Docket No. 50-529

Mr. William F. Conway Executive Vice President Arizona Public Service Company Post Office Box 52034 Phoenix, Arizona 85072-2034

Dear Mr. Conway:

SUBJECT: ISSUANCE OF AMENDMENT NO. 34 TO FACILITY OPERATING LICENSE FOR THE PALO VERDE NUCLEAR GENERATING STATION, UNIT 2 (TAC NO.75372)

The Commission has issued the enclosed Amendment No. 34, to Facility Operating License No. NPF-51 for Palo Verde Nuclear Generating Station, Unit 2. The amendment consists of changes to the Technical Specifications (Appendix A to the license) in response to your application dated November 6, 1989.

The amendment revises those portions of the Technical Specifications regarding Shutdown Margin, Control Element Assembly Insertion Limits, Axial Shape Index, and Departure From Nucleate Boiling Ratio Margin, in support of Cycle 3 operation for Palo Verde, Unit 2.

A copy of the related Safety Evaluation is also enclosed. A Notice of Issuance will be included in the Commission's next regular biweekly <u>Federal</u> Register notice.

Sincerely,

original signed by Sheri Peterson

Terence L. Chan, Senior Project Manager Project Directorate V Division of Reactor Projects III, IV, V and Special Projects Office of Nuclear Reactor Regulation

PALO VERDE NUCLEAR GENERATING STATION, UNIT NO. 2

AMENDMENT TO FACILITY OPERATING LICENSE

Amendment No. 34 License No. NPF-51

- 1. The Nuclear Regulatory Commission (the Commission) has found that:
 - A. The application for amendment, dated November 6, 1989, by the Arizona Public Service Company (APS) on behalf of itself and the Salt River Project Agricultural Improvement and Power District, El Paso Electric Company, Southern California Edison Company, Public Service Company of New Mexico, Los Angeles Department of Water and Power, and Southern California Public Power Authority (licensees), complies with the standards and requirements of the Atomic Energy Act of 1954, as amended (the Act) and the Commission's regulations set forth in 10 CFR Part I;
 - B. The facility will operate in conformity with the application, the provisions of Act, and the regulations of the Commission;
 - C. There is reasonable assurance (i) that the activities authorized by this amendment can be conducted without endangering the health and safety of the public, and (ii) that such activities will be conducted in compliance with the Commission's regulations;
 - D. The issuance of this amendment will not be inimical to the common defense and security or to the health and safety of the public;
 - E. The issuance of this amendment is in accordance with 10 CFR Part 51 of the Commission's regulations and all applicable requirements have been satisfied.
- 2. Accordingly, the license is amended by changes to the Technical Specifications as indicated in the enclosure to this license amendment, and paragraph 2.C(2) of Facility Operating License No. NPF-51 is hereby amended to read as follows:

(2) Technical Specifications and Environmental Protection Plan

The Technical Specifications contained in Appendix A, as revised through Amendment No. $_{34}$, and the Environmental Protection Plan contained in Appendix B, are hereby incorporated into this license. APS shall operate the facility in accordance with the Technical Specifications and the Environmental Protection Plan.

3. This license amendment is effective as of the date of issuance.

UNITED STATES NUCLEAR REGULATORY COMMISSION WASHINGTON, D. C. 20555

SAFETY EVALUATION BY THE OFFICE OF NUCLEAR REACTOR REGULATION

RELATED TO AMENDMENT NO.34 TO FACILITY OPERATING LICENSE NO. NPF-51,

ARIZONA PUBLIC SERVICE COMPANY, ET AL.

PALO VERDE NUCLEAR GENERATING STATION, UNIT 2

DOCKET NO. STN 50-529

1.0 INTRODUCTION

By letter dated November 6, 1989 (Ref. 2), the Arizona Public Service Company (APS) on behalf of itself, the Salt River Project Agricultural Improvement and Power District, Southern California Edison Company, El Paso Electric Company, Public Service Company of New Mexico, Los Angeles Department of Water and Power, and Southern California Public Power Authority (licensees), requested changes to the Technical Specifications for the Palo Verde Nuclear Generating Station, Unit 2 (Appendix A to Facility Operating License No. NPF-51). The proposed changes would revise those portions of the Technical Specifications regarding Shutdown Margin, Control Element Assembly Insertion Limits, Axial Shape Index and Departure From Nucleate Boiling Ratio Margin, in support of Cycle 3 operation for Palo Verde, Unit 2.

In support of both the Technical Specification changes and Cycle 3 operation, the licensees submitted a Reload Analysis Report by letters dated October 24, 1989 (Ref. 2), and April 16, 1990 (Reference 3).

The staff's evaluation of the reload analysis is presented in Section 2.0 through 5.0 below. The evaluation of the specific change to the Technical Specification is presented in Section 7.0 below.

The Cycle 3 core will consist of 241 fuel assemblies. Sixty-nine Batch B and 28 Batch C assemblies will be removed from the Cycle 2 core and replaced by 96 unirradiated Batch E assemblies. All Batch D assemblies and 36 Batch C assemblies from the Cycle 2 core will be retained. In addition, one Batch B assembly discharged at end of Cycle 1 will be reinserted. Burn-up distribution is based on a Cycle 2 length of 420 effective full power days (EFPD). Cycle 3 control element assembly patterns and in-core instrument locations remain the same as in Cycle 2.

2.0 EVALUATION OF FUEL DESIGN

2.1 Mechanical Design

The 96 Batch E assemblies to be added to the Cycle 3 core are identical in

design to the Cycle 2 Batch D assemblies except for changes to the poison rod assembly, the lower end fitting, and center guide tube.

The poison rod assembly was increased in overall length from 160.918 inches to 161.168 inches to improve burnup capability and reduce end-of-life internal pressure. The two-piece lower end fitting was replaced by a one-piece casting with a recess for the center guide tube. The length of the center guide tube was increased from 163.715 inches to 163.965 inches to make it compatible with the redesigned lower end fitting.

The above design changes represent minor improvements which do not affect the fuel mechanical design basis. We therefore find these changes acceptable. Also, based on previous staff reload evaluations, clad collapse analyses of new C-E manufactured fuel do not need to be performed because of the absence of gaps between fuel pellets.

2.2 Thermal Design

The thermal performance of Cycle 3 fuel was analyzed using the NRC-approved FATES3A code and composite fuel pins that envelope the pins of Batches B, C, D, and E. A power history that enveloped the power and burnup levels of the peak pin at each burnup interval, from the beginning of cycle to the end of burnup, was used. The maximum peak pin burnup analyzed bounds that which is expected at the end of Cycle 3. Based on this analysis, the internal pressure in the most limiting fuel rod will stay below the nominal reactor coolant system (RCS) pressure of 2250 psi. Because this satisfies Standard Review Plan (SRP) Section 4.2 criteria, we find the thermal design of the Cycle 3 core to be acceptable.

3.0 EVALUATION OF NUCLEAR DESIGN

3.1 Fuel Management

A general description of the Cycle 3 core is given in Section 1.0. The Cycle 3 core uses a low-leakage fuel management scheme where previously burned Batch C assemblies are placed on the periphery and most of the fresh Batch E assemblies are located throughout the core interior in a pattern which minimizes power peaking. The highest Batch E enrichment is 4.03 weight percent U-235; the PVNGS fuel storage facilities are approved for a maximum enrichment of 4.05 weight percent U-235. Expected Cycle 3 lifetime is 430 EFPD. A comparison of the Cycle 3 nominal characteristic physics parameters with those of Cycle 2 shows very little deviation between the two cycles.

3.2 Power Distribution

Calculated "all-rods-out" relative assembly power densities have been presented for beginning of cycle (BOC), middle of cycle, and end of cycle (EOC). Relative assembly power densities are also given at BOC and EOC for rodded configurations allowed by the power dependent insertion limit at full power. These configurations consist of part length CEAs, Bank 5, and Bank 5 plus the part length CEAs. The Cycle 3 nominal axial peaking factors are estimated to range from 1.21 to 1.11, at BOC and EOC, respectively. As approved for the Cycle 2 reload, densification augmentation factors have been eliminated for Cycle 3 because the same manufacturing process is used in the fuel fabrication. Physics and power distribution calculations are based on the NRC-approved ROCS and MC codes employing DIT code generated neutron cross-sections. The power distribution calculations are, therefore, acceptable.

3.3 Control Requirements

The value of the required shutdown margin varies throughout core life with the most restrictive value occurring at EOC hot zero power (HZP) conditions. This minimum shutdown margin of 6.5% delta k/k is required to control the reactivity transient resulting from the RCS cooldown associated with a steam line break accident at these conditions. For operating temperatures below 350°F, the reactivity transients resulting from any postulated accident are minimal and a 4.0 delta k/k shutdown margin (revised from a value of 3.5 for Cycle 2) provides adequate protection. Sufficient boration capability and net available CEA worth, including a minimum worth stuck CEA and appropriate calculational uncertainties, exist to meet these shutdown margin requirements. These results were derived by approved methods and incorporate appropriate assumptions and are, therefore, acceptable.

4.0 EVALUATION OF THERMAL-HYDRAULIC DESIGN

Steady-state thermal-hydraulic analysis for Cycle 3 is performed using the approved thermal-hydraulic code TORC and the CE-1 critical heat flux (CHF) correlation. The design thermal margin analysis is performed with the fast running variation of the TORC code, CETOP-D. The CETOP-D model has been verified to predict minimum departure from nucleate boiling ratio (DNBR) conservatively relative to TORC.

The uncertainties associated with the system parameters are combined statistically using the NRC-approved modified statistical combination of uncertainties methodology. Using this methodology, the engineering hot channel factors for heat flux, heat input, fuel rod pitch, and cladding diameter are combined statistically with other uncertainty factors to arrive at overall uncertainty penalty factors to be applied to the DNBR calculations performed by the core protection calculators (CPCs) and the Core Operating Limit Supervisory System (COLSS). When used with the Cycle 3 DNBR limit of 1.24, these overall uncertainty penalty factors provide assurance with a 95/95 confidence/probability that the hottest fuel rod will not experience DNB.

The 1.24 value incorporates all applicable penalties, such as for rod bow, the 0.01 DNBR for HID-1 grids, and the penalties specified in the statistical combination of uncertainties. The rod bow value used in the analysis is 1.75% DNBR, for burnups up to 30,000 MWD/MTU. For burnups higher than 30,000 MWD/MTU, sufficient margin exists to offset the rod bow penalty due to lower radial power peaks in these higher burnup assemblies and rods. Therefore, the rod bow penalty is adequate for all anticipated burnups.

Because the thermal-hydraulic design analyses were performed using approved codes and took into account all applicable penalties, we find these analyses acceptable.

5.0 EVALUATION OF NON-LOCA SAFETY ANALYSIS

The design basis events (DBEs) considered in the safety analyses are categorized into two groups: anticipated operational occurrences (AOOs) and postulated accidents (limiting faults). All events were reviewed by the licensee to assess the need for reanalysis as a result of the new core configuration for Cycle 3. The DBEs were evaluated with respect to the following four criteria: fuel performance (DNBR and centerline melt), RCS pressure, loss of shutdown margin, and offsite dose. The limiting fault events corresponding to each criterion were reanalyzed.

Plant response to the DBEs was simulated using the same methods and computer programs which were used and approved for the Cycle 2 analyses. These include the CESEC III, STRIKIN II, TORC and HERMITE computer programs. For some of the reanalyzed DBEs, certain initial core parameters were assumed to be more limiting than the calculated Cycle 3 values in order to bound future cycles. All of the events reanalyzed have results which are within NRC acceptance criteria and, therefore, are acceptable. Two of the reanalyzed events, however, were not bounded by the Cycle 2 analyses. These are the inadvertent opening of a steam generator safety valve or atmospheric dump valve with loss of offsite power, and the single reactor coolant pump shaft seizure/sheared shaft event. For the former event, the amount of predicted failed fuel increased from 8% to 12% as a result of more adverse nuclear power distributions. However, the base case (i.e. without loss of offsite power) is bounded by the Cycle 2 analyses. For the latter event, an increase in predicted fuel failure from 3.79% to 4.5% occurs. The resulting radiological consequences are within 10 CFR 100 guidelines and are acceptable.

6.0 EVALUATION OF ECCS ANALYSIS

An ECCS analysis was performed for the limiting break size LOCA (a doubleended guillotine break with a 1.0 discharge coefficient) for Cycle 3 to demonstrate compliance with the requirements of 10 CFR 50.46. The methodology is the same as for the Cycle 2 analysis. The analysis justifies a 13.5 kw/ft peak linear heat generation rate. Because there have been no significant changes in hardware characterisitics for Cycle 3, only fuel rod clad temperature and oxidation calculations were performed. The code STRIKIN-II was used for this purpose and the fuel performance data were generated using the FATES-3A fuel evaluation code. It was demonstrated that burnup with the highest initial fuel stored energy was limiting. The ECCS analysis methods employed have been previously approved and are acceptable.

The results of the limiting break LOCA analysis for Cycle 3 are bounded by the results obtained in the Cycle 2 analysis, i.e., a peak clad temperature

of 2091°F, a maximum local clad oxidation of 9.0%, and a core wide clad oxidation of less than 0.80%. These values are within the 10 CFR 50.46 limits of 2200°F, 17.0%, and 1.0%, respectively, and are, therefore, acceptable. Similarly, a review of Cycle 3 fuel and core data has confirmed that the small break LOCA analysis results are bounded by the Cycle 2 analysis and is acceptable.

7.0 TECHNICAL SPECIFICATION CHANGES

TS Figure 3.1-1A

The proposed change increases the required shutdown margin from 3.5 to 4.0% delta k/k for the RCS cold leg temperature range zero to 350° F when any full-length CEA is fully withdrawn.

The increased shutdown margin will ensure that the TS are consistent with the safety analyses performed for the Cycle 3 core and that the consequences of DBEs and anticipated operational occurrences are bounded by these analyses. The proposed change is therefore acceptable.

TS Tables 3.1-2, 3.1-3 and 3.1-5

These tables provide frequencies for monitoring RCS boron concentration in the event that one or both startup channel high neutron flux alarms are inoperable.

The proposed changes are more restrictive in that certain monitoring frequencies are increased to ensure that the TS are consistent with the safety analyses performed for the Cycle 3 core and that, in the event of an inadvertent boron dilution, sufficient time will be available to terminate the event prior to loss of shutdown margin. The proposed changes are, therefore, acceptable.

TS Figures 3.1-3 and 3.1-4

Figures 3.1-3 and 3.1-4 provide regulating group CEA insertion limits when the COLSS is in service and out of service, respectively. The proposed change to Figure 3.1-3 will prohibit insertion of regulating group 3 CEAS above 20% of rated thermal power. This is permitted under the existing TS. The proposed change to Figure 3.1-4 will permit slightly increased insertion of regulating group 3 CEAs between 15% and 20% of rated thermal power.

The proposed revisions are necessary to ensure consistency of the TS with the safety analyses performed for the Cycle 3 core. These analyses demonstrate that reactor operation in accordance with the revised insertion limits will ensure that the Specified Acceptable Fuel Design Limits (SAFDLs) will not be exceeded during the most limiting anticipated operational occurrence. The proposed changes are, therefore, acceptable.

TS 3.2.7a

TS 3.2.7a ensures that the actual value of the core average Axia! Shape Index (ASI) remains within the range of values used in the safety analyses when the COLSS is operable. The proposed change revises the limits of core average ASI from -.28 SI .28 to -.27 SI .27 to make the TS consistent with the safety analyses performed for the Cycle 3 core. The proposed change is, therefore, acceptable.

TS Figures 3.2-2 and 3.2-2A

Figure 3.2-2 provides DNBR margin limits when at least one Control Element Assembly Calculator (CEAC) is operable and the COLSS is out of service. Figure 3.2-2A provides the additional DNBR margin necessary when COLSS and both CEACs are out of service. Reactor operation within these limits ensures that the SAFDLs will not be violated during an anticipated operational occurrence.

The proposed changes are necessary to ensure consistency of the TS with the safety analyses performed for the Cycle 3 core and are, therefore, acceptable.

8.0 STARTUP TESTING

The licensee has presented a brief description of the low power physics tests and the power ascension testing to be performed during Cycle 3 startup. The described tests will verify that core performance is consistent with the engineering design and safety analyses. If the acceptance criterion of any of the startup physics tests are not met, an evaluation will be performed by the licensee. Resolution will be required prior to subsequent power escalation. If an unreviewed safety question is involved, the NRC will be notified.

The staff has reviewed the proposed startup test program for Cycle 3 and finds that it conforms to accepted practices and adequately supplements normal surveillance tests which are required by the plant Technical Specifications.

9.0 EVALUATION FINDINGS

The staff has reviewed the fuels, physics, and thermal-hydraulics information presented in the PVNGS Unit 2 Cycle 3 reload report. Also reviewed were the Technical Specification revisions, the startup test procedures, and the safety reanalyses. Based on the evaluations given in the preceding sections, the staff finds the proposed reload acceptable.

10.0 CONTACT WITH STATE OFFICIAL

The Arizona Radiation Regulatory Agency has been advised of the proposed determination of no significant hazards consideration with regard to these changes. No comments were received.

11.0 ENVIRONMENTAL CONSIDERATION

The amendment involves changes in requirements with respect to the installation or use of facility components located within the restricted area as defined in 10 CFR Part 20. The staff has determined that the amendment involves no significant increase in the amount, and no significant change in the type, of any effluent that may be released offsite and that there is no significant increase in individual or cumulative occupational radiation exposure. The Commission has previously issued proposed findings that the amendment involves no significant hazards consideration, and there has been no public comment on such finding. Accordingly, the amendment meets the eligibility criteria for categorical exclusion set forth in 10 CFR 51.22(c)(9). Pursuant to 10 CFR 51.22(b) no environmental impact statement or environmental assessment need to be prepared in connection with the issuance of the amendment.

12.0 CONCLUSION

The staff has concluded, based on the considerations discussed above, that (1) there is reasonable assurance that the health and safety of the public will not be endangered by operation in the proposed manner, (2) such activities will be conducted in compliance with the Commission's regulations, and (3) the issuance of the amendment will not be inimical to the common defense and security or to the health and safety of the public. We, therefore, conclude that the proposed changes are acceptable.
