- For bulky solids, the *Hertz contact stiffness* often provides an appropriate basis for the penalty stiffness. This stiffness can be estimated from the element size and Young's modulus.
- For a uniformly-shaped 3D element, the Hertz stiffness would be approximately  $k_{\text{Hertz}} \cong a \times E$ , where  $a$  is the characteristic element size, and  $E$  is the Young's modulus.

- For 2D elements with thickness ( $t$ ), Hertz stiffness would be approximately  $k_{\text{Hertz}} \cong t \times E$ .
  - For 2D axisymmetric elements, the “thickness” is 1 radian  $\times r$ , giving a Hertz stiffness of approximately  $k_{\text{Hertz}} \cong r \times E$ .

- As a practical matter, a good first trial value for bulky contact stiffness would be  $k_{\text{contact}} = f_{\text{bulk}} \times k_{\text{Hertz}}$ , where  $f_{\text{bulk}}$  is a factor usually between 0.1 and 10 for bulky solids.

- Because the starting estimated value of  $f_{\text{bulk}}$  ranges over at least two orders of magnitude, and because  $k_{\text{contact}}$  will be adjusted by trial-and-error anyway, it is usually not justifiable to worry about the element's size when estimating the penalty stiffness.

- *For bulky solids*, simply estimate the penalty stiffness by

$$k = f_{\text{bulk}} \times E$$

- where the factor  $f_{\text{bulk}}$  is usually between 0.1 and 10, and a good starting value for  $f_{\text{bulk}}$  is often  $f_{\text{bulk}} = 1.0$ .
- This estimate assumes an approximate “unit” element size; for very large or very small elements, you might need to adjust the starting value of  $f_{\text{bulk}}$  accordingly.
