

# Realistic High Burnup $\text{UO}_2$ Fuel Response to a LOCA in a PWR

Mitch Nissley  
SEGFSM Topical Meeting on LOCA Issues  
Argonne National Laboratory  
May 26, 2004

# Objectives

---

- Compare LBLOCA Transient Response for Lead Fresh and High Burnup Assemblies in Same Core
- Realistic Codes will be Used, but Typical Design Basis Assumptions will be Applied (Worst Single Failure, etc.)
- NRC-Approved Uncertainties in Physical Models and Plant Conditions Applied

# Burnup Effects Considered

---

1. Depletion of Fissionable Isotopes ("Burndown")
2. Fuel Thermal Conductivity Degradation
3. Fission Gas Release/Rod Internal Pressure
4. Decay Heat Contributors

# Analysis Tools

---

## WCOBRA/TRAC – System T/H Response Uncertainties

Vessel – two fluid, three fields (vapor, continuous liquid, droplets)

Loops – drift flux

## HOTSPOT – Fuel and heat transfer model uncertainties

1-D conduction code, uses WC/T boundary conditions  
(explicit fuel relocation model for burst node)

# Analysis Method for Fresh Fuel

---

- Non-Parametric Statistical Method
- Sampling From Uncertainty Distributions for ~40 Parameters for Each of 59 Cases
  - Worst case captures at least 95% of PCT distribution with 95% confidence
- Key WC/T Parameters Include Break Flow (1 ft<sup>2</sup> => DEG), Axial Power Shape, Peaking Factors & Burnup (Stored Energy)
- Key HOTSPOT Parameters Include Fuel Conductivity, Gap Conductance, Heat Transfer to Fluid

# Modifications for High Burnup Fuel

---

- Peaking Factor Reductions (25% at 45 GWD/MTU to 40% at 65 GWD/MTU)
- Thermal Conductivity Degradation (Estimated Using NUREG/CR-6534, FRAPCON-3)
- Fission Gas Constituents, Rod Pressure
- Decay Heat  
=> All Other Parameters at Previously Sampled Values

# Burndown for Typical Core Designs (Tech Spec Limit = 1.65)

# Analysis Results (59 Cases)

---

- Fresh Fuel: Worst Case = 1082°C (1980°F)
- High BU Fuel: All Cases < 860°C (1580°F)
- PCT Margin for High Burnup Fuel in Top 5 Fresh Fuel Cases Ranges from 152 – 249°C (274 – 449°F)

# PCT Comparisons – Top Two Fresh Fuel Cases (WCOBRA/TRAC)

4-Loop PWR  
PCT Case 5

4-Loop PWR  
PCT Case 30

# PCT Comparisons – 3<sup>rd</sup> and 4<sup>th</sup> Cases

4-Loop PWR  
PCT Case 29

4-Loop PWR  
PCT Case 34

# PCT Comparison – 5<sup>th</sup> Case

# PCT Results for Fresh Fuel

**PCT vs. Burnup - Fresh Fuel (59 Runs)**

# PCT Results for High Burnup Fuel

PCT vs. Burnup - High Burnup (59 Runs)

# PCT Comparisons vs Burnup

**PCT(Fresh Fuel) - PCT(High Burnup)**  
(Limited to Cases where PCT(Fresh Fuel) > 1600 F)

# Factors Affecting ? PCT Through the Cycle

- Cladding Creepdown in Fresh Fuel Tends to Decrease ? PCT
- Thermal Conductivity Degradation in High Burnup Fuel (Not Modeled in Fresh Fuel) Tends to Decrease ? PCT
- Burndown Tends to Increase ? PCT

# Conclusions/Implications

---

- Depletion of Fissionable Isotopes in  $\text{UO}_2$  Fuel with Burnup Significantly Reduces the Achievable PCT for High Burnup Fuel
  - No High Burnup Case Exceeded  $860^\circ\text{C}$  ( $1580^\circ\text{F}$ )
- Testing of High Burnup  $\text{UO}_2$  Fuel to  $1204^\circ\text{C}$  ( $2200^\circ\text{F}$ ) Clearly Bounding, But Results Need to Be Considered in Realistic Context
  - => Realistic oxidation in high BU  $\text{UO}_2$  fuel expected to be negligible if fresh fuel satisfies 10 CFR 50.46
