TITLE RESPONSE TO DEGRADED CORE COOLING

BKG FR-C.2

NO.

STEP 12

**of** 34

## STEP DESCRIPTION TABLE FOR FR-C.2

<u>STEP</u>: Isolate SI Accumulators:

<u>PURPOSE</u>: To prevent nitrogen injection to the RCS

# **BASIS**:

SI accumulators are isolated to prevent nitrogen injection into the RCS after the RCS pressure criterion has been satisfied. Nitrogen could collect in the high places and produce either a "hard" PRZR bubble or cause gas binding and reduced heat transfer in the SG U-tubes. Venting the nitrogen gas also prevents injection. If it is necessary to vent the nitrogen, the operators should open the vent line and then continue with the procedure.

## ACTIONS:

- Determine if power is available to SI accumulator isolation valves
- Restore power to isolation valves
- Reset SI
- Close all SI accumulator isolation valves
- Place control switches for LD-4A, LD-4B, and LD-4C to CLOSE
- Reset Containment Isolation
- Verify instrument air to Containment
- Vent any unisolated accumulators

# **INSTRUMENTATION:**

- SI accumulator isolation valve power supply indication
- SI signal indication
- SI accumulator isolation valve position indication
- LD orifice valve position indication
- Containment Isolation status
- Air pressure indications
- SI accumulator vent valve position indication

## CONTROL/EQUIPMENT:

- SI accumulator isolation valve power supply controls
- SI reset pushbuttons
- SI accumulator isolation valve switches
- ° Control switches for LD-4A, LD-4B, and LD-4C
- Containment Isolation reset pushbuttons
- Air compressor control switches
- SI accumulator vent valve switches

| When the RXCPs are stopped in the next step, the loss of forced flow<br>through the core will cause core cooling to decrease. Core cooling will<br>continue to degrade until some form of low pressure injection flow to the<br>RCS is established. |                                                           |  |

| In order to exit this FRP. RCS hot leg temperatures must be less than<br>350°F to ensure RCS pressure is less than the shutoff head of the RHR<br>pumps. Core cooling has been restored when the above conditions have been<br>met and SI flow or other make-up flow has been established. Note, these<br>conditions are more stringent than earlier transition conditions since<br>the RCS should now be fully depressurized. |                                         |                      |  |

| The following is a question which has been FR-C.2, RESPONSE TO DEGRADED CORE COOLING                                                                                                                                                                                           | n frequently asked about procedure      |  |
| Q. For a small LOCA event, if high pressure SI fails to operate, does the<br>operator wait until a degraded core cooling condition has been reached<br>before taking action to cool down and depressurize the RCS in order for<br>the SI accumulators and RHR pumps to inject? |                                         |  |
| A. No, IPEOP ES-1.2, POST LOCA COOLDOWN AND DEPRESSURIZATION, provides<br>actions to cool down and depressurize the RCS in order for the SI<br>accumulators and RHR pumps to inject prior to reaching a degraded core<br>cooling condition.                                    |                                         |  |
|                                                                                                                                                                                                                                                                                |                                         |  |

| 1.0 <u>INTRODUCTION</u> 1.1 This procedure should be implemented after any unexpected Reactor Trip or Safety Injection actuation. The purpose of this procedure is to verify proper response of the automatic protection systems following actuation of REACTOR TRIP or SAFETY INJECTION, to assess Plant conditions, and identify the appropriate recevery procedure.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                    |               |                                     |                  |               | 5. |

## 3.0 AUTOMATIC ACTIONS

1

- 3.1 Turbine trip on low condenser vacuum of 10" Hg Abs
- 3.2 On high traveling screen differential pressure, screens shift to fast speed, screen spray starts and runs continuously
- 3.3 Circulating water pumps trip on 2/4 signal from Forebay Lo-Lo Level of  $\leq$  42%

## 3.0 INITIAL CONDITIONS

- 3.1 N-O-O2-CLA in progress. (Refer to N-O-O1-CLF). [PCR011594]
- 3.2 Both RXCPs are operating.
- 3.3 Tave 540-549°F.
- 3.4 RCS pressure 2220-2250 psig.
- 3.5 Pressurizer level 21-40%.
- 3.6 Chemical and Volume Control System operating.
- 3.7 Steam Generator NR level 33-50%.

KEWAUNEE NUCLEAR POWER PLANT

TITLE Plant Cooldown from Hot Shutdown to Cold Shutdown Condition

**OPERATING PROCEDURE** 

## DATE OCT 06 2004 PAGE 2 of 24

2.0 PRECAUTIONS AND LIMITATIONS

- 2.1 When a reduction is made in boron concentration of RCS, at least one RXCP or one RHR Pump shall be operating.
- 2.2 When fuel is in the Reactor, there shall be at least one flow path to the core for boric acid injection.
- 2.3 When Reactor Vessel Head is installed, at least one Przr safety valve shall be operable or removed.
- 2.4 RCS temperature, pressure, and heatup rate shall be limited per figure RD-11.1 of Reactor Data Manual.
- 2.5 When any RCS Cold Leg temperature is less than 140°F, Control Switch for one RXCP shall be tagged in Pullout.
- 2.6 Pressurizer cooldown rate shall NOT exceed 200°F/hr.
- 2.7 If temperature difference between pressurizer and spray fluid is greater than 320°F, pressurizer spray shall <u>NOT</u> be used.
- 2.8 During cooldown, when greater than 350°F and a bubble in pressurizer, maintain subcooling 30-200°F. When less than 350°F and a bubble in pressurizer, maintain subcooling 30-300°F.
- 2.9 During cooldown, maintain temperature difference between loops less than 25°F.
- 2.10 If temperature of Steam Generator is less than 70°F, secondary side of Steam Generator shall <u>NOT</u> be pressurized above 200 psig.
- 2.11 When RCS is above 425 psig, RHR Pumps shall <u>NOT</u> be operated.
- 2.12 When Reactor is critical or average RCS temperature is greater than 500°F, total specific activity of the Reactor Coolant due to nuclides with half lives greater than 30 minutes, excluding tritium, shall NOT exceed A=91/E  $\mu$ Ci/cc and Dose Equivalent I-131 shall NOT exceed 1.0  $\mu$ Ci/gram.
- 2.13 Concentration of oxygen, chloride, and fluoride in RCS shall <u>NOT</u> exceed limits of Tech Spec 3.1.e.

| KEWAUNEE NUCLEAR POWER PLANT       TITLE       Plant Cooldown from Hot Shutdown Cold Shutdown Condition         OPERATING PROCEDURE       DATE       0CT 06 2004       PAGE 3       of 24         2.14       If RCS is to be opened for refueling or repair, hydrogen concentration in Reactor Coolant shall be reduced to less than 5 cc/kg.       2.15         2.15       Maintain maximum CVCS purification flow as allowed by plant conditions.       2.16       If RCS forced circulation is inadvertently lost, <u>60 T0</u> E-0.         2.16       If RCS forced circulation is inadvertently lost, <u>60 T0</u> E-0.       2.17         When average Reactor Coolant temperature is greater than 350°F. the following conditions shall be satisfied:       1.         1.       Two Steam Generators operable.       a.         2.       Auxiliary Feedwater System.       a.         a.       Auxiliary Feedwater pump low discharge pressure trip channels operable.         2.       Auxiliary Feedwater pump low discharge pressure trip channels operable.         3.       A minimum of 41,500 gallons of water (92% combined or 84% for single tank operation) available in Condensate Storage Tanks.         4.       Service Water System operable.       5.         5.       Iodin-131 activity on secondary side of Steam Generators does <u>NOT</u> exceed 0.1 µCU/gram.         6.       One group of Przr Heaters has an emergency power source available.         2.18 <th>WISC</th> <th>ONSIN PUBLIC SERVICE CORPORATION</th> <th>NO.
