> NRR

Laura,

The still incomplete items are

1. Size to which cavity needs to grow to fail at normal (or reasonable) RCS pressure and the associated risk that it could have done so.
2. The probabilities that circ flaws could have developed and caused nozzle ejection

Work continues on both. The second one seems pretty much on-track for completion very soon. The first is proving more difficult. The licensee has declined to complete their analysis, and ORNL/RES is going off in a direction that will make it more difficult for me to use the results (but I'll manage). RES is now talking about finishing "by the end of the week" which is a slight slip from their previous target of "the end of the month" (July).

Still, I think we're getting real close to a preliminary result we can actually use.

Steve

Steve,  
What is the current status of the Davis Besse Risk analysis?
