24 free part was about two and a half meters per second.
25 So given that there was a restriction down at the core

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 plate, three to four maybe.

2 MR. BROWN: It's probably somewhere
3 between those to if you want to try to bound that,
4 yeah. It's definitely higher than AP600.

5 Well, I just wanted to start with that
6 one, just to sort of put it in sort of a system level
7 context, so Steve's gone over some of this before.
8 We've looked at the -- first of all in the upper
9 plenum entrainment. Some of the work by Katoaka-Ishii
10 looked at full entrainment in vessels and identified
11 a near surface region and a momentum controlled
12 region.

13 The near surface region, very, very close
14 to the water surface, was found to correlate simply on
15 a density ratio. The momentum controlled region,
16 where you would move further away from the surface of
17 the liquid, was found to be a function of density
18 ratio, hydraulic diameter, viscosity number, but
19 primarily most strongly upon superficial gas velocity
20 divided by a dimensionless height. So it's really a
21 combination of the two of the J_g star and an H star
22 which are really the dominant terms in the momentum
23 controlled regime.

24 And to help you a little bit we're trying
25 to put this again, in context in terms of what type of

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 events might this be of interest to us or what type of
2 events would we be looking at things where we have,
3 for example, a level in the hot leg, we would be more
4 interested in what is the near surface type of
5 entrainment where we essentially have water already in
6 the hot leg, we're not having to lift it up from the
7 vessel into the hot leg, it's already there, versus
8 events where we would get into a momentum controlled
9 regime where we've got to actually lift the water
10 droplet up into the hot leg.

11 If you think of some of the two slides
12 that Steve just presented, you can see a good -- he
13 had a better picture of that than I do. These would
14 give you an idea of the type of events that we've seen
15 not just from analysis but also from looking back at
16 the OSU tests for example, and all the test programs.
17 Typically, the half inch, the one inch, the two inch
18 cold leg breaks, the hot leg break, two inch DVI and
19 the doubled ended core make-up balance line break, all
20 typically have a level within the hot leg already. So
21 for those events we've got a level in the hot leg.
22 We're in this near surface entrainment regime and
23 looking at the scaling. This indicates that we're
24 simply a function of a density ratio and since we
25 essentially have pressure scale facilities, the

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 scaling is good.

2 So the one in which we have a momentum
3 controlled regime where we don't have a level in the
4 hot leg, really is the DE DVI line break. So this is
5 really the focus of all this. So we even talk about
6 entrainment, you know, trying to put it in a system
7 level context and now in terms of events, which ones
8 are we focused in on. So we really, if you look at
9 all these tests, we're well scaled as far as
10 entrainment is concerned.

11 In the hot leg, for example, we've got
12 mixture levels in there and it's really only the DE
13 DVI line break that we really need to focus in on. So
14 based upon looking at this type of pool entrainment,
15 similar to the work of Kataoka-Ishii, we would say
16 that the entrainment is well scaled in the test
17 facilities for small break LOCAs where we've got a
18 mixture level in the hot leg, which was most of the
19 small break LOCA events I just listed, where pressure
20 is preserved and therefore, density.

21 It's in this momentum entrainment,
22 momentum controlled regime in which we're dependent
23 upon the superficial gas velocity divided by height in
24 which we have a potential distortion in the AP600 test
25 facilities due to the fact that we do have a higher

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

(202) 234-4433

www.nealrgross.com

1 superficial gas velocity in the AP1000 core.

2 MEMBER RANSOM: Excuse me, what is the
3 dimensionless height? Is that just a height through
4 the outlook flow?

5 MR. BROWN: Yes, it's basically, if you
6 did a measurement, yeah, it's basically how far do you
7 have to lift up a droplet in order to carry it away,
8 right.

9 MEMBER KRESS: How do you non-
10 dimensionalize it?

11 MR. BROWN: It's non-dimensionalized, I
12 think, it's got a square root of density difference,
13 gravity and surface tension. I think that's how it's
14 -- so essentially, again, if you have a pressure scale
15 facility, you're just looking at just dimensional H
16 really and the velocity. And we are at this time in
17 the transient, we've essentially depressurized in the
18 facilities. We're to the point where you're really
19 looking at just J_g divided by H, dimensional.

20 It gives you a little better idea, I guess
21 on the next page here. I tried to put this together
22 a little bit in another way to digest this
23 correlation. Some of the details are down below, but
24 essentially if you were to start off with the
25 correlation here that Steve presented earlier, that

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 you've got the J_g divided by H star cubed and the
2 viscosity number and the hydraulic diameter number,
3 you can eventually -- you can relate this for pressure
4 similitude and for saturated conditions in the vessel.
5 You can come up with an expression for J_g and come up
6 with a simple expression like this where you've got
7 core power, area, height, and the hydraulic diameter
8 ratio here as far as looking at entrainment in a pool
9 type situation. So this is really the basis for which
10 to look at.

11 And the key is, is obviously, this term
12 right here is really the -- obviously, the dominant
13 term, the core power and the height and the area.
14 When you try to take this scaling ratio and put some
15 numbers into it, similar to the question you asked Dr.
16 Powers about the velocity and so on, if you sort of
17 range the velocity through the upper core plate up
18 into the upper plenum, you would come up with a number
19 in this range of roughly a quarter to a half, which,
20 you know, based on our criteria, the half were here,
21 based on the criteria that was used previously by
22 Brookhaven for AP600, at roughly a third, it kind of
23 looks like we're -- you know, we're kind of close.

24 So you know, we find that we're certainly
25 in the range at which I think Westinghouse would say

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 that, well, there may be a possible distortion, we're
2 certainly on the non-conservative side, as Steve says,
3 but we don't think that this distortion is very far
4 off that we can't use this data for code validation
5 purposes for AP1000.

6 The next step, I sort of tried to ask
7 myself a little bit presented before to the
8 subcommittee was, well, what does this -- what might
9 this correlation look like? If I were to come up with
10 a little simple model of an upper plenum mode where I
11 had really no water in the hot leg and I was just
12 worried about I've got some mixture level sitting up
13 above the core in the upper plenum at the bottom of
14 the hot leg and what if I put in this pool entrainment
15 correlation and essentially assume that the core decay
16 heat was driving it off. I had just enough liquid
17 here or mass flow to make up and match decay heat at
18 that time. Well, what might happen and how long might
19 it take for this entrained liquid to effect the upper
20 plenum level?

21 So I come up with sort of a simple little
22 model here in which I had a transient conservation of
23 mass here for the upper plenum and I just started with
24 the upper core plate to the bottom of the hot leg as
25 this initial two-phase region. And I used a simple

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 void fraction correlation using the YEH correlation
2 here to determine void fraction in this area right
3 here. And then I used the upper -- for the upper
4 plenum entrainment, then I used the pool entrainment
5 correlation form from Kataoka-Ishii here to try to
6 determine what was the mass flux of the liquid that
7 was entrained out of this mass and then from a
8 conservation of mass on the core, and I just for
9 conservatism I decided not to even account for any of
10 the sub-cooling which might help me here and said,
11 well, even if I just simply have saturated conditions
12 in the core here, what might my steam generation rate,
13 steam velocity be?

14 So then I did this, and I put this into
15 MathCAD. This is the result I got which showed that
16 very, very quickly, extremely quickly, I approached
17 sort of a quasi-steady state level above the top of
18 the core plate here and within seconds, I reached an
19 equilibrium level. So, very, very quickly this very
20 strong function of entrainment, this J_g really dropped
21 me very rapidly but then, of course, remember that
22 it's J_g over H and so H very quickly restores you into
23 sort of a self-limiting type process and so at some
24 point you very rapidly settle out at a steady state
25 level.

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 So it kind of gives you a feeling of what
2 the -- how the correlation and the behavior should be
3 for this type of entrainment. So what I concluded
4 from this was that are entrainment was sufficiently
5 scaled in the upper plenum for all possible events
6 with the exception of maybe the DE DVI line break in
7 which we didn't have a hot leg -- a level up in the
8 hot leg for very long there during this phase. And
9 that the entrainment scaling was really of concern
10 during this transition phase of the DE DVI vent where
11 we were subject potentially to this momentum
12 controlled regime. That this distortion in OSU does
13 not appear to be so large that would render our codes
14 unusable and that the momentum controlled regime, the
15 entrainment in the upper plenum here seems to be
16 somewhat of a self-limiting process because we've got
17 the J_g relative to H and because of this, we don't
18 expect to really see that there's going to be a
19 serious safety issue here with AP1000.

20 We also looked at hot leg entrainment as
21 well, and we expect to see a stratified type pattern,
22 although certainly Steve says we may see some slugs in
23 there and that's possible. I don't expect to see
24 cliescent (phonetic) stratified flow but we certainly
25 expect to see something that's stratified.

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 There's a Froude number type correlation
2 with a length to diameter of up-take type of
3 correlation which is responsible for predicting the
4 onset of entrainment from the flow into the hot leg,
5 into the ADS-4 and this was used to scale this.

6 The results of the scaling indicated that
7 our Froude number seemed to be acceptably scaled to
8 AP600 and AP1000. The real difference was in the
9 dimensionalist ratio of liquid level in the hot leg
10 relative to the ADS-4 pipe, which would indicate,
11 which I would agree with Steve, we would expect to see
12 -- we would expect to see entrainment begin at a lower
13 level in the hot leg in AP1000 relative to AP600 and
14 OSU.

15 However, I guess I'd say on the other
16 hand, the fact that we've got a level in the hot leg
17 and we're looking at those type of events, it's not
18 something I think that's quite as much of a concern.
19 We probably would accumulate less water in the hot
20 legs, however, usually having the hot water -- having
21 the level in the hot leg would tend to indicate we've
22 got core coverage. So we're certainly not as
23 concerned about that event than we would where we're
24 going to go below the hot leg potentially in events
25 such as a DE DVI event.

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 So some of our plans for trying to address
2 this situation in Phase III, we're going to
3 demonstrate through calculation and analysis that the
4 entrainment phenomenon in the upper plenum and hot leg
5 during this limiting small break LOCA does not
6 challenge the safety and see it as sort of using a
7 term of extreme entrainment here would be addressed on
8 one of several ways; assessing margins relative to the
9 regulatory limits, adjusting upper plenum/hot leg
10 correlations to increase entrainment, assessing upper
11 plenum de-entrainment due to the reactor vessel
12 internals, also potentially increasing pressure drop
13 in the ADS vents such as whenever the liquid is being
14 discharged through there and we plan to submit a
15 topical report to address this later this year in
16 June.

17 The overall conclusions that I have from
18 the testing and scaling, again, no new phenomena in
19 AP1000. The separate effects and integral effects
20 tests are acceptably scaled. Upper plenum
21 entrainment, there's a local effect that appears to be
22 self-limiting. We don't think additional testing is
23 required.

24 MEMBER POWERS: Can I ask a question?

25 MR. BROWN: Yes.

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 MEMBER POWERS: Which you showed was a
2 simple calculation --

3 MR. BROWN: Yes.

4 MEMBER POWERS: -- in which you had an
5 entrainment and then you had water feed.

6 MR. BROWN: Uh-huh.

7 MEMBER POWERS: And you said, gee, it
8 starts at one level and it comes to another level.

9 MR. BROWN: Right.

10 MEMBER POWERS: It seems to me that that's
11 an unremarkable conclusion for a first order
12 differential equation with a source and a think term
13 to come to another level. That has nothing to do with
14 the entrainment correlation. It has to do with the
15 fact that you've got a loss term and a gain term.
16 They balance each other if you go out long enough in
17 time.

18 MR. BROWN: That's true, but I think I'm
19 just trying to demonstrate the fact that I think
20 sometimes when the entrainment is presented, people
21 tend to forget about the fact that there is -- that in
22 looking at certainly the relative order, that there
23 certainly is a restoring term in there for H as far as
24 how far that level is.

25 MEMBER POWERS: But that calculation

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 doesn't show that. I mean, the calculation only tells
2 me a loss term and a gain term and the relative
3 magnitudes of those two will determine where that
4 balance is.

5 MR. BROWN: Yeah, and well, we're not
6 trying to make -- at this point, not trying to make
7 any claims about the absolute value of where that
8 steady state level is. I'm not trying to make any
9 claim about that at all. I mean, certainly this is a
10 very simple calculation.

11 MEMBER POWERS: I thought what you were
12 claiming that this was self-limiting because as that
13 H got bigger and bigger it reduced that J over H term
14 to --

15 MR. BROWN: Right.

16 MEMBER POWERS: -- the point that -- and
17 that's just not obvious to me that that's the case at
18 all.

19 MR. CUMMINS: Hello, this is Ed Cummins.
20 I think what Bill did in his calculation just for
21 simplicity, he set the in-flow equal to the out-flow
22 so that the mass was -- the core was covered and what
23 he was trying to assess was the effect of -- the
24 separate effect of entrainment, which is the same
25 thing that Steve was trying to assess. It's not the

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 whole integral effect.

2 So if you assess the separate effect of
3 entrainment, what is the effect of H and J_g working
4 together for the entrainment phenomenon and I think
5 those things suggest that at some level J_g dominates
6 and then after awhile H corrects it.

7 MR. BROWN: The point is to try to find
8 out at what H do we come to some kind of a steady
9 state. I mean, I agree that it's a steady state
10 calculation. I mean, eventually we're getting to that
11 point, but there is an H associated with that J_g in
12 which you balance and the question I have the interest
13 is, is well is it something that looks like it's, you
14 know, a foot or two away or is it 20 feet deep or how
15 far into this thing does it look like it goes and so
16 that was of some use.

17 MEMBER POWERS: I can make that carried
18 out, just by changing your inlet term.

19 MR. BROWN: Well, it was driven by the
20 decay heat in this case. I mean, the decay heat was
21 driving the mass flow which was representative at this
22 point in the transient. So yes, if I picked a
23 different decay heat, sure I would get a different
24 value and this certainly should decrease over time.

25 MR. CUMMINS: If you deal with -- Ed

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 Cummins again. If you deal with the entire system
2 performance, then the top down scaling is appropriate
3 and whether you get in-flow and out-flow depends
4 mostly on the relative pressure drop between the
5 forced states and the pressure available from the
6 IRWST. But as we, I think pretty much agree with the
7 staff, the top down scaling for the AP1000 is
8 acceptable and we happen to be now looking at a bottom
9 up scaling for a particular phenomena which is pool
10 entrainment from the upper head pool and what we were
11 trying to show that performance with some simple
12 calculation to give you a feel for what the
13 characteristics were.

14 MR. BROWN: I mean, it's very similar to
15 some of the things we had done in AP600, looking in
16 the containment. I mean, we all felt eventually that
17 we would, for example, remove the energy through the
18 containment shell. What the question is, is at what
19 temperature would the inlet -- the flow through there
20 balance and that's simply what I was trying to get at
21 was, okay, given that this entrainment occurs, what
22 would be the height at which I would reduce to given
23 the core power which would, again, influence the
24 velocity, at what height at which I would be able to
25 balance the entrainment relative to the flow that was

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 coming in? That's all I was trying to get at.

2 MEMBER POWERS: And again, let me control
3 the source term and I can make that height anything
4 you want.

5 MR. BROWN: Again, I would agree that if
6 we put a different flow rate in there, we'll come to
7 a new value. It's just that I was using typical
8 values that we got from our safety analysis code at
9 the time in which ADS-4 went off to represent to you
10 what might that look like at the time when ADS goes
11 off. And so we went into the code and said, okay,
12 what's the decay heat during that period and said,
13 okay, this is how many BTUs per second we're putting
14 into this point, this is the energy that's driving
15 this. What does that -- what might that steady state
16 height come out to be?

17 Any other questions?

18 MR. CUMMINS: Yeah, I think it's important
19 that we have not completed the calculation in the
20 topical report we plan to submit. When you use the
21 appropriate decay heat for the point of -- the point
22 of time for the transient, I think, you're right, you
23 could put any heat level in you want and drive any
24 answer, but when you put the appropriate decay heat
25 level, we'll have -- essentially we'll see a delta on

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 what the level could be.

2 MR. BROWN: Yeah, and we were curious
3 about that ourselves, so we decided to try it and see
4 what it looked like.

5 MEMBER KRESS: Do you have this model
6 built into your code?

7 MR. BROWN: Not this specific one like
8 this, no, but again, this was again, sort of a --

9 MEMBER KRESS: I mean, the entrainment.

10 MR. BROWN: -- yeah, what would this look
11 like if we were --

12 MR. CUMMINS: Ed Cummins again. I think
13 when we deal with both injection and venting, we go
14 back to the system level performance and we get away
15 from the local effects. And if you remember I think
16 both the staff and Westinghouse feel that on a system-
17 wide basis, the AP1000 scaled well to the test and on
18 a system-wide basis we would expect that the level
19 predicted would be scaled.

20 MR. BROWN: Anyway we do intend to do a
21 topical in which we would actually to certainly some
22 more rigorous calculations here and so on. This was
23 just in the time frame that we could get to present
24 was to get some sort of an order of magnitude of what
25 we were looking at relative to the best information we

1 had as far as decay heat and so on at the time, the
2 best estimate of a velocity we could get there.

3 Yes, Steve.

4 MR. BAJOREK: This is Steve Bajorek from
5 Research. I guess I just want to kind of add to it.
6 Our concern is a couple fold on this. As we look at
7 things from a top down system-wide level, okay, we
8 would agree that most things are okay. However, when
9 we have to look at these bottom up processes, we have
10 to limit ourselves to the steady state behavior and on
11 that basis we are restricted because the correlations
12 that are developed, we have questions on whether they
13 apply strictly to the geometry that we're now trying
14 to extend those two.

15 Secondly, when it goes back to the system-
16 wide effects, we have to add flashing terms back into
17 this. And when we look at both of those occurring
18 simultaneously, this leads to our concern and question
19 that even on a system-wide basis, should we be
20 concerned with additional liquid being flushed out of
21 this upper plenum.

22 So I think at this point we would still
23 disagree with the statement that APEX is well-scaled
24 for this particular process.

25 MEMBER KRESS: Okay, we have what --

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 MR. BROWN: Michael just has a --

2 MR. CORLETTI: Yeah, and I could probably
3 summarize right from here. I think Bill's pretty much
4 summarized our conclusions. Our conclusions with the
5 tests in regard to the applicability of the tests
6 remembering the four issues we were asking the staff
7 to approve here was the applicability of our AP600
8 test to AP1000. We believe we've shown that by and
9 large these tests are applicable and we believe are
10 sufficient for certification for AP1000.

11 The one issue that does remain is this
12 effect of entrainment. We believe we'll be able to
13 demonstrate that when you take it in context with the
14 large margins we have, and not only margin to core
15 uncovering but also margin to regular limits as far as
16 peak clad temperature are essentially -- for instance
17 for one of the loss of core accidents for AP600 where
18 we did have core uncovering that's for the 10-inch
19 break, we had a core heat up of 400 degrees PCT
20 because it was a very short duration.

21 We had -- essentially, this plant is not
22 a small break LOCA limited plant and we will be able
23 to show a very large margin to regulatory limits in
24 that regard. So I think in that context, this is why
25 we believe we'll be able to demonstrate that in our

1 topical report with that sort of a bounding
2 calculation.

3 With regards to our analysis codes, we are
4 -- our conclusions were that they are largely
5 applicable to -- they are applicable to AP1000 and
6 then will be able to be used for design certification.
7 There are certain conditions that the staff has pretty
8 much made clear. They've spelled them out here and
9 our plan is to follow those conditions as far as
10 design certification.

11 In regards to the other issues on the
12 piping DAC and I think we are in agreement with the
13 staff's position on that.

14 MEMBER KRESS: Okay, thank you very much.
15 I think that brings us to the end of this session.
16 We're running a little late. At this time I'm going
17 to declare a break until 11:00 o'clock and some of us
18 will not come back, including our chairman.

19 MEMBER POWERS: And I won't be back here
20 either.

21 MEMBER KRESS: So we won't have a quorum.
22 so I guess we're recessing now till 1:00 o'clock.

23 MEMBER POWERS: And I don't think you need
24 the Reporter any more, do you?

25 MEMBER KRESS: And I think this is the end

CERTIFICATE

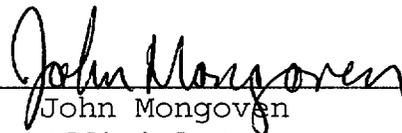

This is to certify that the attached proceedings before the United States Nuclear Regulatory Commission in the matter of:

Name of Proceeding: ACRS 490th Meeting

Docket Number: (Not Applicable)

Location: Rockville, Maryland

were held as herein appears, and that this is the original transcript thereof for the file of the United States Nuclear Regulatory Commission taken by me and, thereafter reduced to typewriting by me or under the direction of the court reporting company, and that the transcript is a true and accurate record of the foregoing proceedings.
