AVAILABILITY NOTICE

Availability of Reference Materials Cited in NRC Publications

Most documents cited in NRC publications will be available from one of the following sources:

1. The NRC Public Document Room, 2120 L Street, NW., Lower Level, Washington, DC 20555-0001
2. The Superintendent of Documents, U.S. Government Printing Office, P. O. Box 37082, Washington, DC 20402-9328
3. The National Technical Information Service, Springfield, VA 22161-0002

Although the listing that follows represents the majority of documents cited in NRC publications, it is not intended to be exhaustive.

Referenced documents available for inspection and copying for a fee from the NRC Public Document Room include NRC correspondence and internal NRC memoranda; NRC bulletins, circulars, information notices, inspection and investigation notices; licensee event reports; vendor reports and correspondence; Commission papers; and applicant and licensee documents and correspondence.

The following documents in the NUREG series are available for purchase from the Government Printing Office: formal NRC staff and contractor reports, NRC-sponsored conference proceedings, international agreement reports, grantee reports, and NRC booklets and brochures. Also available are regulatory guides, NRC regulations in the *Code of Federal Regulations*, and *Nuclear Regulatory Commission Issuances*.

Documents available from the National Technical Information Service include NUREG-series reports and technical reports prepared by other Federal agencies and reports prepared by the Atomic Energy Commission, forerunner agency to the Nuclear Regulatory Commission.

Documents available from public and special technical libraries include all open literature items, such as books, journal articles, and transactions. *Federal Register* notices, Federal and State legislation, and congressional reports can usually be obtained from these libraries.

Documents such as theses, dissertations, foreign reports and translations, and non-NRC conference proceedings are available for purchase from the organization sponsoring the publication cited.

Single copies of NRC draft reports are available free, to the extent of supply, upon written request to the Office of Administration, Distribution and Mail Services Section, U.S. Nuclear Regulatory Commission, Washington DC 20555-0001.

Copies of industry codes and standards used in a substantive manner in the NRC regulatory process are maintained at the NRC Library, Two White Flint North, 11545 Rockville Pike, Rockville, MD 20852-2738, for use by the public. Codes and standards are usually copyrighted and may be purchased from the originating organization or, if they are American National Standards, from the American National Standards Institute, 1430 Broadway, New York, NY 10018-3308.

ABSTRACT

The action being considered in this Final Generic Environmental Impact Statement (GEIS) is an amendment to the Nuclear Regulatory Commission's (NRC) regulations in 10 CFR Part 20 to include radiological criteria for decommissioning of lands and structures at nuclear facilities. Under the National Environmental Policy Act (NEPA), all Federal agencies must consider the effect of their actions on the environment. To fulfill NRC's responsibilities under NEPA, the Commission is preparing this GEIS which analyzes alternative courses of action and the costs and impacts associated with those alternatives.

In preparing the final GEIS, the following approach was taken: (1) a listing was developed of regulatory alternatives for establishing radiological criteria for decommissioning; (2) for each alternative, a detailed analysis and comparison of incremental impacts, both radiological and nonradiological, to workers, members of the public, and the environment, and costs were performed; and (3) based on the analysis of impacts and costs, conclusions on radiological criteria for decommissioning were provided. Contained in the GEIS are results and conclusions related to achieving, as an objective of decommissioning ALARA, reduction to preexisting background, the radiological criterion for unrestricted use, decommissioning ALARA analysis for soils and structures containing contamination, restricted use and alternative analysis for special site-specific situations and groundwater cleanup. In its analyses, the final GEIS includes consideration of comments made on the draft GEIS (NUREG-1496, August 1994) during the public comment period.

APPENDIX A

BACKGROUND AS AN ALTERNATIVE RESIDUAL RADIOACTIVITY CRITERION FOR DECOMMISSIONING

APPENDIX A

A.1 Return to Background

In a return to background alternative residual radioactivity criterion for decommissioning, criteria would be established requiring the removal of all radioactivity attributable to licensed activities. A site would be released for unrestricted use only after all radioactivity attributable to licensed activities has been removed and background levels existing prior to licensing have been achieved.

A.2 Discussion of Background

Background is comprised of various sources of ionizing radiation which collectively produce an average total effective dose equivalent of about 300 mrem/y to a U.S. resident. Radiological doses from background typically range between 100 mrem/y and 1,000 mrem/y in the United States. Although greater radiological doses are possible for people living in houses with very high radon concentrations, 1,000 mrem could be taken as a practical maximum, excepting the extremes of unusual situations. For comparison, the estimate of the average U.S. radiological dose from background is similar to the world average estimate of 240 mrem/y. NUREG-1501 (NRC, 1994) contains a detailed discussion of sources, levels, and variability of background; the following discussion summarizes Section 2 of NUREG-1501.

Table A.1 provides a breakdown of the sources of natural background. In addition to the amounts in Table A.1, relatively minor contributors to the radiological dose from background (less than 1% each) are cosmogenic radionuclides, created by the interaction of cosmic rays with otherwise stable elements present on earth, and man-made fallout radionuclides from nuclear weapons testing.

Background produces radiological doses to the U.S. population that are highly variable between locations (spatial) and also over time at the same place (temporal). For example, cosmic radiation is modulated by the 11-year solar cycle and typically varies about 10% at the same location, but at different times. Temporal variability of background is also tied to atmospheric circulation and precipitation patterns that affect the distribution of cosmogenic and fallout radionuclides. Short-term changes in external gamma exposure arise from redistribution of radon decay products in the atmosphere and washout with precipitation, resulting in changes ranging from a few percent to more than 200% over the course of a day or season. Even larger variations in indoor radon concentrations can occur because of building ventilation changes. Indoor levels of gamma radiation typically vary by about 50% due to the use of different construction materials. Outdoors, changes in soil moisture and snow cover cause external gamma radiation levels to vary seasonally by 10 to 50% at the same location. The concentration of radionuclides that produce internal doses, such as Pb-210 in body tissues, has been observed to vary by about a factor of three throughout the

United States. Spatial variability of cosmic radiation is observed to be as much as 200%, depending greatly on altitude and to a lesser extent on latitude.

Nearly all materials contain naturally occurring radioactivity due to the presence of terrestrial radionuclides, such as K-40, Rb-87, Th-232, and U-238, and cosmogenic radionuclides, such as C-14, H-3, Be-7 and Na-22. The concentration of these radionuclides in soil, water, air, and living matter can vary widely throughout the country because of geological processes, climatic changes, weather, and human activities. For example, concentrations of uranium and thorium in the soil range from as little as one-tenth to as much as four times the average value. Data contained in Table A.2 illustrate a typical range of natural radionuclide concentrations in soil throughout the United States and the world.

The concentration of the principal gamma-emitting radionuclides in soil is directly related to the external gamma radiation levels in a locale. On a nationwide scale, the concentrations of terrestrial radionuclides vary widely, which is reflected in the grouping of external gamma radiation levels into three regions: (1) the Atlantic and Gulf coastal plains, which averages about half of the level seen for Middle America (23 mrad/y); (2) Middle America which has an average level of 46 mrad/y; and (3) the Denver, Colorado area, which has an average level about twice that of Middle America (90 mrad/y). Throughout the United States, concentrations of naturally occurring radionuclides in groundwater can also vary widely. In certain areas of the midwest, for example, the concentration of uranium in water (0.35 pCi/l) is 35 times greater than that found in some eastern states (0.01 pCi/l), but even greater concentrations are reported in western areas of the country, where natural uranium concentrations in groundwater (3.5 pCi/l) are 350 times that of eastern groundwater.

On a smaller scale, such as within an individual State, background radioactivity levels can vary even more. For example, in a particular location in northwestern New Jersey, external gamma radiation levels triple across a small field and, at a nearby rock outcropping, the average soil concentration of naturally occurring radionuclides increases one-hundred-fold, yet 62 miles away from this location, gamma radiation levels fall to less than 10% of the regional average due to the presence of sandy beaches.

Spatial variability in the concentration of background radionuclides can also be caused by human activities. Fallout from a nuclear weapon test can change background abruptly and require a few months to a few decades to decay. Such testing has correspondingly increased the spatial variability of background because the distribution of fallout radionuclides in the United States is not homogeneous. Mining and milling have also increased the spatial variability of background by redistributing the preexisting concentrations of naturally occurring radionuclides in a locale. Another human activity that affects the spatial distribution of background is the combustion of fossil fuels which produces ash that redistributes natural radioactivity from the ground to the air.

In addition to naturally occurring sources of radiation, nuclear technology has led to the creation of man-made radionuclides that contribute to the background radiological dose. Man-

made sources of ionizing radiation exposure account for 18% of the total radiological dose to the U.S. population. Of the man-made sources, medical x-ray examinations are the largest source of exposure, producing 11% of the total dose (39 mrem/y). Nuclear medicine procedures account for 4% of the total population dose, followed by consumer products (3%), weapons test fallout (less than 1%) and occupational exposures (less than 1%). On average, however, 82% of the total dose to the U.S. population comes from naturally occurring radiation sources. The magnitude and variability of radiation doses is directly proportional to the background level that individuals are exposed to and the activities in which they are engaged. Because of their widely varying and ubiquitous characteristics, radiation doses to U.S. residents from background, in turn, vary widely, as well.

A.3 Impacts and Costs for a Dose Criterion of "0" mrem/y Above Background

A "return-to-background" regulatory alternative which requires removal of all residual radioactivity attributable to licensed activities would have a dose criterion value of "0" mrem/y above background. A "0" mrem/y above background alternative was not explicitly studied, but impacts and costs for a "0" mrem/y above background alternative can be analyzed by inference based on Appendices B, C, and D. Based on the low individual doses and the trends indicated in Appendix B, the rate of reduction in health impacts below approximately 3 mrem/y tends to become smaller or negative (indicating net increase in mortality). This trend is expected to continue to "0" mrem/y and suggests that there is not necessarily a further health and safety benefit in establishing a return-to-background alternative that is on the order of "0" mrem/y above background and could also result in a detriment. Appendices C and D suggest that, in general, expenditures made for soil and concrete removal and radiation surveys to reduce impacts to a dose criterion of "0" mrem/y above background may be very large.

A significant consideration in determining the effectiveness of a return-to-background alternative is whether available radiological survey instruments and procedures can measure "0" mrem/y above background at NRC-licensed sites being decommissioned. This determination must account for the sensitivity of the measurement technique in the presence of widely varying radiation levels of background. Information contained in NUREG-1501 (NRC, 1994) and Appendix D indicates that significant resources and sophisticated measurement techniques must be applied to measure very low concentrations of residual radioactivity in the presence of background.

NUREG-1501 (NRC, 1994) discusses the variation in measurement sensitivities for the principal radionuclides of concern (Co-60, Cs-137, Th-232, and natural uranium). Appendix D shows measurement sensitivity and cost trends for these radionuclides also. Based on the above studies, the range of measurement sensitivities for the principal radionuclides are: 3 mrem/y above background for Th-232; 1 mrem/y above background for Sr-90; 0.3 mrem/y above background for Cs-137 or natural uranium; and 0.03 mrem/y above background for Co-60. The increased measurement sensitivity for Co-60 is due to its strong characteristic

emissions and its absence in background, both of which enhance the ability to measure very low concentrations of this radionuclide.

In conclusion, when health impacts and cost are taken into account for a "0" mrem/y above background regulatory alternative for the principal radionuclides studied, decommissioning costs increase significantly but health impacts are not necessarily reduced. Furthermore, due to technological limitations with available radiological measurement techniques in the dose rate range of below 3 mrem/y above background, a "0" mrem/y above background regulatory alternative could present significant implementation difficulties. Thus, it does not appear reasonable to require sites on a generic basis to be returned to background. However, for certain site specific situations, it may be possible that the costs of decontamination and surveys to levels approaching background are not unreasonable compared to the benefit. Such considerations lend support to use of an ALARA approach in considering further reduction to near background levels.

Table A.1. Comparison of the Principal Components of Background Between Estimated Populations of the United States and the World

Component	Annual Effective Dose Equivalent(mSv)		
	U.S. Mean ¹	World Mean ²	World Range ²
Cosmic	0.27	0.36	0.3-2.0
Indoor radon and progeny	2.0	1.1	0.3-5.0

APPENDIX B

IMPACT AND COST ANALYSIS

APPENDIX B

B.1 Purpose

Health impacts and decontamination costs over a range of residual dose rate levels were evaluated for each of four reference facilities. The four reference facilities which are considered include a power reactor, uranium fuel fabrication facility, sealed source manufacturer/broad R&D facility, and rare metals processor. As discussed in Section 3.2.1 of Volume 1 and in Appendix C, these reference facilities are considered sufficiently representative of the facilities covered by this rule to be used in this generic analysis. The reference facilities are described in Appendix C.

B.2 Considerations With Regard to Public Comments

Appendix H presents a summary of comment letters received on the Draft GEIS. As noted there, some of those comment letters criticized the analysis of costs and risks as incomplete and inadequate; some of those letters submitted additional data and calculations in support of those criticisms. In general, some of the major comments suggested, and provided data on, the following:

- (a) Additional data from actual decommissionings should be included which would consider variations in site contamination characteristics, including the concentration and volume of contamination and the profile of the contamination with depth;
- (b) Reevaluation of remediation and survey costs should be conducted, including consideration of variation in waste burial charges, remediation methods, and survey procedures;
- (c) Separate analyses of the cost-effectiveness of soil removal and building removal should be performed. A commenter illustrated that such separate analyses would clarify differences between costs and impacts of cleanup of soils and structures that were not obvious in the Draft GEIS. Commenters also suggested deleting the "knee-in-curve" approach as not clearly illustrating the information regarding costs and impacts for cleanup of both soils and structures; and
- (d) Potential alternative uses of the site lands and facilities should be considered to provide a higher level of realism in the dose estimates. These alternative uses can result in variations in direct exposure and ingestion pathways and in the number of persons exposed and thus the collective exposure and net health effects.

Based on the comments and information received, additional information has been included in the GEIS. Data on contamination submitted by the commenters were reviewed, compared with other existing data, including that in the Draft GEIS, and incorporated into the Final GEIS as appropriate. Appendix C contains considerations of a range of soil and building

contamination, and Appendix D contains analysis of appropriate survey methodology using representative NRC survey approaches. Those appendices also consider a range of disposal costs and survey methods and costs.

Because it appears from a consideration of the comments that separate analysis of soil and buildings can provide added information for use in decision-making, the tables in Appendix B contain results from performing such a separate analyses. In addition, the "knee-in-curve" figures, which provided general information about behavior of costs and impacts associated with cleanup, have been replaced with a set of tables in Appendix B rather than curves. Further, in response to comments suggesting that the Final GEIS consider more realistic post decommissioning uses, Appendix B considers a range of possible uses, including residential farming, denser residential use, industrial/office use, and variations in building occupancy rates. These are described in the sections that follow.

B.3 Estimate of Radiological and Nonradiological Impacts

Impact analyses were performed for each of the reference facilities by calculating estimated incremental mortalities due to radiation exposure and conventional nonradiological accidents (construction and transportation). These calculations were completed for various alternative residual dose criteria representing the exposure to an individual at the site following decommissioning. The alternative criteria selected for these detailed analyses include: 100, 60, 25, 15, and 3 mrem per year. This range of alternative residual dose criteria are considered to be sufficiently representative to demonstrate trends in comparison of costs and impacts based on the information presented in Appendices C and D. In particular, as can be seen from the tables in Attachment C of Appendix C, volumes of soil requiring removal (and resultant costs) to reduce residual radioactivity levels below 3 mrem/y can increase significantly, especially for real world cases studied, compared to the benefit in dose reduction. A similar result can be seen for removal of concrete from a reactor bioshield in Table 7.3.1 of Appendix C. For decontamination of walls and floors in structures, as described in Appendix C (see in particular Tables 7.3.2, 7.4.1, 7.5.1, and 7.6.1), the scabbling process is such that removal of individual layers of concrete remove a large fraction of the remaining activity and thus studying a range of costs below 3 mrem/y is not necessary. Consideration of the impacts of a limit of "0" above background are discussed in Appendix A.

In assessing human health impacts from decommissioning, the analysis considers risks to individuals expressed either in terms of mrem/year when radiation exposure is involved or in accident rates when nonradiological impacts are involved. Sections B.3.1 and B.3.2 discuss the analyses related to radiological and nonradiological impacts, respectively. These assessments also consider collective risk to the population engaged in various activities related to the decommissioning which result in both long-term and short-term impacts. Collective estimated mortality resulting from radiation exposure was estimated for four population groups as described in the following sections: B.3.1.1 - members of the public living on site following decommissioning and license termination; B.3.1.2 - members of the

public assumed to be working or residing within facility buildings following completion of facility decommissioning and license termination; B.3.1.3 - workers performing decommissioning; and B.3.1.4 - persons exposed to radiation in the course of transportation of contaminated building materials and soil (including both transportation workers and the general public). The collective estimated mortality from fatal construction accidents assumed to occur during facility decontamination and soil removal (Section B.3.2.1), and estimated mortality from traffic accidents during transportation of building waste and contaminated soil to a low-level radioactive disposal site (Section B.3.2.2) were also calculated. Because these impacts can take place over different time periods and may affect different persons, a precise comparison or balancing is difficult; however, to provide a comparison of such risk, the analysis in Appendix B estimates the individual and collective risks for these disparate impacts. This is considered to be a reasonable approach in that it permits assessments and conclusions to be made with regard to all of the impacts that may result from a particular decommissioning alternative. The estimated mortalities are based on statistical data regarding probability of mortality related to the level of exposure or activity.

Individual and collective impacts are developed based on risks of exposure to radiation and to nonradiological accident risks as described in Sections B.3.1 and B.3.2. Because of the combination of different types of risks involved, the overall results of the analyses are presented as estimated mortalities.

B.3.1 Incremental Estimated Mortalities from Radiation Exposure

Total incremental estimated mortalities from radiation exposure were determined separately for exposure to soils and structures by adding the incremental estimated mortality from each of three components as follows:

soil - living on site following license termination, performing soil remediation (e.g., excavation), and transporting the resultant waste to a disposal facility;

structures - working or residing on site in facility buildings following license termination, performing structure decontamination (e.g., scabbling concrete), and transporting the resultant waste to a disposal facility.

Incremental estimated mortality from each of these components is discussed below. Parameter values used regarding the number of persons engaged in the activities, the time period over which the activities take place, and other parameters needed to assess collective impacts for each reference facility are summarized in Table A.1.

Individual impacts from radiation exposure consider the models, parameters, and assumptions contained in NUREG/CR-5512 (NRC93). NUREG/CR-5512 analyzes several important potential pathways of exposure for building occupancy, building renovation, drinking water, and residence, which are considered here. The models of NUREG/CR-5512 consider exposure based on prudently conservative but not necessarily "worst case." As indicated in

NUREG/CR-5512, the use of prudently conservative scenarios is intended to account for the vast majority of potential uses of lands and structures and to overestimate the most probable annual dose, while discounting a small fraction of highly unlikely doses that might result in higher doses but would limit the usefulness of potential criteria without providing a significant benefit in protection. The complete discussion of the models, parameters, and assumptions are not repeated in this appendix.

For the impacts associated with living or working on the site following license termination, the analysis assumes exposure of individuals to the residual dose limit, corrected for radioactive decay, over a 1,000 year time period for soil and a 70-year time period for buildings which is assumed to be the lifespan of the building following license termination (analysis of impacts and costs of building demolition after the building's lifetime are described in NUREG-0586 (NRC88)). In the estimate of impacts, a risk coefficient of 5E-4 per rem for the risk of radiation-induced fatal cancer is used based on the cancer-to-dose relationships in the UNSCEAR (UNSCEAR88) and BEIR (BEIR90) reports.

As discussed in Section B.2, because a variety of possible land uses could occur after the facilities are released for unrestricted use, the following sections consider alternative unrestricted public uses of the site. The effect of this consideration is a variation in potential collective exposures which can occur and the resultant variation in net health impacts that can occur. Alternative unrestricted land uses included in the tables are residential farming, industrial use, and high density dwelling use. Alternative unrestricted building uses included in the tables are office use, residential use, and industrial use. Tables A.2.1 - A.2.4 and Tables A.3.1 - A.3.4 list the alternative cases considered in the analysis for soil and structure exposure, respectively. In each of the alternative unrestricted land uses it is assumed that the decommissioning activities result in reducing the residual radioactivity to the same residual contamination level but that the post-decommissioning population usage of the site can vary. For these alternative land uses, there will thus be a variation in both the individual and collective doses resulting from the residual contamination. Thus, for example, the amount of soil removal (and the resultant costs and impacts related to conducting the removal process) are the same for a given dose criteria for Cases 1, 1A, and 1B, but the individual dose received, the number of people exposed, and the collective exposures would differ and, therefore, the incremental results would also differ.

There is a wide range of possible restricted site uses. The draft GEIS (NRC94) evaluated such uses in a qualitative manner and indicated that, because of the site specific nature of restricted use, a generic approach is unlikely to yield a reasonable approximation of all the possible restricted use modes that could be used. As noted in the draft GEIS, such restricted use modes could include industrial zoning for all or part of a site, conversion of the land for parkland, restrictions on agricultural use of the site, restrictions on residence at the site, restrictions regarding length of time a facility can be used, elimination of use of the site, etc. In response to public comments and to provide additional information on restricted use, the tables in Appendices B and C of this final GEIS include a restricted industrial use as an illustration of impacts and costs associated with restricted use.

B.3.1.1 Persons Living On Site Following License Termination

For each of the reference facilities, a scenario is postulated in which a residence is established on the land following decontamination. These residents may be exposed by direct shine from the residual radiation contained in the soil and from the consumption of milk, meat, and vegetables grown in the soil. Based on the area of contaminated soil at each reference facility, the number of persons living on the land is estimated and the collective estimated mortality determined for each case. Table A.1 indicates the alternative site population densities used in the analysis.

The collective estimated mortality for persons living on site following license termination is estimated as follows:

$$\text{Collective Estimated Mortality} = R \times DF \times CF \times Y \times N$$

where:

R = Individual residual dose rate (mrem/year)

DF = Decay factor which considers the radionuclides present and the radioactive half-life of those radionuclides (dimensionless)

C = Risk conversion factor (mortality/rem) (from Section B.3.1)

Y = Exposure time (years)

N = Number of People Exposed

B.3.1.2 Working or Residing in Facility Buildings Following License Termination

For each of the reference facilities, it is assumed that the buildings will be fully utilized for nonnuclear industrial or commercial purposes. In each case, the number of persons likely to work in the facility is estimated. An alternative use case is also evaluated in which the building is used for multiple dwelling residential use. The risk conversion factor noted in Section B.3.1 is multiplied by the residual dose rate and the lifetime of the facility, which is assumed to be 70 years following license termination. Table A.1 indicates the alternative building occupancy densities used in the analysis.

As noted in Tables 7.3.2, 7.4.1, 7.5.1, and 7.6.1 of Appendix C, the actual process of scabbling concrete off walls and floors at the reference facilities is a gross removal process that removes a layer of concrete which likely contains a large fraction of the remaining radioactivity. For example, Table 7.3.2 indicates that scabbling of a layer of concrete reduces the exposure for the reference power reactor from 220 to 10.4 mrem/y. This means that, for the reference case shown in Table 7.3.2, the costs and impacts at the reference power reactor are insensitive to certain of the alternative dose criteria under consideration

(e.g., 100, 60, 25, and 15 mrem/y). Similar removal results occur for the other reference facilities. Because the values in Tables 7.3.2, 7.4.1, 7.5.1, and 7.6.1 of Appendix C are generic for the particular reference facility and thus other doses could occur in other real world situations and because they therefore give little information regarding establishing dose criteria, the analyses in this section provide an illustration of impacts and costs of reducing doses below the alternative dose criteria being considered by a composite analysis of scabbling layers of concrete below the alternative dose criteria. This analysis illustrates the impacts and costs associated with scabbling each layer, but does not include costs and impacts of wet spot and crack removal because they are highly site specific and thus do not lend themselves to generic analysis. Such costs and impacts could be taken into account in a site specific analysis.

The collective estimated mortality for persons working or residing on site in facility buildings after license termination is estimated for each alternative residual dose rate limit as follows:

$$\text{Collective Estimated Mortality} = R \times DF \times CF \times Y \times N$$

where:

R = Individual residual dose rate (mrem/year)

DF = Decay factor which considers the radionuclides present and the radioactive half-life of those radionuclides (dimensionless)

C = Risk conversion factor (mortality/rem) (from Section B.3.1)

Y = Exposure time (years)

N = Number of People Exposed (see Table A.1)

It is also assumed that there will be a small work force involved in renovation of the facility. The collective estimated mortality for these individuals is calculated in a similar manner and added to the exposure estimated above to obtain a total risk to workers.

B.3.1.3 Performing Decontamination

Appendix C discusses the estimation of exposure of workers performing the decontamination, including the evaluation of the parameters used in this analysis, such as cost, waste volume, number of shipments of radioactive waste, and labor hours. These estimates have been made as a function of residual dose rate at each reference facility.

The collective estimated mortality due to radiological exposure corresponding to performing facility decontamination to reduce residual radioactivity to alternative residual dose levels is calculated as follows:

$$\text{Collective Estimated Mortality} = D \times CF$$

where:

D = Dose received by decontamination workers in the process of achieving alternative residual dose rates (person-rem) (taken from the tables in Attachment C to Appendix C)

CF = Risk conversion factor (mortality/rem) (from Section B.3.1)

B.3.1.4 Transporting Waste

Collective estimated mortalities are calculated for transportation workers involved in transporting the waste and by the members of the general public along the route from the reference facility to the disposal site. The derivation of the doses received when transporting the waste to a low-level waste disposal facility (for an average one-way distance of 500 miles) considered amounts and radioactive characteristics of the soil and concrete waste requiring disposal for the full decontamination of each of the reference facilities as described in Section 2.4.3 of this final GEIS and more fully in NUREG-0586 (NRC88) (not simply the amounts indicated in Appendix C for remediating to the alternative residual dose criteria) and the likely combination of soil and concrete packaged together for shipment. For example, for the reference power reactor Appendix C indicates that only a small amount of soil is estimated as requiring disposal, but a very large amount of concrete will require disposal. Thus the radiation exposure caused by the transport of the packaged reference power reactor decommissioning waste was considered to be more realistically represented by the behavior of shipments of activated concrete from the bioshield. Therefore, the doses in this Appendix, as indicated by Table A.1 and Attachment B, are based on such considerations and the information presented in two references: NRC72, "Environmental Survey of Transportation of Radioactive Materials to and from Nuclear Power Plants," and NRC80, "Technology, Safety and Costs of Decommissioning a Reference Uranium Fuel Fabrication Plant." Two scenarios were evaluated for each facility: one in which all removed soil was assumed to be transported without any form of treatment, and one which assumes use of soil washing to reduce the amount of soil to be transported to a disposal facility.

The collective estimated mortality due to radiological exposure for shipping facility decommissioning waste is calculated as follows:

$$\text{Collective Estimated Mortality} = D \times S \times CF$$

where:

D = Dose received by workers and onlookers during shipment (person-rem per shipment) (from Table A.1)

S = Number of shipments (taken from tables in Attachment C to Appendix C)

CF = Risk Conversion Factor (mortalities/rem) (from Section B.3.1)

B.3.2 Incremental Estimated Mortality from Accidents

Impacts not associated with radiation exposure can be incurred as a result of heavy construction activities, such as those involved in the decommissioning of the reference facilities, and as a result of the transportation of materials. The total incremental estimated mortality was obtained by adding the impacts from these two components.

The analysis of individual impacts from nonradiological accidents (such as workplace accidents or highway transportation accidents) is based on published statistical data on accident rates, and as such uses the same approach as for radiation exposure. For those impacts incurred as a result of nonradiological workplace accidents while performing decontamination activities or from nonradiological highway accidents while transporting waste, estimates are made based on the statistical risks of accident fatalities and, as noted above, published statistical data on fatal accident rates.

B.3.2.1 Performing Decontamination

The collective estimated mortality due to heavy construction workplace accidents corresponding to performing facility decontamination to reduce residual radioactivity to alternative residual dose levels is calculated as follows:

$$\text{Collective Estimated Mortality} = A \times L$$

where:

A = Accident risk rate (mortalities/person-hour) (from Table A.1)

L = Labor hours (person-hours) (from tables in Attachment C to Appendix C)

B.3.2.2 Transporting Waste

The collective estimated mortality due to traffic accidents during transport of decommissioning wastes corresponding to reducing residual radioactivity to alternative residual dose levels is calculated as follows:

$$\text{Collective Estimated Mortality} = A \times T$$

where:

A = Accident risk rate (mortalities/km) (from Table A.1)

T = Total distance traveled for all waste shipments (km) (based on roundtrip distance per shipment (from Table A.1) and number of waste shipments needed (from tables in Attachment C to Appendix C))

B.4 Costs

Costs were calculated in Appendices C and D for each of the alternative residual dose criteria for the following three types of decommissioning activity and used in the tables in Appendix B to estimate incremental comparisons of impacts and costs:

- 1) For building decontamination, costs are estimated in Appendix C as a function of alternative residual dose rate. Included in these estimates are direct labor costs to perform the decontamination, overhead costs, cost of materials, and cost of waste packaging, transport, and disposal.
- 2) For soil remediation, costs are estimated in Appendix C as a function of alternative residual dose rate. Included in these estimates are costs for excavation, packaging, transportation, and disposal (with and without treatment by soil washing).
- 3) Cost estimates for performing radiological surveys at the reference facilities are provided in Appendix D for each of the alternative residual dose rates.

Two sets of total costs were calculated for each reference facility: one reflecting the cost of disposal of all soil in an untreated condition, and one reflecting the cost of disposal assuming soil washing to reduce the amount of soil shipped off site for disposal.

B.5 Results

Tables B.1 through B.47 of Attachment B of this Appendix B present, for remediation of soil, results comparing incremental impacts and costs, collective estimated mortalities based on the statistical evaluations noted above, impact and cost calculations, and costs.

Tables B.47 through B.56 of Attachment B of this Appendix B present, for remediation of structures, results comparing incremental impacts and costs, collective estimated mortalities based on the statistical evaluations noted above, impact and cost calculations, and costs. For example, in Table B.1.1, the first row of data indicates the incremental impacts and costs in lowering the dose criteria from 100 to 60 mrem/y. The tables of impact and cost calculations provide the parameter values assumed for each facility and all intermediate results for each dose level and mortality component. An asterisk in the tables represents results where the value of the cost per net health benefit is negative.

As discussed in the previous sections, the costs and impacts in Attachment B of this Appendix B are taken from the concrete and soil removal analyses of Appendix C. Table A.3 indicates the source of data from Appendix C for each of the cases in Appendix B. As discussed in Section B.3.1.2, the analyses of structures provide illustrations of impacts and costs of reducing doses below the alternative dose criteria being considered by a composite analysis of scabbling layers of concrete below the alternative dose criteria. Therefore each of the Tables B.47 - B.56 are developed by assessing the incremental costs and impacts associated with scabbling a layer of concrete at each of the alternative dose levels.

ATTACHMENT A

**TABLES OF PARAMETER VALUES AND DESCRIPTION OF CASES
ANALYZED FOR REFERENCE FACILITIES**

Table A.1
Parameter Values for Reference Facilities

Values Applicable to All Facilities:

Fatal cancer risk rate:	5×10^{-4} per rem
Exposure duration:	1000 years for residential use of the site; 70 years for building occupancy
Disposal volume:	13.6 cubic meters per shipment
Fatal work rate:	4.2×10^{-4} per person-hour
Burial site distance:	1,600 kilometers
Fatal transport rate:	3.8×10^{-4} per kilometer

Values by Individual Facility

Facility	Building Occupancy ^a (# persons)	Building Renovation ^b (# persons)	Contaminated Land Area ^c (sq. ft.)	Land usage (#persons) ^d	Building Waste Shipment Exposure (person-rem per shipment)	Soil Shipment Exposure (person-rem per shipment)
Power Reactor	22 - 210	20	3,000	< 1 - 14	8.72E-02 ^e	8.72E-02 ^e
Uranium Fuel Fabrication Plant	80 - 1000	20	100,000	4 - 460	2.90E-02 ^e	8.00E-06 ^e
Sealed Source Manufacturer	1- 5	5	5,000	< 1 - 23	8.67E-02 ^e	8.67E-02 ^e
Rare Metal Extraction Facility	40 - 500	10	100,000	4 - 460	2.93E-02 ^e	8.07E-06 ^e

^a Assumptions for building occupancy: for each facility assumes a range of reuses including office use at 120 ft²/person, apartment type residential use at 1000 ft²/person, and industrial use as follows:

Nuclear Power Plant - use as a coal fired power plant employing 0.25 persons per megawatt electricity (UD190), with average size of 900 megawatts. The area of occupancy is based on Table 7.1.1 of Appendix C which indicates that there is 250,000 ft² in the reference facility that is 10% contaminated.

Uranium Fuel Fabrication Facilities - use as a chemical processing facility employing the same number of people as a functioning UF₆ facility (NRC85). The area of occupancy is based on Table 7.1.1 of Appendix C which indicates that there is 240,000 ft² in the reference facility that is 50% contaminated.

Sealed Source Manufacturer Facility - use as a laboratory, with typical laboratory size of 60 m² to 80 m² (NRC81). The area of occupancy is based on Table 7.1.1 of Appendix C which indicates that there is 6,000 ft² in the reference facility that is 10% contaminated.

Rare Metal Extraction Facility - use as an industrial facility. The area of occupancy is based on Table 7.1.1 of Appendix C which indicates that there is 150,000 ft² in the reference facility that is 40% contaminated.

^b Estimated based on facility and number of persons for building occupancy scenario.

^c From Appendix C.

^d Derived from NRC72.

^e Derived from NRC80.

^f Assumptions for land occupancy: assumes alternative unrestricted site land area usages including residential agricultural usage of 400 persons/km² (about 2,500 square meters per person (NRC93), industrial use at 10,000 persons/km², and high density dwellings at 50,000 persons/km². Also assumes exposure using the unrestricted use dose conversion factor of Table A.2 of Attachment A of Appendix C for residential agricultural usage of the site; for industrial and high density dwelling alternative unrestricted usages of the site assumes exposure using the following fractions of the values in Table A.2 of Appendix C: power reactor - 0.14; uranium fabrication plant - 0.037; sealed source manufacturer - 0.14; rare metal facility - 0.067. For restricted use assumes industrial use of the site with dose conversion factors given in Table A.3 of Attachment A of Appendix C.

Table A.2.1

Cases⁽¹⁾for Reference Power Reactor
Soil Remediation⁽²⁾

Case 1 -	Diffusion into the soil; \$50/ft ³ burial cost for soil; soil removal after soil washing; unrestricted use with resident farmer use of the site
Case 1A -	Same as Case 1, but with industrial use of the site
Case 1B -	Same as Case 1, but with residential high density dwelling use
Case 2 -	Diffusion, \$50/ft ³ burial cost for soil; no soil washing; unrestricted use with resident farmer use of the site
Case 2A -	Same as Case 2, but with industrial use
Case 2B -	Same as Case 2, but with residential high density dwelling
Case 3 -	Real world soil profile data; \$50/ft ³ burial cost; soil removal after soil washing; unrestricted use with resident farmer use of the site
Case 3A -	Same as Case 3, but with industrial use
Case 3B -	Same as Case 3, but with residential high density dwelling
Case 4 -	Real world soil profile data; \$50/ft ³ burial cost for soil; no soil washing; unrestricted use with resident farmer use of the site
Case 4A -	Same as Case 4, but with industrial use
Case 4B -	Same as Case 4, but with residential high density dwelling
Case 5 -	Same as Case 4, but with restricted industrial use of the site

Notes:

1. For some of the tables in Attachment B, additional information is provided (e.g., alternative soil disposal costs) in addition to the cases defined in this table.

2. All cases use the high soil contamination case from Attachment C of Appendix C.

Table A.2.2

**Cases⁽¹⁾for Reference Uranium Fabrication Facility
Soil Remediation⁽²⁾**

Case 1 -	Diffusion into the soil; \$50/ft ³ burial cost for soil; soil removal after soil washing; unrestricted use with resident farmer use or industrial use of the site
Case 1A -	Same as Case 1, with \$10/ft ³ burial cost for soil
Case 1B -	Same as Case 1, but with residential high density dwelling use
Case 2 -	Diffusion; \$50/ft ³ burial cost for soil; no soil washing; unrestricted use with resident farmer or industrial use of the site
Case 2A -	Same as Case 2, but with \$10/ft ³ burial costs for soil;
Case 2B -	Same as Case 2, but with residential high density dwelling
Case 3 -	Same as Case 1, but with restricted industrial use of the site
Case 4 -	Same as Case 2, but with restricted industrial use of the site
Case 5 -	Real world soil profile data; \$50/ft ³ burial cost for soil; soil removal after soil washing; unrestricted use with resident farmer or industrial use of the site
Case 5A -	Same as Case 5, but with \$10/ft ³ burial cost for soil
Case 5B -	Same as Case 5, but with residential high density dwelling
Case 6 -	Real world soil profile data; \$50/ft ³ burial cost; no soil washing; resident farmer or industrial use
Case 6A -	Same as Case 6, but with \$10/ft ³ burial cost for soil
Case 6B -	Same as Case 6, but with residential high density dwelling
Case 7 -	Same as Case 6, but for restricted use industrial use of the site

Notes:

1. For some of the tables in Attachment B, additional information is provided (e.g., alternative soil disposal costs) in addition to the cases defined in this table.
2. All cases use the high soil contamination case from Attachment C of Appendix C.

REPRODUCED SECTIONS OF CHAPTER 5.3 OF DRAFT GEIS

ATTACHMENT C

REPRODUCED SECTIONS OF CHAPTER 5.3 OF DRAFT GEIS

In this final GEIS, reference is made to analysis and results from Chapter 5.3 of the draft GEIS. To assist the user of this report and to provide completeness, those Sections of Chapter 5.3 of the draft GEIS are reproduced here as Attachment C. The section numbering system indicating that this was Chapter 5.3 has been retained.

5.3 Other Environmental Consequences

Environmental consequences other than those directly affecting human health are evaluated in this section. These include impacts on the biological, socioeconomic, and physical environments both from the decontamination activities and from residual radiation levels. Specifically addressed are the physical and radiological impacts on plant and animal populations; land use changes; social, economic, and cultural resource impacts; noise; aesthetics; and impacts on planned low-level waste disposal capacity.

Impacts were previously evaluated for the entire decommissioning process and are described in NUREG-0586 (NRC, 1988) and supporting documents. Since the decontamination of building structures and areas of contaminated soils is a component of decommissioning, some of the same activities and impacts were discussed in that document. This GEIS focuses on both the costs and environmental effects attributable to activities required to achieve the residual dose criteria indicated in Section 5.2.1.

5.3.1 Biological Environment

During the decommissioning process, biological components of the environment may be affected by the physical removal of contaminated soils from site areas outside of structures and by exposure to any residual radiation. Estimated area and depth of soil contamination for each category of reference facility are given in Table 4-1.

Decontamination activities would include physical removal of the contaminated soils to depths of a few inches to a foot or more, followed by conditioning and revegetating of the disturbed area. Where warranted, site surveys for State or Federally listed or candidate threatened or endangered species would be made prior to any land disturbance outside of the facility structures.

Analysis of the effects on these environmental components is qualitative because radionuclide impact analysis on human health will usually bound the impact on biota, and because the range of residual dose criteria being considered in this GEIS is well below the exposures where effects were observed on biota (SC&A, 1993a). Also, issues related to biota may be very site-specific and will need to be addressed in an EIS prepared for a specific facility.

5.3.1.1 Plants.

Decontamination.

Soils and vegetation would be removed to depths of a few inches to a foot or more at a few hundred sites. Areas affected range from a few hundred square feet to 300 acres of land surface. After excavation to acceptable levels of residual radiation, the disturbed areas would be revegetated. These effects would be local and temporary. It is expected that most

vegetation involved would be grasses, forbs, and shrubs, and successful reestablishment would occur within a few growing seasons.

The IAEA (1992) concluded after a review of the major studies on effects of radiation on plants that "it appears that in the natural environment, the most sensitive plants display acute radiation sensitivities which are similar in magnitude to those found for mammals, but that the majority of data relate to radiation exposures which are not acute for the plant species investigated but are more correctly described as short term or chronic."

Based on a review of the scientific literature, no discernible effects to individual plants or plant communities are expected at residual dose levels of 100 mrem/yr or less. Reduction in shoot growth for the radiosensitive pines occurred at an exposure of 1 R/day, several thousand times the 100 mrem/yr residual dose level.

5.3.1.2 Mammals.

Decontamination.

Earth removal activities would result in loss or displacement of any mammals living or foraging on a few hundred square feet to 300 acres of land surface at several hundred sites. These effects would be local and temporary. Habitat would soon re-establish to former levels. It is expected that the smaller field mammals would be most affected, and these would quickly repopulate the area once revegetation was completed.

Post-decommissioning.

Mammals could be exposed to radionuclides at decommissioned sites both from external irradiation from being on the land surface or living in burrows on the site and by ingestion of any onsite vegetation having increased radionuclide content through uptake from contaminated soil. While the effects of external irradiation have received extensive study, the scientific literature contains little information concerning the effects on animals from ingestion of radionuclides through the food chain.

A summary by Rice and Baptist (1974) indicated that several species of mammals have LD50s slightly lower than man's. It appears that several large domestic animals are at least as radiosensitive as humans to the effects of acute radiation exposure. The LD50s for cattle, dogs, burros, and goats are on the order of 240 to 255 rads, compared with an LD50 of 300 rads for humans. One can speculate that the larger wild animals, such as bear and moose, are comparable to the large domestic animals in radiosensitivity (SC&A, 1993a).

Even the more radiosensitive mammals for which data are available appear to be only slightly more susceptible than humans to radiation effects. Thus, even with the possibility of an added exposure to some mammals from ingestion of vegetation with an added uptake of

radionuclides, no discernible effects to individual mammals or populations are expected at residual dose levels of 100 mrem/yr or less.

5.3.1.3 Birds.

Decontamination.

Earth removal activities would displace any birds living or foraging on a few hundred square feet to 300 acres of land surface at several hundred sites. Soil removal during the nesting season could result in loss of eggs or nestlings. These effects would be local and temporary. It is expected that the ground nesting field birds would be most affected. Habitat and populations would soon re-establish to former levels.

Post-decommissioning.

The radiosensitivity of wild birds appears to range from about 400 to > 1000 R for acute LD50s. Few data are available for assessing the effects of protracted (rather than acute) radiation exposures and the effects of low intensities (IAEA, 1992). Several factors enter into evaluating avian exposure at a decommissioned site. The exposure for each species will differ, based on feeding habits, time spent on site, and nesting habits. Considering the short natural life spans of most wild bird species (typically a few years) and the migratory nature of many species as well as the fact that wild birds appear to be less radiosensitive than humans, no discernible effects on individual wild birds or populations are expected at residual dose levels of 100 mrem/yr or less.

5.3.1.4 Reptiles and Amphibians.

Decontamination.

Earth removal activities would result in loss or displacement of any reptiles and amphibians living or foraging on a few hundred square feet to 300 acres of land surface at several hundred sites. These effects would be local and temporary. Habitat and populations would soon re-establish to former levels.

Post-decommissioning.

While there are few studies of the radiosensitivity of reptiles and amphibians, available data suggest that they may be somewhat less sensitive than birds and mammals, though there appears to be some overlap. At chronic radiation exposure of ~2 R/day over a period of 1 to 2 years, females of two long-lived species of lizards became sterile and populations drifted toward extinction. Another species showed no effects on life spans, age distributions, and sex ratios after 5 years of exposure. Results from another experiment suggest impaired reproduction in several species of lizards after exposures of 1 to 5 rad/day over a 5-year period; many survivors lacked ovaries and many males were sterile.

(IAEA, 1992). However, the exposures in these studies are several thousand times the maximum residual levels contemplated in the proposed standards; no discernible effects on individual reptiles and amphibians or populations are expected at residual dose levels of 100 mrem/yr or less.

5.3.1.5 Invertebrates.

Decontamination.

Earth removal activities would displace any invertebrates living or foraging on a few hundred square feet to 300 acres of land surface at several hundred sites. These effects would be local and temporary. Habitat and populations would soon re-establish to former levels.

Post-decommissioning.

A review by O'Brian and Wolfe (1964) indicated that lethal doses for insects were generally in excess of 10,000 R. The exposures discussed in the review are many orders of magnitude higher than the maximum residual levels contemplated in the proposed standards; no discernible effects on individual invertebrates or populations are expected at residual dose levels of 100 mrem/yr or less.

5.3.2 Socioeconomic Environments

Human social, cultural, and economic institutions exist in the vicinity of the nuclear facility during the time that the facility is operating. These institutions could be affected by specific decommissioning actions and the alternative regulatory approaches being considered, and new social, cultural, and economic institutions may come to exist following license termination. The analysis of the impacts on these environments is qualitative because, for the range of doses being considered, the differential impact on these institutions is not significant. Also, the socioeconomic impacts will be very site-specific and do not lend themselves to generic analysis. The GEIS does not specifically include the impacts on Native American tribal land use. This GEIS evaluation is based on reference facilities, which means that the average or most typical case is characterized. Tribal use is very specific, and impacts can most properly be assessed on a case-by-case basis. Impacts on Native American tribal use of site lands would be better addressed in an Environmental Impact Statement or Environmental Assessment for a specific facility at the time of decommissioning of that facility.

Decontamination.

Decontamination activities at major facilities will require teams of nuclear professionals and construction workers for periods of several months to several years; this work will be carried out by the existing workforce and/or through contracting. At some sites, there may be a temporary influx of construction crews for major demolition and earthmoving work. This may result in temporary increases in local populations, traffic, and demands on community

services. The incremental impact in the person-hours spent working on site attributable to the alternate residual dose criteria being considered is generally small compared to the total amount of labor involved in a decommissioning.

Post-decommissioning.

Socioeconomic effects could occur locally if land use restrictions precluded future industrial or commercial development of the site and no alternate lands were available locally. Certain land uses such as housing, schools, etc., may be precluded at the higher proposed levels of residual radiation. This could result in the site being dedicated to non-occupancy uses such as parking lots, green belts, or open space. These effects will depend on the specific location and local land availability. Site-specific environmental analyses will be prepared for sites where post-decommissioning land uses are restricted.

5.3.3 Physical Environment

The physical environment (water, noise levels, air quality, aesthetics, and low-level waste capacity) could be affected by specific decommissioning actions and the alternative regulatory approaches being considered as part of license termination. Except for low-level waste capacity, analysis of the impacts on these components is qualitative because, for the range of doses being considered, the differential impact on these physical environments is not significant. Also, most of these impacts will be very site-specific and do not lend themselves to generic analysis. However, quantitative analysis of the adequacy and utilization of low-level waste capacity is provided.

5.3.3.1 Noise and Aesthetics.

Decontamination.

Levels of noise attributable to decontamination work will generally be comparable to the normal industrial activities previously carried out at the sites.

Post-decommissioning.

No incremental noise or aesthetic effects will be attributable to the alternative residual dose criteria being considered. Such effects could result from any subsequent uses of the sites but cannot be predicted at this time.

5.3.3.2 Water Resources.

The specific environmental review of impacts on the water resources at a site would be considered in detail in a site-specific environmental statement or assessment. The following is a generic discussion of water resources as it relates to possible incremental impacts from alternate dose criteria.

Surface Water.

At some sites, small areas of ponded surface waters will require decontamination, usually by evaporation. These contaminated waters may not be considered suitable for domestic, agricultural, or wildlife use. Treatment of these contaminated waters will eliminate the risk of release or discharge and contamination of local streams and drainages. Conceivably, during precipitation, there could be some contamination of runoff through leaching or suspension of radionuclide-contaminated soils. The effects of this are not expected to be discernible at the decontamination criteria or residual levels under review.

Groundwater.

Removal of contaminated soils and treatment of contaminated surface waters will remove potential sources of groundwater contamination. Conceivably, during precipitation, contaminated soils could be leached by downward percolating water thereby contaminating local groundwater resources. The effects of this contamination are not expected to be discernible at the decontamination criteria or residual levels under review.

5.3.3.3 Air Quality.

As at any demolition or earthmoving project, during removal of structures and soils, there will be some local degradation of air quality from increased particulates and emissions from diesel or gasoline engines. Workers will be required to follow standard dust suppression practices, maintain appropriate emission controls on diesel and gasoline motors, and follow approved practices for any blasting. Applicable air quality standards should not be exceeded. The incremental impact on air quality attributable to the alternate residual dose criteria being considered should be small based on the type of activities to be carried out and the methods used for controlling emissions.

10. SUPPLEMENTARY NOTES

11. ABSTRACT (200 words or less)

The action being considered in this Final Generic Environmental Impact Statement (GEIS) is an amendment to the Nuclear Regulatory Commission's (NRC) regulations in 10 CFR Part 20 to include radiological criteria for decommissioning of lands and structures at nuclear facilities. Under the National Environmental Policy Act (NEPA), all Federal agencies must consider the effect of their actions on the environment. To fulfill NRC's responsibilities under NEPA, the Commission is preparing this GEIS which analyzes alternative courses of action and the costs and impacts associated with those alternatives.

In preparing the final GEIS, the following approach was taken: (1) a listing was developed of regulatory alternatives for establishing radiological criteria for decommissioning; (2) for each alternative, a detailed analysis and comparison of incremental impacts, both radiological and nonradiological, to workers, members of the public, and the environment, and costs were performed; and (3) based on the analysis of impacts and costs, conclusions on radiological criteria for decommissioning were provided. Contained in the GEIS are results and conclusions related to achieving, as an objective of decommissioning ALARA, reduction to preexisting background, the radiological criterion for unrestricted use, decommissioning ALARA analysis for soils and structures containing contamination, restricted use and alternative analysis for special site-specific situations and groundwater cleanup.
