1.d. Main Steam Tunnel Temperature - High
(TS-1-17A-D, 29A-D, 40A-D, 54A-D)

The Main Steam Tunnel Temperature Function is provided to detect a leak in the RCPB and provides diversity to the high flow instrumentation. The isolation occurs when a very small leak has occurred. If the small leak is allowed to continue without isolation, offsite dose limits may be reached. However, credit for these instruments is not taken in any transient or accident analysis in the FSAR, since bounding analyses are performed for large breaks, such as MSLBs.

Main Steam Tunnel temperature signals are initiated from twelve bimetallic temperature switches and four temperature elements located in the areas being monitored. The four temperature elements monitor the Main Steam Valve Vault area. Sixteen channels of Main Steam Tunnel Temperature - High Function are required to be OPERABLE to ensure that no single instrument failure can preclude the isolation function.

The main steam tunnel temperature detection system Allowable Value is chosen to detect a leak equivalent to between 1% and 10% rated steam flow.

This Function isolates the Group 1 valves excluding the Recirculation Loop Sample valves.
