This document conforms to the requirements of the design specification and the applicable sections of the governing codes.

Note : Signatures and printed names required in the review block.

- * A revision of this document will be ordered by the Project Manager and carried out if any of its contents is materially affected during evolution of this project. The determination as to the need for revision will be made by the Project Manager with input from others, as deemed necessary by him.

I Must be Project Manager or his designee.

x Distribution : C : Client
M : Designated Manufacturer
F : Florida Office

THE REVISION CONTROL OF THIS DOCUMENT IS BY A "SUMMARY OF REVISIONS LOG" PLACED BEFORE THE TEXT OF THE REPORT.

APPENDIX C CALCULATION OF SPRING CONSTANTS FOR HI-STORM SEISMIC ANALYSIS IN STORAGE FACILITY

Scope: Determine all spring rates for HI-STORM seismic model for storage scenario.

C-1.0 Spring rate for concrete contact

Conservatively use elastic spring rate based on classical solution for rigid punch on a semi-infinite half space. We neglect the effect of the underlying soil since this effect is included in the spring set representing the soil behavior. For the purpose of establishing a local spring rate for the pad resistance, the solution for a circular contact patch on a concrete half space is used. Following the reference below,

Reference: Timoshenko and Goodier, Theory of Elasticity, Third Edition, McGraw-Hill, 1970, pp. 407-409.

Properties

Concrete compressive strength

$$f_c := 4000 \cdot \text{psi}$$

Concrete Young's Modulus

$$E_c := 57000 \cdot \sqrt{f_c} \cdot \text{psi} \quad (\text{ACI Code, 318-89, or similar})$$

$$E_c = 3.605 \cdot 10^6 \cdot \text{psi}$$

Poisson's Ratio of Concrete

$$v_c := .17$$

Contact Patch Radius of Each Cask

$$a := \frac{132.5}{2} \cdot \text{in} \quad a = 66.25 \cdot \text{in}$$

$$\text{Area}_t := \pi \cdot a^2 \quad \text{Area}_t = 95.754 \cdot \text{ft}^2$$

The spring rate for the contact between cask and concrete pad is set as

$$K = (E_c (\text{Area}_t)^{1/2}) / (m(1 - v_c^2)) \quad m := .96$$

$$K := \frac{E_c \cdot \sqrt{\text{Area}_t}}{m \cdot (1 - v_c^2)} \quad K = 4.541 \cdot 10^8 \cdot \frac{\text{lbf}}{\text{in}}$$

The resistance to the cask motion is concentrated around the periphery; therefore, if NS is the number of individual springs situated around the periphery, the value for K for each spring is

$$NS := 36 \quad k := \frac{K}{NS} \quad k = 1.261 \cdot 10^7 \cdot \frac{\text{lbf}}{\text{in}}$$
