EXECUTIVE SUMMARY

The Annual Environmental and Effluent Release Report (AEERR) details the results of environmental and effluent monitoring programs conducted at the Perry Nuclear Power Plant (PNPP) from January 01 through December 31, 2003. This report meets all of the requirements in PNPP Technical Specifications, the Environmental Protection Plan (EPP), and Regulatory Guide 1.21. It incorporates the requirements of the Annual Radioactive Effluent Release Report (ARERR), the Annual Radiological Environmental Operating Report (AREOR) and the Annual Environmental Operating Report (AEOR). Report topics include radioactive effluent releases, radiological environmental monitoring, land use census, clam/mussel monitoring, herbicide use, and special reports. The results of the environmental and effluent programs, for 2003, indicate that the operations of the Perry Nuclear Power Plant did not result in any significant environmental impact.

RADIOACTIVE EFFLUENT RELEASES

During the normal operation of a nuclear power plant, small quantities of radioactivity may be released to the environment in liquid and gaseous effluents. Radioactive material may also be released as solid waste. PNPP maintains a comprehensive program to control and monitor the release of radioactive materials from the site in accordance with Nuclear Regulatory Commission (NRC) release regulations.

The dose to the general public from the plant's liquid and gaseous effluents was below the applicable regulatory limits. The calculated hypothetical maximum individual whole body dose potentially received by an individual resulting from PNPP liquid effluents was 1.68E-03 mrem (0.056 % of the applicable limit). The calculated hypothetical maximum individual whole body dose potentially received by an individual resulting from PNPP gaseous effluents was 7.46E-03 mrem (0.15% of the applicable limit). The summation of the hypothetical maximum individual dose from effluents in 2003 is equivalent to < 0.1 % of the total dose an individual living in the PNPP area receives from all sources of radiation.

Shipments of solid waste consisted of waste generated during water treatment, radioactive material generated during normal daily operations and maintenance, and irradiated components. PNPP complied with applicable regulations governing radioactive shipments in 2003, making shipments of solid radioactive waste to a licensed burial site.

During 2003, there were two (2) Offsite Dose Calculation Manual (ODCM) non-compliance conditions and one (1) abnormal release:

- The Radwaste High-Flow Discharge Header Flow Monitor, 0G50-N445, was declared inoperable on 12/2/02. On 1/2/03 the monitor was inoperable in excess of 30 days. The monitor was inoperable due to a broken tooth on the tractor gear for the recorder and other parts issues. The monitor then remained inoperable until the correct parts could be obtained. During the period of inoperable status, the ODCM requirements specified for an inoperable Radwaste High-Flow Discharge Header Flow Monitor (Table 3.3.7.9-1, Action 112) were performed. An Engineering Change Request was submitted to resolve the monitor's obsolete parts issues. Work was completed on 3/14/03, and 0G50-N445 was declared operable on 3/14/03 at 0930.
- The Radwaste High-Flow Discharge Header Flow Monitor, 0G50-N445, was declared inoperable on 06/04/03. On 7/5/04, the monitor was inoperable in excess of 30 days. The monitor was inoperable due to erratic readings. The monitor repairs were delayed due to inability to find parts for an obsolete monitor. Therefore, Engineering had to locate a recorder with similar functionality for installation. Once the correct type of recorder was located, the new recorder was delivered to the plant and installed in the system. During the period of inoperable status, the ODCM requirements specified for an inoperable Radwaste High-Flow Discharge

!

非常,在下的

Header Flow Monitor (Table 3.3.7.9-1, Action 112) were performed. Work was completed on 07/26/03, and 0G50-N445 was declared operable on 07/26/03 at 1055.

During testing of a Feedwater valve (N27-F599A) on 4/28/03 at 1030, an abnormal release to the environment occurred. Testing resulted in a Feedwater line becoming pressurized with air and subsequently being discharged into the Auxiliary Steam Tunnel. The Auxiliary Steam Tunnel doors were open at the time of the system depressurization allowing airborne contamination to escape to the outside environment. Since the Turbine Building and Heater Bay ventilation systems were secured for outage work, there was not a negative pressure in the Steam Tunnel. The dose contributions from this event (refer to Table 13) demonstrated minimal dose consequence to the general public. Refer to Appendix D for meteorological data.

RADIOLOGICAL ENVIRONMENTAL MONITORING

The Radiological Environmental Monitoring Program (REMP) was established in 1981 to monitor the radiological conditions in the environment around PNPP. The REMP is conducted in accordance with PNPP Technical Specifications and the Offsite Dose Calculation Manual (ODCM). This program includes the collection and analysis of environmental samples and evaluation of results.

The REMP was established at PNPP six (6) years before the plant became operational. This preoperational program was designed to provide data on background radiation and radioactivity normally present in the area. PNPP has continued to monitor the environment during plant operation by collecting and analyzing samples of air, precipitation, milk, fish, produce, water and sediment, as well as by measuring radiation directly.

There were over 3000 radioactivity analyses performed on the 1263 radiological environmental samples collected in 2003. The results of the REMP indicate the adequacy of the control of the release of radioactivity in the effluents from PNPP. These results also demonstrate that PNPP complies with applicable federal regulations. The REMP results are divided into four sections: atmospheric monitoring, terrestrial monitoring, aquatic monitoring, and direct radiation monitoring.

Samples of air were collected to monitor the radioactivity in the atmosphere. The 2003 results were similar to those observed for the pre-operational and operational programs from prior years. Only natural background environmental radioactivity was detected.

Terrestrial monitoring included the analysis of milk, produce, and vegetation. The PNPP ODCM does not require vegetation or soil samples to be included in the monitoring program. The results of the sample analyses in 2003 indicated concentrations of radioactivity similar to that found in previous years. Analyses of other terrestrial samples also detected concentrations of natural radioactivity similar to those observed in previous years, and indicated no build-up of radioactivity attributable to the operation of PNPP.

Aquatic monitoring included the collection and analyses of water, fish, and shoreline sediments. The 2003 analytical results for water and fish samples showed normal background radionuclide concentrations. The results of sediment sample analyses indicated that the annual average cesium radioactivity was similar to previous years for the control location. Cesium-137 activity was detected in six (6) of the fourteen (14) samples collected. The average cesium-137 radioactivity for all locations was 565.90 pCi/kg and was within the maximum value of 864 pCi/kg established in 1981.

In 1999, a sediment sample of the northwest drain impoundment (sampling location #64) was analyzed to contain 62 pCi/kg of cobalt-60. During 2003, enhanced monitoring activities continued within the boundaries of the impoundment. The cobalt-60 remained centered within the organic material located at the top of the spillway, with little or no activity found farther upstream. Sample

analyses continue to identify cobalt-60 levels similar to those found in previous years. Refer to Tables 17 and 18 for detailed sample results.

Direct radiation measurements showed no change from previous years. The indicator locations averaged 67.88 mrem/year and control locations averaged 73.59 mrem/year. In 2003, radiation dose in the area of PNPP was similar to the radiation dose measured at locations greater than ten (10) miles away from the Plant.

Based on these results, during 2003, the operation of the PNPP resulted in no significant increase in the radionuclide concentrations observed in the environment.

LAND USE CENSUS

In order to estimate radiation dose attributable to the operation of PNPP, the potential pathways through which public exposure can occur must be known. To identify these exposure pathways, an Annual Land Use Census is performed as part of the REMP. During the census, PNPP personnel travel every public road within a five (5) mile radius of the plant to locate key radiological exposure pathways. These key pathways include the nearest resident, garden, and milk animal in each of the sixteen meteorological sectors. The information obtained from the census is entered into a computer program, which is used to assess the hypothetical dose to members of the public. In recent years, however, it has been noted that tracts of land once used for farming are now being developed as mini industrial parks and residential housing tracts. This is reflected in the loss of available milking animals within a five mile radius of PNPP to support the Radiological Environmental Monitoring Program (REMP). For 2003, the predominant land use within the census area continues to be rural/agricultural.

CLAM/MUSSEL MONITORING

Clam and mussel shells can clog plant piping and components that use water from Lake Erie. For this reason, sampling for clams and mussels has been conducted in Lake Erie in the vicinity of PNPP since 1971. The monitoring is specifically for Corbicula (Asiatic clams), since their introduction into the Great Lakes, in 1981, and for Dreissena (zebra mussels), since their discovery in Lake Erie, in 1989. Since no Corbicula have ever been found at PNPP, routine Corbicula monitoring will provide early detection capability, when this pest species arrives at PNPP. The Dreissena program includes both monitoring and control and is directed at minimizing the mussel's impact on plant operation. As in past years, this program has successfully prevented Dreissena from causing any operational problems at PNPP.

HERBICIDE USE

The use of herbicides on the PNPP site is monitored to ensure compliance with Ohio Environmental Protection Agency (OEPA) requirements and to protect the site's natural areas. Based on the results of on-site herbicide applications, and weekly general site inspections, herbicide use has not had a negative impact on the environment around the plant.

SPECIAL REPORTS

Significant environmental events (for example, spills, releases), noncompliance with environmental regulations [e.g., Ohio Environmental Protection Agency (OEPA) discharge limits], and changes in plant design or operation that affect the environment are reported to regulatory agencies as they occur. These special reports are also summarized in this report.

On January 29, 2003, the OEPA was notified that construction was completed on the dechlorination system upgrade and the system would now be using sodium bisulfate as the dechlorination chemical. This notification was made in accordance with the National Pollutant Discharge Elimination System (NPDES) Permit.

1

On June 30, 2003, the OEPA was notified that the Preliminary Effluent Limit (PEL) for copper was exceeded during the month of June 2003. The increase in copper at the plant effluent coincided with a large increase of copper levels entering the plant from Lake Erie. This notification was made in accordance with the National Pollutant Discharge Elimination System (NPDES) Permit.

On September 30, 2003, the OEPA was notified of maintenance that would be performed on the neutralization basins. This notification was made in accordance with the National Pollutant Discharge Elimination System (NPDES) Permit.

OHIO DEPARTMENT OF NATURAL RESOURCES SURVEY

On February 21, 2003, the Ohio Department of Natural Resources (ODNR), Division of Wildlife contacted Perry requesting permission to access areas where spotted turtles had been previously documented. Perry granted the ODNR representative access, and the environmental staff participated in the surveys of the area. Although no spotted turtles were found in the previously recorded area, this was attributed to the area having been overrun by the *Phragmites sp.* The ODNR representative did state that the extensive wooded wetlands on the property offer excellent habitat as demonstrated by the observations of other turtles, salamanders and frogs. Later in the season, the ODNR representative discovered an open canopy of fens further south on the property. This area has yet to be impacted by *Phragmites sp.* and is considered a prime habitat for Spotted Turtles. Due to discovering this area late in the season, the ODNR representative hopes to return in 2004 to survey this area. INTRODUCTION

11

1 1 Nuclear energy provides an alternative energy source, which is readily available and has very limited impact upon the environment. To more fully understand nuclear energy as a source of generating electricity, one must understand basic radiation concepts and its occurrence in nature.

RADIATION FUNDAMENTALS

1989年最新1日1月,1月17年1月月日。 1999年日 Atoms are the basic building blocks of all matter. Simply described, atoms are made up of positively and negatively charged particles, and particles which are neutral. These particles are called protons, electrons, and neutrons, respectively. The relatively large protons and neutrons are packed together in the center of the atom called the nucleus. Orbiting around the nucleus are one or more smaller electrons. In an electrically neutral atom, the positively charged protons in the nucleus balance the negatively charged electrons. Due to their dissimilar charges, the protons and electrons have a strong attraction for each other, which helps hold the atom together. Other attractive forces between the protons and neutrons keep the densely packed protons from repelling each other, and preventing the nucleus from breaking apart.

Atoms with the same number of protons in their nuclei make up an element. The number of neutrons in the nuclei of an element may vary.' Atoms with the same number of protons but different numbers of neutrons are called isotopes. All isotopes of the same element have the same chemical properties and many are stable or non-radioactive. An unstable or radioactive isotope of an element is called a radioisotope, or radionuclide. Radionuclides contain an excess amount of energy in the nucleus, which is usually due to an excess number of neutrons.

Radioactive atoms attempt to reach a stable, non-radioactive state through a process known as radioactive decay. Radioactive decay is the release of energy from an atom's nucleus through the emission of radiation. Radionuclides vary greatly in the frequency with which their atoms release radiation. The length of time an atom remains radioactive is defined in terms of its half-life. Halflife is defined as the time required for a radioactive substance to lose half its activity through the process of radioactive decay. Half-lives vary from millionths of a second to millions of years.

RADIATION AND RADIOACTIVITY

Radioactive decay is a process in which the nucleus of an unstable atom becomes more stable by spontaneously emitting energy. Radiation refers to the energy that is released when radioactive decay occurs within the nucleus. This section includes a discussion on the three (3) primary forms of radiation produced by radioactive decay.

Alpha Particles

Alpha particles consist of two protons and two neutrons and have a positive charge. Because of their charge and large size, alpha particles do not travel very far when released (less than 4 inches, in air). They are unable to penetrate any solid material, such as paper or skin, to any significant depth. However, if alpha particles are released inside the body, they can damage the soft internal tissues because they deposit all their energy in a small area.

Beta Particles

Beta particles are essentially free electrons, which usually carry a negative electrical charge. They are much smaller than alpha particles and travel at nearly the speed of light. Thus they can travel for longer distances than alpha particles. External beta radiation primarily affects the skin. Because of their electrical charge, paper, plastic or thin metals can stop beta particles.

Gamma Rays

Gamma rays are bundles of electromagnetic energy, called photons, which behave as though they were particles. They are similar to visible light, but of a much higher energy. Gamma rays can travel long distances in air and are often released during radioactive decay, along with alpha and beta particles. Potassium-40 is an example of a naturally occurring radionuclide found in all humans that decays by emitting a gamma ray.

Interaction with Matter

When radiation interacts with other materials, it affects the atoms of those materials principally by knocking the negatively charged electrons out of orbit. This causes an atom to lose its electrical neutrality and become positively charged. An atom that is charged, either positively or negatively, is called an ion and the radiation is called ionizing radiation.

UNITS OF MEASURE

Some of the units of measure used in this report require explanation.

Activity

Activity is the number of atoms in a material that decay per unit of time. Each time an atom decays, radiation is emitted. The curie (Ci) is the unit used to describe the activity of a material and indicates the rate at which the atoms are decaying. One curie of activity indicates the decay of 37 billion atoms per second. Smaller units of the curie are often used in this report. Two common units are the microcurie (μ Ci), one millionth of a curie, and the picocurie (pCi), one trillionth of a curie. The mass, or weight, of radioactive material, which would result in one (1) curie of activity, depends on the disintegration rate. For example, one gram of radium-226 is equivalent to one (1) curie of activity. It would require about 1.5 million grams of natural uranium, however, to equal one (1) curie.

Dose

Biological damage due to alpha, beta, and gamma radiation may result from the ionization caused by these types of radiation. Some types of radiation, especially alpha particles, which causes dense local ionization, can result in much more biological damage for the same energy imparted than does

gamma or beta radiation. Therefore, a quality factor must be applied to account for the different ionizing capabilities of various types of ionizing radiation. When the quality factor is multiplied by the absorbed dose (as measured in rads), the result is the dose equivalent, which is an estimate of the possible biological damage resulting from exposure to any type of ionizing radiation. The dose equivalent is measured in terms of the Roentgen Equivalent Man (rem). When discussing environmental radiation effects, the rem is a large unit. Therefore, a smaller unit, the millirem (mrem) is often used. One mrem is equivalent to 1/1000 of a rem.

LOWER LIMIT OF DETECTION

Sample results are often reported as below the Lower Limit of Detection (LLD). The LLD for an analysis is the smallest amount of radioactive material that will show a positive result for which there can be a 95% confidence that radioactivity is present. This statistical parameter is used as a measure of the sensitivity of a sample analysis. When a measurement is reported as less than the LLD (<LLD), it means that no radioactivity was detected. Had radioactivity been present at (or above) the stated LLD value, it statistically would have been detected. The NRC has established LLD values for environmental and effluent sample analyses.

BACKGROUND RADIATION

Background radiation is a natural part of nature. Natural background radioactive decay occurs in the soil, water, air, and space. Common sources of radiation that contribute to the natural background radiation includes: the decay of radioactive elements in the earth's crust, a steady stream of highenergy particles from space (called cosmic radiation), naturally-occurring radioactive isotopes in the human body like potassium-40, the decay of radioisotopes used in medical procedures, man-made phosphate fertilizers (phosphates and uranium are often found together in nature), fallout from nuclear weapons testing, and even household items like smoke detectors. In the United States, a person's average annual exposure from background radiation is 360 mrem, and is due to the sources shown in Figure 1 [Source: National Council on Radiation Protection and Measurements].

Figure 1: Sources of Background Radiation

Many radionuclides are present in the environment due to sources such as cosmic radiation and fallout from nuclear weapons testing. These radionuclides are expected to be present in many of the environmental samples collected in the vicinity of PNPP. Some of the radionuclides normally present include:

- Beryllium-7, present as a result of the interaction of cosmic radiation with the upper atmosphere,
- Potassium-40, a naturally occurring radionuclide normally found in humans and throughout the environment, and
- Radionuclides from nuclear weapons testing fallout, including tritium and cesium-137. These radionuclides may also be released in minute amounts from nuclear facilities.

Beryllium-7 and potassium-40 are especially common in REMP samples. Since they are naturally occurring and are expected to be present, positive results for these radionuclides are not discussed in the section for the 2003 Sampling Program results. These radionuclides are included; however, in Appendix A, 2003 Inter-Laboratory Cross Check Comparison Program Results.

RADIOACTIVE EFFLUENT RELEASES

INTRODUCTION

The source of radioactive material in a nuclear power plant is the generation of fission products (e.g., noble gas, iodine, and particulate) or neutron activation of water and corrosion products (e.g., tritium and cobalt). The majority of the fission products generated remain within the nuclear fuel pellet and fuel cladding. Most fission products that escape from the fuel cladding, as well as the majority of the activated corrosion products, are removed by plant processing equipment.

Standard Barris and Standard Standards

During the normal operation of a nuclear power plant, small amounts of radioactive material are released in the form of solids, liquids, and gases. PNPP was designed, and is operated in such a manner as to control and monitor these effluent releases. Effluents are controlled to ensure any radioactivity released to the environment is minimal and within regulatory limits. Effluent release programs include the operation of monitoring systems, in-plant sampling and analysis, quality assurance, and detailed procedures covering all aspects of effluent monitoring.

The liquid and gaseous radioactive waste treatment systems at PNPP are designed to collect and process these wastes in order to remove most of the radioactivity. Effluent monitoring systems are used to provide continuous indication of the radioactivity present and are sensitive enough to measure several orders of magnitude lower than the applicable release limits. This monitoring equipment is equipped with alarms and indicators in the plant control room. The alarms are set to provide warnings to alert plant operators when radioactivity levels reach a small fraction of actual limits. The waste streams are sampled and analyzed to identify and quantify the radionuclides being released to the environment.

Gaseous effluent release data is coupled with on-site meteorological data in order to calculate the dose to the general public. Devices are maintained at various locations around PNPP to constantly sample the air in the surrounding environment. Frequent samples of other environmental media are also taken to determine if any radioactive material deposition has occurred. The Radiological Environmental Monitoring Program (REMP) is described in detail in the next section.

Generation of solid waste is carefully monitored to identify opportunities for minimization. Limiting the amount of material taken into the plant, sorting material as radioactive or non-radioactive, shredding and compacting, or incinerating waste once it is identified help to lower the volume of radioactive solid waste generated. Solid waste is shipped to a licensed burial site.

REGULATORY LIMITS

The Nuclear Regulatory Commission has established limits for liquid and gaseous effluents that comply with:

- Title 10 of the Code of Federal Regulations, Part 20 (Standards for Protection Against Radiation) [10CFR20], Appendix B;
- Title 10 of the Code of Federal Regulations, Part 50 (Domestic Licensing of Production and Utilization Facilities) [10CFR50], Appendix I; and
- Title 40 of the Code of Federal Regulations, Part 190 (Environmental Radiation Protection Standards for Nuclear Power Plants) [40CFR190].

These limits were incorporated into the PNPP Technical Specifications, and subsequently into the PNPP Offsite Dose Calculation Manual (ODCM). The ODCM prescribes the maximum doses and dose rates due to radioactive effluents resulting from the operation of PNPP. These limits are defined in several ways to limit the over-all impact on persons living near the plant. Since there are

....

no other fuel sources near the PNPP, the 40CFR190 limits, which are described below, were not exceeded in 2003.

The 40CFR190 limit for total direct-radiation dose is 25 mrem. For 2003, the total whole body dose to a member of the general public, considering all sectors, was 5.4E-01 mrem. This value was determined by summing the annual whole body doses from liquid and gaseous radioactive effluents, the annual gaseous and liquid organ dose (refer to Table 8) and the maximum, direct-radiation dose. Since the direct radiation dose, as determined by TLD, was indistinguishable from natural background (refer to Figure 8), a value of zero was used for the calculation.

Liquid Effluents

The concentration of radioactive material released in liquid effluents to unrestricted areas shall be limited to the concentrations specified in 10CFR20, Appendix B, Table 2, Column 2 for radionuclides other than dissolved or entrained noble gases, as required by the ODCM. For dissolved or entrained noble gases, the concentration shall be limited to 2.0E-04 μ Ci/mL of total activity. These values are the maximum effluent concentrations.

The dose or dose commitment to a member of the public from radioactive materials in liquid effluents released to unrestricted areas shall be limited to the following:

During any calendar quarter:

Less than or equal to 1.5 mrem to the whole body, and

Less than or equal to 5 mrem to any organ.

During any calendar year:

Less than or equal to 3 mrem to the whole body, and

Less than or equal to 10 mrem to any organ.

Gaseous Effluents

Dose rate due to radioactive materials released in gaseous effluents from the site to areas at and beyond the site boundary shall be limited to the following:

Noble gases:

Less than or equal to 500 mrem per year to the whole body, and

Less than or equal to 3000 mrem per year to the skin.

Iodine-131, Iodine-133, Tritium, and all radionuclides in particulate form with half lives greater than eight days:

Less than or equal to 1500 mrem per year to any organ

Air dose due to noble gases to areas at, and beyond the site boundary, shall be limited to the following:

During any calendar quarter:

Less than or equal to 5 mrad for gamma radiation, and

Less than or equal to 10 mrad for beta radiation.

During any calendar year:

Less than or equal to 10 mrad for gamma radiation, and

Less than or equal to 20 mrad for beta radiation.

Dose to a member of the public from iodine-131, iodine-133, tritium, and all radionuclides in particulate form with half lives greater than eight days in gaseous effluents released to areas at and beyond the site boundary shall be limited to the following:

Less than or equal to 7.5 mrem to any organ per any calendar quarter, and

Less than or equal to 15 mrem to any organ per any calendar year.

The PNPP ODCM does not contain a concentration reference for gaseous effluents. For this reason, effluent concentrations are not used to calculate maximum release rates for gaseous effluents. MARY

RELEASE SUMMARY

Effluents are sampled and analyzed to identify both the type and quantity of radionuclides present. This information is combined with effluent path flow measurements to determine the composition, concentration, and dose contribution of the radioactive effluents.

Liquid Effluents

The PNPP liquid radioactive waste system is designed to collect and treat all radioactive liquid waste produced in the plant. The treatment process used for radioactive liquid waste depends on its physical and chemical properties. It is designed to reduce the concentration of radioactive material in the liquid by filtration to remove suspended solids and demineralization to remove dissolved solids. Normally, the effluent from the liquid radioactive waste system is returned to plant systems. To reduce the volume of water stored in plant systems; however, the processed liquid effluent may be discharge from the plant via a controlled release. In this case, effluent activity and dose calculations are performed prior to, and after discharging this processed water to Lake Erie to ensure regulatory compliance and dose minimization principals are maintained.

Liquid radioactive waste system effluents may be intermittently released, which are considered to be "batch" releases. Table 1 provides information on the number and duration of these releases for 2003. Table 1: Liquid Batch Releases

	QUARTER 1	QUARTER 2	QUARTER 3	QUARTER 4	TOTAL
Number of batch releases	21	39	18	0	78
Total time period for batch releases, min	1.77E+04	1.13E+04	3.89E+03	0	3.29E+04
Maximum time for a batch release, min	1.09E+03	3.91E+02	2.50E+02	0	1.09E+03
Average time period for a batch release, min	8.45E+02	2.91E+02	2.16E+02	0	4.22E+02
Minimum time for a batch release, min	7.00E+00	2.21E+02	1.50E+01	0	7.00E+00
Average stream flow during periods of effluent release into a flowing stream, L/min	1.02E+05	1.83E+05	2.23E+05	0	1.44E+05

In addition to batch releases a continuous release may occur with the release of the Turbine Building Supply Plenum Drains. The moisture from the outside air is condensed and flows into a drain pan. During hot, humid months with low wind speed, the potential exists for some of the gaseous effluent exhaust from the plant to be recycled back into the plant through the Turbine Building Supply Plenums. Since the air from the plant gaseous effluents can contain tritium, then the water in the exhaust plenums can also contain tritium. One such continuous release did occur during the year with a duration of 163356 minutes and a discharge volume of 6.13E6 liters. Tritium concentration for this release was 8.35E-07 µCi/ml.

Also, in April 2003, there was detectable tritium in the Emergency Service Water (ESW) composite sample. The source of the tritium was investigated and the most likely source was determined to be recycled flow through the ESW sluice gates during Liquid Batch Releases. Other potential sources that were investigated and subsequently dismissed as potential sources included Residual Heat

Removal heat exchanger tube leaks, Emergency Closed Cooling and Fuel Pool Cooling leaks into the Nuclear Closed Cooling System with subsequent leakage into the ESW system, backflow into the idle ESW loop during Liquid Batch Releases, and sample contamination. Although the ultimate source was concluded to be recycling through the ESW sluice gates, the composite sample for this period was included in the dose calculations for liquid releases. The duration of the release was 30180 minutes with a discharge volume 6.09E+08 liters. Tritium concentration for this release was 2.66E-06 uCi/ml.

Table 2 provides information on the nuclide composition for the liquid radioactive waste system effluent releases. If a radionuclide was not present at a level "greater than or equal to the LLD" (\geq LLD), then the value is expressed as "less than the LLD" (<LLD). In each case, LLDs were met, or were below the levels required by the ODCM.

	QUARTER 1	QUARTER 2	QUARTER 3	QUARTER 4	EST. TOTAL ERROR, %
A. Fission and Activation Products

Table 2: Summation of All Liquid Effluent Releases

<LLD - Less than the lower limit of detection

N/A - Not Applicable, the ODCM does not have a limit for fission and activation products.

* Average diluted concentrations are based on total volume of water released during quarter.

** Dilution Water Volume indicates total dilution volume for the period of the report.

Table 3 lists the total number of curies (Ci) of each radionuclide present in liquid effluent releases for each quarter. If a radionuclide was not present at a level "greater than or equal to the LLD" (\geq LLD), then the value is expressed as "less than the LLD" (\leq LLD). In each case, the LLDs were either met, or were below the levels required by the ODCM.

Gaseous Effluents

Gaseous effluents are made up of fission and activation gases, iodine and particulate releases. The fission and activation gas releases are primarily a result of containment purge operations, small steam leaks, and offgas system operation during plant start up and shut down operations. The iodine and particulate releases are primarily a result of small steam leaks. Gaseous effluents from PNPP exit the plant via one of four effluent vents. Each of these four effluent vents contains radiation detectors that continuously monitor the air to ensure that the levels of radioactivity released are well below regulatory limits. Samples are also collected and analyzed on a routine basis to ensure regulatory compliance and dose minimization principals are maintained. The majority of gaseous effluents released from PNPP are considered continuous and at ground level.

A summation of all gaseous radioactive effluent releases is given in Table 4. If a radionuclide was not present at a level "greater than or equal to the LLD" (\geq LLD), then the value is expressed as "less than the LLD" (<LLD). In each case, the measured LLDs either met or were below the levels required by the PNPP ODCM.

Table 4: Summation of All Gaseous Effluents

<LLD - Less than the lower limit of detection

N/A - Not Applicable, the ODCM does not have a limit for fission and activation products.

The radionuclide composition of all gaseous radioactive effluents for a continuous-mode, groundlevel release is given in Table 5. If a radionuclide was not present at a level "greater than or equal to the LLD" (\geq LLD), then the value is expressed as "less than the LLD" (<LLD). In each case, LLDs were met or were below the levels required by the ODCM.

Solid Waste

There were no shipments of PNPP solid radioactive waste transported, by truck, directly to the Barnwell, South Carolina, disposal facility for burial. Solid radioactive waste from PNPP was processed and combined with waste from several other utilities by intermediate vendors (Duratek in Oak Ridge, TN and Studsvik in Erwin, TN). This waste was ultimately sent to the Barnwell, South Carolina, or Clive, Utah, disposal facilities for burial. Additionally, radioactive waste was shipped from ATG Richland, WA to Clive, UT for final disposal. No irradiated fuel or components were transported from PNPP in 2003. The solid radioactive waste summary in Table 6 includes all PNPP shipments.

A.	Type of Solid Waste Shipped	VOLUME m ³	Α CTIVITY Ci	PERIOD	EST. TOTAL Error %
	Spent resin, filter sludge, evaporator bottoms, etc.	25.3	333.0	1/1/2003- 12/31/2003	+/- 25
	Dry compressible waste, contaminated equipment, etc.	25.7	8.3	1/1/2003- 12/31/2003	+/- 25
	Irradiated components, control rods, etc.	0	0	1/1/2003- 12/31/2003	+/- 25
	Other (describe)	0	0	1/1/2003- 12/31/2003	+/- 25

Table 6: Solid Waste Shipped Offsite for Burial or Disposal

В.	Estimate of Major ⁽¹⁾ Nuclide Composition (by type of waste)	RADIONUCLIDE	ABUNDANCE %	EST. TOTAL Error, %
	Spent Resin, Filter Sludge, Evaporator Bottoms, etc.	Mn-54 Fe-55 Co-58 Co-60 Zn-65	6.0 40.2 1.0 47.0 2.7	±25
	Dry Compressible Waste, Contaminated Equipment, etc.	Mn-54 Fe-55 Co-60 Ni-63 Zn-65	3.0 48.9 43.8 1.2 1.1	± 25
	Irradiated Components, Control Rods, etc.	None	N/A	N/A
	Other (describe)	None	N/A	N/A

C. Disposition	Number of Shipments	Mode of Transportation	Destination
Solid Waste ⁽²⁾	0	N/A	N/A
Irradiated Fuel Shipments	0	N/A	N/A

N/A -- Not Applicable

(1) - "Major" is defined as any individual radionuclide identified as >1% of the waste type abundance.

(2) -- Additional shipments were made to Studsvik, in Erwin, TN; Duratek, Oak Ridge, TN. This waste was combined with waste from other utilities disposed of at Barnwell, SC or Envirocare of Utah.

1_

METEOROLOGICAL DATA

The Meteorological Monitoring System at PNPP consists of a 60-meter tower equipped with two independent systems for measuring wind speed, wind direction, and temperature at both 10-meter and 60-meter heights. The tower also has instrumentation to measure dew point and barometric pressure. Data is logged from the tower through separate data loggers, and transmitted to a common plant computer. This system compiles the data and calculates a variety of atmospheric parameters, communicates with the Meteorological Information Dose Assessment System (MIDAS), and sends data over communication links to the plant Control Room.

DOSE ASSESSMENT

1 :

1

The maximum concentration for any radioactive release is controlled by the limits set forth in Title 10 of the Code of Federal Regulations, Part 20 (10CFR20). Sampling, analyzing, processing, and monitoring the effluent stream ensures compliance with these concentration limits. Dose limit compliance is verified through periodic dose assessment calculations. Some dose calculations are conservatively performed for a hypothetical individual who is assumed to reside on the site boundary at the highest potential dose location all year. This person, called the "maximum individual", would incur the maximum potential dose from direct exposure (air plus ground plus water), inhalation, and ingestion of water, milk, vegetation, and fish. Because no one actually meets these criteria, the actual dose received by a real member of the public is significantly less than what is calculated for this hypothetical individual. a partir de

Dose calculations for this maximum individual at the site boundary are performed for two cases. First, they are performed using data for a 360° radius around the plant site (land and water based meteorological sectors), even though some of these sectors are over Lake Erie, which has no permanent residents. The second calculation is performed considering only those sectors around the plant in which people reside (land-based meteorological sectors).

The calculated hypothetical, maximum individual dose values at the site boundary are provided in Table 7. This table considers all meteorological sectors around PNPP and provides either the whole body or worst-case, organ dose values. If any radionuclide was not present at a level greater than the ·. · ' LLD, it was not used in the dose calculations.

Type of Dose	Organ	ESTIMATED DOSE, mrem	LIMIT	% OF Limit	
Liquid Effluent	Whole body	9.50E-03	3.0E+00	3.2E-01	:
	Liver	1.23E-02	1.0E+01	1.2E-01	· ·

Table 7: Maximum Individual Site Boundary Dose, Considering All Sectors

The calculated hypothetical, maximum population dose values at the site boundary are provided in Table 8. This table considers all meteorological sectors around PNPP and provides either the whole body or worst-case, organ dose values.

	Organ	ESTIMATED Dose person-rem
Liquid Effluent	Whole body	1.8E+00
	Thyroid	9.4E-01
Gaseous Effluent	Whole body	4.3E-03
	Thyroid	1.2E-02

Table 8: Population Dose, Considering All Sectors

Table 9 provides the calculated hypothetical maximum site boundary dose values considering only the land-based sectors. If any radionuclide was not present at a level greater than the LLD, it was not used in the dose calculations.

Type of Dose		Organ	ESTIMATED DOSE, mrem	Limit	% OF Limit
Liquid Effluent		Whole body	9.50E-03	3.0E+00	3.2E-01
		Liver	1.23E-02	1.0E+01	1.2E-01
Noble Gas	Gamma Air	N/A	1.33E-03	1.0E+01	1.3E-02
	Beta Air	N/A	2.43E-03	2.0E+01	1.2E-02
Noble Gas		Whole body	6.21E-04	5.0E+00	1.2E-02
	<u></u>	Skin	1.64E-03	1.5E+01	1.1E-02
Particulate & Io	odine	Thyroid	7.03E-03	1.5E+01	4.7E-02

N/A -- Not Applicable

Other dose calculations are performed for a hypothetical individual who is assumed to be inside the site boundary for some specified amount of time. This person would receive the maximum dose during the time spent inside site boundary. Because no one actually meets the criteria established for these conservative calculations, the actual dose received by a real member of the public is significantly less than what is calculated for this hypothetical individual. This dose is assessed relative to the offsite dose, and considers dilution, dispersion, and occupancy factors.

The highest hypothetical dose from liquid effluents to a member of the public inside the site boundary is to a person who is fishing on Lake Erie from the shore on PNPP property. The calculations assume that this person will spend 60 hours per year fishing, with a liquid dilution factor of 10. The ratio of the exposure pathway to the doses calculated for offsite locations yields the dose values shown in Table 10.

Table 10: Maximum	Site Dose	from Liqu	id Effluents
-------------------	-----------	-----------	--------------

	WHOLE BODY DOSE mrem	ORGAN DOSE mrem
First Quarter	2.3E-04	2.8E-04
Second Quarter	6.8E-04	8.1E-04
Third Quarter	1.1E-04	1.3E-04
Fourth Quarter ⁽¹⁾	0.0E+00	0.0E+00
Annual	1.0E-03	1.2E-03

(1) -- No liquid radioactive effluent releases during this period

Although several cases were evaluated to determine the highest hypothetical dose from gaseous effluents to members of the public inside site boundary, the activity inside the site boundary with the highest dose potential is also shoreline fishing. The cases evaluated included traversing a public road within the site boundary, shoreline fishing (assuming fishing 60 hours per year), non-plant related training, car-pooling, and job interviews. The maximum on-site gaseous doses generated are shown in Table 11.

	WHOLE BODY DOSE mrem	ORGAN DOSE mrem
First Quarter	6.5E-04	1.4E-03
Second Quarter	2.5E-04	9.6E-04
Third Quarter	3.8E-04	1.4E-03
Fourth Quarter	5.3E-05	1.9E-04
Annual	1.3E-03	3.3E-03

Table 11: Maximum Site Dose from Gaseous Effluents

An average whole body dose to individual members of the public at or beyond the site boundary is then determined by combining the dose from gaseous and liquid radiological effluents. The dose from gaseous radiological effluents is based upon the population that lives within 50 miles of PNPP (2,420,000 people). The dose from liquid radiological effluents is determined for the population that receives drinking water from intakes within 50 miles of PNPP (1,820,000 people). The results of this calculation are provided in Table 12.

Table 12: Average Individual Whole Body Dose

	Liquid Effluents (mrem)	Gaseous Effluents (mrem)	
First Quarter	2.9E-07	6.6E-10	
Second Quarter	2.9E-07	5.8E-10	
Third Quarter	1.4E-07	5.8E-10	
Fourth Quarter (1)	0.0E+00	3.2E-11	
Annual	7.4E-07	1.8E-9	

(1)-- No liquid radioactive effluent releases during this period

Abnormal Releases

There was one abnormal radioactive release event during 2003.

Abnormal Release During Feedwater Valve Testing in Steam Tunnel

During testing of a Feedwater valve (N27-F599A), an abnormal release to the environment occurred. Testing resulted in a Feedwater line becoming pressurized with air and subsequently being discharged into the Auxiliary Steam Tunnel. The Auxiliary Steam Tunnel doors were open at the time of the system depressurization allowing airborne contamination to escape to the outside environment. Since the Turbine Building and Heater Bay ventilation systems were secured for outage work, there was not a negative pressure in the Steam Tunnel. The dose contributions from this event (refer to Table 13) demonstrated minimal dose consequence to the general public. Refer to Appendix D for meteorological data.

Table 13: Abnormal Release During Feedwater Valve Testing in Steam Tunnel

NON-COMPLIANCES

There were two (2) non-compliance to the ODCM Controls requirements in 2003:

The Radwaste High-Flow Discharge Header Flow Monitor was inoperable greater than 30 days

The Radwaste High-Flow Discharge Header Flow Monitor, 0G50-N445, was declared inoperable on 12/2/02 due to a tractor gear on the recorder having a broken tooth. This repair was made within two days; however, the surveillance for the turbine flow meter (which provides the signal for the high flow monitor) became overdue and the parts necessary to perform that surveillance were not available. The monitor then remained inoperable until the correct parts could be obtained. An Engineering Change Request was submitted to resolve the obsolete parts issues associated with this monitor. Work was completed on 3/14/03, and 0G50-N445 was declared operable on 3/14/03 at 0930.

The Radwaste High-Flow Discharge Header Flow Monitor was inoperable greater than 30 days

The Radwaste High-Flow Discharge Header Flow Monitor, 0G50-N445, was declared inoperable at 0340 on 06/04/03 due to erratic readings. ODCM controls were entered. The monitor was not repaired and returned to service within 30 days. The cause in the delay is that the installed recorder was obsolete and replacement parts could not be located. Therefore, Engineering had to locate a recorder with similar functionality for installation. Once the correct type of recorder was located, the new recorder was delivered to the plant and installed in the system. Work was completed on 07/26/03, and 0G50-N445 was declared operable on 07/26/03 at 1055.

OFFSITE DOSE CALCULATION MANUAL CHANGES

During this reporting period, there were two (2) revisions to the Offsite Dose Calculation Manual:

Revision 8

- Revised to clarify that the wording in 4.0.2 of Appendix C so you can apply 1.25 times to actions in addition to surveillance items.
- Corrected the frequency note for release path B on page 138 to (b) instead of (c), which was in error.
- Added ingestion and external dose factors for Cu-67 and Sr-87m.
- Added reference to Federal Guidance Report 13 CD Supplement since this was the source for the dose factors for Cu-67 and Sr-87m.
- Clarified that a batch release requires a review under 10CFR50.59.

Revision 9

RADIOLOGICAL ENVIRONMENTAL MONITORING

INTRODUCTION

The Radiological Environmental Monitoring Program (REMP) was established at PNPP for several reasons. First, it verifies the adequacy of plant design and operation to control radioactive materials and limit effluent releases. Second, it assesses the radiological impact, if any, that the plant has had on the surrounding environment. Third, it ensures compliance with regulatory guidelines. The REMP is conducted in accordance with the PNPP Operating License, Appendix B, Technical Specifications and the ODCM. The Nuclear Regulatory Commission (NRC) established the REMP requirements.

A wide variety of samples are collected as part of the PNPP REMP. The selection of sample types, sampling locations, and sample collection frequency are based on many things. Potential pathways for the transfer of radionuclides through the environment to humans, sample availability, local meteorology, population characteristics, land use and NRC requirements are all considered.

To ensure that the REMP data are meaningful and useful, detailed sampling methods and procedures are followed. This ensures that samples are collected in the same manner and from the same locations each time. All samples are packaged on site, then shipped to an independent vendor laboratory for analysis. The vendor laboratory analyzes the samples and reports results to the PNPP Chemistry Unit staff, the Lake County General Health District, and the State of Ohio Department of Health.

The REMP began in 1981 with 24 direct radiation monitoring locations, four sediment locations, and two fish sampling locations. In 1982, collections of air, water, milk, food products, and feed/silage were added. Vegetation, precipitation and soil were added in 1985. Although the NRC did not require these last three media, they were incorporated into the program to establish baseline data. In 1993, feed/silage sampling was dropped from the program, based on ten years worth of data. For the same reason, Strontium analyses were deleted from the program in 1994, gross beta and tritium were deleted from precipitation analyses in 1995, and precipitation sampling was deleted entirely in 1996. In 1999, grass and soil sampling were dropped from the program.

SAMPLING LOCATIONS

REMP samples are collected at numerous locations, both on site and up to 22 miles away from the plant. Sampling locations are divided into two general categories: indicator and control. Indicator locations are those which would be most likely to display effects caused by plant operation. They are relatively close to the plant. Control locations are those which are considered to be unaffected by plant operation. Typically, they are a greater distance from the plant, in the least prevalent wind directions. Data obtained from the indicator locations are compared with data from the control locations. This comparison allows naturally occurring background radiation to be taken into account when evaluating any radiological impact PNPP may have had on the environment. Table 14, Figure 2, Figure 3 and Figure 4 identify the PNPP REMP sampling locations.

Many REMP samples are collected in addition to those required by the PNPP ODCM. The ODCM requirements for each sample type are discussed in more detail below. Sample types and locations required by the ODCM are shown in **Bold** in Table 14.

ANNUAL ENVIRONMENTAL AND EFFLUENT RELEASE REPORT

C03

SAMPLE ANALYSIS

When environmental samples are analyzed for radioactivity, several types of measurements are performed to provide information about the types of radiation and radionuclides present. The major analyses that are performed are discussed below.

Gross beta activity measures the total amount of beta-emitting radioactivity present in a sample, and acts as a tool to identify samples that may require further analysis. Beta radiation may be released by many different radionuclides. Since beta decay results in a continuous energy spectrum rather than the discrete energy levels, or "peaks", associated with gamma radiation, identification of specific beta-emitting nuclides is much more difficult. Therefore, gross beta activity only indicates whether the sample contains normal, or abnormal amounts of beta-emitting radioactivity; it does not specifically identify the radionuclides present.

Gamma spectral analysis provides more specific information than does the analysis for gross beta activity. Gamma spectral analysis identifies each radionuclide, and the amount of radioactivity, present in the sample emitting gamma radiation. Each radionuclide has a very specific "fingerprint" that allows for accurate identification and quantification.

Iodine activity analysis measures the amount of radioactive Iodine present in a sample. Some media (for example, air sample charcoal cartridges) are analyzed directly by gamma spectral analysis. With other media (for example, milk), the radioiodines are extracted by chemical separation before being analyzed by gamma spectral analysis.

Tritium activity analysis measures the amount of the radionuclide tritium (H-3) present in a sample. Tritium is an isotope of hydrogen that emits low-energy beta particles. Tritium occurs naturally and is also man-made.

Gamma doses received by Thermoluminescent Dosimeters (TLD) while in the field are determined by a special laboratory procedure. Thermoluminescence is a process by which ionizing radiation interacts with the sensitive phosphor material in the TLD. Energy is trapped in the TLD material and can be stored for months or years. This capability provides an excellent method to measure the dose received over long periods of time. The amount of energy that was stored in the TLD as a result of interaction with radiation is released by a controlled heating process and measured in a calibrated reading system. As the TLD is heated, the phosphor releases the stored energy as light. The amount of light is directly proportional to the amount of radiation to which the TLD was exposed. The reading process also zeroes the TLD and prepares it for reuse. Table 15 provides a list of the analyses performed on environmental samples collected for the PNPP REMP in 2003.

Sample results are often reported as less than the lower limit of detection (< LLD), which is defined as the smallest amount of radioactive material that will show a positive result for which there can be confidence that radioactivity is present. This statistical parameter is used as a measure of the sensitivity of a sample analysis. When a measurement is reported as < LLD, it means that no radioactivity was detected at a value above, or equal to the appropriate ODCM table value. The NRC has established LLD values for REMP sample analyses. The vendor laboratory for REMP sample analyses complied with those values in 2003.

Table 15: REMP Sample Analyses

2003 SAMPLING PROGRAM

The contribution of radionuclides to the environment resulting from PNPP operation is assessed by comparing results from the 2003 program with pre-operational data (i.e., data from before 1986), operational data from previous years, and control location data. The results for each sample type are discussed below and compared to historical data to determine if there are any observable trends. All results are expressed as concentrations. Refer to Appendix B, 2003 REMP Data Summary Reports for a detailed listing of these results. The NRC requires special reporting whenever sample analysis results exceed set limits. No values exceeded these reporting levels in 2003.

Program Changes

There were no changes in 2003.

Missed Samples

On occasion, samples cannot be collected. This can be due to a variety of events, including equipment malfunction, animal husbandry practices, or lost shipments. Events may also occur which prevent a sample from being collected in the normal way, or prevent a complete sample from being collected. The drying period for goats is an annual occurrence, since unlike cows, goats cannot produce milk year-round. Missing TLDs may be the result of vandalism. When vandalism has been identified as a recurring problem, the TLD is relocated. If the loss of a TLD is determined to be a single or unusual event, it is not normally relocated. Table 16 provides information on samples missed during 2003.

Table 16: Missed REMP Samples in 2003

Atmospheric Monitoring

Air

i :

Air sampling is conducted to detect any increase in the concentration of airborne radionuclides. The PNPP ODCM requires five locations (four indicator and one control). Air sampling pumps are used to draw continuous samples at a rate of approximately two cubic feet per minute. The air is drawn through glass fiber filters (to collect particulate material) and a charcoal cartridge (to adsorb Iodine). The samples are collected on a weekly basis, 52 weeks a year, from each of seven air sampling stations. Six (6) of these locations are within four miles of the plant site; the seventh is used as a control location and is eleven miles from PNPP.

On occasion, air sample locations can experience power losses associated with storms and/or malfunctioning equipment. No power losses or malfunctioning equipment were experienced during 2003.

Air samples are analyzed weekly for gross beta activity and radioiodine activity. The air samples are also analyzed by gamma spectral analysis quarterly. A total of 364 for air particulate and 364 air radioiodine samples were collected and analyzed in 2003.

Gross beta activity was detected in all air samples and ranged up to 0.04 pCi/m³. The annual average gross beta activity at both indicator and control locations was 0.02 pCi/m³. Historically, the concentration of gross beta in air has been essentially identical at indicator and control locations. Figure 5 reflects the average gross beta activity for 2003 and the previous years.

Except for naturally occurring beryllium-7, no radionuclides were identified in the gamma spectral analysis above the LLD values. Iodine-131 was not detected in any sample above the LLD of 0.05 pCi/m³.

Radiological Environmental Monitoring Page 28

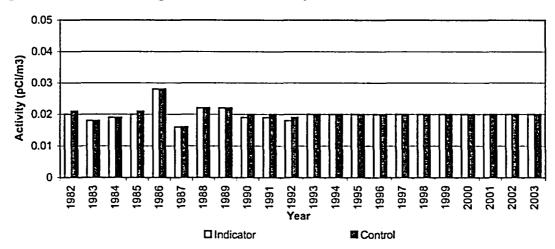

Figure 5: Annual Average Gross Beta Activity, in Air

Terrestrial Monitoring

Collecting and analyzing samples of milk, food products and vegetation provides data to assess the build-up of radionuclides that may be ingested by humans. The historical data from soil and vegetation samples provides information on the atmospheric radionuclide deposition. The PNPP ODCM requires neither vegetation nor soil samples.

Milk

Samples of milk are collected once each month from November through March, and twice each month from April through October. Sampling is increased during the summer because animals usually feed outside on pasture and not on stored feed. Through April 2003 the PNPP REMP included three (3) milk locations that are located between 7.4 and 9.6 miles away from the plant. In early May, milk location #71 retired from farming and withdrew from the program. Since the milk sampling locations did not meet the requirements of the ODCM (no milk-producing animals located within the required areas), food product sampling (discussed below) was performed. Milk was collected from the available locations, even though they did not meet the ODCM requirements. If new locations that meet the ODCM requirements are identified in the future, they will be added to the program.

Milk samples are analyzed by gamma spectral analysis for radioiodines and other radionuclides. A total of 37 milk samples were collected in 2003. Iodine was not detected above the LLD of 0.75 pCi/L in any of the samples. The concentrations of all radionuclides, except naturally occurring potassium-40, were below LLDs in all samples collected.

Food Products

Food products can provide a direct pathway to humans by ingestion. They can absorb radionuclides from atmospheric deposition on soil or from irrigation water drawn from a lake or pond receiving airborne or liquid effluents. Also, radionuclides in the soil may be absorbed by the roots of the plants and become incorporated into the edible portions. Because there is not a sufficient number of milk sampling locations, the PNPP REMP is required to include two food product indicator locations and one control location. Food products are collected monthly during the growing season from five farms in the vicinity of PNPP. The control location for food products is 16.2 miles from PNPP.

A total of sixty five (65) food product samples were collected and analyzed by gamma spectral analysis in 2003. Four (4) food products were collected which included: collard greens, turnip

greens, chinese cabbage and swiss chard. Beryllium-7 and potassium-40, naturally-occurring radionuclides, were found in several samples, as expected. No other radionuclides were detected above the required LLDs.

Aquatic Monitoring

Radionuclides may be present in Lake Erie from many sources other than the PNPP. These sources include atmospheric deposition, run-off/soil erosion, and releases of radioactivity in liquid effluents from hospitals, universities or other industrial facilities. These sources provide two forms of potential radiation exposure, external and internal. External exposure can occur from contact with water or shoreline sediments, while internal exposure can occur from either direct ingestion of radionuclides or the transfer of radionuclides through the aquatic food chain. Direct ingestion can occur from drinking the water, while the transfer via the aquatic food chain occurs from the eventual consumption of aquatic organisms, such as fish. To monitor these pathways, PNPP samples water, shoreline sediments, and fish.

Water

Water is sampled from five locations along Lake Erie in the vicinity of the PNPP as required by the PNPP ODCM. Samples from three locations are collected using composite sample pumps. The pumps are designed to collect water at regular intervals and composite it in a sample container. The containers are emptied monthly and the samples shipped to the laboratory for analysis. Samples from two locations are collected weekly and combined. Each month the combined sample is shipped for analysis.

Fifty-six (56) water samples were collected and analyzed for gross beta activity and gamma spectral analysis in 2003. From these monthly samples, a quarterly composite sample was obtained and analyzed for tritium activity. Refer to Table 16 for an explanation of missed samples.

Gross beta activity was detected in four (4) of the fifty-six (56) samples collected. The detectable (i.e., above the lab LLD value) gross beta activity ranged from 3.02 pCi/L to 3.81 pCi/L. Referring to Figure 6, the annual average gross beta activity was 3.30 pCi/L at the indicator locations and 3.81 pCi/L at the control location, using the mean of values >LLD. The significant difference between the pre-1988 data and post-1988 data has been attributed to a change in vendor laboratories in 1987/1988. A comprehensive explanation for the observed difference is provided in the 1988 Annual Environmental Operating Report.

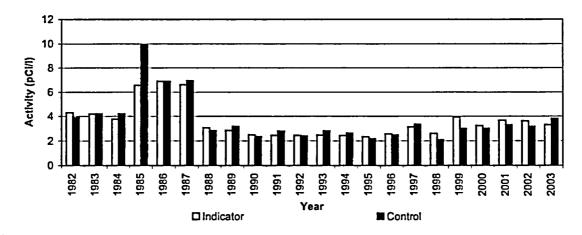

Figure 6: Annual Average Gross Beta Activity, in Water

There were no radionuclides detected by gamma spectral analysis above the LLD. Tritium was not detected above the LLD value in any of the twenty (20) samples analyzed. These results are well within the range of those measured in previous years, which have ranged from below the LLD to 2,200 pCi/L.

Sediment

Sampling lake bottom sediments can provide an indication of the accumulation of particulate radionuclides which may lead to internal exposure to humans through the ingestion of fish, the resuspension into drinking water, or as an external radiation source to fishermen and swimmers from shoreline exposure. Although the PNPP ODCM requires only one location, sediment is sampled twice each year from seven (7) locations. Two (2) of the sampling locations are also fish sampling locations. Sediment samples from offshore are collected using a hand dredge. Shoreline samples are collected using a scoop. Fourteen (14) sediment samples were collected in 2003 and analyzed by gamma spectrometry.

The predominant radionuclide detected by gamma spectral analysis was naturally-occurring potassium-40. Potassium-40 has been detected in all samples, since the program began in 1981.

Cesium-137 activity was detected in six (6) of the fourteen (14) samples collected and ranged from 142.95 pCi/kg to 1134.90 pCi/kg. The annual average cesium-137 activity was 334.56 pCi/kg at the indicator locations and 1028.57 pCi/kg at the control location. The average cesium-137 radioactivity for all locations was 565.90 pCi/kg and was within the maximum value of 864 pCi/kg established in 1981. Year-to-year variations in the lake bottom sediment sample activities is expected and beyond the control of PNPP. For example, cesium-137 activity variations (refer to figure 7) in the control locations from year-to-year may be contributed to:

- 1. The movement of sediment on the lake bottom due to wave action and currents, and
- 2. Sampling in nearly the same location approximately 4½ miles off-shore, even with GPS, is extremely difficult.

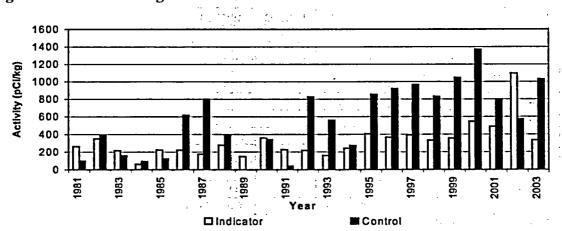

Figure 7: Annual Average Cesium-137 Concentration in Sediment

In 1999, a sediment sample from location #64 (shoreline discharge point of the northwest drain impoundment) was found to contain trace levels of cobalt-60. Ten (10) additional sample locations were established upstream from location #64 and within the impoundment to identify the boundary of the cobalt-60 activity and to support supplemental monitoring activities. For 2003, sample results for cobalt-60 confirm that no activity was identified at the discharge point (Location #64), and continues to remain within the northwest drain impoundment with activity ranging from <14.4 pCi/kg to 193 +/- 32 pCi/kg (Refer to Table 17). Also for comparison, cesium-137 activity within the impoundment is reflected in Table 18.

* No sample available or insufficient sample for analysis

Fish

Fish are analyzed primarily to quantify the dietary radionuclide intake by humans, and secondarily to serve as indicators of radioactivity in the aquatic ecosystem. Fish are collected from two locations, annually during the fishing season as required by the ODCM. An important sport or commercial species is targeted, and only the fillets are sent to the laboratory for analysis. In 2003, fish sampling was performed for PNPP by a local licensed sport fisherman.

Two (2) fish samples representing yellow perch were collected and analyzed by gamma spectral analysis in 2003. As expected, naturally occurring potassium-40 was found in all samples. No other radionuclides were detected above the LLD.

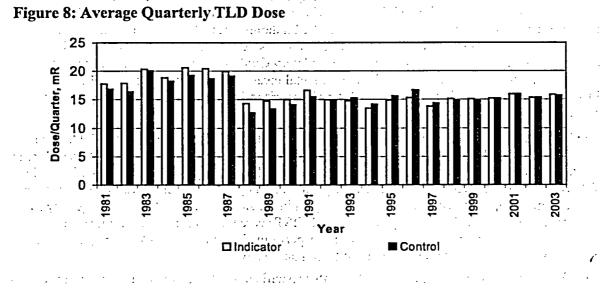

Direct Radiation Monitoring

Thermoluminscent Dosimeter (TLD)

Environmental radiation is measured directly at twenty-eight locations around the PNPP site, two of which are control locations. The locations are positioned in two rings around the plant as well as at the site boundary. The inner ring is within a one-mile radius of the plant site; the outer ring is four to five miles from the plant. The control locations are over ten miles from the plant in the two least prevalent wind directions. Each location is equipped with three TLDs, two of which are changed quarterly and one is changed annually.

A total of 248 TLDs were collected and analyzed in 2003. This includes 223 of 224 collected on a quarterly basis and twenty-five (25) of twenty-eight (28) collected annually. During the 2nd quarter collection of TLDs on 07/01/03, one (1) quarterly TLD at location 15 was found to be missing. Three annual TLDs were found to be missing during the fourth quarter collection performed on 01/06/04. Annual TLDs are not required per the ODCM and are used for supplemental data only.

In 2003, the annual average dose for all indicator locations was 67.88 mrem, and 73.59 mrem for all control locations. Referring to Figure 8, the average quarterly dose for all indicator locations was 15.84 mrem, and 15.71 mrem for all control locations. Prior to 1988, the TLD results were higher due to a change in the vendor laboratory services. A comprehensive explanation of this difference was provided in the 1988 Annual Environmental Operating Report.

Conclusion

Sediment samples continue to confirm cobalt-60 in the northwest drain impoundment. The activity level was just above the detection limits. Additional monitoring is being performed to monitor this location. An environmental evaluation determined that there would be less impact upon the environment by leaving this material in place. Atmospheric monitoring results were consistent with past results. The prevalent radionuclide in air was beryllium-7, which is naturally occurring. Naturally occurring potassium-40 was detected in all terrestrial samples, as expected. The annual concentrations excluding this sample were similar to those measured in previous years.

Finally, direct radiation measurements are consistent with past data.

INTER-LABORATORY CROSS-CHECK COMPARISON PROGRAM

Introduction

The purpose of the Inter-laboratory Cross-Check Comparison Program (ICCCP) is to provide an independent check on the vendor laboratory's analytical procedures. Samples with a known concentration of specific radionuclides are provided to the vendor laboratory. The vendor laboratory measures and reports the concentration of specified radionuclides. The known values are then compared to the vendor results. Results consistently outside established acceptance criteria indicate a need to check instruments or procedures. Regulatory Guide 4.15 specifically required that contractor laboratories that performed environmental measurement participate in the EPA's Environmental Radioactivity Laboratory Inter-Comparison Studies Program, or an equivalent program.

The EPA's program is not longer funded and no longer offered. The reason that the EPA program was referenced in the regulatory guide is that the EPA standards were traceable to National Bureau of Standards (now known as National Institute Standard Technology). In response to this problem, Teledyne (our vendor lab) incorporated a program offered by Environmental Resource Associates (ERA Company), which covered the same analyses in the same matrix at the same frequency as the EPA program. The ERA Company has received NIST accreditation for its program, as an equivalent program. In addition to comparison cross checks performed with the ERA Company, the vendor laboratory routinely monitors the quality of their analyses by:

- Analyzing "spiked" samples (samples with a specific quantity of radioactive material present in them),
- Participating in the Department of Energy's Mixed Analyte Performance Program (MAPEP), and
- Participating in the Environmental Measurements Laboratory Quality Assessment Program (EML).

Conclusion

Appendix A, 2003 Inter-Laboratory Cross Check Comparison Program Results, includes results from both the above referenced programs and the ERA Company cross-check program. In Table A-1, three (3) samples were determined to be outside the ERA program control limits: Sample STW-975 for gross alpha was analyzed twice and still failed, falling outside the control limits on the low side. No cause could be determined, however, subsequent analyses for gross alpha of various media within the Inter-Laboratory Cross-Check Comparison Program were found to be within their control limits. Sample STW-986 for Cs-134 analysis initially failed outside the control limits. Re-analysis results were within the control limits. Sample STW-990 for gross beta analysis initially exceeded the ERA control limits. Re-analysis was within the control limits.

The Vendor Laboratory's cross-check testing of Thermoluminescent Dosimetry, Table A-2 and Table A-3, the In-House "Spike" Samples were all within their control limits.

In Table A-4, In-House "Blank" Samples, two (2) milk samples (SPMI-2056, 4018) analyzed for Sr-90 were found to be outside the program acceptance criteria. Low levels of Sr-90 remain in the environment and concentrations of (1-5 pCi/l) found in milk is not unusual.

For Table A-5, In-House "Duplicate" Samples, two samples (SL-2910, 4399) for gross beta and 1 sample (CF-1049) for K-40 experienced longer count times resulting in lower errors.

For the MAPEP Program Table A-6, all analyses were within the expected control limits.

In Table A-7 the Environmental Measurements Laboratory Quality Assessment Program (EML), one sample result was found to be outside the expected control limits and the second was an error in preliminary reporting. Sample STW-978 for cesium-134 was analyzed and reported as lower than the EML result. The Vendor Lab found no errors with its equipment or efficiencies. This low bias of Cs-134 activity has been observed by the Vendor Lab in the past and will be corrected through additional spike analyses and calculation corrections. Sample STW-978 for tritium (H-3) was identified as a reporting error. During the conversion of pC to Bq, the incorrect result of 297.3 Bq/L was reported to EML. The value of 341.9 Bq/L referenced in Table A-7 is correct. All other analysis results performed under these programs were within the control limits established.

LAND USE CENSUS

Introduction

Each year a land use census, which is required by Section 3/4.12.2 of the PNPP ODCM, is conducted to identify the locations of the nearest milk animal, garden (of greater than 500 square feet), and residence in each of the meteorological sectors that is over land. Information gathered during the Land Use Census is used for off-site dose assessment and to update sampling locations for the Radiological Environmental Monitoring Program. The census is conducted by traveling all roads within a five-mile radius of the plant site, and recording and mapping the location of the nearest resident, milk animal, and vegetable garden. The 2003 Land Use Census, which was conducted July 9th and 10th provided the garden, residence and milk animal locations tabulated in Tables 19, 20 and 21 and depicted in Figure 9. Note that the W, WNW, NNW, NW, N, and NNE sectors extend over Lake Erie, and therefore, are not included in the survey.

Discussions and Results

In general, the predominant land use within the census area continues to be rural/agricultural. In recent years however, it has been noted that tracts of land once used for farming are now being developed as mini industrial parks and residential housing tracts. This is reflected in the loss of available milking animals within a five mile radius of PNPP to support the Radiological Environmental Monitoring Program (REMP). The 2003 Land Use Survey used the 1999 survey map produced by the Commercial Survey Co. of Cleveland. GPS units are used for more accurate location identification.

Table 19 identifies the nearest residences, by sector, to the PNPP. The table is updated annually to reflect any changes identified during the annual Land Use Census. For 2003, there is one (1) change noted for the "nearest residence" in the SSE sector. A name change occurred for the extension of Parmly Road. It is now known as Redmill Valley Road.

CLAM/MUSSEL MONITORING

INTRODUCTION

Sampling for benthic macro-invertebrates (clams and mussels) has been conducted in Lake Erie in the vicinity of PNPP, since 1971. The clam/mussel program currently focuses on two species: *Corbicula fluminea* (Asiatic clam) and *Dreissena polymorpha* (zebra mussel).

CORBICULA PROGRAM

Monitoring specifically for Corbicula was initiated in response to a NRC bulletin and concerns of the Atomic Safety and Licensing Board. The 2003 monitoring was done as part of the Environmental Protection Plan (Operating License, Appendix B). The program consists of visually inspecting the raw water systems, whenever they are opened for maintenance. The purpose of this program is to detect Corbicula, should it appear at PNPP.

No Corbicula have ever been found in any sample collected from PNPP or from Lake Erie in the vicinity of PNPP. Two Corbicula were found in a sample collected from the Eastlake plant in June, 1987. No Corbicula have been found in any other sample collected since that time. A more detailed program history can be found in the 1986 and 1987 PNPP Annual Environmental Operating Reports.

Monitoring

In 2003, samples were collected from the Service Water (SW), Emergency Service Water (ESW), Fire Water, and Circulating Water (CW) systems at PNPP. All samples were collected by Ponar hand dredge, hand scoop, or scraper. They were examined for asiatic clam shells and fragments. In addition to sample collections, plant components that use raw water are inspected whenever opened for maintenance or repair. Sample collection/inspection dates are listed in Table 22.

Table 22: 2003 Corbicula Monitoring

Conclusions

The sample collected in June, 1987, was the only indication of Corbicula in the vicinity of PNPP. Although the presence of Corbicula was detected at the Eastlake Power Plant, it has not been demonstrated that their presence has created any operational problems there, or at PNPP. As in the past, the 2003 monitoring program did not identify Corbicula in any sample collected.

DREISSENA PROGRAM

Dreissena, or Zebra mussels were first discovered at PNPP in September, 1988. The initial collection of 19 mussels was made as part of the Corbicula monitoring program. The Dreissena monitoring program began in 1989, with monitoring and testing. The current control program was designed and implemented in 1990.

Monitoring

In addition to visually inspecting the plant's raw water systems when they are opened for maintenance or repair, monitoring methods include the use of commercial divers, side-stream monitors, and plankton nets. Commercial divers monitor mussel infestation during the inspection of forebays, basins, and the intake and discharge structures. Divers have also been used to take underwater videotapes of the water basins and intake tunnel. Side-stream monitors are flow-through containers that receive water diverted from plant systems, and are normally used in three in-plant locations during the mussel season. The side-stream monitors are fitted with slides and inspected for veliger settlement. In 2003, a plankton net was used on a limited basis to help trend veligers during the spawning season and samples from the side-stream monitors were filtered and evaluated.

Treatment

Chemicals used for mussel control in 2003 included chlorine and a commercial molluscicide. The chlorine is intermittently injected into the plant service water, emergency service water, and circulating water systems by metering sodium hypochlorite into each system's influent. Sodium sulfite or sodium bisulfite is added at the plant discharge structure for dechlorination prior to return into Lake Erie.

The use of a commercial molluscicide requires approval by the Ohio Environmental Protection Agency (OEPA). The chemical selected for use at the PNPP in 2003 was alkyl-dimethyl-benzyl-ammonium chloride. One treatment was applied in September, 2003. The active ingredients were detoxified by adsorption onto bentonite clay, prior to discharge into Lake Erie.

Results

The effectiveness of the intermittent chlorination treatment has been determined in several ways. First, visual inspections of raw water system components are conducted when systems are open during maintenance or repair. In addition, settlement monitors were inspected for new settlement. No live settlement has been found in any plant component to date.

The effectiveness of the application of the commercial molluscicide was measured by observing mortality of mussels placed in a flow-through container placed in plant service water and subjected to the chemical treatment. The observed mortality rate in the flow-through container was 99%. To date, PNPP has had no problems related to zebra mussels.

CONCLUSIONS

Perry Nuclear Power Plant has taken the approach that the best method for avoiding problems with zebra mussels is preventive treatment of plant water systems. The current program of monitoring and chemical treatment will be continued to minimize the possibility that PNPP will experience future problems due to zebra mussels.

HERBICIDE APPLICATIONS

Herbicides are used sparingly on the PNPP site. A request must be made to, and approved by the PNPP Chemistry Unit prior to spraying to ensure that only approved chemicals are used, and only in approved areas.

In 2003, three (3) general and one (1) specific herbicide requests were initiated for chemical applications. Each application was in compliance with the Ohio Environmental Protection Agency's rules and regulations. There were no adverse environmental impacts observed during weekly site environmental inspections as a result of these applications. The herbicides approved for use in the Owner-Controlled Area are Round-Up, Riverdale, Karmex, Peptoil and Glypro Plus. For each application, the type of weed to be treated dictated the herbicide and concentration to be used. Table 23 provides detailed documentation for each application in 2003. The quantity represents the amount of herbicide applied, after any dilution.

Application Date	Location	Area sq ft	Quantity gal or Ibs	Chemical Conc.	Chemical Name

SPECIAL REPORTS

NON-COMPLIANCES

NPDES Permit

The National Pollutant Discharge Elimination System (NPDES) permit is issued by the Ohio Environmental Protection Agency (OEPA). It establishes monitoring requirements and limits for discharges from the PNPP. It also specifies the locations from which the plant is allowed to discharge.

There was one NPDES non-compliance issue identified in 2003:

On June 30, 2003, the OEPA was notified that the Preliminary Effluent Limit (PEL) for copper was exceeded during the month of June 2003. The increase in copper at the plant effluent coincided with a large increase of copper levels entering the plant from Lake Erie. This notification was made in accordance with the National Pollutant Discharge Elimination System (NPDES) Permit. Environmental Protection Plan

The Environmental Protection Plan (EPP), which is a part of the PNPP Operating License, requires a non-radiological environmental monitoring and reporting program be established at the PNPP. There were no instances of an EPP non-compliance identified in 2003.

UNREVIEWED ENVIRONMENTAL QUESTIONS

All proposed changes to the PNPP design or operation, as well as tests or experiments, must be evaluated for potential environmental impacts in accordance with the EPP and administrative quality assurance procedures. In 2003, these reviews ensured that no changes to the facility or programs were performed, which could have resulted in an adverse environmental impact. Therefore, there were no potentially significant unreviewed environmental questions identified. NON-ROUTINE REPORTS

There were three (3) non-routine reports submitted in 2003.

On January 29, 2003, the OEPA was notified that construction was completed on the dechlorination system upgrade and the system would now be using sodium bisulfate as the dechlorination chemical. This notification was made in accordance with the National Pollutant Discharge Elimination System (NPDES) Permit.

On June 30, 2003, the OEPA was notified that the Preliminary Effluent Limit (PEL) for copper was exceeded during the month of June 2003. The increase in copper at the plant effluent coincided with a large increase of copper levels entering the plant from Lake Erie. This notification was made in accordance with the National Pollutant Discharge Elimination System (NPDES) Permit.

On September 30, 2003, the OEPA was notified of maintenance that would be performed on the neutralization basins. This notification was made in accordance with the National Pollutant Discharge Elimination System (NPDES) Permit.

OHIO DEPARTMENT OF NATURAL RESOURCES SURVEY

On February 21, 2003, the Ohio Department of Natural Resources (ODNR), Division of Wildlife contacted Perry requesting permission to access areas where spotted turtles had been previously documented. Perry granted the ODNR representative access, and the environmental staff participated in the surveys of the area. Although no spotted turtles were found in the previously recorded area, this was attributed to the area having been overrun by the *Phragmites sp.*

At the time of this report, the ODNR did not have their final report complete. Below is an excerpt from the draft summary of the report:

"Records indicate that the Spotted Turtle was at one time fairly common in the powerline right-ofway east of the Perry Nuclear Power Plant. In 1986, the NUS Corporation estimated a population size of 148 in a 22 acre area, based on a five year mark-recapture survey. A total of 66 Spotted Turtles were captured during this period.

The 2003 survey did not result in the capture of any Spotted Turtles on the Perry Nuclear Power Plant property. The wet prairies and meadows along the powerline right-of-way have been overrun by *Phragmites sp.* reducing their suitability as Spotted Turtle habitat. (It is believed that this native plant has been hybridized with European *Phragmites sp.*, causing it to become more aggressive in many areas.) The discovery of an open canopy fen late in 2003, however, has renewed hopes that the Spotted Turtle may still be found on the property. This fen has yet to be substantially impacted by *Phragmites sp.*

One other reptile species, the Common Snapping Turtle (*Chelydra serpentina serpentina*) was observed during the 2003 surveys. Amphibians observed on the property include the Spotted Salamander (*Ambystoma maculatum*), Red-backed Salamander (*Plethodon cinereus*), and Western Chorus Frog (*Pseudacris triseriata triseriata*). The extensive wooded wetlands on the property offer excellent habitat for these species."

The ODNR representative has also stated verbally to the environmental staff, that the plant's protection of these areas has maintained excellent habitat for various species. It was also stated that one of the species of salamanders observed is not commonly found in Ohio. Perry will continue to cooperate with the ODNR on any further request to access the property for surveys.

Appendix A

Interlaboratory Comparison Program Results

Environmental, Inc., Midwest Laboratory, formerly Teledyne Brown Engineering Environmental Services Midwest Laboratory has participated in interlaboratory comparison (crosscheck) programs since the formulation of it's quality control program in December 1971. These programs are operated by agencies which supply environmental type samples containing concentrations of radionuclides known to the issuing agency but not to participant laboratories. The purpose of such a program is to provide an independent check on a laboratory's analytical procedures and to alert it of any possible problems.

Participant laboratories measure the concentration of specified radionuclides and report them to the issuing agency. Several months later, the agency reports the known values to the participant laboratories and specifies control limits. Results consistently higher or lower than the known values or outside the control limits indicate a need to check the instruments or procedures used.

Results in Table A-1 were obtained through participation in the environmental sample crosscheck program administered by Environmental Resources Associates, serving as a replacement for studies conducted previously by the U.S. EPA Environmental Monitoring Systems Laboratory, Las Vegas, Nevada.

The results in Table A-2 were obtained for Thermoluminescent Dosimeters (TLDs), via International Intercomparison of Environmental Dosimeters under the sponsorships listed in Table A-2. Results of internal laboratory testing is also listed.

Table A-3 lists results of the analyses on in-house "spiked" samples for the past twelve months. All samples are prepared using NIST traceable sources. Data for previous years available upon request.

Table A-4 lists results of the analyses on in-house "blank" samples for the past twelve months. Data for previous years available upon request.

Table A-5 list results of the in-house "duplicate" program for the past twelve months. Acceptance is based on the difference of the results being less than the sum of the errors. Data for previous years available upon request.

The results in Table A-6 were obtained through participation in the Mixed Analyte Performance Evaluation Program.

The results in Table A-7 were obtained through participation in the Environmental Measurement Laboratory Quality Assessment Program.

Attachment A lists acceptance criteria for "spiked" samples.

Out-of-limit results are explained directly below the result.

Results obtained by Environmental, Inc., Midwest Laboratory as a participant in the environmental samples crosscheck program operated by Environmental Resources Associates (ERA).

^b Unless otherwise indicated, the laboratory result is given as the mean ± standard deviation for three determinations. ^c Results are presented as the known values, expected laboratory precision (1 sigma, 1 determination) and control limits

as provided by ERA.

1

- ^d Recount of the original sample still low. The ERA blank was spiked in the lab;
- known value of 20.1 pCi/L, measured 21.5 ± 1.1 pCl/L. No explanation for ERA test failure. * Lower bias observed for gamma spectroscopic analysis. The undiluted sample was reanalyzed;
- Results of reanalysis, Co-60: 62.3 pCi/L., Cs-134: 69.2 pCi/L., Cs-137: 152.3 pCi/L.
- ¹ Reason for deviation unknown. A recount of the original planchets averaged 43.4 pCi/L.

Cs-137activity by gamma spectroscopy; 28.3 pCi/L. Result of reanalysis; 29.3 pCi/L.

Attachment A

ACCEPTANCE CRITERIA FOR "SPIKED" SAMPLES

LABORATORY PRECISION: ONE STANDARD DEVIATION VALUES FOR VARIOUS ANALYSES^a

Analysis	Level	One standard deviation for single determination
Gamma Emitters	5 to 100 pCi/liter or kg > 100 pCi/liter or kg	5.0 pCi/liter 5% of known value
Strontium-89 ^b	5 to 50 pCi/liter or kg > 50 pCi/liter or kg	5.0 pCi/liter 10% of known value
Strontium-90 ^b	2 to 30 pCi/liter or kg > 30 pCi/liter or kg	5.0 pCi/liter 10% of known value
Potassium-40	> 0.1 g/liter or kg	5% of known value
Gross alpha	20 pCi/liter > 20 pCi/liter	5.0 pCi/liter 25% of known value
Gross beta	100 pCi/liter > 100 pCi/liter	5.0 pCi/liter 5% of known value
Tritium	4,000 pCi/liter	1s = (pCi/liter) = 169.85 x (known) ^{0.0933}
	> 4,000 pCi/liter	10% of known value
Radium-226,-228	0.1 pCi/liter	15% of known value
Plutonium	0.1 pCi/liter, gram, or sample	10% of known value
Iodine-131, Iodine-129 ⁶	55 pCi/liter > 55 pCi/liter	6.0 pCi/liter 10% of known value
Uranium-238, Nickel-63 ^b Technetium-99 ^b	35 pCi/liter > 35 pCi/liter	6.0 pCi/liter 15% of known value
Iron-55 ^b	50 to 100 pCi/liter > 100 pCi/liter	10 pCi/liter 10% of known value
Others ^b	-	20% of known value

From EPA publication, *Environmental Radioactivity Laboratory Intercomparison Studies Program, Fiscal Year, 1981-1982, EPA-600/4-81-004.

^b Laboratory limit.

ĩ

Liquid sample results are reported in pCi/Liter, air filters (pCi/filter), charcoal (pCi/charcoal canister), and solid samples (pCi/kg).

^b The activity reported is the net activity result.

Ĩ

ł

.

^b The activity reported is the net activity result.
 ^c Low levels of Sr-90 are still detected in the environment. A concentration of (1-5 pCi/L) in milk is not unusual.

1

Note: Duplicate analyses are performed on every twentieth sample received in-house. Results are not listed for those analyses with activities that measure below the LLD.

^a Results are reported in units of pCi/L, except for air filters (pCi/Filter), food products, vegetation, soil, sediment (pCi/g).

^b 200 minute count time or longer, resulting in lower error.

TABLE A-6. Department of Energy's Mixed Analyte Performance Evaluation Program (MAPEP)^a.

^a Results obtained by Environmental, Inc. ,Midwest Laboratory as a participant in the Department of Energy's Mixed Analyte Performance Evaluation Program, Idaho Operations office, Idaho Falls, Idaho

1, 50 ,

^b All results are in Bq/kg or Bq/L as requested by the Department of Energy.

11

1

^c MAPEP results are presented as the known values and expected laboratory precision (1 sigma, 1 determination) and control limits as defined by the MAPEP.

TABLE A-7. Environmental Measurements Laboratory Quality Assessment Program (EML)

* Results are reported in Bq/L with the following exceptions: Air Filters (Bq/Filter), Soil and Vegetation (Bq/kg).

^b The EML result listed is the mean of replicate determinations for each nuclide ± the standard error of the mean.

^c Control limits are reported by EML as the ratio of Reported Value / EML value.

^d A low bias for Cs-134 activity has been observed in the past. No errors have been found in the library or efficiency. Additional spike analyses will be performed and a correction factored into the calculation.

* Reporting error.

APPENDIX E, 2002 CORRECTIONS TO AEERR

Appendix E Page 50

Corrections for Table 6: Solid Waste Shipped Offsite for Burial or Disposal (Not Irradiated Fuel) are reflected below. This revised table is the result of late reporting by one of Perry Power Plant's contracted waste processors, creating inaccuracies in previously reported volumes and activity.

Α.	Type of Waste	VOLUME m ³	ACTIVITY Ci	Period	Est. Total Error %
	Spent resin, filter sludge, evaporator bottoms, etc.	14.5	900.1	1/1/2003- 12/31/2003	+/- 25
	Dry compressible waste, contaminated equipment, etc.	47.47	13.6	1/1/2003- 12/31/2003	+/- 25
	Irradiated components, control rods, etc.	••••0	0	1/1/2003- 12/31/2003	+/- 25
	Other (describe)	0	• • • • • • • • • • • • • • • • • • •	1/1/2003- 12/31/2003	+/- 25

A: Solid Waste Shipped Offsite for Burial or Disposal (Not irradiated fuel)

B.	Estimate of Major ⁽¹⁾ Nuclide Composition (by type of waste)	RADIONUCLIDE	ABUNDANCE %	EST. TOTAL ERROR, %
	Spent Resin, Filter Sludge, Evaporator Bottoms, etc.	Mn-54 Fe-55 Co-60 Zn-65 Ag-110m Cs-137 Ce-144	10.2 26.9 52.5 3.5 1.4 1.2 1.1	±25
	Dry Compressible Waste, Contaminated Equipment, etc.	Mn-54 Fe-55 Co-60 Zn-65 Ce-144	4.1 48.4 36.5 2.7 5.7	± 25
	Irradiated Components, Control Rods, etc.	None	0	N/A
	Other (describe)	None	N/0	N/A

C. Disposition	Number of Shipments	Mode of Transportation	Destination
Solid Waste ⁽²⁾	2	Truck	Barnwell, SC
Irradiated Fuel Shipments	0	N/A	N/A

N/A -- Not Applicable

 (1) - "Major" is defined as any individual radionuclide identified as >1% of the waste type abundance.
 (2) - Additional shipments were made to Studsvik, in Erwin, TN; Duratek, Oak Ridge, TN. This waste was combined with waste from other utilities disposed of at Barnwell, SC or Envirocare of Utah.

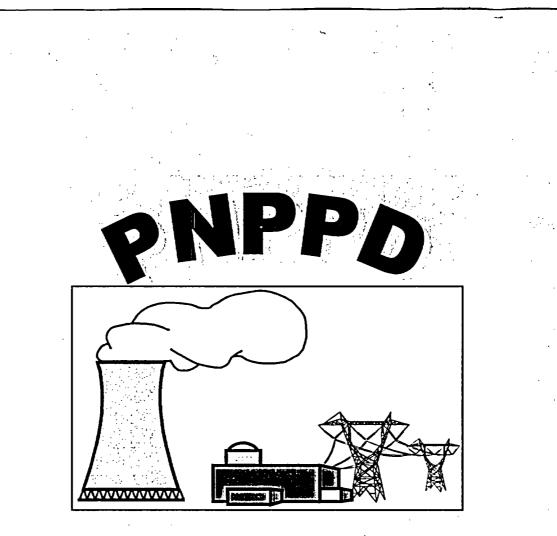

Corrections for Tables 19 and 21: Revisions to X/Q and D/Q values for Nearest Residence and Nearest Garden were not performed for the 2002 AEERR The updated tables are as follows:

SECTOR	LOCATION ADDRESS	MILES FROM PNPP	X/Q VALUE, sec/m ³	MAP LOCATOR NUMBER
NE	4384 Lockwood	0.7	2.66E-06	1
ENE	4460 Lockwood	0.8	1.59E-06	2
E	2626 Antioch	1.1	6.77E-07	3
ESE	2750 Antioch	1.0	8.57E-07	4
SE	4537 North Ridge	1.3	3.44E-07	5
SSE	4247 Parmly	1.1	5.52E-07	6
S	3119 Parmly	0.9	2.25E-06	7
SSW	3121 Center	0.9	1.11E-06	8
SW	3440 Clark	1.3	4.42E-07	9
WSW	3462 Parmly	1.1	8.67E-07	10

Table 19: Nearest Residence, By Sector

Table 21: Nearest Garden, By Sector

SECTOR	LOCATION ADDRESS	MILES FROM PNPP	D/Q VALUE, m ⁻²	MAP LOCATOR NUMBER
NE	No gardens available	N/A	N/A	N/A
ENE	2382 Antioch	1.1	4.77E-09	12
