Dr. Enrico Conti Waste Management Branch Division of Radiation Programs and Earth Sciences Office of Nuclear Regulatory Research U.S. Nuclear Regulatory Commission Washington, DC 20555

Dear Dr. Conti:

Enclosed is the requested review of the issues regarding the use of backfill materials in a basalt repository and a tuff repository. I have also enclosed a report I solicited from Prof. Donald Peacor, Dept. of Geological Sciences, University of Michigan.

There are two key points in my report. First, in short-term laboratory tests, the ability of bentonite to swell in water is severely degraded by moisture at temperatures approaching 250°C. This may place serious constraints on the design of backfill mixtures for high-temperature use in a basalt repository. Second, I believe that the use of bentonite in a tuff repository has been rejected partly for misleading or erroneous reasons, and that properly used, bentonite-based backfill may increase the margin of safety of a tuff repository.

With regard to a basalt repository, Prof. Peacor is of the opinion that a high clay/filler ratio is needed to ensure that the system remains closed, and therefore to prevent degradation of the backfill material. I agree that if bentonite does not retain its very high initial swelling capacity, 25% bentonite will not be sufficient to maintain a closed system.

If you or your staff have any questions, please do not hesitate to call me at FTS 972-4385 or -4383.

Sincerely.
