Perry Nuclear Power Plant Docket No. 50-440 LER 2002-002-00

Ladies and Gentlemen:

Enclosed is Licensee Event Report (LER) 2002-002, Failure of the High Pressure Core Spray Pump to Start. This event is being reported in accordance with 10CFR50.73(a)(2)(v)(D), as an event or condition that could have prevented the fulfillment of the safety function of structures or systems that are needed to mitigate the consequences of an accident. There are no regulatory commitments contained in this letter. Any actions discussed in this document that represent intended or planned actions, are described for the NRC's information, and are not regulatory commitments.

If you have questions or require additional information, please contact Mr. Vernon K. Higaki, Manager – Regulatory Affairs, at (440)-280-5294.

truly yours

Por William R. Kanda Enclosure: LER 2002-002

16. ABSTRACT (Limit to 1400 spaces, i.e., approximately 15 single-spaced typewritten lines)

On October 23, 2002, at 1113, the High Pressure Core Spray (HPCS) pump failed to start during routine testing of the HPCS Room Cooler at the Perry Nuclear Power Plant (PNPP). At the time of the failure, the HPCS system was inoperable for the conduct of the testing and required Technical Specification actions had already been completed.

The root cause of the failure was determined to be mechanical wear of the pump motor breaker cell switch operating linkage. Contributing to the failure was misalignment of this linkage related to a previous breaker replacement, and inadequate visual inspection of the cell switch contact alignment due to inadequate procedural detail. Following adjustment of the cell switch linkage and verification of proper operation, HPCS was returned to operable status at 1529 on October 24, 2002.

Adequate redundant Emergency Core Cooling Systems remained available during the unavailability of HPCS, but HPCS is significant from a risk perspective. Therefore, this event is considered to have had moderate safety significance.

This event was reported to the NRC via the Emergency Notification System on October 23, 2002, at 1216, (ENF #39311) in accordance with 10CFR50.72(b)(3)(v)(D) as a condition that could have prevented the fulfillment of a safety function needed to mitigate the consequences of an accident.

## I) INTRODUCTION

The High Pressure Core Spray (HPCS) system [BG] is one of four Emergency Core Cooling Systems (ECCS) at the Perry Nuclear Power Plant (PNPP). The primary purpose of the HPCS system is to maintain reactor vessel water inventory following a small reactor coolant boundary break, which does not depressurize the reactor vessel. HPCS also provides spray cooling during reactor coolant boundary breaks that result in uncovering the reactor core.

The HPCS system includes a motor-driven centrifugal pump, powered from a safety related diesel backed electrical bus. The pump discharges into the reactor vessel through a spray sparger located above the reactor core using associated system piping, valves, controls, and instruments.

The plant was in Mode 1 at 98.3 percent of rated thermal power and at normal operating pressure and temperature at 1113 on October 23, 2002. The HPCS system had been administratively declared inoperable to support periodic testing of the HPCS Pump Room Cooler [BG-CLR]. Technical Specification (TS) required actions for inoperability of the HPCS system had been completed.

## **II) EVENT DESCRIPTION**

Testing of the HPCS Room Cooler had progressed to the step that called for starting the HPCS pump. HPCS system indications appeared to be normal prior to the attempt to start the pump. The control room staff attempted to the start the pump in accordance with the System Operating Instruction (SOI). When the pump did not initially start, the Unit Supervisor directed the operator to make a second attempt to start the pump, believing that the control switch may not have been held in the start position long enough. Again the pump did not start.

A visual inspection of the breaker [BG-BKR] and cell switch [BG-SWGR] was conducted. This inspection noted no obvious, abnormal indications. The as-found conditions were preserved by placing the area under quarantine for investigation. Results of this initial inspection were reported to the Control Room. The Control Room staff re-verified that the TS required actions for inoperability of HPCS had been completed.

A Condition Report (CR 02-03972) was written to document the event, and a work order was generated to determine and correct the cause of the failure. Troubleshooting activities included breaker/cubicle interface checks, a visual inspection of the breaker, and an operational test of the breaker using a test box which were performed with satisfactory results. Troubleshooting identified that one of the rotary contacts of the breaker closure circuit cell switch had not engaged to make a proper connection and resulted in an open pump start circuit. The cell switch is a unit that contains eight individually adjustable double-break rotary contacts mounted on a shaft. The seven other cell switch contacts were all in the proper position. The contacts are positioned by a mechanical linkage driven by the racking action of the breaker.

Breaker position indication power is independent of the cell switch positions and indicated that power was available to start the pump.

This event is being reported in accordance with 10CFR50.73(a)(2)(v)(D), as an event or condition that could have prevented the fulfillment of the safety function of structures or systems that are needed to mitigate the consequences of an accident.

## **III) CAUSE OF EVENT**

The root cause of the failure was determined to be mechanical wear of the pump motor breaker cell switch operating linkage. Contributing to the failure was misalignment of this linkage related to a previous breaker replacement (in 1994), and inadequate visual inspection of the cell switch contact alignment due to inadequate procedural detail.
