TABLE OF CONTENTS

Enclosure 1 contains the Table of Contents.

Enclosure 2 contains the Summary Explanation, or Executive Summary.

Enclosure 3 contains the State and Local Government Official Agreement Documentation.

Enclosure 4 contains the Detailed Justification and is divided into five attachments:

Attachment 1: Red-line of the Technical Basis Document Attachment 2: Clean Copy of the Technical Basis Document Attachment 3: Justification Matrix Attachment 4: EAL Wall Chart ¹ Attachment 5: 10 CFR 50.54(q)

Enclosure 5 contains a compact disk of enclosures, references, and supporting documentation.

¹ When approved, the EAL wall chart will be inserted into the Emergency Plan. Also, the approved wall chart and a clean copy of the technical bases document will be inserted into the EAL implementing procedure (EPIP-AD-02) as attachments.

SUMMARY EXPLANATION

This submittal includes the transmittal letter and five enclosures. The enclosures include a table of contents (Enclosure 1), this summary explanation (Enclosure 2), documentation of state and local government officials agreements (Enclosure 3), detailed justifications for each emergency action level (EAL) (Enclosure 4), and supporting information (Enclosure 5).

The Site Emergency Plan for KNPP currently uses the NUREG-0654 EAL scheme. Nuclear Management Company, LLC (NMC) requests approval to change the existing scheme for KNPP to that described in NEI 99-01, Revision 4, "Methodology for Development of Emergency Action Levels," January 2003, as endorsed by the Nuclear Regulatory Commission (NRC) in Regulatory Guide 1.101, "Emergency Planning and Preparedness for Nuclear Power Reactors," Revision 4, July 2003.

The following state and local government officials' agreement is contained in Enclosure 3:

Lori Hucek, Emergency Director, Kewaunee County Emergency Management. Nancy Crowley, Emergency Director, Manitowoc County Emergency Management. Paul Schmidt, Nuclear Engineering Manager, Wisconsin Radiation Protection Section. Bill Clare, Planning Section Supervisor, Wisconsin Emergency Management.

The detailed justification for the proposed EAL changes is contained in Enclosure 4. There are five attachments within Enclosure 4. Attachment 1 contains a red-line, highlighted copy of the Technical Basis Document. This document includes the pertinent information to describe each EAL (category, description, modes, basis, etc). The red-line and highlighted areas indicate changes made to the information contained in NEI 99-01, Revision 4, in order to develop site-specific EALs. All changes are described in the detailed justification matrix (Attachment 3) as either a difference, or a deviation. Attachment 2 contains a clean copy of the Technical Basis Document. Attachment 3 contains the detailed justification matrix. This matrix provides the crossreference comparing the current NEI 99-01, revision 4 EALs, to the proposed EALs, specific identification and discussion of differences and deviations, and mode applicability. Attachment 4 is the Wall Chart and attachment 5 is the 50.54(q) effectiveness evaluation.

The Technical Basis Document, justification matrix, and supporting reference material are contained on compact disk in Enclosure 5.

In summary, this submittal provides the basis and justification for changing the KNPP EAL scheme from the NUREG-0654 requirements to the NEI 99-01 requirements and demonstrates compliance with 10 CFR 50.54(q).

Dear Nancy:

PROPOSED CONVERSION OF EMERGENCY ACTION LEVEL SCHEME

Thank you for your time to discuss the proposed changes to Kewaunee Nuclear Plant Emergency Action Levels (EALs) at the meeting conducted on Thursday, October 7, 2004, held at Stevens Point.

The purpose of the meeting was to discuss the difference between the current NUREG-0654 scheme EALs and proposed conversion to NEI 99-01, Rev. 4 scheme.

The NRC approved the current Kewaunee Nuclear Plant EALs in their 1982 Safety Evaluation Report. The changes we discussed today will incorporate the NEI 99-01 EAL scheme into the Kewaunee Nuclear Plant EALs. The NRC endorsed the NEI 99-01, Rev. 4 scheme via Reg. Guide 1.101, Rev. 4, July 2003.

10 CFR 50, Appendix E, states "...emergency action levels shall be discussed and agreed on by the applicant and State and local governmental authorities and approved by the NRC."

Please review the Kewaunee EAL Bases document by October 21, 2004. If you have any questions or comments during your review, please contact John Egdorf at (920) 776-2141. To document your agreement with these changes, please sign below and fax this document back to me. My fax number is (920) 388-8117.

Thank you again for your time. If you have any questions, please call me at (920) 388-8719.

Sincerely. a Colesian

Dear Nancy:

PROPOSED CONVERSION OF EMERGENCY ACTION LEVEL SCHEME

Thank you for your time this morning to discuss the proposed changes to Kewaunee Nuclear Plant Emergency Action Levels (EALs). Listed in Attachment 1 are the significant changes made to the KNPP NEI 99-01 EAL scheme since our meeting on October 7, 2004. The changes are based upon feedback from the NRC, Challenge Board, Plant Operation Review Committee and NMC Peer Group.

10 CFR 50, Appendix E, states "...emergency action levels shall be discussed and agreed on by the applicant and State and local governmental authorities and approved by the NRC."

Based on the discussion we this moming, I understand that you find the changes acceptable and concur with Kewaunee's additional changes to convert to NEI 99-01, Rev. 4 scheme. If you have any questions or comments during your review, please contact John Egdorf at (920) 776-2141. To document your agreement with these changes, please sign below and fax this document back to me. My fax number is (920) 388-8675.

Thank you again for your time. If you have any questions, please call me at (920) 388-8719.

Sincerely,

Jerrie Coleman Emergency Preparedness Manager Kewaunee

Attachment 1

Tab 2 Abnormal Rad Levels / Radiological Effluent Section RU1.1 RA1.1

Radiation values for radiation monitors R-13, R-14, R-12 and R-21 have been corrected for the Alert and Unusual Event setpoints. The value remains two times the ODCM setpoints as stated in the EAL document. Incorrect base numbers led to the error.

Radiation Monitor for Waste Disposal System Liquid (R-18) setpoint was changed to 2x's the Calculated ODCM Setpoint for UE and 200x's the Calculated ODCM Setpoint for Alert. This change was due to alarm setpoint being calculated for each discharge permit and is dependent upon flow rate of discharge.

Normal Effluent Release Monitor Classification Thresholds			
Monitor	Alart	LIE	
Aurillarv Building			
R-13 Aux, Bldg. Vent Exhaust	2.61E+07 cpm	2,61E+05 cpm	
R-14 Aux. Bldg. Vent Exhaust	2.61E+07 cpm	2.62E+05 cpm	
Reactor Bailding			
R-12 Contzirunent Gas	4.41E+07 cpm	4.41E+05 cpm	
R-21 Containment Vent	4.40E+07 cpm	4.40E+05 cpm	
Liquid Redwaste	[
R-18 Waste Disposal System Liquid	200 X Calculated ODCM Setpoint	2 X Calculated ODCM Setpoint	

RA2.2

Based upon a formal calculation performed at KNPP, water level in Refueling Cavity was corrected to 50% Refueling Cavity level

RA3.2

NMC EAL Peer Group discussed the setpoint associated with this EAL and agreed that the method of determining radiation level value should be consistent but the stay times would be site specific. Per discussions with the KNPP Operation Group, it was decided to use 30 minutes (was 15 minutes) as a stay time and therefore changed radiation level value to 6 R/hr from 12 R/hr.

Tab 3 Cold Shutdown / Refueling System Malfunction

CU5

Based upon NRC feedback to the NMC and Challenge Board, it would not be acceptable to delete NEI 99-01 CU5 EAL #1. NEI 99-01 CU5 EAL #1 states, "(Site-specific) radiation monitor readings indicate fuel clad degradation greater than Technical Specification allowable limit". KNPP added an EAL to CU5.1 (CU5.1) to address the NEI EAL. The added KNPP EAL uses R-9, Letdown Radiation Monitor to detect the failed fuel clad at a value of 2.0 R/hr.

October 21, 2004

Ms. Jerrie Coleman Emergency Preparedness Manager Kewaunee Nuclear Power Plant N490 Hwy. 42 Kewaunee, WI 54216-9511

Dear Ms. Coleman,

Re: October 7 Steven's Point meeting and October 21 conference call regarding EAL changes for Kewaunee Nuclear Power Plant.

The purpose of the meetings was to discuss the difference between the current NUREG-0654 scheme EALs and the proposed conversion to NEI 99-01, Rev. 4 scheme and changes made since the October 7 meeting based on feedback from the NRC, Challenge Board, Plant Operation Review Committee and the NMC Peer Group.

The NRC approved the current Kewaunce Nuclear Plant EALs in their 1982 Safety Evaluation Report. The changes we discussed today will incorporate the NEI 99-01 EAL scheme into the Kewaunce Nuclear Plant EALs. The NRC endorsed the NEI 99-01, Rev. 4 scheme via Reg. Guide 1.101, Rev. 4, July 2003.

Bob Host participated in the October 7 meeting discussion and both Bob Host and Teri Engelhart participated in the October 21 conference call discussion regarding the proposed changes to Kewaunee Nuclear Plant Emergency Action Levels (EALs).

The changes discussed will be included in the Kewaunce Nuclear Power Plant Emergency Plan upon approval by the Nuclear Regulatory Commission.

10 CFR 50, Appendix E, states "... emergency action levels shall be discussed and agreed on by the applicant and State and local governmental authorities and approved by the NRC."

I have reviewed the changes and concur with Kewaunee's plan to implement these changes.

If you have any questions or if I can be of further assistance please contact me.

Sincerely,

William Clare Planning Section Supervisor

1. PURPOSE

This document provides the detailed set of Emergency Action Levels (EALs) applicable to the Kewaunee Nuclear Plant (KNP) and the associated Technical Bases using the EAL development methodology found in NEI 99-01 Revision 4 [Ref. 2.1]. Personnel responsible for implementation of EPIP-AD-02 "Emergency Class Determination" [Ref. 2.2], and the Emergency Action Level Matrix [Ref. 2.3] may use this document as a technical reference and an aid in EAL interpretation.

The primary tool for determining the emergency classification level is the Emergency Action Level Matrix. The user of the Emergency Action Level Matrix may (but is not required) to) consult the EAL Technical Basis Document in order to obtain additional information concerning the EALs under classification consideration.

2. **REFERENCES**

- 2.1 NEI 99-01 Revision 4, Methodology for Development of Emergency Action Levels, January 2003
- 2.2 EPIP-AD-02-Emergency Class Determination
- 2.3 Emergency-Action-Level-Matrix
- 2.24 KNPP Technical Specifications, Section 1.0 Definitions, Amendments 162, 172 and 176.

3. DISCUSSION

3.1 Background

EALs are the plant-specific indications, conditions or instrument readings that are utilized to classify emergency conditions defined in the KNPP Emergency Plan.

In 1992, the NRC endorsed NUMARC/NESP-007 "Methodology for Development of Emergency Action Levels" as an alternative to NUREG 0654 EAL guidance.

NEI 99-01 (NUMARC/NESP-007) Revision 4 represents the most recent NRC endorsed methodology per RG 1.101 Rev 4, "Emergency Planning and Preparedness for Nuclear Power Reactors." Enhancements over earlier revisions included:

- Consolidating the system malfunction initiating conditions and example emergency action levels which address conditions that may be postulated to occur during plant shutdown conditions.
- Addressing initiating conditions and example emergency action levels that fully address conditions that may be postulated to occur at permanently Defueled Stations and Independent Spent Fuel Storage Installations.
- Simplifying the fission product barrier EAL threshold for a Site Area Emergency.

Using NEI 99-01 Rev. 4, KNPP conducted an EAL implementation upgrade project that produced the EALs discussed herein. While the upgraded EALs are site-specific, an objective of the project was to ensure to the extent possible EAL conformity and consistency between the NMC plant sites.

3.2 Key Definitions in EAL Methodology

The following definitions apply to the generic EAL methodology:

EMERGENCY CLASS: One of a minimum set of names or titles, established by the Nuclear Regulatory Commission (NRC), for grouping of normal nuclear power plant conditions according to (1) their relative radiological seriousness, and (2) the time sensitive onsite and off site radiological emergency preparedness actions necessary to respond to such conditions. The existing radiological emergency classes, in ascending order of seriousness, are called:

- Notification of Unusual Event (UE)
- Alert
- Site Area Emergency (SAE)
- General Emergency (GE)

Section 3.3 provides further discussion of the emergency classes.

INITIATING CONDITION (IC): One of a predetermined subset of nuclear power plant conditions when either the potential exists for a radiological emergency, or such an emergency has occurred.

- An IC is an emergency condition which sets it apart from the broad class of conditions that may or may not have the potential to escalate into a radiological emergency.
- It can be a continuous, measurable function that is outside technical specifications, such as elevated RCS temperature or falling reactor coolant level (a symptom).
- It also encompasses occurrences such as FIRE (an event) or reactor coolant pipe failure (an event or a barrier breach).

EMERGENCY ACTION LEVEL (EAL): A pre determined, site-specific, observable threshold for a plant Initiating Condition that places the plant in a given emergency class. An EAL can be: an instrument reading; an equipment status indicator; a measurable parameter (onsite or offsite); a discrete, observable event; results of analyses; entry into specific emergency operating procedures; or another phenomenon which, if it occurs, indicates entry into a particular emergency class.

- There are times when an EAL will be a threshold point on a measurable continuous function, such as a primary system coolant leak that has exceeded technical specifications.
- At other times, the EAL and the IC will coincide, both identified by a discrete event that places the plant in a particular emergency class.
- 3.3 Recognition Categories

ICs and EALs are grouped in one of several categories. This classification scheme incorporates symptom-based, event-based, and barrier-based ICs and EALs.

- R Abnormal Rad Levels/Radiological Effluent
- C Cold Shutdown./ Refueling System Malfunction
- F Fission Product Barrier Degradation
- H Hazards
- S System Malfunction

Some recognition categories are further divided into one or more subcategories depending on the types and number of plant conditions that dictate emergency classifications. An EAL may or may not exist for each subcategory at all four classification levels. Similarly, more than one EAL may exist for a subcategory in a given emergency classification when appropriate (i.e., no EAL at the General Emergency level but three EALs at the Unusual Event level).

3.4 Emergency Class Descriptions

There are three considerations related to the emergency classes. These are:

- The potential impact on radiological safety, either as now known or as can be reasonably projected.
- How far the plant is beyond its predefined design, safety and operating envelopes.
- Whether or not conditions that threaten health are expected to be confined to within the site boundary.

The ICs deal explicitly with radiological safety affect by escalating from levels corresponding to releases within regulatory limits to releases beyond EPA Protective Action Guideline (PAG) plume exposure levels.

NOTIFICATION-OF-UNUSUAL EVENT: Events are in process or have occurred which indicate a potential degradation of the level of safety of the plant. No releases of radioactive material requiring offsite response or monitoring are expected unless further degradation of safety systems occurs.

- Potential degradation of the level of safety of the plant is indicated primarily by exceeding plant technical specification Limiting Condition of Operation (LCO) allowable action statement time for achieving required mode change.
- Precursors of more serious events may be included because precursors represent a potential degradation in the level of safety of the plant.
- Minor releases of radioactive materials are included. In this emergency class, however, releases do not require monitoring or offsite response (e.g., dose consequences of less than 10 millirem).

ALERT: Events are in process or have occurred which involve an actual or potential substantial degradation of the level of safety of the plant. Any releases are expected to be limited to small fractions of the EPA Protective Action Guideline exposure levels.

SITE AREA EMERGENCY: Events are in progress or have occurred which involve actual or likely major failures of plant functions needed for protection of the public. Any releases are not expected to result in exposure levels which exceed EPA Protective Action Guideline (PAG) exposure levels beyond the site boundary.

- The discriminator (threshold) between Site Area Emergency and General Emergency is whether or not the EPA PAG plume exposure levels are expected to be exceeded outside the site boundary.
- This threshold, in addition to dynamic dose assessment considerations discussed in the EAL guidelines, clearly addresses NRC and offsite emergency response agency concerns as to timely declaration of a General Emergency.

GENERAL EMERGENCY: Events are in process or have occurred which involve actual or imminent substantial core degradation or melting with potential for loss of containment integrity. Releases can be reasonably expected to exceed EPA Protective Action Guideline exposure levels offsite for more than the immediate site area.

- The bottom line for the General Emergency is whether evacuation or sheltering of the general public is indicated based on EPA PAGs and, therefore, should be interpreted to include radionuclide release regardless of cause.
- To better assure timely notification, EALs in this category are primarily expressed in terms of plant function status, with secondary reliance on dose projection. In terms of fission product barriers, loss of two barriers with loss or potential loss of the third barrier constitutes a General Emergency.
- 3.5 Operating Mode Applicability

Technical Specifications [Ref. 2.4] provides definitions for the following operating modes:

1 Operating (OP)

Reactivity $\Delta k/k$ is LESS THAN Technical Specification minimum required (0.25%) and EQUAL TO OR GREATER than 2% fission power.

2 Hot Standby (HSB)

Reactivity $\Delta k/k$ is LESS THAN Technical Specification minimum required (0.25%) and LESS THAN 2% fission power.

3 Hot Shutdown (HSD)

Reactivity $\Delta k/k$ as specified in the Core Operating Limits Report with coolant temperature (Tavg) GREATER THAN OR EQUAL TO 540°F.

4 Intermediate Shutdown (ISD)

Reactivity $\Delta k/k$ as specified in the Core Operating Limits Report with coolant temperature (Tavg) LESS THAN 540°F and GREATER THAN 200°F.

5 Cold Shutdown (CSD)

Reactivity $\Delta k/k$ GREATER THAN OR EQUAL TO Technical Specification minimum required (-1%) with coolant temperature (Tavg) LESS THAN OR EQUAL TO 200°F.

6 <u>Refueling (REF)</u>

Reactivity $\Delta k/k$ GREATER THAN OR EQUAL TO Technical Specification minimum required for refueling operations (-5%) and coolant temperature (Tavg) LESS THAN OR EQUAL TO 140°F.

In addition to the Technical Specification operating modes, NEI 99-01 [Ref. 1] defines the following additional mode:

D <u>Defueled</u>

All reactor fuel removed from Reactor Vessel (full core off load during refueling or extended outage)

The plant operating mode that exists at the time that the event occurs (prior to any protective system or operator action is initiated in response to the condition) should be compared to the mode applicability of the EALs. If a lower or higher plant operating mode is reached before the emergency classification is made, the declaration shall be based on the mode that existed at the time the event occurred.

Recognition categories are associated with the operating modes listed in the following matrix:

	Recognition Category				
Mode	R	С	F	Н	S
Operations	Х		Х	Х	Х
Hot Standby	Х		Х	Х	Х
Hot Shutdown	Х		Х	Х	Х
Intermediate Shutdown	Х		Х	Х	Х
Cold Shutdown	Х	X		Х	
Refueling	Х	X		X	
Defueled	Х	X		Х	

3.6 Fission Product Barriers

Many of the EALs derived from the NEI methodology are fission product barrier based. That is, the conditions that define the EALs are based upon loss of or potential loss of one or more of the three fission product barriers. "Loss" and "potential loss" signify the relative damage and threat of damage to the barrier. "Loss" means the barrier no longer assures containment of radioactive materials and "potential loss" means imminent loss of the barrier.

The primary fission product barriers are:

- <u>Fuel Cladding (FC)</u>: Zirconium tubes which house the ceramic uranium oxide pellets along with the end plugs which are welded into each end of the fuel rods comprise the FC barrier.
- <u>Reactor Coolant System (RCS)</u>: The reactor vessel shell, vessel head, vessel nozzles and penetrations and all primary systems directly connected to the reactor vessel up to the first containment isolation valve comprise the RCS barrier.
- <u>Containment (CMT)</u>: The vapor containment structure and all isolation valves required to maintain containment integrity under accident conditions comprise the Containment barrier.
- 3.7 Emergency Classification Based on Fission Product Barrier Degradation

The following criteria are the bases for event classification related to fission product barrier loss or challenge:

• <u>Notification-of-Unusual_Event</u>:

Any loss or any potential loss of Containment

• <u>Alert</u>:

Any loss or any potential loss of either Fuel Cladding or RCS

• <u>Site Area Emergency</u>:

Loss or potential loss of any two barriers

• General Emergency:

Loss of any two barriers and loss or potential loss of third barrier

3.8 EAL Relationship to EOPs and Critical Safety Function Status

Where possible, the EALs have been made consistent with and utilize the conditions defined in the Critical Safety Function Status Trees (CSFSTs). While the symptoms that drive operator actions specified in the CSFSTs are not indicative of <u>all</u> possible conditions which warrant emergency classification, they define the symptoms, independent of initiating events, for which reactor plant safety and/or fission product barrier integrity are threatened. Where these symptoms are clearly representative of one of the NEI Initiating Conditions, they have been utilized as an EAL. This permits rapid classification of emergency situations based on plant conditions without the need for additional evaluation or event diagnosis. Although some of the EALs presented here are based on conditions defined in the CSFSTs, classification of emergencies using these EALs is not dependent upon Emergency Operating Procedures (EOP) entry or execution. The EALs can be utilized independently or in conjunction with the EOPs.

3.9 Symptom Based vs. Event Based Approach

To the extent possible, the EALs are symptom based. That is, the action level is defined by values of key plant operating parameters that identify emergency or potential emergency conditions. This approach is appropriate because it allows the full scope of variations in the types of events to be classified as emergencies. But, a purely symptom based approach is not sufficient to address all events for which emergency classification is appropriate. Particular events to which no predetermined symptoms can be ascribed have also been utilized as EALs since they may be indicative of potentially more serious conditions not yet fully realized.

Category R - Abnormal Rad Levels/Radiological Effluent and Category F - Fission Product Barrier Degradation are primarily symptom-based. The symptoms are indicative of actual or potential degradation of either fission product barriers or personnel safety.

Other categories tend to be event-based. For example, System Malfunctions are abnormal and emergency events associated with vital plant system failures, while Hazards are those non-plant system related events that have affected or may affect plant safety.

3.10 Treatment of Emergency Class Upgrading

The emergency class is based on the highest EAL reached. For example, two Alerts remain in the Alert category. Or, an Alert and a Site Area Emergency is a Site Area Emergency.

3.11 Classifying Transient Events

For some events, the condition may be corrected before a declaration has been made. For example, an emergency classification is warranted when automatic and manual actions taken within the control room do not result in a required reactor trip. However, it is likely that actions taken outside of the control room will be successful, probably before the Emergency Director classifies the event. The key consideration in this situation is to determine whether or not further plant damage occurred while the corrective actions were being taken. In some situations, this can be readily determined. In other situations, further analyses (e.g., coolant sampling) may be necessary.

KNPP

10/22/04

In general, observe the following guidance: Classify the event as indicated and terminate the emergency once assessment shows that there were no consequences from the event and other termination criteria are met. For example, a momentary event, such as an ATWS or an earthquake, requires declaration even though the condition may have been resolved by the time the declaration is made.

- An ATWS represents a failure of a front line Reactor Protection System (RPS) designed to protect the health and safety of the public.
- The affect of an earthquake on plant equipment and structures may not be readily apparent until investigations are conducted.

There may be cases in which a plant condition that exceeded an EAL threshold was not recognized at the time of occurrence, but is identified well after the condition has occurred (e.g., as a result of routine log or record review) and the condition no longer exists. In these cases, an emergency should not be declared. Reporting requirements of 10- CFR CFR 50.72 are applicable and the guidance of NUREG-1022, Rev. 1, Section 3 should be applied.

3.12 Imminent EAL Thresholds

Although the majority of the EALs provide very specific thresholds, the Emergency Director must remain alert to events or conditions that lead to the conclusion that exceeding the EAL threshold is imminent. If, in the judgment of the Emergency Director, an imminent situation is at hand, the classification should be made as if the thresholds has been exceeded. While this is particularly prudent at the higher emergency classes (as the early classification may provide for more effective implementation of protective measures), it is nonetheless applicable to all emergency classes. Explicit EALs, specifying use of Emergency Director judgment, are given in the Hazards, ISFSI and Fission Product Barrier Degradation categories.

4. TECHNICAL BASES INFORMATION

4.1 Recognition Category Organization

The technical bases of the EALs are provided under Recognition Categories R, C, F, H and S of this document. A table summarizing the Initiating Conditions introduces each category. The tables provide an overview of how the ICs are related under each emergency class. ICs within each category are listed according to classification (as as applicable) in the following order: Notification of-Unusual Event, Alert, Site Area Emergency, and General Emergency.

For Recognition Category F, Table F-0 defines the emergency classifications associated with barrier loss and potential loss. Table F-1 lists the thresholds associated with the loss and potential loss of each fission product barrier. The presentation method shown for Table F-1 was chosen to clearly show the synergism among the EALs and to support more accurate dynamic assessments. Basis discussion of the thresholds immediately follows Table F-1.

4.2 Initiating Condition Structure

ICs in Recognition Categories R, C, H and S are structured in the following manner:

- Recognition Category Title
- IC Identifier:
 - o First character identifies the category by letter (R, C, H and S)
 - Second character identifies the emergency classification level (U for Notification of Unusual Event, A for Alert, S for Site Area Emergency, and G for General Emergency)
 - Third character is the numerical sequence as given in Revision 4 of NEI
 NEI 99–01 [Ref. 1] (e.g., SA2). Due to document revisions, certain NEI ICs have been deleted, leaving gaps in the numerical sequence.
- Emergency Class: Notification of Unusual Event, Alert, Site Area Emergency, or General Emergency
- IC Description
- Operating Mode Applicability: Refers to the operating mode during which the IC/EAL is applicable

- Emergency Action Level(s): EALs are the conditions applicable to the criteria of the IC and are used to determine the need to classify an event/condition. If more than one EAL is applicable to an IC, emergency classification is required when any EAL within the IC reaches the EAL threshold. To clarify this intent, ICs with multiple EALs include a parenthetical phrase in the EAL title line, indicating that each constitutes an emergency classification. For example, the phrase "(RA1.1 or RA1.2)" indicates that either EAL is a Notification of Unusual Event.
- Basis: Provides information that explains the IC and EAL(s). Plant source document references are provided as needed to substantiate site-specific information included in the EALs and bases.

4.3 EAL Identification

The EAL identifier is the IC identifier followed by a period and sequence number (e.g., RU1.1, RU1.2, etc.). If only one EAL is assigned to an IC, the EAL is given the number one.

The primary purpose of the EAL identifier is to uniquely distinguish each classifiable condition. Secondary purposes are to assist location of an EAL within the EAL classification scheme and to announce the emergency classification level.

5. **DEFINITIONS**

In the ICs and EALs, selected words are in uppercase print. These words are defined terms. Definitions are provided below.

AFFECTING SAFE SHUTDOWN: event in progress has adversely affected functions that are necessary to bring the plant to and maintain it in the applicable HOT or COLD SHUTDOWN condition. Plant condition applicability is determined by Technical Specification LCOs in effect.

Example 1: Event causes damage that results in entry into an LCO that requires the plant to be placed in HOT SHUTDOWN. HOT SHUTDOWN is achievable, but COLD SHUTDOWN is not. This event is not "AFFECTING SAFE SHUTDOWN."

Example 2: Event causes damage that results in entry into an LCO that requires the plant to be placed in COLD SHUTDOWN. HOT SHUTDOWN is achievable, but COLD SHUTDOWN is not. This event is "AFFECTING SAFE SHUTDOWN."

BOMB: an explosive device suspected of having sufficient force to damage plant systems or structures.

CIVIL DISTURBANCE: a group of unexpected or unauthorized individuals(site-specific #) or-more persons violently protesting station operations or activities at the site.

CONFINEMENT BOUNDARY: the barrier(s) between areas containing radioactive substances and the environment.

CONTAINMENT CLOSURE: defined by N-CCI-56A, "Open Containment Boundary Tracking".

EXPLOSION: a rapid, violent, unconfined combustion, or catastrophic failure of pressurized equipment that imparts energy of sufficient force to potentially damage permanent structures, systems, or components.

EXTORTION: an attempt to cause an action at the station by threat of force.

FAULTED: a steam generator, the existence of secondary side leakage that results in an uncontrolled decrease in steam generator pressure or the steam generator being completely depressurized.

FIRE: combustion characterized by heat and light. Sources of smoke such as slipping drive belts or overheated electrical equipment do not constitute FIREs. Observation of flame is preferred but is NOT required if large quantities of smoke and heat are observed.

HOSTAGE: a person(s) held as leverage against the station to ensure that demands will be met by the station.

HOSTILE FORCE: one or more individuals who are engaged in a determined assault, overtly or by stealth and deception, equipped with suitable weapons capable of killing, maiming, or causing destruction.

KNPP

IMMEDIATELY DANGEROUS TO LIFE AND HEALTH (IDLH): A condition that either poses an immediate threat to life and health or an immediate threat of severe exposure to contaminants which are likely to have adverse delayed effects on health.

INTRUSION / INTRUDER: person(s) present in a specified area without authorization. Discovery of a BOMB in a specified area is indication of INTRUSION into that area by a HOSTILE FORCE.

LOWER FLAMMABILITY LIMIT (LFL): The minimum concentration of a combustible substance that is capable of propagating a flame through a homogenous mixture of the combustible and a gaseous oxidizer.

NORMAL PLANT OPERATIONS: activities at the plant site associated with routine testing, maintenance, or equipment operations, in accordance with normal operating or administrative procedures. Entry into abnormal or emergency operating procedures, or deviation from normal security or radiological controls posture, is a departure from NORMAL PLANT OPERATIONS.

PROTECTED AREA: boundary is-within the security isolation zone-and is defined in the KNPP Security Plan and depicted in Drawing A-449, Plan of Plant Area, Fence, Lighting and CCTV Support.

RUPTURED: In a steam generator, existence of primary-to-secondary leakage of a magnitude sufficient to require or cause a reactor trip and safety injection.

SABOTAGE: deliberate damage, misalignment, or mis-operation of plant equipment with the intent to render the equipment inoperable. Equipment found tampered with or damaged due to malicious mischief may NOT meet the definition of SABOTAGE until this determination is made by security supervision.

SIGNIFICANT TRANSIENT: an UNPLANNED event involving one or more of the following: (1) automatic turbine runback >25% thermal reactor power, (2) electrical load rejection >25% full electrical load, (3) Reactor Trip, (4) Safety Injection Activation, or (5) thermal power oscillations >10%.

STRIKE ACTION: a work stoppage within the PROTECTED AREA by a body of workers to enforce compliance with demands. The STRIKE ACTION must threaten to interrupt NORMAL PLANT OPERATIONS.

UNPLANNED: A parameter change or an event that is not the result of an intended evolution and requires corrective or mitigative actions.

VALID: An indication, report, or condition is considered to be VALID when it is verified by (1) an instrument channel check, or (2) indications on related or redundant indicators, or (3) by direct observation by plant personnel, such that doubt related to the indicator operability, the condition existence, or the report accuracy is removed. Implicit in this definition is the need for timely assessment.

VISIBLE DAMAGE: damage to equipment or structure that is readily observable without measurements, testing, or analysis. Damage is sufficient to cause concern regarding the continued operability or reliability of affected safety structure, system, or component. Example damage includes: deformation due to heat or impact, denting, penetration, rupture, cracking, paint blistering. Surface blemishes (e.g., paint chipping, scratches) should not be included.

VITAL AREA-is any a: Area, normally within the PROTECTED AREA, which contains equipment, systems, components, or material,; the failure, destruction, or release of which could directly or indirectly endanger the public health and safety by exposure to radiation.

RAU1

Initiating Condition -- NOTIFICATION OF UNUSUAL EVENT

Any UNPLANNED Release of Gaseous or Liquid Radioactivity to the Environment that Exceeds Two Times the Radiological-Effluent Technical-SpecificationsOffsite Dose Calculation Manual for 60 Minutes or Longer.

Operating Mode Applicability: All

Example Emergency Action Levels: Emergency Action Levels: (RU1.1 or RU1.2 or RU1.3 or 4 or 5)

RU1.1. VALID reading on any effluent monitor that exceeds-is GREATER THAN two times the alarm setpoint established by a current radioactivity discharge permit for 60 minutes or longer.

Auxiliary Building	Action Value
R-13 Aux. Bldg. Vent Exhaust	2.61E+05 cpm
R-14 Aux. Bldg. Vent Exhaust	2.62E+05 cpm
Reactor Building	
R-12 Containment Gas	4.41E+05 cpm
R-21 Containment Vent	4.40E+05 cpm
Liquid Radwaste	
R-18 Waste Disposal System Liquid	2 X Calculated

RU1.2. VALID reading on one or more of the following radiation monitors that exceeds-is GREATER THAN the reading shown for 60 minutes or longer.

Liquid Radwaste	Action Value
R-16 Containment FCU SW Return	3.38E+05 cpm
R-19 S/G Blowdown Liquid	2.58E+06 cpm
R-20 Aux Bldg SW Return	1.03E+05 cpm

-(sito-specific-list)

RU1.3. Confirmed sample analyses for gaseous or liquid releases indicates concentrations or release rates, with a release duration of 60 minutes or longer, in excess of two times (site-specific technical specifications) the ODCM limit.

- 4. ----VALID-reading-on-perimeter-radiation-monitoring-system-greater-than-0.10-mR/hr-above normal-background-sustained-for--60-minutes-or-longer-[for-sites-having-telemetered perimeter-monitors].

Basis:

Refer to Appendix A for a detailed basis of the radiological offluent IC/EALs.

This IC addresses a potential or actual decrease in the level of safety of the plant as indicated by a radiological release that exceeds regulatory commitments for an extended period of time. Nuclear power-plantsKNPP incorporates features intended to control the release of radioactive effluents to the environment. Further, there are administrative controls established to prevent unintentional releases, or control and monitor intentional releases. These controls are located in the Offsite Dose Calculation Manual (ODCM) [Ref. 2, 3], and for-plants-that have-not-implemented-Generic Letter 89-01, in the Radiological-Effluent-Technical-Specifications (RETS). The occurrence of extended, uncontrolled radioactive releases to the environment is indicative of a degradation in these features and/or controls. Some sites-may-find it advantageous to address gaseous and liquid releases with separate initiating conditions and EALs.

The RETS-ODCM multiples are specified in ICs AU1-RU1 and AA1-RA1 only to distinguish between non-emergency conditions, and from each other. While these multiples obviously correspond to an offsite dose or dose rate, the emphasis in classifying these events is the degradation in the level of safety of the plant, NOT the magnitude of the associated dose or dose rate. Releases should not be prorated or averaged. For example, a release exceeding 4x RETS ODCM for 30 minutes does not meet the threshold for this IC.

UNPLANNED, as used in this context, includes any release for which a radioactivity discharge permit was not prepared, or a release that exceeds the conditions (e.g., minimum dilution flow, maximum discharge flow, alarm setpoints, etc.) on the applicable permit. The Emergency Director should not wait until 60 minutes has elapsed, but should declare the event as soon as it is determined that the release duration has or will likely exceed 60 minutes. Also, if an ongoing release is detected and the starting time for that release is unknown, the Emergency Director should, in the absence of data to the contrary, assume that the release has exceeded 60 minutes.

EAL-#1RU1.1 addresses radioactivity releases, that for whatever reason, cause effluent radiation monitor readings to exceed two times the Technical-SpecificationODCM limit and releases are not terminated within 60 minutes. The "UE" values are two times the monitor high alarm setpoints or ODCM release limits. The setpoints are established to ensure the ODCM release limits are not exceeded [Ref. 2, 3]. This-These alarm setpoints may be associated with a planned batch release, or a continuous release path. In either case, the setpoint is established by the ODCM to warn of a release that is not in compliance with the RETSODCM. Indexing the EAL threshold to the ODCM setpoints in this manner insures that the EAL threshold will never be less than the setpoint established by a specific discharge permit. Escalation-will-be-based-on-radiation-readings increasing-per the-followingEach liquid discharge permit includes a value for R-18, calculated in accordance with the ODCM that will vary based on the discharge flow rate. Therefore 2 X

Calculated ODCM Setpoint was used as the threshold. Escalation will be based on radiation readings increasing per the following:

Normal Effluent Release Monitor Classification Thresholds				
Monitor	GE	SAE	Alert	UE

Liquid Radwaste		ана С		
R-18 Waste Disposal System Liquid	N/A	N/A	200 X Calculated ODCM Setpoint	2 X Calculated ODCM Setpoint

EAL-#2RU1.2 is intended for licensees that have established effluent monitoring on non-routine release pathways for which a discharge permit would not normally be prepared. The ODCM establishes a methodology for determining effluent radiation monitor setpoints. The ODCM specifies default source terms and, for gaseous releases, prescribes the use of pre-determined annual average meteorology in the most limiting downwind sector for showing compliance with the regulatory commitments. These monitor reading EALs should behave been determined using this methodology. The "UE" values are two times the monitor high alarm setpoints or ODCM release limits. The setpoints are established to ensure the ODCM release limits are not exceeded [Ref. 2, 3]. Escalation will be based on radiation readings increasing per the following:

Abnormal Effluent Release Monitor Classification Thresholds				
Monitor	Elite GE	SAE	Alert	UE

R-20 Aux Bldg SW Return	N/A	N/A	1.03E+07 cpm	1.03E+05 cpm

EAL-#3RU1.3 addresses uncontrolled releases that are detected by sample analyses, particularly on unmonitored pathways, e.g., spills of radioactive liquids into storm drains, heat exchanger leakage in riverlake water systems, etc.

The 0.10 mR/hr value in EAL #4-is based on a release rate not exceeding 500 mrom per year, as provided in the ODCM / RETS, prorated over 8766 hours, multiplied by two, and rounded. (500 + 8766 × 2 = 0.114). This is also the basis of the site specific value in EAL #5.

EALs #1-and #2RU1.1 and RU1.2 directly correlate with the IC since annual average meteorology is required to be used in showing compliance with the RETS-ODCM and is used in calculating the alarm setpoints. EALs #4-and #5 are a function of actual meteorology, which will likely be different from the limiting annual average value. Thus, there will likely be a numerical inconsistency. However, the The fundamental basis of this IC is NOT a dose or dose rate, but rather the degradation in the level of safety of the plant implied by the uncontrolled release. Exceeding EAL #4 or EAL #5 is an indication of an uncontrolled release meeting the fundamental

	Unexpected Increase-Rise in Plant Radiation.
ļ	Operating Mode Applicability: All
	Example-Emergency-Action-Levels:Emergency Action Levels: (RU2.1 or RU2.2)
	RU2.1. aVALID (site-specific) indication of uncontrolled water level decrease-lowering in the reactor refueling cavity, spent fuel pool, or fuel transfer canal with all irradiated fuel assemblies remaining covered by water as indicated by Spent Fuel Pool low water level alarm setpoint (3 ft 4 in. below floor, SER 159/160) OR visual observation
	AND
	 b.—Any UNPLANNED VALID (site-specific) Direct Area Radiation Monitor reading increases-rises as indicated by: R-2 Containment Area ALERT Alarm R-5 Fuel Handling Area ALERT Alarm R-10 New Fuel Pit Area ALERT Alarm
	RU2.2. Any UNPLANNED VALID Direct -Area Radiation Monitor readings increases-rises by a factor of 1000 over normal* levels.
1	*Normal levels can be considered as the highest reading in the past twenty-four hours excluding the current peak value.
	Basis:
	This IC addresses increased radiation levels as a result of water level decreases above the RPV Reactor Vessel flange or events that have resulted, or may result, in unexpected increases in radiation dose rates within plant buildings. These radiation increases represent a loss of control over radioactive material and may represent a potential degradation in the level of safety of the plant.
	In light of Reactor Cavity Seal failure incidents at two different PWRs and loss of water in the Spent Fuel Pit/Fuel Transfer Canal at a BWR, explicit coverage of these types of events via EAL #1RU2.1 is appropriate given their potential for increased doses to plant staff. Classification as an NOUE is warranted as a precursor to a more serious event. Site-specific iIndications may-include instrumentation such as water level and local area radiation monitors, and personnel (e.g.,

refueling crew) reports. If available, security video cameras may allow remote observation. Depending on available level instrumentation, the declaration threshold may need to be based on indications of water makeup rate or decrease in refueling water storage tank level.

While a radiation monitor could detect an increase in dose rate due to a drop in the water level, it might not be a reliable indication of whether or not the fuel is covered. For example, the reading on an area radiation monitor located on the refueling bridge may increase due to planned evolutions such as head lift, or even a fuel assembly being raised in the manipulator mast. Generally, increased radiation monitor indications will need to combined with another indicator (or personnel report) of water loss. For refueling events where the water level drops below the RPV Reactor Vessel flange classification would be via CU2. This event escalates to an Alert per IC AA2 RA2 if irradiated fuel outside the reactor vessel is uncovered. For events involving irradiated fuel in the reactor vessel, escalation would be via the Fission Product Barrier Matrix for events in Operating through Intermediate Shutdown operating modes-1-4.

The Spent Fuel Pool (SFP) low level alarm is actuated by LA-16640-02 (SER 159) and LA--16641--02 (SER 160) at 3 ft 4 in. below floor level. The North (A) and South (B) Spent Fuel Pools are located in the Auxiliary Building refueling area. The pools can be isolated from each other by a removable gate, which is normally removed. The top of each pool is at 649 ft 6 in. el. and the bottom is at 608 ft el. Fuel occupies the bottom 14 ft. [Ref. 3].

EAL #2RU2.2 addresses UNPLANNED increases in in-plant radiation levels that represent a degradation in the control of radioactive material, and represent a potential degradation in the level of safety of the plant. This event escalates to an Alert per IC AA3-RA3 if the increase in dose rates impedes personnel access necessary for safe operation.

*Normal levels can be considered as the highest reading in the past twenty-four hours excluding the current peak value.

ABNORMAL RAD LEVELS/RADIOLOGICAL EFFLUENT

AA1RA1

Initiating Condition – ALERT

Any UNPLANNED Release of Gaseous or Liquid Radioactivity to the Environment that Exceeds 200 Times the Radiological Effluent Technical SpecificationsOffsite Dose Calculation Manual for 15 Minutes or Longer.

Operating Mode Applicability: All

Example Emergency Action Levels: Emergency Action Levels: (RA1.1 or RA1.2 or RA1.3 or 4 or 5)

RA1.1. VALID reading on any effluent monitor that exceeds GREATER THAN 200 times the alarm setpoint established by a current radioactivity discharge permit for 15 minutes or longer.

Auxiliary Building	Action Value
R-13 Aux. Bldg. Vent Exhaust	2.61E+07 cpm
R-14 Aux. Bldg. Vent Exhaust	2.62E+07 cpm
Reactor_Building	
R-12 Containment Gas	4.41E+07 cpm
R-21 Containment Vent	4.40E+07 cpm
Liquid Radwaste	
R-18 Waste Disposal System Liquid	200 X Calculated ODCM Setpoint

RA1.2. VALID reading on one or more of the following radiation monitors that exceeds GREATER THAN the reading shown for 15 minutes or longer:

Liquid Radwaste	Action Value
R-16 Containment FCU SW Return	3.38E+07 cpm
R-19 S/G Blowdown Liquid	2.58E+08 cpm
R-20 Aux Bldg SW Return	1.03E+07 cpm

-(site-specific list)

RA1.3. Confirmed sample analyses for gaseous or liquid releases indicates concentrations or release rates, with a release duration of 15 minutes or longer, in excess of 200 times (site-specific technical specifications) ODCM limit.

- 4.——VALID-reading-on-perimeter-radiation-monitoring-system-greater-than-10.0-mR/hr-above normal-background-sustained-for-15-minutes-or-longer-[for-sites-having-telemetered perimeter-monitors].
- 5. --VALID-indication-on-automatic-real-time-dose-assessment-capability-greater-than-(sitespecific-value) for 15-minutes or longer-[for sites having such capability].

Basis:

Refer to Appendix A for a detailed basis of the radiological offluent IC/EALs.

This IC addresses a potential or actual decrease in the level of safety of the plant as indicated by a radiological release that exceeds regulatory commitments for an extended period of time. Nuclear power-plantsKNPP incorporates features intended to control the release of radioactive effluents to the environment. Further, there are administrative controls established to prevent unintentional releases, or control and monitor intentional releases. These controls are located in the Offsite Dose Calculation Manual (ODCM)), and for-plants that have not implemented Generic Letter-89-01, in the Radiological Effluent Technical Specifications (RETS). The occurrence of extended, uncontrolled radioactive releases to the environment is indicative of a degradation in these features and/or controls. Some-sites-may-find-it-advantageous-to-address-gaseous-and-liquid releases with separate initiating conditions and EALs.

The RETS-ODCM multiples are multiples are specified in ICs AU1-RU1 and AA1-RA1 only to distinguish between non-emergency conditions, and from each other. While these multiples obviously correspond to an offsite dose or dose rate, the emphasis in classifying these events is the degradation in the level of safety of the plant, NOT the magnitude of the associated dose or dose rate. Releases should not be prorated or averaged.

UNPLANNED, as used in this context, includes any release for which a radioactivity discharge permit was not prepared, or a release that exceeds the conditions (e.g., minimum dilution flow, maximum discharge flow, alarm setpoints, etc.) on the applicable permit. The Emergency Director should not wait until 15 minutes has elapsed, but should declare the event as soon as it is determined that the release duration has or will likely exceed 15 minutes. Also, if an ongoing release is detected and the starting time for that release is unknown, the Emergency Director should, in the absence of data to the contrary, assume that the release has exceeded 15 minutes.

EAL-#1RA1.1 addresses radioactivity releases that for whatever reason cause effluent radiation monitor readings that exceed two hundred times the alarm setpoint established by the radioactivity discharge permit. The "Alert" values shown for each monitor are two hundred times the alarm setpoints or calculated ODCM release limits as specified in Reference 4. The setpoints are established to ensure the ODCM release limits are not exceeded [Ref. 2, 3]. This-The alarm setpoints may be associated with a planned batch release, or a continuous release path. In either case, the setpoint is established by the ODCM to warn of a release that is not in compliance with the RETSODCM. Indexing the EAL threshold to the ODCM setpoints in this manner insures that the EAL threshold will never be less than the setpoint established by a specific discharge permit. Each liquid discharge permit includes a value for R-18, calculated in accordance with the ODCM, that will vary based on the discharge flow rate, therefore "200 X Calculated ODCM Setpoint" was used as the threshold. Escalation will be based on radiation readings increasing per the following: Escalation will be based on radiation readings increasing per the following:

	Normal Effluent Release Monitor Classification Thresholds

EAL #2-is-similar to EAL #1, but-isRA1.2 intended to addresses effluent or accident radiation monitors on non-routine release pathways (i.e., for which a discharge permit would not normally be prepared) [Ref. 1]. The ODCM establishes a methodology for determining effluent radiation monitor setpoints. The ODCM specifies default source terms and, for gaseous releases, prescribes the use of pre-determined annual average meteorology in the most limiting downwind sector for showing compliance with the regulatory commitments. These monitor reading EALs should behave been determined using this methodology. The "Alert" values for each monitor are two hundred times the alarm setpoints or calculated ODCM release limits as specified in Reference 4. The setpoints are established to ensure the ODCM release limits are not exceeded [Ref. 2, 3]. Escalation will be on based radiation readings increasing per the following:

Abnormal Effluent Release Monitor Classification Thresholds				
Monitor	GE	SAE	Alert	UE

R-20 Aux Bldg SW Return	N/A	N/A	1.03E+07 cpm	1.03E+05 cpm

EAL #3RA1.3 addresses uncontrolled releases that are detected by sample analyses, particularly on unmonitored pathways, e.g., spills of radioactive liquids into storm drains, heat exchanger leakage in riverlake water systems, etc.

The 10.0 mR/hr value in EAL #4 is based on a release rate not exceeding 500 mrem per year, as provided in the ODCM / RETS, prorated over 8766 hours, multiplied by 200, and rounded. (500 ÷ 8766 × 200 = 11.4). This is also the basis of the site specific value in EAL #5.

EALs #1-and #2RA1.1 and RA1.2 directly correlate with the IC since annual average meteorology is required to be used in showing compliance with the RETS-ODCM and is used in calculating the alarm setpoints. EALs #4-and #5 are a function of actual meteorology, which will likely be different from the limiting-annual average-value. Thus, there will likely be a numerical inconsistency. However, the The fundamental basis of this IC is NOT a dose or dose rate, but rather the degradation in the level of safety of the plant implied by the uncontrolled release. Exceeding EAL #4-or EAL #5 is an indication of an uncontrolled release meeting the fundamental basis for this IC.

Due to the uncertainty associated with meteorology, emergency implementing procedures should call for the timely performance of dose assessments using actual (real-time) meteorology in the event of a gaseous radioactivity release of this magnitude. The results of these assessments should be compared to the ICs AS1-RS1 and AG1-RG1 to determine if the event classification should be escalated.

Contrary-to-the-practices-specified-in-revision-2-of-this-document, classification-should-not-be delayed pending the results of these dose assessments.

ABNORMAL RAD LEVELS/RADIOLOGICAL EFFLUENT

AA2RA2

Initiating Condition --- ALERT

Damage to Irradiated Fuel or Loss of Water Level that Has or Will Result in the Uncovering of Irradiated Fuel Outside the Reactor Vessel.

Operating Mode Applicability: All

Example Emergency Action Levels: Emergency Action Levels: (RA2.1 or RA2.2)

- RA2.1. A VALID radiation indication high (site-specific)-alarm or reading on one or more of the following radiation monitors resulting from damage to irradiated fuel or loss of water level:
 - R-2 Containment Area
 - R-5 Fuel Handling Area
 - R-13 or R-14 Aux Bldg Vent Exhaust
 - R-11 or R-12 Containment Particulate / Gas Ventilation
 - R-21 Containment Vent

-(site-specific monitors)

------Fuel Handling Building Ventilation Monitor

------Refueling-Bridge-Area Radiation Monitor

RA2.2. Water level LESS THAN 50% Wide Range Refueling Water Level Reactor Refueling Cavity-OR GREATER THAN 14 feet below top of Spent Fuel Pool that will result in irradiated fuel uncoveringless than (site-specific) feet for the reactor refueling cavity, spent fuel pool and fuel transfer canal that will result in irradiated fuel uncovering.

Basis:

This IC addresses specific events that have resulted, or may result, in unexpected increases in radiation dose rates within plant buildings, and may be a precursor to a radioactivity release to the environment. These events represent a loss of control over radioactive material and represent a degradation in the level of safety of the plant. These events escalate from IC AU2-RU2 in that fuel activity has been released, or is anticipated due to fuel heatup. This IC applies to spent fuel requiring water coverage and is not intended to address spent fuel which is licensed for dry storage, which is discussed in IC E-AEU1.

EAL-#1RA2.1 addresses radiation monitor indications [Ref. 1, 2, 3] of fuel uncovery and/or fuel damage. Increased readings on ventilation monitors may be indication of a radioactivity release from the fuel, confirming that damage has occurred. Increased background at the monitor due to water level decrease may mask increased ventilation exhaust airborne activity and needs to be considered. While a radiation monitor could detect an increase in dose rate due to a drop in the water level, it might not be a reliable indication of whether or not the fuel is covered. For example, the monitor could in fact be properly responding to a known event involving transfer or relocation

In EAL-#2RA2.2, site-specific-indications may-include instrumentation such as water level and local area radiation monitors, and personnel (e.g., refueling crew) reports. Wide Range Refueling Water Level is measured by L9053A for channel A and L9054A for channel B. If available, security video cameras may allow remote observation. The top of each pool is at 649 ft 6 in. el. and the bottom is at 608 ft el. Fuel occupies the bottom 14 ft. [Ref. 4]. Depending on available level indication, the dDeclaration threshold-may need to be based on indications of water makeup rate or decrease in refueling water storage tank level.

Escalation, if appropriate, would occur via IC AS1-RS1 or AG1-RG1 or Emergency Director judgment.

ABNORMAL RAD LEVELS/RADIOLOGICAL EFFLUENT

AA3RA3

Initiating Condition -- ALERT

Release of Radioactive Material or Increases-Rise in Radiation Levels Within the Facility That Impedes Operation of Systems Required to Maintain Safe Operations or to Establish or Maintain Cold Shutdown

Operating Mode Applicability: All

Example-Emergency Action Levels: Emergency Action Levels: (RA3.1 or RA3.2)

RA3.1. VALID (site-specific) radiation monitor readings GREATER THAN 15 mR/hr in areas requiring continuous occupancy to maintain plant safety functions:

Control Room (Rad monitor R-1) OR Central Alarm Station (Rad monitor R-1)

OR

Secondary Alarm Station (by survey)

-(Site-specific)-list

- RA3.2. Any VALID (site-specific)-radiation monitor readings GREATER THAN <site-specific> values6 R/hr in areas requiring infrequent access to maintain plant safety functions.
 - Auxiliary Building
 - Safeguards Alley
 - Diesel Generator Rooms (includes "A" Diesel Room to Screen House Tunnel)
 - Screenhouse/Forebay
 - Relay Room
 - Safeguard Battery Room

(Site-specific)-list

Basis:

This IC addresses increased radiation levels that impede necessary access to operating stations, or other areas containing equipment that must be operated manually or that requires local monitoring, in order to maintain safe operation or perform a safe shutdown. It is this impaired ability to operate the plant that results in the actual or potential substantial degradation of the level of safety of the plant. The cause and/or magnitude of the increase in radiation levels is not a concern of this IC. The Emergency Director must consider the source or cause of the increased radiation levels and determine if any other IC may be involved. For example, a dose rate of 45 15 mR/hr in the control room may be a problem in itself. However, the increase may also be indicative of high dose rates in the containment due to a LOCA. In this latter case, an SAE or GE may be indicated by the fission product barrier matrix ICs.

At-multiple-unit-sites,-the example EALs could result in declaration of an Alert at one-unit due to a radioactivity-release or radiation-shine-resulting from a major accident at the other-unit. This is appropriate if the increase impairs operations at the operating unit.

This IC is not meant to apply to increases in the containment dome-radiation monitors, as these are events which are addressed in the fission product barrier matrix ICs. Nor is it intended to apply to anticipated temporary increases due to planned events (e.g., incore-detector-movement, radwaste container movement, depleted resin transfers, etc.)

For RA3.1 areas requiring continuous occupancy include the Control Room and the central alarm station (CAS). The CAS has no installed radiation monitoring capability [Ref. 3]. Areas requiring continuous occupancy includes the control room and, as appropriate to the site, any other control stations that are manned continuously, such as a radwaste control room or a contral security alarm station.—The value of 15mR/hr is derived from the GDC 19 value of 5 rem in 30 days with adjustment for expected occupancy times. Although Section III.D.3 of NUREG-0737, *"Clarification of TMI Action Plan Requirements"* [Ref. 1, 2], provides that the 15 mR/hr value can be averaged over the 30 days, the value is used here without averaging, as a 30 day duration implies an event potentially more significant than an Alert.

For RA3.2 areas requiring infrequent access, the basis of the 6 R/hr value is as follows:

The KNPP annual administrative personnel exposure limit is 2 Rem/Year. Assuming an emergency worker is at his administrative limit, any emergency worker needing access to a plant area for the safe shutdown of the plant could receive up to an additional 3 Rem without exceeding the legal 10CFR20 annual exposure limit of 5 Rem [Ref. 4] and thus the need for emergency exposure authorization. Assuming that an activity required to be performed in the plant would, on average, require a 30 minute stay time in that area, an area exposure rate of 6 R/hr would not unduly impede access to areas necessary for safe plant shutdown.the-site-specific value(s)-should-be based-on-radiation-levels-which-result-in exposure-control measures intended-to-maintain doses within normal-occupational-exposure guidelines-and limits (i.e., 10 CFR 20), and in doing so, will impede necessary access.

As used here, *impede*, includes hindering or interfering provided that the interference or delay is sufficient to significantly threaten the safe operation of the plant. RA3.2 provides the list of safe shutdown areas requiring infrequent access. The listed areas contain functions and systems required for the safe shutdown of the plant. KNPP safe shutdown analyses were consulted for equipment and plant areas required for the applicable mode [Ref 5].

In-plant radiation surveys and Area Radiation Monitor (ARM) readings are methods available to assess this EAL. Radiation monitors are not specified in the EAL wording because portable monitoring devices may be used to determine area accessibility. It would then be possible to erroneously exclude information gained from portable monitor surveys when interpreting the EAL.

Emergency-planners-developing-the-site-specific-lists-may-refer to the-site's abnormal operating procedures, emergency-operating procedures, the 10 CFR 50 Appendix-R-analysis, and/or, the analyses performed in response to Section 2.1.6b of NUREG-0578, "TMI-2-Lessons Learned Task Force-Status Report and Short-term Recommendations"

, when -identifying areas containing safe shutdown equipment. Do not use the dose ratespostulated in the NUREG-0578 analyses as a basis for the radiation monitor readings for this IC,KNPP6-R-1710/22/04

as the design envelope for the NUREG-0578 analyses correspond to general emergency conditions.

Dose assessment using actual meteorology indicates doses GREATER THAN 100 mRem TEDE or 500 mRem thyroid CDE at or beyond the site boundary. A-VALID reading sustained for 15 minutes or longer on perimeter radiation monitoring system greater than 100 mR/hr. [for sites having telemetered perimeter monitors] 4RS1.3. Field survey results indicate closed window dose rates exceeding 100 mRem/hr expected to continue for more than one hour, at or beyond the site boundary; or-OR

Offsite Dose Resulting from an Actual or Imminent Release of Gaseous Radioactivity Exceeds 100 mRem TEDE or 500 mRem Thyroid CDE for the Actual or Projected Duration of the Release.

be based on EAL #2RS1.2 instead of EAL #1RS1.1. While necessary declarations should not be delayed awaiting results, the dose assessment should be initiated / completed in

AS1RS1

Aanalyses of field survey samples indicate thyroid CDE of 500 mRem for one hour of inhalation, at or beyond the site boundary.

Basis:

Refer to Appendix A for a detailed basis of the radiological effluent IC/EALs.

This IC addresses radioactivity releases that result in doses at or beyond the site boundary that exceed a small fraction of the EPA Protective Action Guides (PAGs). Releases of this magnitude are associated with the failure of plant systems needed for the protection of the public. While these failures are addressed by other ICs, this IC provides appropriate diversity and addresses events which may not be able to be classified on the basis of plant status alone, e.g., fuel handling accident in spent fuel building.

The TEDE dose is set at 10% of the EPA PAG, while the 500 mRem thyroid CDE was established in consideration of the 1:5 ratio of the EPA PAG for TEDE and thyroid CDE.

The Emergency Director should not wait until 15 minutes has elapsed, but should declare the event as soon as it is determined that the release duration has or will likely exceed 15 minutes.

The (site specific)-monitor list in EAL-#1-RS1.1 should-includes monitors on all potential release pathways [Ref. 1, 3, 4].

The EPA PAGs are expressed in terms of the sum of the effective dose equivalent (EDE) and the committed effective dose equivalent (CEDE), or as the thyroid committed dose equivalent (CDE). For the purpose of these IC/EALs, the dose quantity total effective dose equivalent (TEDE), as defined in 10 CFR 20, is used in lieu of *"...sum of EDE and CEDE...."* The EPA PAG guidance provides for the use adult thyroid dose conversion factors. However, some states have decided to calculate child thyroid CDE. Utility IC/EALs need to be consistent with those of the states involved in the facility's emergency planning zone.

The "SAE" effluent monitor readings are derived from Reference 2.

The monitor-reading EALs should be determined using a dose assessment method that back calculates from the dose values specified in the IC. The meteorology and source term (noble gases, particulates, and halogens) used should be the same as those used for determining the monitor-reading EALs in ICs AU1 and AA1. This protocol will maintain intervals between the EALs for the four classifications. Since doses are generally not monitored in real-time, it is suggested that a release duration of one hour be assumed, and that the EALs be based on a site boundary (or beyond) dose of 100 mR/hour whole body or 500 mR/hour thyroid, whichever is more limiting (as was done for EALs #3 and #4). If individual site analyses indicate a longer or shorter duration for the period in which the substantial pertion of the activity is released, the longer duration should be used.

Since dose assessment is based on actual meteorology, whereas the monitor reading EALs are not, the results from these assessments may indicate that the classification is not warranted, or may indicate that a higher classification is warranted. For this reason, emergency implementing procedures should-call for the timely performance of dose assessments using actual meteorology and release information. If the results of these dose assessments are available when the classification is made (e.g., initiated at a lower classification level), the dose assessment results override the monitor reading EALs.

Contrary to the practices specified in revision 2 of this document, classification should not be delayed pending the results of these dose assessments.

Escalation will be on based radiation readings increasing per the following:

site-specific-list)

RG1.2. Dose assessment using actual meteorology indicates doses GREATER THAN 1000 mRem TEDE or 5000 mRem thyroid CDE at or beyond the site boundary.

- 3. A VALID reading sustained for 15 minutes or longer on perimeter radiation monitoring system greater than 1000 mR/hr. [for sites having telemetered perimeter monitors]
- 4RG1.3. Field survey results indicate closed window dose rates exceeding 1000 mRem/hr expected to continue for more than one hour, at or beyond site boundary.; or a OR

Analyses of field survey samples indicate thyroid CDE of 5000 mRem for one hour of inhalation, at or beyond site boundary.

Basis:

Refer to Appendix A for a detailed basis of the radiological effluent-IC/EALs.

This IC addresses radioactivity releases that result in doses at or beyond the site boundary that exceed the EPA Protective Action Guides (PAGs). Public protective actions will be necessary. Releases of this magnitude are associated with the failure of plant systems needed for the protection of the public and likely involve fuel damage. While these failures are addressed by other ICs, this IC provides appropriate diversity and addresses events which may not be able to be classified on the basis of plant status alone. It is important to note that, for the more severe accidents, the release may be unmonitored or there may be large uncertainties associated with the source term and/or meteorology.

The Emergency Director should not wait until 15 minutes has elapsed, but should declare the event as soon as it is determined that the release duration has or will likely exceed 15 minutes.

The (site specific) monitor list in EAL #1RG1.1 should-includes monitors on all potential release pathways [Ref. 1, 3, 4].

The EPA-PAGs are expressed in terms of the sum of the effective dose equivalent (EDE) and the committed effective dose equivalent (CEDE), or as the thyroid committed dose equivalent (CDE). For the purpose of these IC/EALs, the dose quantity total effective dose equivalent (TEDE), as defined in 10 CFR-20, is used in lieu of "...sum of EDE and CEDE...." The EPA PAG guidance provides for the use adult thyroid dose conversion factors. However, some states have decided to calculate child thyroid CDE. Utility IC/EALs need to be consistent with those of the states involved in the facilities emergency planning zone.

The "GE" effluent monitor readings are derived from Reference 2.

The-monitor-reading EALs should be-determined using a dose assessment method that backcalculates from the dose values specified in the IC. The meteorology and source term (noble gases, particulates, and halogens) used should be the same as those used for determining the monitor reading EALs in ICs AU1 and AA1. This protocol will maintain intervals between the EALs for the four classifications. Since doses are generally not monitored in real-time, it is suggested that a release duration of one hour be assumed, and that the EALs be based on a site boundary (or beyond) dose of 1000 mR/hour whole body or 5000 mR/hour thyroid, whichever is more limiting (as was done for EALs #3 and #4). If individual site analyses indicate a longer or shorter duration

for the period-in which the substantial portion of the activity is released, the longer duration should be used.

Since dose assessment is based on actual meteorology, whereas the monitor reading EALs are not, the results from these assessments may indicate that the classification is not warranted, or may indicate that a higher classification is warranted. For this reason, emergency implementing procedures should-call for the timely performance of dose assessments using actual meteorology and release information. If the results of these dose assessments are available when the classification is made (e.g., initiated at a lower classification level), the dose assessment results override the monitor reading EALs.

Contrary to the practices specified in revision 2 of this document, classification should not be delayed pending the results of these dose assessments.

SYSTEM MALFUNCTION

CU1

Initiating Condition -- NOTIFICATION OF UNUSUAL EVENT

RCS Leakage.

Operating Mode Applicability: Cold Shutdown

Example-Emergency Action Levels: (CU1.1 or CU1.2)

CU1.1. Unidentified or pressure boundary leakage GREATER THAN 10 gpm.

CU1.2. Identified leakage GREATER THAN 25 gpm.

Basis:

This IC is included as a NOUE-UE because it is considered to be a potential degradation of the level of safety of the plant. Positive indications in the Control Room of Reactor Coolant System (RCS) leakage to the containment are provided by equipment that monitors:

- Charging/Letdown flow mismatch
- Containment air activity
- Containment humidity
- Containment Sump A In-leakage

[Ref. 1, 2],

The 10 gpm value for the unidentified and pressure boundary leakage was selected as it is sufficiently large to be observable via normally installed instrumentation (e.g., Pressurizer level, RCS loop level instrumentation, etc...) or reduced inventory instrumentation such as tygon level hese-indication. Lesser values must generally be determined through time-consuming surveillance tests (e.g., mass balances). The EAL for identified leakage is set at a higher value due to the lesser significance of identified leakage in comparison to unidentified or pressure boundary leakage. Prolonged loss of RCS Inventory may result in escalation to the Alert level via either IC CA1 (Loss of RCS Inventory with Irradiated Fuel in the RPVReactor Vessel) or CA4 (Inability to Maintain Plant in Cold Shutdown with Irradiated Fuel in the RPVReactor Vessel).

The difference between CU1 and CU2 deals with the RCS conditions that exist between cold shutdown and refueling mode applicability. In cold shutdown the RCS will normally be intact and RCS inventory and level monitoring means such as Pressurizer level indication and makeup volume control tank levels are normally available. In the refueling mode the RCS is not intact and RPVReactor Vessel level and inventory are monitored by different means.

Expanded-basis for these assumptions is provided in Appendix-C.

____

SYSTEM MALFUNCTION

CU2

Initiating Condition -- NOTIFICATION OF UNUSUAL EVENT

UNPLANNED Loss of RCS Inventory with Irradiated Fuel in the RPVReactor Vessel.

Operating Mode Applicability: Refueling

Example Emergency Action Levels: Emergency Action Levels: (CU2.1 or CU2.2)

- CU2.1. UNPLANNED RCS level decrease-lowering below the RPV-Reactor Vessel flange (21.5%) for >-GREATER THAN OR EQUAL TO 15 minutes
- CU2.2. a.—Loss of RPV-Reactor Vessel inventory as indicated by unexplained Containment Sump A, Containment Sump C or Liquid Waste Disposal System {site-specific}-sump-and tank-level increaserise

AND

b. RPV-Reactor Vessel level cannot be monitored

Basis:

This IC is included as an NOUE-UE because it may be a precursor of more serious conditions and, as result, is considered to be a potential degradation of the level of safety of the plant. Refueling evolutions that decrease RCS water level below the RPV-Reactor Vessel flange are carefully | planned and procedurally controlled. An UNPLANNED event that results in water level decreasing below the RPV-Reactor Vessel flange warrants declaration of an NOUE-Unusual Event due to the | reduced RCS inventory that is available to keep the core covered. The allowance of 15 minutes was chosen because it is reasonable to assume that level can be restored within this time frame using one or more of the redundant means of refill that should be available. If level cannot be restored in this time frame then it may indicate a more serious condition exists. Continued loss of RCS Inventory will result in escalation to the Alert level via either IC CA2 (Loss of RPV-Reactor Vessel Inventory with Irradiated Fuel in the RPVReactor Vessel) or CA4 (Inability to Maintain Plant in Cold Shutdown with Irradiated Fuel in the RPVReactor Vessel).

The difference between CU1 and CU2 deals with the RCS conditions that exist between cold shutdown and refueling modes. In cold shutdown the RCS will normally be intact and standard RCS inventory and level monitoring means are available. In the refueling mode the RCS is not intact and RPV-Reactor Vessel level and inventory are monitored by different means.

In the refueling shutdown mode, normal means of core temperature indication and RCS level indication may not be available. Redundant means of RPVReactor Vessel level indication will normally be installed (including the ability to monitor level visually) to assure that the ability to monitor level will not be interrupted. However, if all level indication were to be lost during a loss of RCS inventory event, the operators would need to determine that RPVReactor Vessel inventory loss was occurring by observing sump-Containment Sump A, Containment Sump C and tank Liquid Waste Disposal System level changes [Ref. 1, 2]. Sump-Sump and tank level increaserises KNPP 6-C-6 10/22/04

must be evaluated against other potential sources of leakage such as cooling water sources inside the containment to ensure they are indicative of RCS leakage. When CONTAINMENT SUMP A LEVEL HIGH is received, the corresponding leakrate within containment is calculated from sump pump run history. Escalation to Alert would be via either CA2 or RCS heatup via CA4.

EAL-1CU2.1 involves a decrease in RCS level below the top of the RPVReactor Vessel flange that continues for 15 minutes due to an UNPLANNED event. The level at the Reactor Vessel flange is monitored by:

- Wide Range Refueling Water Level (L9053A for channel A and L9054A for channel B) indication: Reactor Vessel/Refueling level indication: 21.5%
- RVLIS: 52.8%
- Sightglass/Tygon: 340 in. WC

[Ref. 3]-

This EAL is not applicable to decreases in flooded reactor cavity level (covered by AU2 EAL1RU2.1) until such time as the level decreases to the level of the vessel flange. For-BWRs, if RPV-level-continues to decrease and reaches the Low-Low-ECCS Actuation Setpoint then escalation to CA2 would be appropriate. For-PWRs, ilf RPVReactor Vessel level continues to decrease and reaches the Bottom ID of the RCS Loop, (Refueling Level, 0% RVLIS, 252 in. sightglass), then escalation to CA2 would be appropriate. Note that the Bottom ID of the RCS Loop Setpoint should be the level equalcorresponds to the bottom of the RPVReactor Vessel loop penetration (not the low point of the loop).

Expanded basis for these assumptions is provided in Appendix-C.

SYSTEM MALFUNCTION

CU3

Initiating Condition -- NOTIFICATION OF UNUSUAL EVENT

Loss of All Offsite Power to Essential Busses for Greater-ThaREATER THANn 15 Minutes.

Operating Mode Applicability:

Cold Shutdown Refueling

Example-Emergency Action Level:

CU3.1. a.-Loss of all offsite power to (site-specific) transformersBus 5 AND Bus 6 for GREATER THANgreater than 15 minutes.

AND

b.—At least (site-specific)[number-ofone emergency diesel generator is are-supplying power to emergency bussesBus 5 or Bus 6.

Basis:

Prolonged loss of AC power reduces required redundancy and potentially degrades the level of safety of the plant by rendering the plant more vulnerable to a complete Loss of AC Power (e.g., ., Station Blackout). Fifteen minutes was selected as a threshold to exclude transient or momentary power losses.

The 4160 VAC system is divided into six busses, two of which are Engineered Safety Function (ESF) Busses 5 and 6. The ESF busses supply power to Safety Injection (SI) pumps, Residual Heat Removal (RHR) pumps, containment heat removal equipment, etc.

Offsite power is available from the 345 kVAC and 138 kVAC systems. The 345 kVAC system is connected to the North Appleton line, the Point Beach line, the main transformers, and transformer T-10. The 345 kVAC is the normal supply to the 13.8 kVAC system through transformer T-10, which feeds the Tertiary Auxiliary Transformer (TAT). The TAT normally provides power to ESF bus 5. The TAT is not considered available to power both ESF busses in an emergency situation due to its size. As a contingency, however, it is acceptable to use the TAT to power both ESF busses when guidance for sequencing and monitoring TAT loads is available in the Control Room. The Reserve Auxiliary Transformer (RAT) and Main Auxiliary Transformer (MAT) provide backup sources to bus 5, in that order.

The 138 kVAC system is connected to the Shoto/Mishicot line, the East Krok line and transformer T-10. The 138 kVAC system is the normal supply to the Reserve Auxiliary Transformer (RAT) via the East and West substation busses. (When the 345 kVAC system is unavailable, the 138 kVAC system can supply power to transformer T-10 and the TAT.) The RAT normally provides power to ESF bus 6. The TAT and MAT provide backup sources to bus 6 in that order.

When the main turbine generator is on line, generator output supplies power to the Main Auxiliary
Transformer (MAT) and the 4160 VAC busses. When the main turbine generator is off line, the
345 kVAC system can be aligned to backfeed the MAT. Note that the time required to effect the
KNPP6-C-810/22/04

backfeed is likely longer than the fifteen-minute interval associated with this EAL. If shutdown plant conditions have already established the backfeed, however, its power to the ESF busses may be considered an offsite power source.

Following a loss of power, ECA 0.0 provides guidance to restore power to ESF busses. For the purpose of classification under this EAL, offsite power sources include any of the following:

- 345 kVAC system supplying power to transformer T-10 and the TAT
- 138 kVAC system supplying power to transformer T-10 and the TAT
- 138 kVAC system supplying power to the RAT
- 345 kVAC system supplying power to the MAT on backfeed through the main transformers when the main turbine generator is off line

Plants that have the capability to cross-tie AC-power from a companion unit-may take credit for-the-redundant-power-source-in-the-associated-EAL-for this-IC. Inability-to-effect-the cross-tie within 15-minutes warrants-declaring a NOUE.

CU4

Initiating Condition - NOTIFICATION OF UNUSUAL EVENT

UNPLANNED Loss of Decay Heat Removal Capability with Irradiated Fuel in the RPVReactor Vessel.

Operating Mode Applicability:

Cold Shutdown Refueling

Example Emergency Action Levels: Emergency Action Levels: (CU4.1 or CU4.2)

- CU4.1. An UNPLANNED event results in RCS temperature exceedingGREATER THAN -the Technical-Specification cold shutdown temperature limit]200°F
- CU4.2. Loss of all RCS temperature and RPVReactor Vessel level indication for >-GREATER THAN 15 minutes.

Basis:

This IC is included as an NOUE-UE because it may be a precursor of more serious conditions and, as a result, is considered to be a potential degradation of the level of safety of the plant. In cold shutdown the ability to remove decay heat relies primarily on forced cooling flow. Operation of the systems that provide this forced cooling may be jeopardized due to the unlikely loss of electrical power or RCS inventory. Since the RCS usually remains intact in the cold shutdown mode a large inventory of water is available to keep the core covered. In cold shutdown the decay heat available to raise RCS temperature during a loss of inventory or heat removal event may be significantly greater than in the refueling mode. Entry into cold shutdown conditions may be attained within hours of operating at power. Entry into the refueling mode procedurally may not occur for typically 100 hours {site specific} or longer after the reactor has been shutdown. Thus the heatup threat | and therefore the threat to damaging the fuel clad may be lower for events that occur in the refueling mode with irradiated fuel in the RPVReactor Vessel (note that the heatup threat could be | lower for cold shutdown conditions if the entry into cold shutdown was following a refueling). In addition, the operators should be able to monitor RCS temperature and RPVReactor Vessel level | so that escalation to the alert level via CA4 or CA1 will occur if required.

During refueling the level in the RPVReactor Vessel will normally be maintained above the RPVReactor Vessel flange. Refueling evolutions that decrease water level below the RPVReactor Vessel flange are carefully planned and procedurally controlled. Loss of forced decay heat removal at reduced inventory may result in more rapid increaserises in RCS/RPVReactor Vessel temperatures depending on the time since shutdown. Escalation to the Alert level via CA4. is provided should an UNPLANNED event result in RCS temperature exceeding the Technical Specification cold shutdown temperature limit for greater than 30 minutes with CONTAINMENT CLOSURE not established.

Unlike the cold shutdown mode, normal means of core temperature indication and RCS level indication may not be available in the refueling mode. Redundant means of RPVReactor Vessel | level indication are therefore procedurally installed to assure that the ability to monitor level will not be interrupted. However, if all level and temperature indication were to be lost in either the cold KNPP 6-C-10 10/22/04 |

shutdown of refueling modes, EAL-2CU4.2 would result in declaration of an NOUE-Unusual Event if either temperature or level indication cannot be restored within 15 minutes from the loss of both means of indication. Escalation to Alert would be via CA2 based on an inventory loss or CA4 based on exceeding its temperature criteria (200°F) [Ref. 1].

Reactor Vessel water level is normally monitored using the following instruments:

- 21158 Refueling Water Level Narrow Range (L9055A)
- 21159 Refueling Water Level B Wide Range (L9054A)
- 24068 Refueling Water Level A Wide Range (L9053A)
- LI-41337 Reactor Cavity Lvl
- Local Rx Vessel Level Sightglass/Tygon (252 in. to 645 in.)
- RVLIS 41622 Train A
- RVLIS 41623 Train B

Refueling Water Level B Wide Range instrument is calibrated to provide indication from the top of active fuel (0% or 200 in. WC) to the refueling floor (68.5% or 645 in. WC). The Reactor Vessel Level Indicating System (RVLIS) is part of the Post Accident Monitoring Instrumentation. RVLIS is provided for verification and long term surveillance of core cooling and indicates from the bottom of the RCS hot leg penetration (0% or 252 in. WC) to above the high point of the Reactor Vessel head (100% or 419 in.). Procedures N-RC-36E, Draining the Reactor Coolant System, and N-RHR-34C, RHR Operation at a Reduced Inventory Condition, provide a cross-reference table of indicated water levels and sightglass readings.

[Ref. 2, 3, 4]

Several instruments are capable of providing indication of RCS temperature with respect to the Technical Specification cold shutdown temperature limit (200°F). N-0-01, Plant Startup from Cold Shutdown Condition to Hot Shutdown Condition, specifies the use of the highest of the wide range, RHR inlet, or Core Exit Thermocouples to monitor RCS temperature in the Cold Shutdown or Refueling Mode.

The Emergency Director must remain attentive to events or conditions that lead to the conclusion that exceeding the EAL threshold is imminent. If, in the judgment of the Emergency Director, an imminent situation is at hand, the classification should be made as if the threshold has been exceeded.

Expanded-basis for these assumptions is provided in Appendix-C.

CU5

Initiating Condition -- NOTIFICATION OF UNUSUAL EVENT

Fuel Clad Degradation.

Operating Mode Applicability:

Cold Shutdown Refueling

Example Emergency Action Levels:Emergency Action Levels: (CU5.1 or CU5.2)

- CU5.1. RCS Letdown Line (R-9) radiation monitor GREATER THAN 2000 mR/hr indicating fuel clad degradation(Site-specific) radiation monitor readings indicating fuel clad-degradation greater than Technical Specification allowable limits.
- CU5.2. (Site-specific)-Ceoolant sample activity value-GREATER THAN ANY of the following indicating fuel clad degradation:
 - 1.0 µCi/gram dose equivalent lodine-131 for more than 48 hours in one continuous time interval
 - 60 μCi/gram dose equivalent lodine-131.
 - 91/Ē µCi/cc gross radioactivity

indicating fuel clad degradation greater than Technical Specification allowable limits.

Basis:

This IC is included as a NOUE because it is considered to be a potential degradation in the level of safety of the plant and a potential precursor of more serious problems. EAL #CU5.1 addresses RCS Letdown Line (R-9) site-specific radiation monitor readings that provide indication of fuel clad integrity [Ref. 4 & 5]. EAL #2CU5.2 addresses coolant samples exceeding coolant technical specifications for iodine spike [Ref. 1].

2000 mR/hr was calculated using the following:

0.01% fuel cladding defect equals 7.2E+1 mR/hr increase on R-9 [Ref. 4] 0.2745% fuel cladding defect equals 1.0 μCi/gram dose equivalent lodine-131 [Ref. 5].

Therefore 1976.4 mR/hr increase on R-9 is equal to 1.0 μ Ci/gram dose equivalent lodine-131

R-9 background is equivalent to 56 mR/hr [Ref. 4], which is added to the calculated dose rate above.

With the addition of background R-9 will read 2032.4 mR/hr (rounded to 2000 mR/hr) equal to 1.0 μ Ci/gram dose equivalent lodine-131.

Although the Technical Specification is applicable when average reactor coolant temperature is GREATER THAN 500°F, it is appropriate that this EAL be applicable in cold shutdown and refueling modes, as it indicates a potential degradation in the level of safety of the plant.

CU6 Initiating Condition -- NOTIFICATION-OF UNUSUAL EVENT UNPLANNED Loss of All Onsite or Offsite Communications Capabilities. **Operating Mode Applicability:** Cold Shutdown Refueling Example-Emergency-Action-Levels:Emergency Action Levels: (CU6.1 or CU6.2) CU6.1. Loss of all (site-specific list)-Table C-1 onsite communications capability affecting the ability to perform routine operations. Table C-1 Onsite Communications Systems Intraplant Paging (Gai-tronics) Sound powered phones PBX telephone system Personal communications system (PCS phones) Portable radio communications system

CU6.2. Loss of all (site-specific-list)-Table C-2 offsite communications capability.

	Table C-2 Offsite Communications Systems
•	PBX telephone system
•	NRC FTS System (including ENS and HPN)
•	Dial select phones

Basis:

The purpose of this IC and its associated EALs is to recognize a loss of communications capability that either defeats the plant operations staff ability to perform routine tasks necessary for plant operations or the ability to communicate problems with offsite authorities. The loss of offsite communications ability is expected to be significantly more comprehensive than the condition addressed by 10 CFR 50.72.

The availability of one method of ordinary offsite communications is sufficient to inform state and local authorities of plant problems. This EAL is intended to be used only when extraordinary means (e.g., relaying of information from radio transmissions, individuals being sent to offsite locations, etc.) are being utilized to make communications possible.

Site-specific-list-forTable C-1 onsite communications loss <u>-must--</u>encompasses the loss of all means of routine communications (e.g., commercial telephones, sound powered phone systems, page party system and radios / walkie talkies). Due to its limited capability, the emergency gaitronics is not listed in Table C-1.

Site-specific list-forTable C-2 offsite communications loss-must— encompasses the loss of all means of communications with offsite authorities. This should_includes the NRC FTS System (including Emergency Notification System - ENS and Health Physics Network - HPN)ENS, commercial telephone lines, telecopy transmissions, and dedicated phone systems.

1.-a. CU7.1 -UNPLANNED Loss of Vital DC power to required DC busses based on (sitespecific) bus voltage indications LESS THAN 105 VDC on Train A <u>AND</u> Train B Safeguards DC Distribution System.

AND

b.-Failure to restore power to at least one required Train of the Safeguards DC Distribution System DC bus-within 15 minutes from the time of loss.

Basis:

The purpose of this IC and its associated EALs is to recognize a loss of DC power compromising the ability to monitor and control the removal of decay heat during Cold Shutdown or Refueling operations. This EAL is intended to be anticipatory in as much as the operating crew may not have necessary indication and control of equipment needed to respond to the loss.

UNPLANNED is included in this IC and EAL to preclude the declaration of an emergency as a result of planned maintenance activities. Routinely plants will perform maintenance on a Train related basis during shutdown periods. It is intended that the loss of the operating (operable) train is to be considered. If this loss results in the inability to maintain cold shutdown, the escalation to an Alert will be per EAL CA4 "Inability to Maintain Plant in Cold Shutdown with Irradiated Fuel in the RPVReactor Vessel."

(Site-specific)LESS THAN 105 VDC bus voltage should beis based on the minimum bus voltage necessary for the operation of safety related equipment [Ref. 1, 2]. This voltage value should incorporate a margin of at least 15 minutes of operation before the onset of inability to operate those loads. This voltage is usually near the minimum voltage selected when battery sizing is performed. Typically the value for the ontire battery set is approximately 105 VDC. For a 60 cell string of batteries the cell voltage 1.75 Volts per cell. For a 58 string battery set the minimum voltage is typically 1.81 Volts per cell. The loss of a safeguards DC train consists of a combination of loss of power to specified DC distribution panels. These panels include: BRA (BRB)-102, and BRA (BRB)-104. In all cases, BRA (BRB)-102 panel indicating less than 105 VDC constitutes a loss of the associated DC distribution train. However, a loss of power to the BRA (BRB) -104 panel, which does not have voltage indication, also constitutes a loss of the associated DC distribution train.

125 VDC safeguard main distribution cabinets (BRA-102 and BRB-102) supply two safeguard subdistribution cabinets (BRA-104 and BRB-104) and provide for connection of safeguard batteries (BRA-101 and BRB-101) to their associated battery chargers (BRA-108 and BRB-108). The combination of low voltages on the specified distribution cabinets results in a total loss of vital 125 VDC power. The 125 VDC safeguards system powers circuit breaker control, Control Room alarms, Control Room controls, diesel generator controls, and the Reactor Protection System. It is also the standby power source to the AC inverters. BRA-102 and BRB-102 voltage is displayed on Control Room indicators 4494001 and 4494002, respectively. Undervoltage is alarmed on Control Room Sequence of Event Recorder (SER) points 490011196 and 490011200 and annunciators 447101A and 47101B, respectively.

Each of the 125 VDC batteries has been sized to carry the expected shutdown loads following a reactor trip and a loss of all AC power for a period of eight hours without battery terminal voltage falling below 105 VDC. This voltage value therefore incorporates a margin of at least 15 minutes of operation before the onset of inability to operate loads. The nominal battery cell voltage is 2.20 VDC. Low battery terminal voltage activates Control Room SER point 49001832 and annunciator 47105A. The batteries are located in Battery Rooms A and B on the Turbine Building Mezzanine Floor (606 ft el.).

CU8

Initiating Condition -- NOTIFICATION OF UNUSUAL EVENT

Inadvertent Criticality.

Operating Mode Applicability:

Cold Shutdown Refueling

Example-Emergency-Action Levels:Emergency Action Level:(1-or-2)

1. An UNPLANNED extended positive period observed on nuclear-instrumentation

CU8.21. An UNPLANNED sustained positive startup rate observed on nuclear instrumentation.

Basis:

This IC addresses criticality events that occur in Cold Shutdown or Refueling modes (NUREG NUREG 1449, Shutdown and Low-Power Operation at Commercial Nuclear Power Plants in the United States) such as fuel mis-loading events and inadvertent dilution events. This IC indicates a potential degradation of the level of safety of the plant, warranting an NOUE-Unusual Event | classification. This IC excludes inadvertent criticalities that occur during planned reactivity changes associated with reactor startups (e.g., criticality earlier than estimated) which are addressed in the companion IC SU8.

This condition can be identified using period-monitors/startup rate monitormeters. The terms "extended" and "sustained" are-is used in order to allow exclusion of expected short term positive periods/startup rates from planned fuel bundle or control rod movements during core alteration-for PWRs and BWRs. These short term positive periods/startup rates are the result of the increaserise in neutron population due to subcritical multiplication.

This condition can be identified using startup rate meters (NI-31D/32D - Source Range Startup Rate).

Escalation would be by Emergency Director Judgment.

CA1

Initiating Condition -- ALERT

Loss of RCS Inventory.

Operating Mode Applicability: Cold Shutdown

Example-Emergency Action Levels:Emergency Action Levels: (CA1.1 or CA1.2)

CA1.1. Loss of RCS inventory as indicated by one or more of the following:

- Wide Range Refueling Water Level LESS THAN RPVReactor Vessel level less thanLESS THAN-8%
- RVLIS at 0%
- Sightglass water level LESS THAN 252 in

. {site-specific-level}.

(low-low ECCS actuation setpoint) (BWR) (bottom ID of the RCS loop) (PWR)

CA1.2. a.—Loss of RCS inventory as indicated by unexplained level rise in any of the following:
Containment Sump A

- Containment Sump C
- Liquid Waste Disposal System

{site-specific}-sump-and-tank-level-increase

AND

b.—RCS level cannot be monitored for ≻GREATER THAN 15 minutes

Basis:

These example-EALs serve as precursors to a loss of ability to adequately cool the fuel. The magnitude of this loss of water indicates that makeup systems have not been effective and may not be capable of preventing further RPVReactor Vessel level decrease and potential core uncovery. The 8% Refueling Level (0% RVLIS, 252 in. sightglass) threshold corresponds to the bottom inside diameter of the RCS hot leg [Ref. 2]. This condition will result in a minimum classification of Alert. The BWR Low-Low ECCS Actuation Setpoint was chosen because it is a standard setpoint at which all available injection systems automatically start. The PWR-Bottom ID of the RCS Loop-hot leg Setpoint was chosen because at this level remote RCS level indication may be lost and loss of suction to decay heat removal systems has occurred. The Bottom ID of the RCS hot legLoop Setpoint should be the level equal to the bottom of the RPVReactor Vessel loop penetration (not the low point of the loop). The inability to restore and maintain level after reaching this setpoint would therefore be indicative of a failure of the RCS barrier.

The elevation of the bottom of the RCS hot leg can be monitored by:

KNPP

- Wide Range Refueling Water Level (L9053A for channel A and L9054A for channel B) indication:Reactor-Vessel/Refueling level-indication: 7.95% rounded to 8% for readability
- RVLIS: 0%
- Sightglass/Tygon: 252 in. WC

Reactor Vessel water level is normally monitored using the following instruments:

- 21158 Refueling Water Level Narrow Range (L9055A)
- 21159 Refueling Water Level B Wide Range (L9054A)
- 24068 Refueling Water Level A Wide Range (L9053A)
- LI-41337 Reactor Cavity Lvl

- RVLIS 41623

RVLIS-41623-Train-B

[Ref 2]

[Ref. 2].

In cold shutdown the decay heat available to raise RCS temperature during a loss of inventory or heat removal event may be significantly greater than in the refueling mode. Entry into cold shutdown conditions may be attained within hours of operating at power or hours after refueling is completed. Entry into the refueling mode procedurally may not occur for typically 100 hours {site-specific}-or longer after the reactor has been shutdown. Thus the heatup threat and therefore the threat to damaging the fuel clad may be lower for events that occur in the refueling mode with irradiated fuel in the RPVReactor Vessel (note that the heatup threat could be lower for cold shutdown conditions if the entry into cold shutdown was following a refueling). The above forms the basis for needing both a cold shutdown specific IC (CA1) and a refueling specific IC (CA2).

In the cold shutdown mode, if the RCS is pressurized, then the refueling water level indication (including sightglass / tygon) will not be in service. In this case, RVLIS will serve as the means for declaration of this EAL.normal-RCS-level-and-RPVReactor-Vessel-level-instrumentation-systems will normally be available. However, if all level indication were to be lost during a loss of RCS inventory event, the operators would need to determine that RPVReactor Vessel inventory loss was occurring by observing Containment Sump A, Containment Sump C and Liquid Waste Disposal System level changes [Ref. 1, 5]. Each time annunciator CONTAINMENT SUMP A LEVEL HIGH sump-and-tank-level-changes.- is received, the corresponding leakrate within containment is calculated from sump pump run history. Sump and tank level increaserises must be evaluated against other potential sources of leakage such as cooling water sources inside the containment to ensure they are indicative of RCS leakage [Ref. 1, 2, 4]. The 15-minute duration for the loss of level indication was chosen because it is half of the CS1 Site Area Emergency EAL duration. The 15-minute duration allows CA1 to be an effective precursor to CS1. Significant fuel damage is not expected to occur until the core has been uncovered for greater than 1 hour per the analysis referenced in the CS1 basis. Therefore this EAL meets the definition for an Alert emergency.

The difference between CA1 and CA2 deals with the RCS conditions that exist between cold shutdown and refueling mode applicability. In cold shutdown the RCS will normally be intact and standard RCS inventory and level monitoring means are available. In the refueling mode the RCS is not intact and RPVReactor Vessel level and inventory are monitored by different means.

If RPVReactor Vessel level continues to decrease then escalation to Site Area Emergency will be via CS1 (Loss of Inventory Affecting Core Decay Heat Removal Capability with Irradiated Fuel in the RPVReactor Vessel).

Expanded basis for these assumptions is provided in Appendix C.

 - Liquid Waste Disposal System

{site-specific}-sump-and-tank-level-increase

AND

b. RPVReactor Vessel level cannot be monitored for >GREATER THAN 15 minutes

Basis:

These example EALs serve as precursors to a loss of heat removal. The magnitude of this loss of water indicates that makeup systems have not been effective and may not be capable of preventing further RPVReactor Vessel level decrease and potential core uncovery. The 8% Refueling Level (0% RVLIS, 252 in. sightglass) threshold corresponds to the bottom inside diameter of the RCS loop [Ref. 2]. This condition will result in a minimum classification of Alert. The BWR Low Low ECCS Actuation Setpoint was chosen because it is a standard setpoint at which all available injection systems automatically start. The Bottom ID of the RCS Loop hot leg Setpoint was chosen because at this level remote RCS level indication may be lost and loss of suction to decay heat removal systems may occur. The Bottom ID of the RCS hot legLoop Setpoint should beis the level equal to the bottom of the RPVReactor Vessel loop penetration (not the low point of the loop). The inability to restore and maintain level after reaching this setpoint would therefore be indicative of a failure of the RCS barrier.

The elevation of the bottom of the RCS hot leg can be monitored by:

- Wide Range Refueling Water Level (L9053A for channel A and L9054A for channel B) indicationReactor Vessel/Refueling level indication: 7.95% rounded to 8% for readability
- RVLIS: 0%

• Sightglass/Tygon: 252 in. WC

Reactor Vessel water level is normally monitored using the following instruments:

- LI-41337 Reactor Cavity Lvl
- Local Rx Vessel Level Sightglass/Tygon (252 in. to 645 in.)
- RVLIS 41622 Train A
- RVLIS 41623 Train B

[Ref. 2]

In cold shutdown the decay heat available to raise RCS temperature during a loss of inventory or heat removal event may be significantly greater than in the refueling mode. Entry into cold shutdown conditions may be attained within hours of operating at power or hours after refueling is completed. Entry into the refueling mode procedurally may not occur for typically 100 hours {site-specific}-or longer after the reactor has been shutdown. Thus the heatup threat and therefore the threat to damaging the fuel clad may be lower for events that occur in the refueling mode with irradiated fuel in the RPVReactor Vessel (note that the heatup threat could be lower for cold shutdown conditions if the entry into cold shutdown was following a refueling). The above forms the basis for needing both a cold shutdown specific IC (CA1) and a refueling specific IC (CA2).

In the refueling mode, normal means of RPVReactor Vessel level indication may not be available. Redundant means of RPVReactor Vessel level indication will be normally installed (including the ability to monitor level visually) to assure that the ability to monitor level will not be interrupted. However, if all level indication were to be lost during a loss of RCS inventory event, the operators would need to determine that RPVReactor Vessel inventory loss was occurring by observing Containment Sump A, Containment Sump C and Liquid Waste Disposal System level changes [Ref. 1, 5]. Each time annunciator CONTAINMENT SUMP A LEVEL HIGH sump-and-tank-level changes.-is received, the corresponding leakrate within containment is calculated from sump pump run history. [Ref. 1, 2, 3] Sump and tank level increaserises must be evaluated against other potential sources of leakage such as cooling water sources inside the containment to ensure they are indicative of RCS leakage. The 15-minute duration for the loss of level indication was chosen because it is half of the CS2 Site Area Emergency EAL duration. The 15-minute duration allows CA2 to be an effective precursor to CS2. Significant fuel damage is not expected to occur until the core has been uncovered for greater than 1 hour per the analysis referenced in the CS2 basis. Therefore this EAL meets the definition for an Alert.

The difference between CA1 and CA2 deals with the RCS conditions that exist between cold shutdown and refueling mode applicability. In cold shutdown the RCS will normally be intact and standard RCS inventory and level monitoring means are available. In the refueling mode the RCS is not intact and RPVReactor Vessel level and inventory are monitored by different means.

If RPVReactor Vessel level continues to decrease then escalation to Site Area Emergency will be via CS1 (Loss of Inventory Affecting Core Decay Heat Removal Capability with Irradiated Fuel in the RPVReactor Vessel).

CA3

Initiating Condition – ALERT

Loss of All Offsite Power and Loss of All Onsite AC Power to Essential Busses.

Operating Mode Applicability:

Cold Shutdown Refueling Defueled

Example-EmergencyEmergencyAction Level:

CA3.1. a.-Loss of ALL offsite-power to Bus 5 AND Bus 6 for GREATER THAN 15 minutes.

power-to (site-specific) transformers.

AND

b.-Failure of (site-specific) emergency generators to supply power to

AND

Basis:

Loss of all AC power compromises all plant safety systems requiring electric power including RHR, ECCS, Containment Heat Removal, Spent Fuel Heat Removal and the Ultimate Heat-SinkService Water System. When in cold shutdown, refueling, or defueled mode the event can be classified as an Alert, because of the significantly reduced decay heat, lower temperature and pressure, increasing the time to restore one of the emergency busses, relative to that specified for the Site Area Emergency EAL. Escalating to Site Area Emergency-IC-SS1, if appropriate, is by Abnormal Rad Levels / Radiological Effluent, or Emergency Director Judgment ICs. Fifteen minutes was selected as a threshold to exclude transient or momentary power losses.

This EAL is indicated by the loss of all offsite and onsite AC power to the 4160 VAC ESF busses. Offsite power sources include the 345 kVAC system or 138 kVAC system to the Tertiary Auxiliary Transformer (TAT), the 345 kVAC system or 138 kVAC system to the Reserve Auxiliary Transformer (RAT), and the 345 kVAC system to the Main Auxiliary Transformer (MAT) on backfeed through the main transformers. Note that the time required to effect a backfeed to the MAT is likely longer than the fifteen-minute interval. If off-normalshutdown plant conditions have already established the backfeed, however, its power to the ESF busses may be considered an offsite power source. Onsite power sources consist of Diesel Generator A to Bus 5 and Diesel Generator-B to Bus 6. [Ref. 1, 2, 3, 4, 5].

Consideration should be given to operable loads necessary to remove decay heat or provide Reactor Vessel makeup capability when evaluating loss of AC power to essential busses. Even though an essential bus may be energized, if necessary loads (i.e., loads that if lost would inhibit decay heat removal capability or Reactor Vessel makeup capability) are not operable on the energized bus then the bus should not be considered operable.

RCS integrity <u>not</u>-NOT established <u>or</u>-OR Wide Range Refueling Water Level LESS THAN Refueling Level LESS THAN OR EQUAL-TO-17.0%RCS inventory reduced, A

an UNPLANNED event results in RCS temperature exceedingGREATER THAN the Technical Specification cold-shutdown temperature limit200°F for greater thanGREATER THAN 20 minutes*¹.

⁴*NoteNOTE: If RHR system is in operation within this time frame and RCS temperature is being reduced then this EAL is not applicable.

- CA4.3. An UNPLANNED event results in RCS temperature exceedingGREATER THAN the Technical Specification cold shutdown temperature limit200°F for GREATER THANgreater than 60 minutes*.⁴ or
 - OR

Rresults in an RCS pressure increase of GREATER THANgreater-than {site-specific}10 psig.

¹*NOTE Note: If RHR system is in operation within this time frame and RCS temperature is being reduced then this EAL is not applicable.

CA4

⁴Note: if an RCS heat removal system is in operation within this time frame and RCS temperature is being reduced then this EAL is not applicable.

Basis:

EAL-1CA4.1 addresses complete loss of functions required for core cooling during refueling and cold shutdown modes when neither CONTAINMENT CLOSURE nor RCS integrity are established. RCS integrity is in place when the RCS pressure boundary is in its normal condition for the cold shutdown mode of operation (e.g., reactor head on with studs tensioned, S/G and PRZR manways installed, PRZR safety valves installed, no freeze seals or nozzle dams). No delay time is allowed for EAL1-CA4.1 because the evaporated reactor coolant that may be released into the Containment during this heatup condition could also be directly released to the environment.

EAL-2CA4.2 addresses the complete loss of functions required for core cooling for >GREATER THAN 20 minutes during refueling and cold shutdown modes when CONTAINMENT CLOSURE is established but RCS integrity is not established or RCS inventory is reduced (e.g., mid loop operation in PWRs). As in EAL-1CA4.1, RCS integrity should be assumed to be in place when the RCS pressure boundary is in its normal condition for the cold shutdown mode of operation (e.g., reactor head on with studs tensioned, S/G and PRZR man-ways installed, PRZR safety valves installed, no freeze seals or nozzle dams). (e.g., no freeze seals or nozzle dams). The allowed 20 minute time frame was included to allow operator action to restore the heat removal function, if possible. The allowed time frame is consistent with the guidance provided by Generic Letter 88-17, "Loss of Decay Heat Removal" (discussed later in this basis) and is believed to be conservative given that a low pressure Containment barrier to fission product release is established. The Note 4-for CA4.2 indicates that EAL-2CA4.2 is not applicable if actions are successful in restoring an RCS heat removal system to operation and RCS temperature is being reduced within the 20 minute time frame. Wide Range Refueling Water Level is measured by L9053A for channel A and L9054A for channel B.

EAL-3CA4.3 addresses complete loss of functions required for core cooling for >GREATER THAN 60 minutes during refueling and cold shutdown modes when RCS integrity is established. As in EAL-1CA4.1 and 2CA4.2, RCS integrity should be considered to be in place when the RCS pressure boundary is in its normal condition for the cold shutdown mode of operation (e.g., reactor head on with studs tensioned, S/G and PRZR man-ways installed, PRZR safety valves installed, no freeze seals or nozzle dams). The status of CONTAINMENT CLOSURE in this EAL is immaterial given that the RCS is providing a high pressure barrier to fission product release to the environment. The 60 minute time frame should allow sufficient time to restore cooling without there being a substantial degradation in plant safety. The {site-specific}10 psig pressure increaserise covers situations where, due to high decay heat loads, the time provided to restore temperature control, should be less than 60 minutes. RCS Pressure Narrow Range instrument PI-420 and PPCS/SPDS point P0420A are capable of measuring pressure to less than 10 psig. [Ref. 3, 27]. The Note for CA4.3The-RCS-pressure-setpoint-chosen-should-be-10-psig-or-the-lowest pressure-that-the-site-can-read-on-installed-Control-Board-instrumentation-that-is-equal-to-or greater than 10 psig. - Note 1-indicates that EAL-3CA4.3 is not applicable if actions are successful in restoring an-RCS-heat-removal the RHR system to operation and RCS temperature is being reduced within the 60 minute time frame assuming that the RCS pressure increaserise has remained less than the site specific pressure value.

Several instruments are capable of providing indication of RCS temperature with respect to the Technical Specification cold shutdown temperature limit (200°F). N-0-01, Plant Startup from Cold Shutdown Condition to Hot Shutdown Condition, specifies the use of the highest of the wide range, RHR inlet, or Core Exit Thermocouples to monitor RCS temperature in the Cold Shutdown or Refueling Mode.

[Ref. 2, 3,] KNPP Escalation to Site Area Emergency would be via CS1 or CS2 should boiling result in significant RPVReactor Vessel level loss leading to core uncovery.

For PWRs, tThis-IC and its associated EALs are based on concerns raised by Generic Letter 88-17, "Loss of Decay Heat-Removal." A number of phenomena such as pressurization, vortexing, steam-generator U-tube draining, RCS level differences when operating at a mid-loop condition, decay heat-removal system design, and level instrumentation problems can lead to conditions where decay heat removal is lost and core uncovery can occur. NRC analyses show that sequences that can cause core uncovery in 15 to 20 minutes and severe core damage within an hour after decay heat removal is lost.

A loss of Technical Specification components alone is not intended to constitute an Alert. The same is true of a momentary UNPLANNED excursion above 200 degrees _F when the heat | removal function is available.

The Emergency Director must remain alert to events or conditions that lead to the conclusion that exceeding the EAL threshold is imminent. If, in the judgment of the Emergency Director, an imminent situation is at hand, the classification should be made as if the threshold has been exceeded.

Basis:					

Under the conditions specified by this IC, continued decrease in RPVReactor Vessel level is indicative of a loss of inventory control. Inventory loss may be due to an RPVReactor Vessel breach, pressure boundary leakage, or continued boiling in the RPVReactor Vessel. KNPP 6-C-33 10/22/04

In cold shutdown the decay heat available to raise RCS temperature during a loss of inventory or heat removal event may be significantly greater than in the refueling mode. Entry into cold shutdown conditions may be attained within hours of operating at power or hours after refueling is completed. Entry into the refueling mode procedurally may not occur for typically 100 hours {site-specific}-or longer after the reactor has been shutdown. Thus the heatup threat and therefore the threat to damaging the fuel clad may be lower for events that occur in the refueling mode with irradiated fuel in the RPVReactor Vessel (note that the heatup threat could be lower for cold shutdown conditions if the entry into cold shutdown was following a refueling). The above forms the basis for needing both a cold shutdown specific IC (CS1) and a refueling specific IC (CS2).

In the cold shutdown mode, normal RCS level and reactor vessel level indication systems (RVLIS) will normally be available. If the RCS is pressurized, then the Wide Range Refueling Water Level indication will not be in service. However, if all level indication were to be lost during a loss of RCS inventory event, the operators would need to determine that RPVReactor Vessel inventory loss was occurring by observing sump and tank level changes. RVLIS indication is considered lost if leakage reduces RCS level below its indicating range. Each time annunciator CONTAINMENT SUMP A LEVEL HIGH is received, the corresponding leakrate within containment is calculated from sump pump run history. [Ref. 1, 5] Sump and tank level increases must be evaluated against other potential sources of leakage such as cooling water sources inside the containment to ensure they are indicative of RCS leakage.

These example EALs are based on concerns raised by Generic Letter 88-17, Loss of Decay Heat Removal, SECY 91-283, Evaluation of Shutdown and Low Power Risk Issues, NUREG-1449, Shutdown and Low Power Operation at Commercial Nuclear Power Plants in the United States, and, NUMARC 91-06, Guidelines for Industry Actions to Assess Shutdown Management. A number of variables, (BWRs – e.g., such as initial vessel level, or shutdown heat removal system design) (PWRs – e.g., mid-loop, reduced level/flange level, head in place, or cavity flooded, RCS venting strategy, decay heat removal system design, vortexing pre-disposition, steam generator Utube draining) can have a significant impact on heat removal capability challenging the fuel clad barrier. Analysis in the above references indicates that core damage may occur within an hour following continued core uncovery therefore, conservatively, 30-minutes was chosen.

When Reactor Vessel water level drops to 616 ft 4 in. el., the level associated without CONTAINMENT CLOSURE established, level is six inches below the bottom of the RCS hot leg vessel penetration. This level can be monitored by Wide Range Refueling Water Level (L9053A for channel A and L9054A for channel B) indication at 7.1% (rounded to 7% for readability). The following indications are off scale low and as such are not available:

- RVLIS: <0%
- Sightglass/Tygon level equal to 246 in. WC.

When Reactor Vessel water level drops to 612 ft 4 in. el., the level associated with CONTAINMENT CLOSURE established, core uncovery is about to occur. Wide Range Refueling Water Level indication of 0% is approximately the top of active fuel.

[Ref. 1, 2]

If a PWRs RVLIS is unable to distinguish 6" below the bottom ID of the RCS loop penetration, then the first observable point below the bottom ID of the loop should be chosen as the setpoint. If a RVLIS is not available such that the PWR EAL setpoint cannot be determined, then EAL 1.b should be used to determine if the IC has been met.

The 30-minute duration allowed when CONTAINMENT CLOSURE is established allows sufficient time for actions to be performed to recover needed cooling equipment and is considered to be conservative given that level is being monitored via CS1 and CS2. For PWRs the Eeffluent release is not expected with closure established.

For BWRs releases would be monitored and escalation would be via Category A ICs if required.

Thus, for both PWR and BWR declaration of a Site Area Emergency is warranted under the conditions specified by the IC. Escalation to a General Emergency is via CG1 (Loss of RPVReactor Vessel Inventory Affecting Fuel Clad Integrity with Containment Challenged with Irradiated Fuel in the RPVReactor Vessel) or radiological effluent IC AG1 (Offsite Dose Resulting from an Actual or Imminent Release of Gaseous Radioactivity Exceeds 1000 mRem TEDE or 5000 mRem Thyroid CDE for the Actual or Projected Duration of the Release Using Actual Meteorology).

Expanded basis for these assumptions is provided in Appendix-C. KNPP Basis Reference(s):

CS2

Initiating Condition - SITE AREA EMERGENCY

Loss of RPVReactor Vessel Inventory Affecting Core Decay Heat Removal Capability with Irradiated Fuel in the RPVReactor Vessel.

Operating Mode Applicability: Refueling

Example Emergency Action Levels: Emergency Action Levels: (CS2.1 or CS2.2)

CS2.1. With CONTAINMENT CLOSURE -NOT established:

a. RPVReactor Vessel inventory as indicated by Wide Range Refueling Water Level LESS THAN 7% Reactor-Vessel-inventory-as-indicated-by-RPVReactor-Vessel-level less thanLESS THAN {site-specific level}

OR

- b. RPVReactor Vessel level cannot be monitored with Indication of core uncovery as evidenced by one or more of the following:
 - Containment High-RangeArea Radiation Monitor (R-2) reading GREATER
 THAN 100 mRem/hr
- CS2.2. With CONTAINMENT CLOSURE established
 - a. RPVReactor Vessel inventory as indicated by Wide Range Refueling Water Level RPVReactor Vessel level less than EQUAL TO 0%-Refueling LevelTOAF

OR

- b. RPVReactor Vessel level cannot be monitored with Indication of core uncovery as evidenced by one or more of the following:
 - Containment High-RangeArea Radiation Monitor (R-2) reading >-GREATER THAN {site-specific} setpoint100 mRem/hr
 - Erratic Source Range Monitor Indication
 Other {site-specific} indications

Basis:

Under the conditions specified by this IC, continued decrease in RPVReactor Vessel level is indicative of a loss of inventory control. Inventory loss may be due to an RPVReactor Vessel breach or continued boiling in the RPVReactor Vessel. Since BWRs have RCS penetrations below the setpoint, continued level decrease may be indicative of pressure boundary leakage.

In cold shutdown the decay heat available to raise RCS temperature during a loss of inventory or heat removal event may be significantly greater than in the refueling mode Entry into cold shutdown conditions may be attained within hours of operating at power or hours after refueling is completed. Entry into the refueling mode procedurally may not occur for typically 100 hours {site-specific}-or longer after the reactor has been shutdown. Thus the heatup threat and therefore the threat to damaging the fuel clad may be lower for events that occur in the refueling mode with irradiated fuel in the RPVReactor Vessel (note that the heatup threat could be lower for cold shutdown conditions if the entry into cold shutdown was following a refueling). The above forms the basis for needing both a cold shutdown specific IC (CS1) and a refueling specific IC (CS2).

These-example-EALs are based on concerns raised by Generic Letter 88-17, Loss of Decay Heat Removal, SECY-91-283, Evaluation of Shutdown and Low Power Risk Issues, NUREG-1449, Shutdown and Low Power Operation at Commercial Nuclear Power Plants in the United States, and, NUMARC NUMARC 91-06, Guidelines for Industry Actions to Assess Shutdown Management. A number of variables, (BWRs - e.g., such as initial vessel level, or shutdown heat removal system design) (PWRs - (e.g., mid-loop, reduced level/flange-level, head in place, or cavity flooded, RCS venting strategy, decay heat removal system design, vortexing predisposition, steam-generator U--tube-draining) can have a significant impact on heat removal capability challenging the fuel clad barrier. Analysis in the above references indicates that core damage may occur within an hour following continued core uncovery therefore, conservatively, 30 minutes was chosen.

When Reactor Vessel water level drops to 616 ft 4 in. el., the level associated without CONTAINMENT CLOSURE established, level is six inches below the bottom of the RCS hot leg vessel penetration. This level can be monitored by Wide Range Refueling Water Level (L9053A for channel A and L9054A for channel B) indication at 7.1% (rounded to 7% for readability). The following indications are off scale low and as such are not available:

- RVLIS: <0%
- Sightglass/Tygon level equal to 246 in. WC.

When Reactor Vessel water level drops to 612 ft 4 in. el., the level associated with CONTAINMENT CLOSURE established, core uncovery is about to occur. Wide Range Refueling Water Level indication of 0% is approximately the top of active fuel.

[Ref. 1, 2]

If a PWRs RVLIS is unable to distinguish 6"-below the bottom ID of the RCS loop penetration, then the first observable point-below the bottom ID of the loop should be chosen as the setpoint. If a RVLIS is not-available such that the PWR-EAL setpoint cannot be determined, then EAL 1.b should be used to determine if the IC has been met.

In Refuel mode at the levels of interest, RVLIS is unavailable but alternate means of level indication (refueling level) are installed to assure that the ability to monitor level will not be interrupted. If all means of level monitoring are not available, however, the Reactor Vessel inventory loss may be detected by the following indirect methods:

• As water level in the Reactor Vessel lowers, the dose rate above the core will rise. The dose rate due to this core shine should result in an unplanned alarm on the Containment Area Monitor (R-2). R-2 is used instead of the high range containment monitors because if a small amount of fuel was uncovered, the location of the high range monitors would preclude them reading on scale. Therefore the alarm setpoint of R-2 was selected to indicate a rise in containment radiation resulting from the conditions of this EAL [Ref. 8]}.

 Post-TMI studies indicated that the installed nuclear instrumentation will operate erratically when the core is uncovered and Source Range Monitors (SRM) N-31B and N-32B can be used as a tool for making such determinations. SRM count rate can also be indicated in the Control Room by the audible SRM count rate monitor.

As water-level in the RPV-lowers, the dose-rate above the core-will increase. The dose-rate due to this core shine-should result in-up-scaled Containment-High-Range-Monitor indication and possible alarm. EAL 1.b and EAL 2.b calculations should be performed to conservatively estimate a site-specific dose-rate-setpoint-indicative of core-uncovery (ic., level at TOAF). Additionally, post-TMI studies-indicated-that-the-installed-nuclear-instrumentation will-operate-erratically when the core is uncovered and that this should be used as a tool for making such determinations.

For EAL-2-in-the-refueling-mode, normal-means-of-RPV-level-indication-may-not-be-available. Redundant-means-of-RPV-level-indication-will-be-normally-installed-(including-the-ability-to-monitor level visually) to assure that the ability to monitor level-will not be interrupted.

For PWRs the eEffluent release is not expected with closure CONTAINMENT CLOSURE established.

For BWRs releases would be monitored and escalation would be via Category A ICs if required.

Thus, for both PWR and BWR declaration of a Site Area Emergency is warranted under the conditions specified by the IC. Escalation to a General Emergency is via CG1 (Loss of RPVReactor Vessel Inventory Affecting Fuel Clad Integrity with Containment Challenged with Irradiated Fuel in the RPVReactor Vessel) or radiological effluent IC AG1 (Offsite Dose Resulting from an Actual or Imminent Release of Gaseous Radioactivity Exceeds 1000 mRem TEDE or 5000 mRem Thyroid CDE for the Actual or Projected Duration of the Release Using Actual Meteorology).

Expanded basis for these assumptions is provided in Appendix C.

CG1

Initiating Condition -- GENERAL EMERGENCY

Loss of RPVReactor Vessel Inventory Affecting Fuel Clad Integrity with Containment Challenged with Irradiated Fuel in the RPVReactor Vessel.

Operating Mode Applicability:

Cold Shutdown Refueling

Example-EmergencyEmergency Action Level: -(1 and 2 and 3)

CG1.1. Loss of RPV-Reactor Vessel inventory as indicated by unexplained level rise in Containment Sump A, Containment Sump C <u>OR</u> Liquid Waste Disposal System

AND

Reactor Vessel Level (a or b): -{site-specific}-sump and tank-level increase

2. RPV-Level:

a. EQUAL TO 0% Wide Range Refueling Water Level Refueling-Level-less-than TOAF-for- >GREATER THAN- 30 minutes

OR

- b. cannot be monitored with Indication-indication of core uncovery for >GREATER THAN 30 minutes as evidenced by one or more of the following:
 - Containment High-RangeArea Radiation Monitor (R-2) reading >GREATER THAN {site-specific} setpoint100 mRem/hr
 - Erratic Source Range Monitor Indication

Other-{site-specific}-indications

AND

3___

{Site specific} indication of CONTAINMENT challenged as indicated by one or more of the following:

- Explosive mixture inside GREATER THAN OR EQUAL TO 6% hydrogen in containment
- CONTAINMENT CLOSURE NOT established
- 6.• CONTAINMENT pPressure above {site specific} value:
 - 46 psig <u>IF</u> Containment Integrity or Reduced Inventory Containment Integrity is established

OR

 46 psig <u>IF</u> -Refueling Containment Integrity is established with no loop seal penetrations installed at Penetration 42N or 43N.

OR

• 0.6 psig <u>IF</u> Refueling Containment Integrity is established with loop seal penetration installed at either Penetration 42N or 43N.

7.CONTAINMENT-CLOSURE-not-established

Escondary Containment radiation monitors above {site specific} value (BWR-only)

Basis:

For EAL 1-iIn the cold shutdown mode, normal RCS level and RPV-Reactor Vessel level instrumentation systems will normally be available. If the RCS is pressurized, then the Wide Range Refueling Water Level indication will not be in service. However, if all level indication were to be lost during a loss of RCS inventory event, the operators would need to determine that RPV Reactor Vessel inventory loss was occurring by observing sump and tank level changes. <u>RVLIS indication is considered lost if leakage reduces RCS level below its indicating range.</u>

-Sump and tank level increases must be evaluated against other potential sources of leakage such as cooling water sources inside the containment to ensure they are indicative of RCS leakage.

For-EAL-1-iIn the refueling mode, normal means of RPV-Reactor Vessel level indication may not be available. Redundant means of RPV-Reactor Vessel level indication will be normally installed (including the ability to monitor level visually) to assure that the ability to monitor level will not be interrupted. However, if all level indication were to be lost during a loss of RCS inventory event, the operators would need to determine that RPV-Reactor Vessel inventory loss was occurring by observing sump and tank level changes. Wide Range Refueling Water Level is measured by L9053A for channel A and L9054A for channel B.

For-both-cold-shutdown-and-refueling-modes-sump-and-tank-level-increases-must-be-evaluated against-other-potential sources of leakage-such-as-cooling water sources-inside-the-containment to ensure they are indicative of RCS leakage.

Containment Sump A, Containment Sump C or Liquid Waste Disposal System level changes may be indicative of a loss of RCS inventory. Containment Sump A receives all liquid waste from floor and equipment drains inside containment including that from Containment Sump C. Each time annunciator CONTAINMENT SUMP A LEVEL HIGH is received, the corresponding leakrate within containment is calculated from sump pump run history. [Ref. 1, 58] Sump level rises must be evaluated against other potential sources of leakage such as cooling water sources inside the containment to ensure they are indicative of RCS leakage. [Ref. 1419]

EAL-2This EAL represents the inability to restore and maintain RPVReactor Vessel level to above the top of active fuel. Fuel damage is probable if RPVReactor Vessel level cannot be restored, as available decay heat will cause boiling, further reducing the RPVReactor Vessel level. When Reactor Vessel water level drops to 612 ft 4 in. el., core uncovery is about to occur. Wide Range Refueling Water Level indication of 0% is approximately the top of active fuel. [Ref. 2]

These-exampleis EALs isare based on concerns raised by Generic Letter 88-17, Loss of Decay Hoat Removal, SECY 91-283, Evaluation of Shutdown and Low Power Risk Issues, NUREG-1449, Shutdown and Low Power Operation at Commercial Nuclear Power Plants in the United States, and, NUMARC--NUMARC 91-06, Guidelines for Industry Actions to Assess Shutdown Management. A number of variables, (BWRs - e.g., such as initial vessel level, or shutdown heat removal system design) (PWRs --- (e.g., mid-loop, reduced level/flange level, head in place, or cavity_flooded, RCS venting strategy, decay_heat_removal_system_design, vortexing_pre-KNPP 6-C-42 10/22/04 disposition, steam-generator U-tube-draining) can have a significant impact on heat removal capability challenging the fuel clad barrier. Analysis in the above references indicates that core damage may occur within an hour following continued core uncovery therefore, conservatively, 30 minutes was chosen.

If all means of level monitoring are not available, the Reactor Vessel inventory loss may be detected by the following indirect methods:

- As water level in the Reactor Vessel lowers, the dose rate above the core will rise. The
 dose rate due to this core shine should result in an unplanned alarm on the Containment
 Area Monitor (R-2). R-2 is used instead of the high range containment monitors because if
 a small amount of fuel was uncovered, the location of the high range monitors would
 preclude them reading on scale. Therefore the alarm setpoint of R-2 was selected to
 indicate a rise in containment radiation resulting from the conditions of this EAL- [Ref. 3].
- Post-TMI studies indicated that the installed nuclear instrumentation will operate erratically when the core is uncovered and Source Range Monitors (N-31 and N-32) can be used as a tool for making such determinations.

The GE is declared on the occurrence of the loss or imminent loss of function of <u>all three</u> barriers. Based on the above discussion, RCS barrier failure resulting in core uncovery for 30 minutes or more may cause fuel clad failure. With the CONTAINMENT breached or challenged then the potential for unmonitored fission product release to the environment is high. This represents a direct path for radioactive inventory to be released to the environment. This is consistent with the definition of a GE.

In the context of EAL 3, CONTAINMENT CLOSURE is the action taken to secure containment and its associated structures, systems, and components as a functional barrier to fission product release under existing plant conditions. CONTAINMENT CLOSURE should not be confused with Rrefueling Ceontainment lintegrity as described in fined-in technical specificationsN-FH-53-CLA or CLB [Ref 6, 7]. Reduced Inventory Containment Integrity is described in N-CCI-56A–CLA or CLB [Ref 9, 10]. Site shutdown contingency plans typically provide for re-establishing CONTAINMENT CLOSURE following a loss of heat removal or RCS inventory functions. If the closure is re-established prior to exceeding the temperature or level thresholds of the RCS Barrier and Fuel Clad Barrier EALs, escalation to GE would not occur.

The site-specific-pressure at which CONTAINMENT is considered challenged may change is based on the condition of the CONTAINMENT. If-When the Unit is in the cold shutdown mode and the CONTAINMENT is fully intact, Containment is considered challenged at then the site-specific setpoint should be equivalent to the CONTAINMENT design pressure of 46 psig. Refueling CONTAINMENT Integrity establishes normal CONTAINMENT isolation except that penetrations 42N and 43N may have loop seal penetrations installed. When a loop seal penetration is installed, CONTAINMENT is considered challenged when CONTAINMENT pressure exceeds 0.6 psig. If fiber optic penetration is installed with no loop seal penetration installed, CONTAINMENT is considered challenged at full CONTAINMENT design pressure of 46 psig. [Ref. 4520 and 216]This is consistent with typical owner's groups Emergency Response Procedures. If CONTAINMENT CLOSURE is established intentionally by the plant staff in preparations for inspection, maintenance, or refueling then the site-specific setpoint should be based on the sitespecific pressure assumed for CONTAINMENT CLOSURE.

For-BWRs, the use of secondary containment radiation monitors should provide indication of increased release that may be indicative of a challenge to secondary containment. The site

specific-radiation-monitor-values-should-be-based on the EOP "maximum safe values" because these values are easily recognizable and have an emergency basis.

In the early stages of a core uncovery event, it is unlikely that hydrogen buildup due to a core uncovery could result in an explosive mixture of dissolved gasses in CONTAINMENT. However, CONTAINMENT monitoring and/or sampling should be performed to verify this assumption and a General Emergency declared if it is determined that an explosive mixture exists. When hydrogen and oxygen concentrations reach or exceed the deflagration limits (equal to or greater than 6% hydrogen), loss of the containment barrier is possible [Ref. 813, 150, 164]. Containment hydrogen concentration can be obtained from PPCS/SPDS point X8001A and X8002A, or Control Room meters 41615 and 41616.

Expanded-basis for these assumptions is provided in Appendix C.

| KNPP

D-AU1

Initiating Condition --- NOTIFICATION OF UNUSUAL EVENT

UNPLANNED release of gaseous or liquid radioactivity to the environment <u>> 2 times</u> the Technical Specification Release Limit for <u>> 60 Minutes</u>.

Operating-Mode-Applicability: Not-Applicable

Example-Emergency Action-Levels:-(1-or-2)

- 1. UNPLANNED VALID reading on any offluent monitor that exceeds two times the Technical Specification Release Limit for > 60 Minutes.
- 2. Grab-sample-results-indicate-UNPLANNED-gaseous-release-rates-or-liquid-concentrations-2 2-times-the-Technical-Specification-Release-Limit for 2-60-Minutes.

Basis:

An UNPLANNED release that cannot be terminated in 60 minutes represents an uncontrolled situation that is a potential degradation of the level of safety of the plant. The degradation in plant control implied by the fact that the release can not be terminated in 60 minutes is the primary concern. The Emergency Director should not-wait until 60 minutes has elapsed, but should declare an UNUSUAL EVENT as soon as the release is determined to be uncontrolled or projected to be unisolable within 60 minutes.

The EAL-1-limit-ensures-compliance with 10CFR20.1301 dose limits to the public. This limit also ensures the concentration of liquid effluents released is < 2 times the value specified in 10CFR20, Appendix-B.

The-EAL 2 grab samples are used to determine gaseous release rates or liquid concentrations to confirm monitor readings or when the offluent monitors are not in service.

D-AU2

Initiating Condition -- NOTIFICATION OF UNUSUAL EVENT

UNCONTROLLED increase in plant radiation levels.

Operating-Mode Applicability:-----Not Applicable

Example-Emergency-Action-Level:

1.Area-Radiation-Monitor-readings-or-survey-results-indicate-an-uncontrolled-increase-in-radiation level by 25 mR/hr that is not the result of a planned evolution.

Basis:

UNCONTROLLED means an increase in <-12 hours of monitored radiation level that is not the result of a planned evolution and the source of the increased is not immediately recognized and controlled.

Classification-of-an-UNUSUAL EVENT is warranted-as-a-precursor-to-more-serious-events. The concern-of-this-EAL-is-the-loss of control-of-radioactive-material-representing-a-potential degradation of the level of safety of the plant.

D-SU1

Initiating Condition --- NOTIFICATION OF UNUSUAL EVENT

Decrease in Spent Fuel Pool Level OR temperature increase that is not the result of a planned evolution.

Operating-Mode-Applicability: Not Applicable

Example-Emergency-Action-Levels:-(1-or-2)

1.—a. VALID (site-specific) indication of uncontrolled water level decrease in spent fuel pool-with all irradiated fuel assemblies remaining covered by water.

_____AND

------b. UNPLANNED VALID (site-specific)-Direct Area Radiation Monitor reading increases

2. Spent-Fuel-Pool-temperature increase to > [site-specific].⁶F-that is not the result of a planned evolution.

Basis:

Classification of an NOUE for the EAL threshold value is warranted as a precursor to more serious events and a potential degradation in the level of safety of the plant. Since loss of level or continued pool boiling would result in increased radiation levels exceeding the criteria of D-AA2, continued system related loss of level type events are bounded by D-AA2.

The EAL1-site-specific value-for-level-should be based-on-a-calculated-level-that will result in prohibitive-radiation-levels-in-the-Fuel-Building. The-site-specific radiation-monitors should be chosen so that indication of decreasing pool levels is provided.

The EAL2-site-specific temperature should be chosen based on the initial temperature starting point for fuel damage calculations (typically 125 to 150°F) in the Safety Analysis Report (SAR).

D-HU4

Initiating Condition --- NOTIFICATION OF UNUSUAL EVENT

Confirmed Security Event with potential loss of level of safety of the plant.

Operating Mode Applicability: Not Applicable

Example-Emergency-Action-Levels:

1. Security-Event as determined from (site-specific) Safeguards Contingency Plan and reported by the (site-specific) security shift supervision.

Basis:

This-EAL-is based on (site-specific) Site Security Plans. Security events which do not represent a potential degradation in the level of safety of the plant, are reported under 10 CFR-73.71 or in some cases under 10 CFR-50.72.

INTRUSION-into-the-Fuel-Building-or-Control-Room-by-a-HOSTILE-FORCE-would-result-in-EAL escalation to an ALERT.

Reference-is-made to (site-specific) security-shift-supervision-because these-individuals are the designated personnel on site-qualified and trained to confirm that a security event is occurring or has occurred. Training on security event-classification confirmation is closely controlled due to the strict secrecy controls placed on the plant-Security Plan.

÷,

D-HU2

1

Initiating Condition --- NOTIFICATION OF UNUSUAL EVENT

Other conditions judged warranting declaration of an UNUSUAL EVENT

Operating-Mode-Applicability: Not-Applicable

Example-Emergency-Action-Levels:

1. Other-conditions-exist-which-in-the-judgment-of-the-Shift-Supervisor-/Emergency-Director indicate a potential-degradation-in-the-level-of-safety-of-the-plant.

Basis:

Any-condition-not-explicitly-detailed as an EAL-threshold value, which, in the judgment-of-the Emergency-Director, is a potential degradation in the level of safety of the plant. Emergency Director judgment-is to be based on known conditions and the expected response to mitigating activities within a short time period.

D-HU3

Initiating Condition --- NOTIFICATION OF UNUSUAL EVENT

Natural or destructive phenomena inside the PROTECTED AREA affecting the ability to maintain spent-fuel integrity

Operating Mode Applicability: _____Not Applicable

Example-Emergency-Action-Levels: (1 or 2 or 3 or 4 or 5 or 6 or 7 or 8)

- 1. (Site-Specific) method indicates felt earthquake.
- 2. Report-by-plant-personnel of tornado-or-high-winds-greater than (site-specific)-mph-striking within the PROTECTED-AREA that has the potential to affect equipment needed to maintain spent fuel integrity.
- 3. Vehicle-crash-into-plant-structures-or-systems within PROTECTED AREA boundary that has the potential to affect equipment needed to maintain spent-fuel integrity.
- 4.——Report by plant-personnel-of-an-unanticipated_EXPLOSION-within_PROTECTED_AREA boundary-resulting in VISIBLE-DAMAGE that has the potential to affect equipment needed to maintain spent fuel integrity.
- 5. Uncontrolled_flooding_in_(site-specific)_areas_of_the_plant_that_has_the_potential_to_affect equipment_needed_to-maintain_spent_fuel_integrity.
- 6. FIRE in the following (Site-Specific) buildings or areas not extinguished within 15 minutes of Control Room notification or verification of a control room alarm that has the potential to affect equipment needed to maintain spent fuel integrity.
- 7. Toxic or flammable-gas-within-the PROTECTED AREA-that-has-the potential to affect-the operation of equipment needed to maintain spent fuel integrity.
- 8. (Site-Specific) occurrences affecting the PROTECTED AREA that has the potential to affect equipment needed to maintain spent fuel integrity.

Basis:

NOUE-in this IC are categorized on the basis of the occurrence of an event of sufficient magnitude to be of concern to plant-operators. Areas identified in the EALs define the location of the event based on the potential for damage to equipment contained therein.

EAL-#1-should-be-developed on site-specific basis. Damage may be caused to some portions of the site, but should not affect ability to operate spent fuel pool equipment. Method of detection can be based on instrumentation, validated by a reliable source, or operator assessment. As defined in the EPRI-sponsored "Guidelines for Nuclear Plant-Response to an Earthquake", dated October 1989, a "felt earthquake" is: KNPP 56-D-8 An-earthquake of sufficient intensity-such that: (a) the vibratory-ground-motion is felt-at-the nuclear-plant-site and recognized as an earthquake based on a consensus of control room operators on duty-at-the-time, and (b) for-plants with operable seismic instrumentation, the seismic switches of the plant are activated. For most-plants with seismic instrumentation, the seismic switches are set at an acceleration of about 0.01g.

EAL #2-is-based on the assumption that a tornado striking (touching down) or high winds within the protected area may have potentially damaged plant structures containing functions or systems required to maintain spent fuel integrity. The high wind site specific value in EAL#2-should be based on site specific FSAR design basis.

EAL #3-is-intended-to-address-crashes-of-vehicles-that-cause-significant-damage-to-plant structures containing functions-and-systems necessary to maintain-spent-fuel-integrity.

EAL-#4-addresses only those EXPLOSIONs of sufficient force to damage equipment needed to maintain spent-fuel integrity. No attempt is made in this EAL to assess the actual magnitude of the damage. The occurrence of the EXPLOSION with reports of evidence of damage is sufficient for declaration. The Emergency Director also needs to consider any security aspects of the EXPLOSION, if applicable.

EAL #5-addresses the effect of flooding caused by internal events such as component failures or equipment-misalignment that has the potential to affect equipment needed to maintain spent-fuel integrity. The site-specific areas include those areas that contain systems required to maintain fuel integrity, that are not designed to be wetted or submerged.

EAL #6 addresses FIREs that may have the potential to affect the ability to maintain spent fuel integrity. As used here, *Dotection* is visual observation and report by plant personnel or sensor alarm indication. The 15 minute time period begins within a credible notification that a FIRE is occurring, or indication of a VALID fire detection system alarm. Verification of a fire detection system alarm includes actions that can be taken with the control room or other nearby site specific location to ensure that the alarm is not spurious. A verified alarm is assumed to be an indication of a FIRE unless it is disproved within the 15 minute period by personnel dispatched to the scene. In other words, a personnel report from the scene may be used to verify the alarm.

The intent of this 15-minute duration is to size the FIRE and to discriminate against small FIREs that are readily extinguished (e.g., smoldering waste paper basket). The site-specific list should be limited and applies to buildings and areas containing equipment important to maintaining spent fuel integrity. This excludes FIREs within administration buildings, waste basket FIREs, and other small FIREs of no safety consequence.

EAL #7-addresses toxic or-flammable gas in the protected area that has the potential to affect the ability to maintain spent fuel integrity due to the potential damage to equipment or the evacuation of personnel preventing operation or maintenance of spent fuel pool equipment.

EAL #8 covers other site specific phenomena such as hurricane, flood, or seiche that have the potential to result loss of spent fuel integrity.

Escalation to the ALERT-level-will be via D-AA2 if any of the above events has caused damage that results in radiation levels increasing by 100 mr/hr and impedes operation of systems needed to maintain spent fuel integrity.

D-AA1

Initiating Condition – ALERT

UNPLANNED release of gaseous or liquid radioactivity to the environment > 200 times the Technical Specification Release Limit for > 15 Minutes.

Operating-Mode-Applicability: Not-Applicable

Example-Emergency-Action Levels: (1 or 2 or 3)

- 1. UNPLANNED VALID reading on any offluent monitor that exceeds 200 times the Technical Specification Release Limit for-> 15 Minutes.
- 2. Confirmed sample analyses for gaseous or liquid releases indicates concentrations or release rates, with a duration of 15 minutes or longer, in excess of 200 times (site specific Technical Specifications.

Basis

An UNPLANNED release of this magnitude that cannot be terminated in 15-minutes represents an uncontrolled-situation that is an actual or potential substantial degradation of the level of safety of the plant. The degradation in plant control implied by the fact that the release can not be terminated in 15 minutes is the primary concern. The Emergency Director should not wait until 15 minutes has elapsed, but should declare an ALERT as soon as the release is determined to be uncontrolled or projected to be unisolable within 15 minutes.

The EAL1 release rate limit ensures compliance with 10CFR20.1301 dose limits to the public. This limit-also ensures the concentration of liquid effluents is < 200-times the value specified in 10CFR20, Appendix B.

The-EAL2 grab samples are used to determine gaseous release rates or liquid concentrations to confirm monitor readings or when the effluent monitors are not in service.

D-AA2

Initiating Condition -- ALERT

UNCONTROLLED increase in plant-radiation levels that impede operations

Operating-Mode Applicability: Not Applicable

Example Emergency Action Levels: (1 or 2)

1.— Area Radiation Monitor readings or survey results indicate an UNCONTROLLED increase in radiation level by 100 mR/hr that is not the result of a planned evolution and impedes access to areas needed to maintain control of radioactive material or operation of systems needed to maintain spent fuel integrity.

(Sito-specific) list

2.— VALID (site-specific) radiation monitor readings GREATER THAN 15 mR/hr in areas requiring continuous occupancy:

(Site-specific)-list

Basis:

The site specific list for EAL1-will-include available Fuel Handling building radiation monitors.

An increase in radiation levels that is not the result of a planned evolution that impedes operations necessary to allow maintenance of spent fuel integrity warrants the classification of an ALERT.

Damage-to-spent fuel represents a substantial degradation in the level of safety of the plant-and therefore warrants an ALERT classification.

The value of 15mR/hr is derived from the GDC 19 value of 5 rem in 30 days with adjustment for expected occupancy-times. Although Section III.D.3 of NUREG-0737, "Clarification of TMI Action Plan Requirements", provides that the 15 mR/hr value can be averaged over the 30 days, the value is used here without averaging, as a 30 day duration implies an event potentially more significant than an Alert.

D-HA1

Initiating Condition -- ALERT

Confirmed Security Event in the Fuel-Building or Control Room.

Operating Mode Applicability: _____ Not Applicable

Example-Emergency-Action-Levels:

1. INTRUSION into the Fuel Building or Control Room by a HOSTILE FORCE.

Basis:

This class of security events represents an escalated threat to plant safety above that contained in the NOUE. A confirmed INTRUSION report is satisfied if physical evidence indicates the presence of a HOSTILE FORCE within the Fuel Handling-Building or Control Room.

D-HA2

Initiating Condition -- ALERT

Other-conditions-judged-warranting-declaration-of-ALERT.

Operating-Mode-Applicability: Not-Applicable

Example-Emergency-Action-Levels:

1. Other-conditions-exist which in the judgment of the Emergency Director indicate that plant systems-may-be-substantially-degraded and that increased monitoring of plant functions is warranted. Any releases-are expected to be limited to small fractions of the EPA-Protective Action Guideline exposure levels.

Basis:

A condition exists which, in the judgement of the Emergency Director, presents an actual or potential substantial degradation in the level of safety of the plant. Emergency Director judgement is to be based on known conditions and the expected response to mitigating activities.

Initiating Condition -- NOTIFICATION OF UNUSUAL EVENT

Damage to a loaded cask CONFINEMENT-BOUNDARY.

Operating-Mode-Applicability: Not-applicable

Example-Emergency-Action-Level: (1-or-2-or-3)

1. --- Natural-phenomena-events-affecting-a-loaded-cask-CONFINEMENT-BOUNDARY.

(site-specific-list)

2. Accident-conditions affecting a loaded cask-CONFINEMENT-BOUNDARY.

(site-specific list)

3. Any condition in the opinion of the Emergency Director that indicates loss of loaded fuel storage cask CONFINEMENT-BOUNDARY.

Basis:

A NOUE in this IC is categorized on the basis of the occurrence of an event of sufficient magnitude-that a loaded-cask CONFINEMENT BOUNDARY-is damaged or violated. This-includes-classification-based on a loaded fuel storage cask CONFINEMENT BOUNDARY-loss loading-to-the degradation of the fuel-during storage or posing an operational safety problem with respect to its removal from storage.

For EAL #1-and EAL #2,-the-results of the ISFSI-Safety Analysis-Report (SAR) per NUREG 1536-or SAR referenced in the cask('s) Certificate of Compliance and the related NRC Safety Evaluation Report should be used to develop the site specific list of natural phenomena events and accident conditions. These EALs would address responses to a dropped cask, a tipped over cask, explosion, missile damage, fire damage or natural phenomena affecting a cask (e.g., seismic event, tornado, etc.).

For EAL-#3, any condition not explicitly detailed as an EAL-threshold value, which, in the judgment of the Emergency Director, is a potential degradation in the level of safety of the ISFSI. Emergency Director judgment is to be based on known conditions and the expected response to mitigating activities within a short time period.

EVENTS RELATED TO ISFSI

E-HU2

Initiating Condition -- NOTIFICATION OF UNUSUAL EVENT

Confirmed-Security-Event-with potential loss of level of safety of the ISFSI.

Operating-Mode-Applicability: Not-applicable

Example-Emergency Action Levels:

1. Security Event as determined from (site-specific) Security Plan and reported by the (site-specific) security shift-supervision.

Basis:

This-EAL is based on (site-specific) Security Plans. Security events which do not represent a potential degradation in the level of safety of the ISFSI, are reported under 10 CFR 73.71 or in some cases under 10 CFR 50.72.

Reference-is-made-to (site-specific) security shift supervision because these-individuals are the designated personnel qualified and trained to confirm that a security event is occurring or has occurred. Training on security event classification confirmation is closely controlled due to the strict secrecy controls placed on the Security Plan.

NOTES

- 1. The logic used for these initiating conditions reflects the following considerations:
 - The Fuel Clad Barrier and the RCS Barrier are weighted more heavily than the Containment Barrier-(See-Sections-3.4-and-3.8). NOUE ICs associated with RCS and Fuel Clad Barriers are addressed under System Malfunction ICs.
 - At the Site Area Emergency level, there must be some ability to dynamically assess how far present conditions are from the threshold for a General
 Emergency. For example, if Fuel Clad and RCS Barrier "Loss" EALs existed, that, in addition to offsite dose assessments, would require continual
 assessments of radioactive inventory and containment integrity. Alternatively, if both Fuel Clad and RCS Barrier "Potential Loss" EALs existed, the
 Emergency Director would have more assurance that there was no immediate need to escalate to a General Emergency.
 - The ability to escalate to higher emergency classes as an event deteriorates must be maintained. For example, RCS leakage steadily increasing would represent an increasing risk to public health and safety.
- Fission Product Barrier ICs must be capable of addressing event dynamics. Thus, the EAL Reference Table 3-and-4F-1 states that imminent (i.e., within 2-2 hours) Loss or Potential Loss should result in a classification as if the affected threshold(s) are already exceeded, particularly for the higher emergency classes.

Basis Information For Table 5-F-2 BWR Emergency Action Level Fission Product Barrier Reference Table

FUEL-CLAD BARRIER-EXAMPLE-EAL6: (1 or 2 or 3 or 4 or 5)

The Fuel Clad barrier is the zircalloy or stainless steel tubes that contain the fuel pellets.

1. Primary-Coolant-Activity-Level

This (site-specific)--value corresponds to -300 - µCi/gm -I₁₃₁ - equivalent. Assessment by the NUMARC-EAL Task Force indicates that this amount of coolant activity is well above that expected for iodine spikes and corresponds to less than 5% fuel clad damage. This amount of radioactivity indicates significant clad damage and thus the Fuel Clad Barrier is considered lest. The value expressed can be either in mR/hr observed on the sample or as uCi/gm results from analysis.

There is no equivalent "Potential Loss"-EAL-for this item.

2.----Reactor Vessel Water Level

The "Loss" EAL (site-specific)-value-corresponds to the level which is used in EOPs to indicate challenge of core cooling. Depending on the plant this may be top of active fuel or 2/3 coverage of active-fuel. This is the minimum value to assure core cooling without-further-degradation of the clad. The "Potential Loss" EAL is the same as the RCS barrier "Loss" EAL #2 below and corresponds to the (site-specific) water level at the top of the active fuel. Thus, this EAL indicates a "Loss" of RCS barrier and a "Potential Loss" of the Fuel Clad Barrier. This EAL appropriately escalates the emergency class to a Site Area Emergency. If the "Loss" value is also the Top of Active Fuel, the "Potential Loss" value must be a value indicating a higher level also corresponding to a higher level indicated in the RCS barrier "Loss" EAL #2.

3. Drywell-Radiation-Monitoring

The (site-specific) reading is a value which indicates the release of reactor coolant, with elevated activity indicative of fuel damage, into the drywell. The reading should be calculated assuming the instantaneous release and dispersal of the reactor coolant noble gas and iodine inventory associated with a concentration of 300 µCi/gm dose equivalent I-131 or the calculated concentration equivalent to the clad damage used in EAL #1 into the drywell atmosphere. Reactor coolant concentrations of this magnitude are several times larger than the maximum concentrations (including iodine spiking) allowed within technical specifications and are therefore indicative of fuel damage. This value is higher than that specified for RCS barrier Loss EAL-#4. Thus, this EAL indicates a loss of both Fuel Clad barrier and RCS barrier.

Caution: it is important to recognize that in the event the radiation monitor is sensitive to shine from the reactor vessel or piping, spurious readings will be present and another indicator of fuel clad damage is necessary or compensated for in the threshold value.

There-is-no "Potential-Loss"-EAL-associated with this item.

4. Other (Site-Specific) Indications

This EAL is to cover other (site specific) indications that may indicate loss or potential loss of the Fuel-Clad barrier, including indications from containment air monitors or any other (site specific) instrumentation.

5.----Emergency-Director-Judgment

This EAL addresses any other factors that are to be used by the Emergency Director in determining whether the Fuel Clad barrier is lost or potentially lost. In addition, the inability to monitor the barrier should also be incorporated in this EAL as a factor in Emergency Director judgment that the barrier may be considered lost or potentially lost. (See also IC SG1, "Prolonged Loss of All Offsite Power and Prolonged Loss of All Onsite AC Power", for additional information.)

RCS BARRIER EXAMPLE EALs: (1 or 2 or 3 or 4 or 5 or 6)

The RCS-Barrier is the reactor coolant-system pressure boundary and includes the reactor vessel and all reactor coolant-system piping up to the isolation valves.

1. Drywell Pressure

The (site-specific) drywell pressure is based on the drywell high pressure set point which indicates a LOCA by automatically initiating the ECCS or equivalent makeup system.

There is no "Potential Loss"-EAL corresponding to this item.

2. Reactor Vessel Water Level

This "Loss" EAL-is-the-same-as-"Potential-Loss" Fuel-Clad-Barrier-EAL #2. The (site-specific) water-level corresponds to the level which is used in EOPs to indicate challenge of core cooling. Depending on the plant-this may-be-top of-active fuel or 2/3 coverage of active fuel. This EAL appropriately escalates the emergency class to a Site Area Emergency. Thus, this EAL-indicates a loss of the RCS barrier and a Potential Loss of the Fuel Clad Barrier.

There is no "Potential Loss" EAL corresponding to this item.

3. RCS Leak Rate

An unisolable MSL break is a breach of the RCS barrier. Thus, this EAL is included for consistency with the Alert-emergency classification. The potential loss of RCS based on leakage is set at a level indicative of a small breach of the RCS but which is well within the makeup capability of normal and emergency high pressure systems. Core uncovery is not a significant concern for a 50 gpm leak, however, break propagation leading to significantly larger loss of inventory is possible. Many-BWRs may be unable to measure an RCS leak of this size because the leak would likely increase drywell pressure above the drywell isolation set point. The system normally used to monitor leakage is typically isolated as part of the drywell isolation and is therefore unavailable. If primary system leak rate information is unavailable, other indicators of RCS leakage should be used.

Potential loss of RCS based on primary system leakage outside the drywell is determined from site-specific temperature or area radiation alarms low setpoint in the areas of the main steam line tunnel, main turbine generator, RCIC, HPCI, etc., which indicate a direct path from the RCS to areas outside primary containment. The indicators should be confirmed to be caused by RCS leakage. The area temperature or radiation low alarm setpoints are indicated for this example to Revision 01/2003KNPP 56-F-5 10/22/04

enable-an-Alert-classification.---An-unisolable-leak-which-is-indicated-by-a-high-alarm-setpoint escalates-to-a-Site-Area-Emergency-when-combined-with-Containment-Barrier-EAL-3 (after-a containment-isolation)-and-a-General-Emergency-when-the-Fuel-Clad-Barrier-criteria-is-also exceeded.

4. Drywell-Radiation-Monitoring

The (site-specific) reading is a value which indicates the release of reactor coolant to the drywell. The reading should be calculated assuming the instantaneous release and dispersal of the reactor coolant-noble-gas-and-iodine-inventory-associated with-normal-operating-concentrations-(i.e., within-T/S) into the drywell atmosphere. This reading will be less than that specified for-Fuel-Clad Barrier EAL-#3. Thus, this EAL would be indicative of a RCS leak only. If the radiation monitor reading-increased to that value specified by Fuel-Clad Barrier EAL #3, fuel-damage would also be indicated.

However, if the site specific physical location of the drywell radiation monitor is such that radiation from a cloud of released RCS gases could not be distinguished from radiation from adjacent piping and components containing elevated reactor coolant activity, this EAL should be omitted and other site specific indications of RCS leakage substituted.

There is no "Potential Loss" EAL associated with this item.

5. Other-(Site-Specific) Indications

This EAL is to cover other (site-specific) indications that may indicate loss or potential loss of the RCS barrier.

6. Emergency-Director-Judgment

This-EAL addresses any other factors that are to be used by the Emergency Director in determining whether the RCS barrier is lost or potentially lost. In addition, the inability to monitor the barrier should also be incorporated in this EAL as a factor in Emergency Director judgment that the barrier may be considered lost or potentially lost. (See also IC-SG1, "Prolonged Loss of Offsite Power and Prolonged Loss of All Onsite AC Power", for additional information.)

PRIMARY CONTAINMENT BARRIER EXAMPLE EALs: (1 or 2 or 3 or 4 or 5 or 6)

The Primary Containment Barrier includes the drywell, the wetwell, their respective interconnecting paths, and other-connections up to and including the outermost-containment-isolation valves. Containment-Barrier-EALs are used primarily as discriminators for escalation from an Alert to a Site Area Emergency or a General Emergency.

1. Drywell Pressure

Rapid-unexplained-loss-of-pressure (i.e., not-attributable to drywell-spray or condensation effects) following-an-initial-pressure-increase-indicates-a-loss-of-containment-integrity. Drywell-pressure should-increase-as-a-result-of-mass-and-energy-release-into-containment-from-a-LOCA. Thus, drywell-pressure-not-increasing-under-these-conditions-indicates-a-loss-of-containment-integrity. This indicator-relies on-the operators recognition-of-an-unexpected-response for-the-condition-and therefore-does-not-have-a-specific-value-associated. The-unexpected-response-is-important because-it-is-the-indicator-for-a-containment-bypass-condition. The (site-specific) PSIG for-potential loss-of-containment-is-based-on-the-containment-drywell-design-pressure.-Existence-of-an explosive-mixture-means-a-hydrogen-and-oxygen-concentration-of-at-least-the-lower-deflagration

Revision 01/2003KNPP

limit-curve-exists. This-applies-to-BWRs-with-Mark-III-containments, as-well-as-Mark-I-and-II containment designs when they are de-inerted.

2. Reactor-Vessel-Water-Level

The entry into the Primary Containment-Flooding emergency procedure indicates reactor vessel water-level-can not be restored and that a core melt sequence is in progress. EOPs direct the operators to enter Containment Flooding when Reactor Vessel Level cannot be restored to greater than a Site Specific value (generally 2/3 core height) or is unknown. Entry-into Containment Flooding procedures is a logical escalation in response to the inability to maintain reactor vessel level.

The conditions in this potential loss EAL represent imminent core melt sequences which, if not corrected, could lead to vessel failure and increased potential for containment failure. In conjunction with and an escalation of the level EALs in the Fuel and RCS barrier columns, this EAL will result in the declaration of a General Emergency -- loss of two barriers and the potential less of a third. If the emergency operating procedures have been ineffective in restoring reactor vessel level above the RCS and Fuel Clad Barrier Threshold Values, there is not a "success" path and a core melt sequence is in progress. Entry into Containment flooding procedures is a logical escalation in response to the inability to maintain reactor vessel level.

Severe accident analysis (e.g., NUREG-1150) have concluded that function restoration procedures can arrest-core degradation with the reactor vessel in a significant fraction of the core damage scenarios, and the likelihood of containment failure is very small in these events. Given this, it is appropriate to provide a reasonable period to allow emergency operating procedures to arrest the core melt sequence. Whether or not the procedures will be effective should be apparent within the time provided. The Emergency Director should make the declaration as soon as it is determined that the procedures have been, or will be, ineffective. There is no "loss" EAL associated with this item.

3.——Containment-Isolation-Failure-or-Bypass

This EAL is intended to cover the inability to isolate the containment when containment isolation is required. In addition, the presence of area radiation or temperature alarms high setpoint indicating unisolable primary system leakage outside the drywell are covered after a containment-isolation. The indicators should be confirmed to be caused by RCS leakage. Also, an intentional venting of primary containment for pressure control per EOPs to the secondary containment and/or the environment is considered a loss of containment. Containment venting for temperature or pressure when not in an accident situation should not be considered.

There is no "Potential Loss"-EAL associated with this item.

4. Significant-Radioactive Inventory In Containment

The (site-specific) reading is a value which indicates significant fuel damage well in excess of that required for loss of RCS and Fuel Clad. As stated in Section 3.8, a major release of radioactivity requiring offsite-protective actions from core damage is not possible unless a major failure of fuel cladding allows radioactive material to be released from the core into the reactor coolant. Regardless of whether containment is challenged, this amount of activity in containment, if released, could have such severe consequences that it is prudent to treat this as a potential loss of containment, such that a General Emergency declaration is warranted. NUREG-1228, "Source Estimations During Incident Response to Severe Nuclear Power Plant Accidents," indicates that such conditions do not exist when the amount of clad damage is less than 20%. Unless there is a

(site-specific) analysis justifying a higher value, it is recommended that a radiation monitor reading corresponding to 20% fuel clad damage be specified here.

There is no "Loss" EAL associated with this item.

5. Other (Site-Specific) Indications

This EAL is to cover other (site-specific) indications that may indicate loss or potential loss of the containment barrier.

6. Emergency Director Judgment

This EAL addresses any other factors that are to be used by the Emergency-Director in determining whether the Containment barrier is lost or potentially lost. In addition, the inability to monitor the barrier should also be incorporated in this EAL as a factor in Emergency Director judgment that the barrier may be considered lost or potentially lost. (See also IC SG1, "Prolonged Loss of All Offsite Power and Prolonged Loss of All Onsite AC Power", for additional information.)

*Determine which combination of the three barriers are lost or have a potential loss and use the following key to classify the event. Also an event for multiple events could occur which result in the conclusion that exceeding the loss or potential loss thresholds is imminent (i.e., within 1 to 2 hours). In this imminent loss situation use judgment and classify as if the thresholds are exceeded.

Basis Information For Table 5-F-41 PWR-KNPP Emergency Action Level Fission Product Barrier Reference Table

FUEL CLAD BARRIER EXAMPLE-EALs: (1 or 2 or 3 or 4 or 5 or 6-or-7)

The Fuel Clad Barrier is the zircalloy or stainless steel tubes that contain the fuel pellets.

1. Critical Safety Function Status

This EAL is for PWRs using Critical Safety Function Status Tree (CSFST) monitoring and functional restoration procedures. For more information, please refer to Section 3.9 of this report. RED path indicates an extreme challenge to the safety function. ORANGE path indicates a severe challenge to the safety function.

Core Cooling - ORANGE indicates subcooling has been lost and that some clad damage may occur. Core Cooling-ORANGE path is entered if:

- RCS subcooling based on CETs is equal to or less than 30°F [65°F] and
- No RCPs are running., and
- Core Exit Thermocouples (CETs) are reading between 700°F and 1200°F

OR

- RCS subcooling based on CETs is equal to or less than 30°F [65°F]-,], and
- At least one RCP is running, and
- RVLIS Void Fraction is Rising

[Ref. 1, 2]

Heat Sink - RED indicates the ultimate heat sink function is under extreme challenge and thus these two items (Core Cooling – ORANGE or Heat Sink – RED) indicate potential loss of the Fuel Clad Barrier. Heat Sink-Red path is entered if narrow range level in both S/Gs is less than 4% [15%] and total feedwater flow to S/Gs is less than 200 gpm.

[Ref. 4, 5]

Core Cooling - RED indicates significant superheating and core uncovery and is considered to indicate loss of the Fuel Clad Barrier. Core Cooling-RED path is entered if Core Exit Thermocouples (CETs) are equal to or greater than 1200°F.

CSFST setpoints enclosed in brackets (e.g., [65°F], etc.) are used under adverse containment conditions. Adverse containment condition thresholds apply when containment pressure is greater than 4 psig or containment radiation exceeds 10E+05 R/hr.

2. Primary Coolant Activity Level

This (site-specific)-value corresponds to is 300 μ Ci/gm I₁₃₁ equivalent. Assessment by the NUMARC EAL Task Force indicates that this amount of coolant activity is well above that expected for iodine spikes and corresponds to less than 5% fuel clad damage. This amount of radioactivity indicates significant clad damage and thus the Fuel Clad Barrier is considered lost. The value expressed can be either in mR/hr observed on the sample or as μ Ci/gm results from analysis.

There is no equivalent "Potential Loss" EAL for this item.

3. Core Exit Thermocouple Readings

Core Exit Thermocouple Readings are included in addition to the Critical Safety Functions to include conditions when the CSFs may not be in use (initiation after SI is blocked). or plants which do not have a CSF scheme.

The "Loss" EAL 1200 degrees F(site-specific) reading should correspond to significant superheating of the coolant. This value typically_corresponds to the temperature reading that indicates core cooling - RED in Fuel Clad Barrier EAL #1 which is usually about-1200 degrees F. [Ref. 1, 6]

The "Potential Loss" EAL 700 degrees F(site-specific) reading should correspond to loss of subcooling. This value typically-corresponds to the temperature reading that indicates core cooling - ORANGE in Fuel Clad Barrier EAL #1 which is usually about-700 to 900-degrees F. [Ref.1, 2]

4. Reactor Vessel Water Level

There is no "Loss" EAL corresponding to this item because it is better covered by the other Fuel Clad Barrier "Loss" EALs.

The (site specific) value for the "Potential Loss" EAL corresponds to is indicative of core uncovery the top of the active fuel. but, when the reactor is at pressure and temperature, RVLIS should not be used for a quantitative value (i.e., top of active fuel). Functional restoration procedure FR-C.2 specifies monitoring of RVLIS void fraction trend and RCS subcooling instead of the water level corresponding to the top of active fuel.

For sites using CSFSTs, tThe "Potential Loss" EAL is therefore defined by the Core Cooling -ORANGE path. -The trend in RVLIS RCS void fraction is used to check the effectiveness of safety injection in restoring RCS inventory. If void fraction percent is decreasing and RCS subcooling based on Core Exit Thermocouples (CETs) is greater than 30°F [65°F], safety injection has been successful in restoring RCS inventory and core cooling. In the event that RCS void fraction is increasing and subcooling requirements are not met, core cooling continues to be degraded and some fuel cladding damage may occur. Setpoints enclosed in brackets are used under adverse containment conditions. Adverse containment condition thresholds apply when containment pressure is greater than 4 psig or containment radiation exceeds 10E+05 R/hr. [Ref. 7] The (site specific) value in this EAL should be consistent with the CSFST-value.

5. Containment Radiation Monitoring

The (site-specific)1000 R/hr reading is a value which indicates the release of reactor coolant, with elevated activity indicative of fuel damage, into the containment. The reading should beis calculated assuming the instantaneous release and dispersal of the reactor coolant noble gas and iodine inventory associated with a concentration of 300 μ Ci/gm dose equivalent I-131 into the

Revision 01/2003KNPP

containment atmosphere. [Ref. 8, 9, 10] Reactor coolant concentrations of this magnitude are several times larger than the maximum concentrations (including iodine spiking) allowed within technical specifications and are therefore indicative of fuel damage. This value is higher than that specified for RCS barrier Loss EAL #4. Thus, this EAL indicates a loss of both the fuel clad barrier and a loss of RCS barrier.

Monitors used for this fission product barrier loss threshold are the containment high-range area monitors R-40 and R-41.

There is no "Potential Loss" EAL associated with this item.

6.——Other (Site-Specific) Indications

This EAL-is to cover other (site-specific) indications that may indicate loss or potential loss of the Fuel-Clad-barrier, including indications from containment air monitors or any other (site-specific) instrumentation.

76. Emergency Director Judgment

This EAL addresses any other factors that are to be used by the Emergency Director in determining whether the Fuel Clad barrier is lost or potentially lost. Such a determination should include imminent barrier degradation, barrier monitoring capability and dominant accident sequences.

- <u>Imminent barrier degradation</u> exists if the degradation will likely occur within two hours based on a projection of current safety system performance. The term "imminent" refers to recognition of the inability to reach safety acceptance criteria before completion of all checks.
- <u>Barrier monitoring</u> capability is decreased if there is a loss or lack of reliable indicators. This assessment should include instrumentation operability concerns, readings from portable instrumentation and consideration of offsite monitoring results.
- <u>Dominant accident sequences</u> lead to degradation of all fission product barriers and likely entry to the CSFSTs. The Emergency Director should be mindful of the Loss of AC power (Station Blackout) and ATWS EALs to assure timely emergency classification declarations.

In addition, the inability to monitor the barrier should also be incorporated in this EAL as a factor in Emergency Director judgment that the barrier may be considered lost or potentially lost. (See also IC-SG1, "Prolonged-Loss or All Offsite-Power and Prolonged-Loss of All-Onsite AC-Power", for additional information.)

RCS BARRIER EXAMPLE-EALs: (1 or 2 or 3 or 4 or 5-or-6)

The RCS Barrier includes the RCS primary side and its connections up to and including the pressurizer safety and relief valves, and other connections up to and including the primary-isolation valves.

1. Critical Safety Function Status

This EAL is for PWRs using Critical Safety Function Status Tree (CSFST) monitoring and functional restoration procedures. For more information, please refer to Section 3.9 of this report. RED path indicates an extreme challenge to the safety function derived from appropriate instrument readings, and these CSFs indicate a potential loss of RCS barrier.

RCS Integrity-Red path is entered if:

- Temperature decrease in both RCS cold legs is equal to or greater than 100°F in the last 60 minutes, and
- Any RCS cold leg temperatures are equal to or less than 274°F.

The combination of these two conditions indicates the RCS barrier is under extreme challenge and should be considered a Potential Loss of the RCS barrier. [Ref. 11, 12] The combination of these two conditions indicates the RCS barrier is under significant challenge and should be considered a challenge of RCS barrier. [Ref.]

Heat Sink-Red path is entered if:

- Narrow range level in both S/Gs is less than 4% [15%]
- Total feedwater flow to S/Gs is less than 200 gpm.

The combination of these two conditions indicates the heat sink function is under extreme challenge. This condition addresses loss of functions required for hot shutdown with the reactor at pressure and temperature and should be considered a Potential Loss of the RCS barrier. [Ref.- 4, 5]

Critical Safety Function Status Tree (CSFST) setpoints enclosed in brackets are used under adverse containment conditions. Adverse containment condition thresholds apply when containment pressure is greater than 4 psig or containment radiation exceeds 10E+05 R/hr.

There is no "Loss" EAL associated with this item.

2. RCS Leak Rate

The "Loss" EAL addresses conditions where leakage from the RCS is greater than available inventory control capacity such that a loss of subcooling has occurred. The loss of subcooling is the fundamental indication that the inventory control systems are inadequate in maintaining RCS pressure and inventory against the mass loss through the leak. Loss of subcooling is defined by:

- LESS THAN 20°F if the reactor is critical
- LESS THAN 30°F if the reactor is sub-critical

Core exit thermocouples LESS THAN 20°F is the subcooling margin threshold while critical. This is based on the minimum subcooling allowed for normal operation defined in Operating Procedure A-RC-36-D. [Ref. 23]

Core exit thermocouples LESS THAN 30°F is the subcooling margin threshold while subcritical. This is the level specified in Critical Safety Function Status Trees. IPEOPs define this value as a loss of RCS subcooling. [Ref. 1]

The "Potential Loss" EAL is based on the inability to maintain normal liquid inventory within the Reactor Coolant System (RCS) by normal operation of the Chemical and Volume Control System which is considered as one centrifugal-variable-speed, positive displacement charging pump discharging to the charging header. A second charging pump being required is indicative of a substantial RCS leak. 60 gpm is the design flow rate for each charging pump. For plants with low capacity charging pumps, a 50 gpm-loak rate value may be used to indicate the Potential Loss. [Ref. 13]

3. SG Tube Rupture

This EAL is intended to address the full spectrum of Steam Generator (SG) tube rupture events in conjunction with Containment Barrier "Loss" EAL #4 and Fuel Clad Barrier EALs. The "Loss" EAL addresses RUPTURED SG(s) for which the leakage is large enough to cause actuation of ECCS (SI). ECCS (SI) actuation is caused by:

- PRZR pressure less than 1815 psig
- S/G pressure less than 500 psig
- Containment pressure greater than 4 psig

Per IPEOP E-0, Reactor Trip or Safety Injection, the Operators are directed to perform a manual Safety Injection actuation if PRZR level is less than 5% or RCS subcooling based on Core Exit Thermocouples (CETs) is less than 30°F.

This is consistent to the RCS-Barrier "Potential Loss" EAL #2. For plants that have implemented W.O.G. emergency response guides, this condition is described by "entry-into E-3 required by EOPs". By itself, this EAL will result in the declaration of an Alert. However, if the SG is also FAULTED (i.e., two barriers failed), the declaration escalates to a Site Area-Emergency per Containment Barrier "Loss" EAL #4. [Ref. 13, 14]

There is no "Potential Loss" EAL.

4. Containment Radiation Monitoring

The (site-specific)30 R/hr reading is a value which indicates the release of reactor coolant to the containment. The reading should-beis calculated assuming the instantaneous release and dispersal of the reactor coolant noble gas and iodine inventory associated with normal operating concentrations (i.e., within T/STechnical Specifications) into the containment atmosphere. [Ref. 8, 9, 10] This reading will-beis less than that specified for Fuel Clad Barrier EAL #5. Thus, this EAL would be indicative of a RCS leak only. If the radiation monitor reading increased to that specified by Fuel Clad Barrier EAL #5, fuel damage would also be indicated.

Monitors used for this fission product barrier loss threshold are the containment high-range area monitors R-40 and R-41.

However, if the site specific physical location of the containment radiation monitor is such that radiation from a cloud of released RCS gases could not be distinguished from radiation from nearby piping and components containing elevated reactor coolant activity, this EAL should be omitted and other site specific indications of RCS leakage substituted.

There is no "Potential Loss" EAL associated with this item.

5.----Other (Site-Specific) Indications

This EAL is to cover other (site-specific) indications that may indicate loss or potential loss of the RCS-barrier, including indications from containment air monitors or any other (site-specific) instrumentation.

65. Emergency Director Judgment

This EAL addresses any other factors that are to be used by the Emergency Director in determining whether the RCS barrier is lost or potentially lost. Such a determination should include imminent barrier degradation, barrier monitoring capability and dominant accident sequences.

- <u>Imminent barrier degradation</u> exists if the degradation will likely occur within two hours based on a projection of current safety system performance. The term "imminent" refers to recognition of the inability to reach safety acceptance criteria before completion of all checks.
- <u>Barrier monitoring</u> capability is decreased if there is a loss or lack of reliable indicators. This assessment should include instrumentation operability concerns, readings from portable instrumentation and consideration of offsite monitoring results.
- <u>Dominant accident sequences</u> lead to degradation of all fission product barriers and likely entry to the CSFSTs. The Emergency Director should be mindful of the Loss of AC power (Station Blackout) and ATWS EALs to assure timely emergency classification declarations.

-In addition, the inability to monitor the barrier should also be incorporated in this EAL as a factor in Emergency Director judgment that the barrier may be considered lost or potentially lost. (See also IC-SG1, "Prolonged Loss of All Offsite Power and Prolonged Loss of All Onsite AC-Power", for additional information.)
CONTAINMENT BARRIER EXAMPLE-EALs: (1 or 2 or 3 or 4 or 5 or 6 or 7-or-8)

The Containment Barrier includes the Shield Building and Ceontainment building, and its connections up to and including the outermost containment isolation valves. This barrier also includes the main steam, feedwater, and blowdown lines extensions +outside the Ceontainment building up to and including the outermost secondary side-isolation valve(s).

1. Critical Safety Function Status

There is no "Loss" EAL associated with this item.

This EAL is for PWRs using Critical Safety Function Status Tree (CSFST) monitoring and functional restoration procedures. For more information, please refer to Section 3.9 of this report. RED path indicates an extreme challenge to the safety function. Containment-Red path is entered if containment pressure is equal to or greater than 46 psig. This pressure is the containment design pressure and is in excess of that expected from the design basis loss of coolant accident derived from appropriate instrument readings and/or sampling results, and thus represents a potential loss of containment. Conditions leading to a containment RED path result from RCS barrier and/or Fuel Clad Barrier Loss. Thus, this EAL is primarily a discriminator between Site Area Emergency and General Emergency representing a potential loss of the third barrier. [Ref. 15, 16, 17]

There is no "Loss" EAL associated with this item.

2. Containment Pressure

Rapid unexplained loss of pressure (i.e., not attributable to containment spray or condensation effects) following an initial pressure increaserise indicates a loss of containment integrity. USAR Section- 14.3.4.2 describes containment pressure response for a bounding LOCA. [Ref. 17]

Containment pressure and sump levels should increaserise as a result of the mass and energy release into containment from a LOCA. Thus, sump level or pressure not increasing indicates containment bypass and a loss of containment integrity.

The (site-specific)-46 PSIG for potential loss of containment is based on the containment design pressure. [Ref.- 15, 16, 17]

If hydrogen concentration reaches or exceeds 6% in an oxygen rich environment, an explosive mixture exists. If the combustible mixture ignites inside containment, loss of the Containment barrier could occur.- To generate such levels of combustible gas, loss of the Fuel Cladding and RCS barriers must also have occurred Existence of an explosive mixture means a hydrogen and exygen concentration of at least the lower deflagration limit curve exists. The indications of potential loss under this EAL corresponds to some of those leading to the RED path in EAL #1 above and may be declared by those sites using CSFSTs. As described above, this EAL is primarily a discriminator between Site Area-Emergency and General Emergency representing a potential loss of the third barrier. [Ref. 6, 18]

The second-third potential loss EAL represents a potential loss of containment in that the containment heat removal/depressurization system (e.g., containment sprays, ice condenser fans, etc., (but not including containment venting strategies) are either lost or performing in a degraded manner, as indicated by containment pressure greater than the setpoint (23 psig) at which the equipment was supposed to have actuated. One internal containment spray pump and two containment fan cooler units comprise one train of depressurization equipment. This equipment

will provide 100% of the required cooling capacity during post-accident conditions. Each internal containment spray system consists of a spray pump, spray header, nozzles, valves, piping, instruments, and controls to ensure an operable flow path capable of taking suction from the RWST upon an ESF actuation signal. Each containment fan cooler unit consists of cooling coils, accident backdraft damper, accident fan, service water outlet valves, and controls necessary to ensure an operable service water flow path.- [Ref. 15, 16, 19, 20, 21]

3. Core Exit Thermocouples

There is no "Loss" EAL associated with this item.

In this EAL, the function restoration procedures are those emergency operating procedures that address the recovery of the core cooling critical safety functions. The procedure is considered effective if the temperature is decreasing or if the vessel water level is increasing. For units using the CSF status trees a direct correlation to those status trees can be made if the effectiveness of the restoration procedures is also evaluated as stated below.

Severe accident analyses (e.g., NUREG-1150) have concluded that function restoration procedures can arrest core degradation within the reactor vessel in a significant fraction of the core damage scenarios, and that the likelihood of containment failure is very small in these events. Given this, it is appropriate to provide a reasonable period to allow function restoration procedures to arrest the core melt sequence. Whether or not the procedures will be effective should be apparent within 15 minutes. The Emergency Director should make the declaration as soon as it is determined that the procedures have been, or will be ineffective. The reactor vessel level chosen should be consistent with the emergency response guides applicable to the facility.

RVLIS void fraction increasing and RCS subcooling less than or equal to 30°F [65°F] is indicative of core uncovery. When the reactor is at pressure and temperature, RVLIS should not be used for a quantitative value (i.e., top of active fuel). Function restoration procedure FR-C.2 specifies monitoring of RVLIS void fraction trend and RCS subcooling instead of the water level corresponding to the top of active fuel. This is defined by the Core Cooling - ORANGE path. The trend in RVLIS RCS void fraction is used to check the effectiveness of safety injection in restoring RCS inventory. If void fraction percent is decreasing and RCS subcooling based on Core Exit Thermocouples (CETs) is greater than 30°F [65°F], safety injection has been successful in restoring RCS inventory and core cooling. In the event that RCS void fraction is increasing and subcooling requirements are not met, core cooling continues to be degraded and some fuel cladding damage may occur. Setpoints enclosed in brackets are used under adverse containment conditions. Adverse containment condition thresholds apply when containment pressure is greater than 4 psig or containment radiation exceeds 10E+05 R/hr.

The conditions in this potential loss EAL represent an imminent core melt sequence which, if not corrected, could lead to vessel failure and an increased potential for containment failure. In conjunction with the Core Cooling and Heat Sink criteria in the Fuel and RCS barrier columns, this EAL would result in the declaration of a General Emergency -- loss of two barriers and the potential loss of a third. If the function restoration procedures are ineffective, the Operating Crew will be directed to go to Severe Accident Management Guidelines (SACRG-1)re-is-no-"success" path. [Ref. 1, 6, 7]

There is no "Loss" EAL associated with this item.

4. SG Secondary Side Release With Primary To Secondary Leakage

This "loss" EAL recognizes that SG tube leakage can represent a bypass of the containment barrier as well as a loss of the RCS barrier. The first "loss" EAL addresses the condition in which a RUPTURED steam generator is also FAULTED. This condition represents a bypass of the RCS and containment barriers. In conjunction with RCS Barrier "loss" EAL #3, this would always result in the declaration of a Site Area-Emergency. A faulted S/G means the existence of secondary side leakage that results in an uncontrolled lowering in steam generator pressure or the steam

Revision-01/2003KNPP

generator being completely depressurized. A ruptured S/G means the existence of primary-tosecondary leakage of a magnitude sufficient to require or cause a reactor trip and safety injection. Confirmation should be based on diagnostic activities consistent with E-0, Reactor Trip or Safety Injection. [Ref. 14]

The second "loss" EAL addresses SG tube leaks that exceed 10 gpm in conjunction with a nonisolable release path to the environment from the affected steam generator. The threshold for establishing the nonisolable secondary side release is intended to be a prolonged release of radioactivity from the RUPTURED steam generator directly to the environment. This could be expected to occur when the main condenser is unavailable to accept the contaminated steam (i.e., ., SGTR with concurrent loss of offsite power and the RUPTURED steam generator is required for plant cooldown or a stuck open relief valve). If the main condenser is available, there may be releases via air ejectors, gland seal exhausters, and other similar controlled, and often monitored, pathways. These pathways do not meet the intent of a nonisolable release path to the environment. This was recognized during the development process. The inclusion of an EAL that uses Emegency Procedure commonly used terms like "ruptured and faulted" adds to the ease of the classification process and has been included based on this human factor concern.

The leakage threshold for this EAL has been increased with Revision 3. In the earlier revision, the threshold was leakage greater than T/S allowable. Since the prior revision, many plants have implemented reduced steam generator T/S limits (e.g., 150 gpd) as a defense in depth associated with alternate steam generator plugging criteria. The 150 gpd threshold is deemed too low for use as an emergency threshold. A pressure boundary leakage of 10 gpm was is used as the threshold in IC SU5.1, RCS Leakage, and is deemed appropriate for this EAL. For smaller breaks, not exceeding the normal charging capacity threshold in RCS Barrier "Potential Loss" EAL #2 (RCS Leak Rate) or not resulting in ECCS actuation in EAL #3 (SG Tube Rupture), this EAL results in a NOUE. For larger breaks, RCS barrier EALs #2 and #3 would result in an Alert. For SG tube ruptures which may involve multiple steam generators or unisolable secondary line breaks, this EAL would exist in conjunction with RCS barrier "Loss" EAL #3 and would result in a Site Area Emergency. Escalation to General Emergency would be based on "Potential Loss" of the Fuel Clad Barrier.

5. Containment Isolation Valve Status After Containment Isolation

This EAL is intended to address incomplete containment isolation that allows direct release to the environment. It represents a loss of the containment barrier.

The use of the modifier "direct" in defining the release path clarifies that release paths through interfacing liquid systems is not applicable to this EALdiscriminates against release paths through interfacing liquid systems. The existence of an in-line charcoal filter does not make a release path indirect since the filter is not effective at removing fission noble gases. Typical filters have an efficiency of 95-99% removal of iodine. Given the magnitude of the core inventory of iodine, significant releases could still occur. In addition, since the fission product release would be driven by boiling in the reactor vessel, the high humidity in the release stream can be expected to render the filters ineffective in a short period.

There is no "Potential Loss" EAL associated with this item.

6. Significant Radioactive Inventory in Containment

There is no "Loss" EAL associated with this item.

Revision-01/2003KNPP

The <u>(site-specific)</u>4000 R/hr reading is a value which indicates significant fuel damage well in excess of the EALs associated with both loss of Fuel Clad and loss of RCS Barriers. [Ref. 8, 9, 10] As stated in Section 3.8, aA major release of radioactivity requiring offsite protective actions from core damage is not possible unless a major failure of fuel cladding allows radioactive material to be released from the core into the reactor coolant.

Regardless of whether containment is challenged, this amount of activity in containment, if released, could have such severe consequences that it is prudent to treat this as a potential loss of containment, such that a General Emergency declaration is warranted. NUREG-1228, "Source Estimations During Incident Response to Severe Nuclear Power Plant Accidents," indicates that such conditions do not exist when the amount of clad damage is less than 20%.

Monitors used for this fission product barrier loss threshold are the containment high-range area monitors R-40 and R-41.

Unless-there_is-a (site-specific) analysis justifying a higher value, it is recommended that a radiation monitor reading corresponding to 20% fuel clad damage be specified here.

There is no "Loss" EAL-associated with this item.

7. --- Other (Site-Specific) Indications

This EAL-should cover other (site-specific)-indications that may unambiguously-indicate-loss or potential loss of the containment barrier, including indications from area or ventilation monitors in containment annulus or other contiguous buildings. If site emergency operating procedures provide for venting of the containment during an emergency as a means of preventing catastrophic failure, a Loss EAL should be included for the containment barrier. This EAL should be declared as soon as such venting is imminent. Containment venting as part of recovery actions is classified in accordance with the radiological effluent ICs.

87. Emergency Director Judgment

This EAL addresses any other factors that are to be used by the Emergency Director in determining whether the Containment barrier is lost or potentially lost. Such a determination should include imminent barrier degradation, barrier monitoring capability and dominant accident sequences.

- <u>Imminent barrier degradation</u> exists if the degradation will likely occur within two hours based on a projection of current safety system performance. The term "imminent" refers to recognition of the inability to reach safety acceptance criteria before completion of all checks.
- <u>Barrier monitoring</u> capability is decreased if there is a loss or lack of reliable indicators. This assessment should include instrumentation operability concerns, readings from portable instrumentation and consideration of offsite monitoring results.
- <u>Dominant accident sequences</u> lead to degradation of all fission product barriers and likely entry to the CSFSTs. The Emergency Director should be mindful of the Loss of AC power (Station Blackout) and ATWS EALs to assure timely emergency classification declarations.

-In addition, the inability to monitor the barrier should also be incorporated in this EAL as a factor in Emergency Director judgment that the barrier may be considered lost or potentially lost. (See also

IC-SG1, "Prolonged-Loss of All-Offsite Power and Prolonged-Loss of All-Onsite AC Power", for additional information.)

HU1

Initiating Condition - NOTIFICATION OF UNUSUAL EVENT

Natural and Destructive Phenomena Affecting the PROTECTED AREA.

Operating Mode Applicability: All

Example EmergencyEmergency Action Level: (HU1.1 or HU1.2 or HU1.3 or HU1.4 or HU1.5 or HU1.6 -or HU1.7)

HU1.1. Earthquake felt in plant as indicated by: {(Site-Specific)-method-of-indicatinges felt earthquake.]

Consensus of Control Room operators on duty **AND** Activation of seismic monitor with Trigger light lit in Relay Room on RR159 (SER 330 Seismic Monitor Event)

- HU1.2. Report by plant personnel of tornado or high winds greater thanGREATER THAN 100(site-specific) mph striking within PROTECTED AREA boundary.
- HU1.3. Vehicle crash into plant structures containing functions and systems required for safe shutdown of the plantor systems within the PROTECTED AREA boundary.
- HU1.4. Report by plant personnel of an unanticipated EXPLOSION within PROTECTED AREA boundary resulting in VISIBLE DAMAGE to permanent structure or equipment.
- HU1.5. Report of turbine failure resulting in casing penetration or damage to turbine or generator seals.
- HU1.6. Uncontrolled flooding in the following(site-specific)- areas of the plant that has the potential to affect safety related equipment needed for the current operating mode:
 - Diesel Generator A Room
 - Diesel Generator B Room
 - Safeguards Alley
 - Relay Room
 - CRDM Equipment Room
 - RHR Pump Pits
 - Auxiliary Building Basement
 - Screen House

HU1.7. High or low lake level in excess of column "Unusual Event", Lake-Forebay Level Thresholds, Table H-2 for >GREATER THAN 15 minutes.

(Site-Specific) occurrences affecting the PROTECTED AREA.							
Table H-2 Lake-Forebay Level Thresholds (GREATER THAN 15 min.)							
	Unusual	Event		_ Alert			
Level	Num Circulating	ber of Runn Water Pun Pumps	ing nps Water	Level	ing umps

* Computer point L9075A

Basis:

NOUEs in this IC are categorized on the basis of the occurrence of an event of sufficient | magnitude to be of concern to plant operators. Areas identified in the EALs define the location of the event based on the potential for damage to equipment contained therein. Escalation of the event to an Alert occurs when the magnitude of the event is sufficient to result in damage to equipment contained in the specified location.

EAL-#1HU1.1-should-be-developed-on-site-specific basis. Damage may be caused to some portions of the site, but should not affect ability of safety functions to operate. Method of detection can be based on instrumentation, validated by a reliable source, or operator assessment [Ref. 1, 2]. Consensus of the Control Room operators with respect to ground motion helps avoid unnecessary classification if the seismic switches inadvertently trip or detect vibrations not related to an earthquake. As defined in the EPRI-sponsored "Guidelines for Nuclear Plant Response to an Earthquake", dated October 1989, a "felt earthquake" is:

An earthquake of sufficient intensity such that: (a) the vibratory ground motion is felt at the nuclear plant site and recognized as an earthquake based on a consensus of control room operators on duty at the time, and (b) for plants with operable seismic instrumentation, the seismic switches of the plant are activated. For most plants with seismic instrumentation, the seismic switches are set at an acceleration of about 0.01g.

EAL #2HU1.2 is based on the assumption that a tornado striking (touching down) or high winds within the PROTECTED AREA may have potentially damaged plant structures containing functions or systems required for safe shutdown of the plant. The high wind site-specific-value in EAL#2-should beis based on site-specific FSAR design basis [Ref. 3]. If such damage is confirmed visually or by other in-plant indications, the event may be escalated to Alert. Even though the

meteorological towers are outside of the Protected Area, winds in excess of 100 mph detected there can be assumed to be inside of the Protected Area.

EAL-#3HU1.3 is intended to address crashes of vehicle types large enough to cause significant | damage to plant structures containing functions and systems required for safe shutdown of the plant [Ref.- 4]. If the crash is confirmed to affect a plant VITAL AREA, the event may be escalated | to Alert.

For EAL #4HU1.4 only those EXPLOSIONs of sufficient force to damage permanent structures or equipment within the PROTECTED AREA should be considered [Ref. 4]. No attempt is made in this EAL to assess the actual magnitude of the damage. The occurrence of the EXPLOSION with reports of evidence of damage is sufficient for declaration. The Emergency director also needs to consider any security aspects of the EXPLOSION, if applicable.

EAL #5HU1.5 is intended to address main turbine rotating component failures of sufficient magnitude to cause observable damage to the turbine casing or to the seals of the turbine generator. Of major concern is the potential for leakage of combustible fluids (lubricating oils) and gases (hydrogen cooling) to the plant environs. Actual FIREs and flammable gas build up are appropriately classified via HU2 and HU3. Generator seal damage observed after generator purge does not meet the intent of this EAL because it did not impact normal operation of the plant. This EAL is consistent with the definition of a NOUEUE while maintaining the anticipatory nature desired and recognizing the risk to non-safety related equipment. Escalation of the emergency classification is based on potential damage done by missiles generated by the failure or by the radiological releases for a BWR, or in conjunction with a steam generator tube rupture, for a PWR. These latter events would be classified by the radiological ICs or Fission Product Barrier ICs.

EAL #6HU1.6 addresses the effect of flooding caused by internal events such as component failures, equipment misalignment, or outage activity mishaps. The site-specific-listed internal flooding areas are those vulnerable areas indicated in the KNPP PRA that, should significant internal flooding occur (such as a Service Water or Circulating Water pipe rupture), could impact areas that contain systems required for safe shutdown of the plant areas-include those areas that contain systems required for safe shutdown of the plant, that are not designed to be wetted or submerged [Ref. 5]. Escalation of the emergency classification is based on the damage caused or by access restrictions that prevent necessary plant operations or systems monitoring.

The plant's IPEEE may provide insight into areas to be considered when developing this EAL.

EAL-#7HU1.7 covers other site specific phenomena such as hurricane, flood, or seiche. These EALs can also be precursors of more serious events. In particular, sites subject to severe weather as defined in the NUMARC station blackout initiatives, should include an EAL-based on activation of the severe weather mitigation procedures (e.g., precautionary shutdowns, diesel testing, staff call-outs, etc.). high lake (forebay) water level conditions that could be a precursor of more serious events as well as low lake (forebay) water level conditions which may threaten operability of plant cooling systems. Lake water level greater than or equal to 586 ft. International Great Lakes Datum (IGLD) corresponds to the floor elevation of the Service Water Pump Room and access tunnel. Lake water level less than 569.5 ft IGLD corresponds to one foot below the Alert (design) threshold [Ref. 6, 7, 8].

KNPP does not have instrumentation for taking direct readings of the lake level. However the intake forebay level is monitored for this purpose. When no circulating water pumps are operating, the intake forebay level is equal to lake level. However, when the Circulating Water Pumps are operating forebay level is reduced compared to actual lake level due to the hydraulic resistance of

the plant intake. KNPP has correlated the intake forebay level with actual lake level when either one or both Circulating Water Pumps are operating, adjusting the EAL thresholds accordingly. In most cases the Circulating Water Pumps will trip (42% indicated forebay level) prior to exceeding the forebay level that corresponds to the low lake level threshold.

The classification should be declared if the threshold is exceeded for greater than 15 minutes. This allows for short duration dynamic effects associated with the KNPP forebay and will avoid unnecessary event declaration due to shifting of Circulating Water Pumps and other dynamic effects in the forebay.

The International Great Lakes Datum (IGLD 1955) is a reference used to represent water levels in the Great Lakes region.

HU2

Initiating Condition - NOTIFICATION OF-UNUSUAL EVENT

FIRE Within PROTECTED AREA Boundary Not Extinguished Within 15 Minutes of Detection.

Operating Mode Applicability:

Example-EmergencyEmergency Action Level:

HU2.1. FIRE in buildings or areas contiguous to any of the following (site-specific) areasthe PROTECTED AREA not extinguished within 15 minutes of control room notification or verification of a control room alarm

(Site-specific) list

Basis:

The purpose of this IC is to address the magnitude and extent of FIREs that may be potentially significant precursors to damage to safety systems. As used here, Detection is visual observation and report by plant personnel or sensor alarm indication. The 15 minute time period begins with a credible notification that a FIRE is occurring, or indication of a VALID fire detection system alarm. Verification of a fire detection system alarm includes actions that can be taken with the control room or other nearby site specific location to ensure that the alarm is not spurious. An verified alarm is assumed to be an indication of a FIRE unless it is disproved within the 15 minute period by personnel dispatched to the scene. In other words, a personnel report from the scene may be used to disprove a sensor alarm if received within 15 minutes of the alarm, but shall not be required to verify the alarm.

The intent of this 15 minute duration is to size the FIRE and to discriminate against small FIREs that are readily extinguished (e.g., smoldering waste paper basket). The <u>site-specific list-should</u> beapplicable areas are limited and <u>applies</u>-apply to buildings and areas contiguous (in actual contact with or immediately adjacent) to plant VITAL AREAs or other significant buildings or areas. The intent of this-IC is not to include buildings (i.e., warehouses) or areas that are not contiguous (in actual contact with or immediately adjacent) to plant VITAL AREAs. This excludes FIREs within administration buildings, waste-basket FIREs, and other small FIREs of no safety consequence.

Escalation to a higher emergency class is by IC HA2, "FIRE or EXPLOSION Affecting the Operability of Plant Safety Systems Required to Establish or Maintain Safe Shutdown".

HU3

Initiating Condition -- NOTIFICATION OF- UNUSUAL EVENT

Release of Toxic or Flammable Gases Deemed Detrimental to Normal Operation of the Plant.

Operating Mode Applicability: All

Example Emergency Action Levels: Emergency Action Levels: (HU3.1 or HU3.2)

- HU3.1. Report or detection of toxic or flammable gases that has or could enter the site area boundary in amounts that can affect NORMAL PLANT OPERATIONS.
- HU3.2. Report by Local, County or State Officials for evacuation or sheltering of site personnel based on an offsite event.

Basis:

This IC is based on the existence of uncontrolled releases of toxic or flammable gas that may enter the site boundary and affect normal plant operations. It is intended that releases of toxic or flammable gases are of sufficient quantity, and the release point of such gases is such that normal plant operations would be affected. This would preclude small or incidental releases, or releases that do not impact structures needed for plant operation. The EALs are intended to not require significant assessment or quantification. The IC assumes an uncontrolled process that has the potential to affect plant operations, or personnel safety.

Escalation of this EAL is via HA3, which involves a quantified release of toxic or flammable gas affecting VITAL AREAs.

KNPP Basis Reference(s):

None

Confirmed Security Event Which Indicates a Potential Degradation in the Level of Safety of the Plant.

Operating Mode Applicability: All

Example-Emergency-Action Levels:Emergency Action Levels: (HU4.1 or HU4.2)

1. Security events as determined from (site-specific) Safeguards Contingency Plan and reported by the (site-specific) security shift supervision

- HU4.1. 2.——Security [Supervision title] Shift Supervisor reports ANY of the following: A credible site specific security threat notification.
 - Suspected sabotage device discovered within the plant PROTECTED AREA
 - Suspected sabotage device discovered outside the PROTECTED AREA or in the plant switchyard
 - Confirmed tampering with safety-related equipment
 - A hostage or extortion situation that disrupts NORMAL PLANT OPERATIONS
 - Civil disturbance or strike which disrupts NORMAL PLANT OPERATIONS
 - Internal disturbance that is <u>not</u> a short lived or that is not a harmless outburst involving ANY individuals within the PROTECTED AREA
 - Malevolent use of a vehicle outside the PROTECTED AREA which disrupts normal plant operations

HU4.2 A credible site specific security threat notification

Basis:

Reference is made to (site-specific) security shift-supervision the Security Shift Supervisor because these-this individuals are is the designated personnel on-site qualified and trained to confirm that a security event is occurring or has occurred. Training on security event classification confirmation is closely controlled due to the strict secrecy controls placed on the plant Safeguards Contingency Plan.

This-EAL-1-HU4.1 is based on (site-specific)-Site-Security-Plansthe Security And Safeguards Contingency Plan. Security events which do not represent a potential degradation in the level of safety of the plant, are reported under 10- CFR-CFR 73.71 or in some cases under 10 CFR 50.72. Examples of security events that indicate Potential Degradation in the Level of Safety of the Plant are provided below for consideration.

Consideration-should be given to the following-types of events when evaluating an event againstthe criteria of the site specific Security Contingency Plan: SABOTAGE, HOSTAGE./EXTORTION, CIVIL-DISTURBANCE, and STRIKE ACTION.KNPP56-H-910/22/04

INTRUSION into the plant PROTECTED AREA by a HOSTILE FORCE would result in EAL escalation to an ALERT or higher.

The intent of EAL-2-HU4.2 is to ensure that appropriate notifications for the security threat are made in a timely manner. Only the plant to which the specific threat is made need declare the Notification of an Unusual Event.

The determination of "credible" is made through use of information found in the (site-specific) Security And Safeguards Contingency Plan.

A credible site specific security threat is a threat of physical attack to the plant that represents a potential degradation of the level of safety to the plant.

A higher initial classification could be made based upon the nature and timing of the threat and potential consequences. The licensee shall consider upgrading the emergency response status and emergency classification in accordance with the [site security specificSecurity] And Safeguards Contingency Plan and Emergency Plans.

HU5

Initiating Condition -- NOTIFICATION-OF-UNUSUAL EVENT

Other Conditions Existing Which in the Judgment of the Emergency Director Warrant Declaration of a NOUEUE.

Operating Mode Applicability: All

Example-EmergencyEmergency Action Level:

HU5.1. Other conditions exist which in the judgment of the Emergency Director indicate that events are in process or have occurred which indicate a potential degradation of the level of safety of the plant. No releases of radioactive material requiring offsite response or monitoring are expected unless further degradation of safety systems occurs.

Basis:

This EAL is intended to address unanticipated conditions not addressed explicitly elsewhere but that warrant declaration of an emergency because conditions exist which are believed by the Emergency Director to fall under the NOUEUE emergency class.

From a broad perspective, one area that may warrant Emergency Director judgment is related to likely or actual breakdown of site-specific event mitigating actions. Examples to consider include inadequate emergency response procedures, transient response either unexpected or not understood, failure or unavailability of emergency systems during an accident in excess of that assumed in accident analysis, or insufficient availability of equipment and/or support personnel.

KNPP Basis Reference(s):

* Computer point L9075A

Basis:

The EALs in this IC escalate from the NOUEUE EALs in HU1 in that the occurrence of the event has resulted in VISIBLE DAMAGE to plant structures or areas containing equipment necessary for a safe shutdown, or has caused damage to the safety systems in those structures evidenced by control indications of degraded system response or performance. The occurrence of VISIBLE DAMAGE and/or degraded system response is intended to discriminate against lesser events. The initial "report" should not be interpreted as mandating a lengthy damage assessment prior to classification. No attempt is made in this EAL to assess the actual magnitude of the damage. The significance here is not that a particular system or structure was damaged, but rather, that the event was of sufficient magnitude to cause this degradation. Escalation to higher classifications occurs on the basis of other ICs (e.g., System Malfunction).

EAL-#1HA1.1 is based on the USAR design basis operating earthquake of 0.06 g horizontal or 0.04 g vertical acceleration.the FSAR operating basis earthquake (OBE) of 0. g acceleration. should be based on site-specific FSAR design basis. Seismic events of this magnitude can result in a plant VITAL AREA being subjected to forces beyond design limits, and thus damage may be assumed to have occurred to plant safety systems. [Ref. 1, 2]See EPRI-sponsored "Guidelines for Nuclear Plant Response to an Earthquake", dated October 1989, for information on seismic event categories.

EAL #2HA1.2 is based on the FSAR design basis wind speed of 100 mphshould be based on sitespecific FSAR design basis [Ref. 3, 4, 5]. Wind loads of this magnitude can cause damage to safety functions.

EAL-#s-2, 3, 4, 5 should specify site-specific structures or areas containing systems and functions required for safe shutdown of the plant.

EAL-#3HA1.3 is intended to address crashes of vehicle types large enough to cause significant damage to plant structures containing functions and systems required for safe shutdown of the plant.

EAL-#HA1.4 is intended to address the threat to safety related equipment imposed by missiles generated by main turbine rotating component failures. Table H-1 lists areas that contain systems and components required for the safe shutdown functions of the plant. This site specific list of areas should include all areas containing safety-related equipment, their controls, and their power supplies. This EAL is, therefore, consistent with the definition of an ALERT in that if missiles have damaged or penetrated areas containing safety-related equipment the potential exists for substantial degradation of the level of safety of the plant.

EAL #5HA1.5 addresses the effect of internal flooding that has resulted in degraded performance of systems affected by the flooding, or has created industrial safety hazards (e.g., electrical shock) that preclude necessary access to operate or monitor safety equipment. The inability to operate or monitor safety equipment represents a potential for substantial degradation of the level of safety of the plant. This flooding may have been caused by internal events such as component failures, equipment misalignment, or outage activity mishaps. The listed internal flooding areas are those vulnerable areas indicated in the KNPP PRA that should significant internal flooding occur (such as a Service Water or Circulating Water pipe rupture), could impact areas that contain systems required for safe shutdown of the plant that are not designed to be wetted or submerged. [Ref.- 6, 7]. The site specific areas includes those areas that contain systems required for safe shutdown of the plant to be wetted or submerged. The plant's IPEEE may provide insight into areas to be considered when developing this EAL.

EAL-#6HA1.6 covers other-site-specific-phenomena-such-as-hurricane,-flooding, or seiche. These-This EALs can also-be a precursors of more serious events. Lake water level ≥greater than or equal to 588 ft International Great Lakes Datum (IGLD) corresponds to levels approaching design limits which if exceeded threatens operability of safety related equipment. Lake water level <less than 568.5 ft IGLD corresponds to design levels (with added conservatism) to ensure Service Water Pumps have adequate NPSH and that vortexing does not occur [Ref. 8, 9].

KNPP does not have instrumentation for taking direct readings of the lake level. However the intake forebay level is monitored for this purpose. When no circulating water pumps are operating, the intake forebay level is equivalent to lake level. However, when the Circulating Water Pumps are operating forebay level is reduced compared to actual lake level due to the hydraulic resistance of the plant intake. KNPP has correlated the intake forebay level with actual lake level when either one or both Circulating Water Pumps are operating, adjusting the EAL thresholds accordingly. In most cases the Circulating Water Pumps will trip (42% indicated forebay level) prior to exceeding the forebay level that corresponds to the low lake level threshold.

The classification should be declared if the threshold is exceeded for greater than 15 minutes. This allows for short duration dynamic effects associated with the KNPP forebay and will avoid unnecessary event declaration due to shifting of Circulating Water Pumps and other dynamic effects in the forebay.

The International Great Lakes Datum (IGLD 1955) is a reference used to represent water levels in the Great Lakes region.

HA2

Initiating Condition -- ALERT

FIRE or EXPLOSION Affecting the Operability of Plant Safety Systems Required to Establish or Maintain Safe Shutdown.

Operating Mode Applicability: All

Example-EmergencyEmergency Action Level:

HA2.1. FIRE or EXPLOSION in any of the following (site-specific)-areas (Table H-1):

	Table H-1 Safe Shutdown/VITAL Areas
•	Shield Building (Reactor Building)
•	Auxiliary Building
•	Safeguards Alley
•	Diesel Generator Rooms (includes "A" Diesel Room to Screen House Tunnel)
•	Screenhouse/Forebay
•	Technical Support Center Basement
•	Control Room
•	Control Room AC Equipment Room
•	Relay Room
•	Safeguards Battery Rooms

(Site-specific)-list

AND

Affected safety system parameter indications show degraded performance or plant personnel report VISIBLE DAMAGE to permanent structures or equipment within-the specified areaneeded for safe shutdown.

Basis:

These areas contain systems and components required for the safe shutdown functions of the plant. The KNPP safe shutdown analyses were consulted for equipment and plant areas required for the applicable mode. Site-specific areas containing functions and systems required for the safe shutdown of the plant should be specified. Site-Specific Safe Shutdown Analysis should be consulted for equipment and plant areas required to establish or maintain safe shutdown. This will make it easier to determine if the FIRE or EXPLOSION is potentially affecting one or more KNPP 56-H-17 10/22/04

redundant trains of safety systems [Ref. 1, 2]. Escalation to a higher emergency class, if appropriate, will be based on System Malfunction, Fission Product Barrier Degradation, Abnormal Rad Levels / Radiological Effluent, or Emergency Director Judgment ICs.

This EAL addresses a FIRE / EXPLOSION and not the degradation in performance of affected systems. System degradation is addressed in the System Malfunction EALs. The reference to damage of systems is used to identify the magnitude of the FIRE / EXPLOSION and to discriminate against minor FIREs / EXPLOSIONs. The reference to safety systems is included to discriminate against FIREs / EXPLOSIONs in areas having a low probability of affecting safe operation. The significance here is not that a safety system was degraded but the fact that the FIRE / EXPLOSION was large enough to cause damage to these systems. Thus, the designation of a single train was intentional and is appropriate when the FIRE / EXPLOSION is large enough to affect more than one component.

This situation is not the same as removing equipment for maintenance that is covered by a plant's Technical Specifications. Removal of equipment for maintenance is a planned activity controlled in accordance with procedures and, as such, does not constitute a substantial degradation in the level of safety of the plant. A FIRE / EXPLOSION is an UNPLANNED activity and, as such, does constitute a substantial degradation in the level of safety of the plant. In this situation, an Alert classification is warranted.

The inclusion of a "report of VISIBLE DAMAGE" should not be interpreted as mandating a lengthy damage assessment prior to classification. No attempt is made in this EAL to assess the actual magnitude of the damage. The occurrence of the EXPLOSION with reports of evidence of damage is sufficient for declaration. The declaration of an Alert and the activation of the Technical Support Center will provide the Emergency Director with the resources needed to perform these damage assessments. The Emergency Director also needs to consider any security aspects of the EXPLOSIONs, if applicable.

HA3

Initiating Condition -- ALERT

Release of Toxic or Flammable Gases Within or Contiguous to a VITAL AREA Which Jeopardizes Operation of Systems Required to Maintain Safe Operations or Establish or Maintain Safe Shutdown.

Operating Mode Applicability: All

Example-Emergency-Action-Levels:Emergency Action Levels: (HA3.1 or HA3.2)

HA3.1. Report or detection of toxic gases within or contiguous to a Safe Shutdown/VITAL AREA (Table H-1)VITAL AREA in concentrations that may result in an atmosphere IMMEDIATELY DANGEROUS TO LIFE AND HEALTH (IDLH).

Table I	H-1 Safe Shutdown/VITAL Areas
Shield	d Building (Reactor Building)
Auxilia	ary Building
 Safeg 	guards Alley
Diese Scree	el Generator Rooms (includes "A" Diesel Room to en House Tunnel)
Scree	enhouse/Forebay
Techr	nical Support Center Basement
Contr	rol Room
Contr	rol Room AC Equipment Room
Relay	Room
Safeg	guards Battery Rooms

HA3.2. Report or detection of gases in concentration greater than the LOWER FLAMMABILITY LIMIT within or contiguous to a Safe Shutdown/VITAL AREA (Table H-1)VITAL AREA.

Basis:

This IC is based on gases that affect the safe operation of the plant. This IC applies to buildings and areas contiguous (in actual contact with or immediately adjacent) to plant Safe Shutdown/VITAL AREAs or other significant buildings or areas-(i.e., service-water-pump-house) [Ref. 1, 2]. The intent of this IC is not to include buildings (e.g., warehouses) or other areas that are not contiguous or immediately adjacent to plant Safe Shutdown/VITAL AREAs. It is KNPP 56-H-19 10/22/04 appropriate that increased monitoring be done to ascertain whether consequential damage has occurred. Escalation to a higher emergency class, if appropriate, will be based on System Malfunction, Fission Product Barrier Degradation, Abnormal Rad Levels / Radioactive Effluent, or Emergency Director Judgment ICs.

EAL #1HA3.1 is met if measurement of toxic gas concentration results in an atmosphere that is IDLH within a Safe Shutdown/VITAL AREA or any area or building contiguous to Safe Shutdown/VITAL AREA. Exposure to an IDLH atmosphere will result in immediate harm to unprotected personnel, and would preclude access to any such affected areas.

EAL #2HA3.2 is met when the flammable gas concentration in a Safe Shutdown/VITAL AREA or any building or area contiguous to a Safe Shutdown/VITAL AREA exceed the LOWER FLAMMABILITY LIMIT. Flammable gasses, such as hydrogen and acetylene, are routinely used to maintain plant systems (hydrogen) or to repair equipment/components (acetylene - used in welding). This EAL addresses concentrations at which gases can ignite/support combustion. An uncontrolled release of flammable gasses within a facility structure has the potential to affect safe operation of the plant by limiting either operator or equipment operations due to the potential for ignition and resulting equipment damage/personnel injury. Once it has been determined that an uncontrolled release is occurring, then sampling must be done to determine if the concentration of the released gas is within this range.

HA4

Initiating Condition -- ALERT

Confirmed Security Event in a Plant PROTECTED AREA.

Operating Mode Applicability: All

Example-Emergency Action Levels:Emergency Action Levels: (HA4.1 or HA4.2)

HA4.1. INTRUSION into the plant PROTECTED AREA by a HOSTILE FORCE.

HA4.2. Security [Supervision-title]Shift Supervisor reports any of the following:

- Sabotage device discovered in the plant PROTECTED AREA
- Standoff attack on the protected area by a HOSTILE FORCE (i.e., Sniper)
- ANY Security event of increasing severity that persists for > 30 minutes:
 - Credible bomb threats
 - Hostage / Extortion
 - Suspicious Fire or Explosion
 - Significant Security System Hardware Failure
 - Loss of contact with Security Officers

Other security events as determined from (site-specific)-Safeguards Contingency-Plan and reported by the (site-specific) security shift supervision

Basis:

This class of security events represents an escalated threat to plant safety above that contained in the NOUEUE. A confirmed INTRUSION report is satisfied if physical evidence indicates the presence of a HOSTILE FORCE within the PROTECTED AREA.

The Security And Safeguards Contingency Plan identifies numerous events/conditions that constitute a threat/compromise to station security. Only those events that involve actual or potential substantial degradation to the level of safety of the plant need to be considered. Consideration-should-be-given-to-the-following-types-of-events-when-evaluating-an event-against the criteria of the site specific Security Contingency Plan: SABOTAGE, HOSTAGE/ EXTORTION, and STRIKE-ACTION. The Safeguards-Contingency-Plan identifies-numerous events/conditions-that-constitute-a-threat/compromise-to-a-Station's security. Only those events that involve Actual or Potential Substantial degradation to the level of safety of the plant-need to be considered. The following events-would-not-normally-meet-this requirement; (e.g., Failure-by-a Member-of-the-Security-Force-to-carry-out-an-assigned/required-duty,-internal-disturbances, loss/compromise-of-safeguards-materials-or-strike-actions).

INTRUSION into a VITAL AREA by a HOSTILE FORCE will escalate this event to a Site Area Emergency.

KNPP

Reference is made to (site-specific) sSecurity sShift sSupervisionor because these-this individuals are-is the designated personnel on-site qualified and trained to confirm that a security event is occurring or has occurred. Training on security event classification confirmation is closely controlled due to the strict secrecy controls placed on the plant Physical Security Plan.

HA5

Initiating Condition -- ALERT

Control Room Evacuation Has Been Initiated.

Operating Mode Applicability: All

Example-EmergencyEmergency Action Level:

HA5.1. Entry into E-O-06, Fire in Alternate Fire Zone [(site-specific) procedure number(s) and title(s)] for control room evacuation.

Basis:

With the control room evacuated, additional support, monitoring and direction through the Technical Support Center and/or other emergency response facility is necessary. E-O-06, Fire in Alternate Fire Zone, provides specific instructions for evacuating the Control Room/Building and establishing plant control at the Dedicated Shutdown Panel and in alternate locations. Inability to establish plant control from outside the control room will escalate this event to a Site Area Emergency.

KNPP Basis Reference(s):

1. E-O-06, Fire in Alternate Fire Zone, Rev. W

HA6

Initiating Condition -- ALERT

Other Conditions Existing Which in the Judgment of the Emergency Director Warrant Declaration of an Alert.

Operating Mode Applicability: All

Example-EmergencyEmergency Action Level:

HA6.1. Other conditions exist which in the judgment of the Emergency Director indicate that events are in process or have occurred which involve actual or likely potential substantial degradation of the level of safety of the plant. Any releases are expected to be limited to small fractions of the EPA Protective Action Guideline exposure levels.

Basis:

This EAL is intended to address unanticipated conditions not addressed explicitly elsewhere but that warrant declaration of an emergency because conditions exist which are believed by the Emergency Director to fall under the Alert emergency class. Refer to EPIP-AD-19 for EPA Protective Action Guideline exposure levels.

- 1. EPA 400, Manual of Protective Action Guides And Protective Actions For Nuclear Incidents, October 1991
- 2. EPIP-AD-19 -Determining Protective Action Recommendations, Rev. T

HS1

Initiating Condition – SITE AREA EMERGENCY

Confirmed Security Event in a Plant VITAL AREA.

Operating Mode Applicability: All

Example-Emergency-Action-Levels:Emergency Action Levels: (HS1.1 or HS1.2)

HS1.1. INTRUSION into the plant VITAL AREA by a HOSTILE FORCE.

HS1.2. Security Supervision reports ANY of the following:

- A security event that results in the loss of control of ANY VITAL AREAS (other than Control Room)
- Imminent loss of physical control of the facility (remote shutdown capability) due to a security event
- A confirmed sabotage discovered in a VITAL AREA

Other security events as determined from (site-specific) Safeguards Contingency Plan and reported by the (site-specific) security shift supervision

Basis:

This class of security events represents an escalated threat to plant safety above that contained in the Alert IC in that a HOSTILE FORCE has progressed from the PROTECTED AREA to a VITAL AREA.

Consideration should beis given to the following types of events when evaluating an event against the criteria of the site specific Security Contingency Plan: SABOTAGE and HOSTAGE / EXTORTION. The Safeguards Contingency Plan identifies numerous events/conditions that constitute a threat/compromise to a Station's security. Only those events that involve Actual or Likely Major failures of plant functions needed for protection of the public need to be considered. The following events would not normally meet this requirement; (e.g., Failure by a Member of the Security Force to carry out an assigned/required duty, internal disturbances, loss/compromise of safeguards materials or strike actions).

Loss of Plant Control would escalate this event to a GENERAL EMERGENCY.

Reference is made to <u>(site-specific)</u> s Security sShift sSupervisionor because these-this individuals are-is the designated personnel on-site qualified and trained to confirm that a security event is occurring or has occurred. Training on security event classification confirmation is closely controlled due to the strict secrecy controls placed on the plant Physical Security Plan.

HS2

Initiating Condition – SITE AREA EMERGENCY

Control Room Evacuation Has Been Initiated and Plant Control Cannot Be Established.

Operating Mode Applicability:

Example-EmergencyEmergency Action Level:

HS2.1. Control room evacuation has been initiated.

AND

Control of the plant cannot be established per E-O-06, Fire in Alternate Fire Zone [(site-specific) procedure number(s) and name(s)] within [(site-specific]15) minutes.

Basis:

Expeditious transfer of safety systems has not occurred but fission product barrier damage may not yet be indicated. The intent of this IC is to capture those events where control of the plant cannot be reestablished in a timely manner. Site-specific time-for-transfer-based on analysis or assessments as to how quickly-control-must be reestablished without-core uncovering and/or-core damage. This time should not exceed 15 minutes without additional justification. The determination of whether or not control is established at the Dedicated Shutdown Panelremote shutdown panel is based on Emergency Director (ED) judgment. The ED is expected to make a reasonable, informed judgment within the site-specific-time for transfer that the licensee-operator has control of the plant from the Dedicated Shutdown Panelremote shutdown panelPanel.

E-O-06, Fire in Alternate Fire Zone, provides specific instructions for evacuating the Control Room/Building and establishing plant control at the Dedicated Shutdown Panel and in alternate locations.

The intent of the EAL is to establish control of important plant equipment and knowledge of important plant parameters in a timely manner. Primary emphasis should be placed on those components and instruments that supply protection for and information about safety functions. Typically, these safety functions are reactivity control (ability to shutdown the reactor and maintain it shutdown), RCS inventoryreactor water level (ability to cool the core), and secondary heat removaldecay heat-removal (ability to maintain a heat sink)-for a BWR. The equivalent functions for a PWR-are reactivity control, RCS inventory, and secondary heat removal.

Escalation of this event, if appropriate, would be by Fission Product Barrier Degradation, Abnormal Rad Levels/Radiological Effluent, or Emergency Director Judgment ICs.

1. E-O-06, Fire in Alternate Fire Zone, Rev. W

.
HAZARDS AND OTHER CONDITIONS AFFECTING PLANT SAFETY

Initiating Condition – SITE AREA EMERGENCY

Other Conditions Existing Which in the Judgment of the Emergency Director Warrant Declaration of Site Area Emergency.

Operating Mode Applicability: All

Example-Emergency Action Level:

HS3.1. Other conditions exist which in the judgment of the Emergency Director indicate that events are in process or have occurred which involve actual or likely major failures of plant functions needed for protection of the public. Any releases are not expected to result in exposure levels which exceed EPA Protective Action Guideline exposure levels beyond the site boundary.

Basis:

This EAL is intended to address unanticipated conditions not addressed explicitly elsewhere but that warrant declaration of an emergency because conditions exist which are believed by the Emergency Director to fall under the emergency class description for Site Area Emergency. Refer to EPIP-AD-19 for EPA Protective Action Guideline exposure levels.

- 1. EPA 400, Manual of Protective Action Guides And Protective Actions For Nuclear Incidents, October 1991
- 2. EPIP-AD-19- Determining Protective Action Recommendations, Rev. T

HAZARDS AND OTHER CONDITIONS AFFECTING PLANT SAFETY

HG1

Initiating Condition – GENERAL EMERGENCY

Security Event Resulting in Loss Of Physical Control of the Facility.

Operating Mode Applicability: All

Example-EmergencyEmergency Action Level:

HG1.1. A HOSTILE FORCE has taken control of plant equipment such that plant personnel are unable to operate equipment required to maintain safety functions as indicated by loss of physical control of EITHER:

A VITAL AREA (including the Control Room) such that operation of equipment required for safe shutdown is lost

OR

Spent fuel pool cooling systems if imminent fuel damage is likely

Basis:

This IC encompasses conditions under which a HOSTILE FORCE has taken physical control of VITAL AREAs (containing vital equipment or controls of vital equipment, including the Control Room) required to maintain safety functions and control of that equipment cannot be transferred to and operated from another location. Typically, these safety functions are reactivity control (ability to shut down the reactor and keep it shutdown) reactor water levelRCS inventory (ability to cool the core), and decay-secondary heat removal (ability to maintain a heat sink)-for a BWR. The equivalent functions for a PWR are reactivity control, RCS inventory, and secondary heat removal. If control of the plant equipment necessary to maintain safety functions can be transferred to another location, then the above initiating condition is not met.

This EAL should also address loss of physical control of spent fuel pool cooling systems if imminent fuel damage is likely (e.g., freshly off-loaded reactor core in pool).

Loss of physical control of the control room or remote shutdown capability alone-may not-prevent the ability to maintain safety functions-per-se.-Design-of-the-remote-shutdown-capability-and-the location of the transfer-switches should be taken into account.

- 1. NRC Safeguards Advisory 10/6/01
- 2. Security And Safeguards Contingency Plan
- 3. Letter from Mr. B. A. Boger (NRC) to Ms. Lynette Hendricks (NEI) dated 2/4/02

4. Physical Security Plan

:

HAZARDS AND OTHER CONDITIONS AFFECTING PLANT SAFETY

Initiating Condition – GENERAL EMERGENCY

Other Conditions Existing Which in the Judgment of the Emergency Director Warrant Declaration of General Emergency.

Operating Mode Applicability: All

Example-EmergencyEmergency Action Level:

HG2.1. Other conditions exist which in the judgment of the Emergency Director indicate that events are in process or have occurred which involve actual or imminent substantial core degradation or melting with potential for loss of containment integrity. Releases can be reasonably expected to exceed EPA Protective Action Guideline exposure levels offsite for more than the immediate site area.

Basis:

This EAL is intended to address unanticipated conditions not addressed explicitly elsewhere but that warrant declaration of an emergency because conditions exist which are believed by the Emergency Director to fall under the General Emergency class. Refer to EPIP-AD-19 for EPA Protective Action Guideline exposure levels.

- 1. EPA 400, Manual of Protective Action Guides And Protective Actions For Nuclear Incidents, October 1991

SU1

Initiating Condition - NOTIFICATION OF UNUSUAL EVENT

Loss of All Offsite Power to Essential Busses for GREATER THANreater Than 15 Minutes.

Operating Mode Applicability:

Power Operation Startup Hot Standby Hot Shutdown Intermediate Shutdown

Example-EmergencyEmergency Action Level:

SU1.1. Loss of all offsite power to Bus 5 AND Bus 6 (site-specific)-transformers for GREATER THANgreater than 15 minutes.

AND

At least (site-specific) eEmergency diesel generators are supplying power to emergency bussesBus 5 AND Bus 6.

Basis:

Prolonged loss of AC power reduces required redundancy and potentially degrades the level of safety of the plant by rendering the plant more vulnerable to a complete Loss of AC Power (e.g., Station Blackout). Fifteen minutes was selected as a threshold to exclude transient or momentary power losses.

The 4160 VAC system is divided into six busses, two of which are Engineered Safety Features (ESF) busses 5 and 6. The ESF busses supply power to Safety Injection (SI) pumps, Residual Heat Removal (RHR) pumps, containment heat removal equipment, etc.

Offsite power is available from the 345 kVAC and 138 kVAC systems. The 345 kVAC system is connected to the North Appleton line, the Point Beach line, the main transformers, and transformer T-10. The 345 kVAC is the normal supply to the 13.8 kVAC system through transformer T-10, which feeds the Tertiary Auxiliary Transformer (TAT). The TAT normally provides power to ESF bus 5. The TAT is not considered available to power both ESF busses in an emergency situation due to its size. As a contingency, however, it is acceptable to use the TAT to power both ESF busses when guidance for sequencing and monitoring TAT loads is available in the Control Room. The Reserve Auxiliary Transformer (RAT) and Main Auxiliary Transformer (MAT) provide backup sources to bus 5, in that order.

The 138 kVAC system is connected to the Shoto/Mishicot line, the East Krok line and transformer T-10. The 138 kVAC system is the normal supply to the Reserve Auxiliary Transformer (RAT) via the East and West substation busses. (When the 345 kVAC system is unavailable, the 138 kVAC system can supply power to transformer T-10 and the TAT.) The RAT normally provides power to ESF bus 6. The TAT and MAT provide backup sources to bus 6 in that order.

When the main turbine generator is on line, generator output supplies power to the Main Auxiliary Transformer (MAT) and the 4160 VAC busses. When the main turbine generator is off line, the 345 kVAC system can be aligned to backfeed the MAT. Note that the time required to effect the backfeed is likely longer than the fifteen-minute interval associated with this EAL. If off-normal plant conditions have already established the backfeed, however, its power to the ESF busses may be considered an offsite power source.

Following a loss of power, ECA 0.0 provides guidance to restore power to ESF busses. For the purpose of classification under this EAL, offsite power sources include any of the following:

- 345 kVAC system supplying power to transformer T-10 and the TAT
- 138 kVAC system supplying power to transformer T-10 and the TAT
- 138 kVAC system supplying power to the RAT
- 345 kVAC system supplying power to the MAT on backfeed through the main transformers when the main turbine generator is off line

KNPP Basis Reference(s):

- 1. ECA-0.0 Loss of All AC Power, Rev. AB
- 2. USAR Figure 8.2-2, Rev. 16
- 3. USAR Section 8.2.3, Rev. 18
- 4. GNP-08.04.01 Shutdown Safety Assessment, Rev. K

Plants that have the capability to cross-tie AC-power from a companion unit-may-take credit for the redundant-power-source in the associated EAL-for this IC. Inability to effect the cross-tie within 15 minutes warrants declaring a NOUE.

SU2

Initiating Condition -- NOTIFICATION OF UNUSUAL EVENT

Inability to Reach Required Shutdown Within Technical Specification Limits.

Operating Mode Applicability:

Power Operation Startup -Hot Standby Hot Shutdown Intermediate Shutdown

Example-EmergencyEmergency Action Level:

SU2.1. Plant is not brought to required operating mode within (site-specific)-Technical Specifications LCO Action Statement Time.

Basis:

Limiting Conditions of Operation (LCOs) require the plant to be brought to a required shutdown mode when the Technical Specification required configuration cannot be restored. Depending on the circumstances, this may or may not be an emergency or precursor to a more severe condition. In any case, the initiation of plant shutdown required by the site-KNPP Technical Specifications | requires a one hour report under 10 CFR 50.72 (b) Non-emergency events. The plant is within its safety envelope when being shut down within the allowable action statement time in the Technical Specifications. An immediate NOUE is required when the plant is not brought to the required | operating mode within the allowable action statement time in the Technical Specifications. Declaration of a NOUE is based on the time at which the LCO-specified action statement time | period elapses under the site Technical Specifications and is not related to how long a condition may have existed. Other required Technical Specification shutdowns that involve precursors to more serious events are addressed by other System Malfunction, Hazards, or Fission Product Barrier Degradation ICs.

KNPP Basis Reference(s):

1. KNPP Technical Specifications

SU3

Initiating Condition -- NOTIFICATION-OF-UNUSUAL EVENT

UNPLANNED Loss of Most or All Safety System Annunciation or Indication in The Control Room for Greater ThanGREATER THAN 15 Minutes

Operating Mode Applicability:

Power Operation Startup Hot Standby Hot Shutdown Intermediate Shutdown

Example-EmergencyEmergencyAction Level:

SU3.1. UNPLANNED loss of most or all (site-specific) annunciators or indicators associated with safety systems for greater thanGREATER THAN 15 minutes on Mechanical Vertical Panels A, B and C, Mechanical Control Consoles A, B and C, Electrical Vertical Panel and Electrical Control Console

Basis:

This IC and its associated EAL are intended to recognize the difficulty associated with monitoring changing plant conditions without the use of a major portion of the annunciation or indication equipment.

Recognition of the availability of computer based indication equipment is considered (e.g., PPCS, SER or SPDS, plant-computer, etc.).

Quantification of "Most" is arbitrary, however, it is estimated that if approximately 75% of the safety system annunciators or indicators are lost, there is an increased risk that a degraded plant condition could go undetected. It is not intended that plant personnel perform a detailed count of the instrumentation lost but use the value as a judgment threshold for determining the severity of the plant conditions.

It is further recognized that most-plant designs provides redundant safety system indication | powered from separate uninterruptable power supplies. While failure of a large portion of annunciators is more likely than a failure of a large portion of indications, the concern is included in this EAL due to difficulty associated with assessment of plant conditions. The loss of specific, or several, safety system indicators should remain a function of that specific system or component operability status. This will-be addressed by the specific Technical Specification. The initiation of a Technical Specification imposed plant shutdown related to the instrument loss will be reported via 10 CFR 50.72. If the shutdown is not in compliance with the Technical Specification action, the NOUE is based on SU2 "Inability to Reach Required Shutdown Within Technical Specification | Limits."

(Site-specific)The specified panels for this EAL include annunciators or-and indicators-panels for this EAL-must-include-those identified in the Abnormal Operating Procedures, in the Emergency Operating Procedures, and in other EALs (e.g., area, process, and/or effluent rad monitors, etc.).

Fifteen minutes was selected as a threshold to exclude transient or momentary power losses. Due to the limited number of safety systems in operation during cold shutdown, refueling, and defueled modes, no IC is indicated during these modes of operation.

This NOUE will be escalated to an Alert if a transient is in progress during the loss of annunciation or indication.

- 4. A-CP-46 Abnormal Honeywell Plant Process Computer, Rev. AR
- 5. N-SER-52 Control Room Sequential Event Recorder, Rev. D

SU4

Initiating Condition -- NOTIFICATION OF-UNUSUAL EVENT

Fuel Clad Degradation.

Operating Mode Applicability:

Power Operation Startup -Hot Standby Hot Shutdown Intermediate Shutdown

Example-Emergency-Action Levels:Emergency Action Levels: (SU4.1 or SU4.2)

- SU4.1. RCS Letdown Line (R-9) radiation monitor GREATER THAN 2000 mR/hr indicating fuel clad degradation(Site-specific) radiation monitor readings-indicating-fuel-clad-degradation greater than Technical-Specification allowable-limits.
- SU4.2. (Site-specific) cCoolant sample activity GREATER THAN ANY of the following indicating fuel clad degradation:
 - 1.0 µCi/gram dose equivalent lodine-131 for more than 48 hours in one continuous time interval
 - 60 µCi/gram dose equivalent lodine-131
 - 91/Ē µʉCi/cc gross radioactivity

value indicating fuel clad degradation greater than Technical Specification allowable limits.

Basis:

This IC is included as a NOUE because it is considered to be a potential degradation in the level of safety of the plant and a potential precursor of more serious problems. SU5.1 addresses RCS Letdown Line (R-9) radiation monitor readings that provide indication of fuel clad integrity. [Ref. 4 & 5] EAL #1-addresses site-specific radiation-monitor-readings such as BWR-air-ejector-monitors, PWR-failed_fuel_monitors, etc., that_provide_indication_of_fuel_clad_integrity. EAL #2SU4.2 addresses coolant samples exceeding coolant technical specifications for iodine spike[Ref. 1].

2000 mR/hr was calculated using the following:

0.01% fuel cladding defect equals 7.2E+1 mR/hr increase on R-9 [Ref. 4] 0.2745% fuel cladding defect equals 1.0 μCi/gram dose equivalent lodine-131 [Ref. 5].

Therefore 1976.4 mR/hr increase on R-9 is equal to 1.0 µCi/gram dose equivalent lodine-131

R-9 background is equivalent to 56 mR/hr [Ref. 4], which is added to the calculated dose rate above.

With the addition of background R-9 will read 2032.4 mR/hr (rounded to 2000 mR/hr) equal to 1.0 µCi/gram dose equivalent lodine-131.

Escalation of this IC to the Alert level is via the Fission Product Barrier Degradation Monitoring ICs. Though the referenced Technical Specification limits are applicable when average reactor coolant temperature is GREATER THAN 500°Fmode_dependent, it is appropriate that the EAL's be applicable in all modes, as they indicate a potential degradation in the level of safety of the plant. The companion IC to SU4 for the Cold Shutdown/Refueling modes is CU5.

- 1. Technical Specifications LCO 3.1.c.1.A, Amendment No. 167
- 2. E-2021 Integrated Logic Diagram Radiation Monitoring, Rev. X

- 4. USAR Section 9, Rev. 16
- 5. CN-CRA-99-28 Rev. 1

SU5

Initiating Condition -- NOTIFICATION-OF-UNUSUAL EVENT

RCS Leakage.

Operating Mode Applicability:

Power Operation Startup –Hot Standby Hot Shutdown Intermediate Shutdown

Example-Emergency-Action Levels:Emergency Action Levels: (SU5.1 or SU5.2)

SU5.1. Unidentified or pressure boundary leakage GREATER THAN 10 gpm.

SU5.2. Identified leakage GREATER THAN 25 gpm.

Basis:

This IC is included as a NOUE because it may be a precursor of more serious conditions and, as result, is considered to be a potential degradation of the level of safety of the plant. Positive indications in the Control Room of Reactor Coolant System (RCS) leakage to the containment are provided by equipment that monitors:

- Charging/Letdown flow mismatch
- Containment air activity
- Containment atmosphere humidity
- Containment Sump A in leakage

[Ref. 1, 2]

The 10 gpm value for the unidentified and pressure boundary leakage was selected as it is observable with normal control room indications. Lesser values must generally be determined through time-consuming surveillance tests (e.g., mass balances). SP-36-82 provides instructions for calculating primary system leak rate by water inventory balances for off-normal events and for operations troubleshooting [Ref, 2]. The EAL for identified leakage is set at a higher value due to the lesser significance of identified leakage in comparison to unidentified or pressure boundary leakage. In either case, escalation of this IC to the Alert level is via Fission Product Barrier Degradation ICs.

- 1. Technical Specifications LCO 3.1.d, Amendment No. 165
- 2. SP-36-82 Reactor Coolant System Leak Rate Check, Rev. AE

SU6

Initiating Condition -- NOTIFICATION-OF-UNUSUAL EVENT

UNPLANNED Loss of All Onsite or Offsite Communications Capabilities.

Operating Mode Applicability:

Power Operation Startup -Hot Standby Hot Shutdown Intermediate Shutdown

Example-Emergency Action Levels:Emergency Action Levels: (SU6.1 or SU6.2)

SU6.1. Loss of all Table C-1(site-specific list) onsite communications capability affecting the ability to perform routine operations.

- Intraplant Paging (Gai-tronics)
- Sound powered phones
- PBX telephone system
- Personal communications system (PCS phones)
- Portable radio communications system

SU6.2. Loss of all Table C-2(site-specific-list) offsite communications capability.

Table C-2 Offsite Communications Systems

- PBX telephone system
- NRC FTS System (including ENS and HPN)
- Dial select phones

Basis:

The purpose of this IC and its associated EALs is to recognize a loss of communications capability that either defeats the plant operations staff ability to perform routine tasks necessary for plant operations or the ability to communicate problems with offsite authorities. The loss of offsite communications ability is expected to be significantly more comprehensive than the condition addressed by 10 CFR 50.72.

The availability of one method of ordinary offsite communications is sufficient to inform state and local authorities of plant problems. This EAL is intended to be used only when extraordinary

means (e.g., relaying of information from radio transmissions, individuals being sent to offsite locations, etc.) are being utilized to make communications possible.

Site-specific-list-forTable C-1 onsite communications loss <u>-must-</u>encompasses the loss of all means of routine communications (e.g., commercial telephones, sound powered phone systems, page party system (Gaitronics) and radios / walkie talkies). Due to its limited capability, the emergency gai-tronics is not listed in Table C-1.

Site-specific list for Table C-2 offsite communications loss must-encompasses the loss of all means of communications with offsite authorities. This should-includes the NRC FTS System (including Emergency Notification System - ENS and Health Physics Network – HPN)ENS, commercial telephone lines, telecopy transmissions, and dedicated phone systems.

KNPP Basis Reference(s):

SU8

Initiating Condition – **NOTIFICATION OF UNUSUAL EVENT**

Inadvertent Criticality.

Operating Mode Applicability: OPERATING MODE APPLICABILITY Hot Standby

> ——Hot Shutdown Intermediate Shutdown

Example-EmergencyEmergency Action Level: (1-or-2)

1. An UNPLANNED extended positive period observed on nuclear instrumentation.

SU8.21. An UNPLANNED sustained positive startup rate observed on nuclear instrumentation.

Basis:

This IC addresses inadvertent criticality events. While the primary concern of this IC is criticality events that occur in Cold Shutdown or Refueling modes (NUREG 1449, Shutdown and Low-Power Operation at Commercial Nuclear Power Plants in the United States), the IC is applicable in other modes in which inadvertent criticalities are possible. This IC indicates a potential degradation of the level of safety of the plant, warranting an NOUE-Unusual Event classification. This IC excludes and vertent criticalities that occur during planned reactivity changes associated with reactor startups (e.g., criticality earlier than estimated). The Cold Shutdown/Refueling IC is CU8.

This condition can be identified using the <u>period</u>-monitors/startup rate monitor. The term "extendedsustained" is used in order to allow exclusion of expected short term positive <u>periods</u>/startup rates from planned control rod movements for <u>PWRs</u>-and <u>BWRs</u>-(such as shutdown bank withdrawal-for <u>PWRs</u>). These short term positive <u>periods</u>/startup rates are the result of the <u>increase</u>-rise in neutron population due to subcritical multiplication.

This condition can be identified using startup rate monitors (NI-31D/32D - Source Range Startup Rate).

Escalation would be by the Fission Product Barrier Matrix, as appropriate to the operating mode at the time of the event, or by Emergency Director Judgment.

Note: This EAL is SU8 following SU6. SU7 is not used in NEI 99-01 Revision 4 and that convention is carried forward here.

KNPP Basis Reference(s):

1. N-0-02 Plant Startup from Hot Shutdown to 35% Power, Rev. AN

SA2

Initiating Condition -- ALERT

Failure of Reactor Protection System Instrumentation to Complete or Initiate an Automatic Reactor Scram-Trip Once a Reactor Protection System Setpoint Has Been Exceeded and Manual Scram-Reactor Trip Was Successful.

Operating Mode Applicability:	Power Operation	
	Startup	
	——Hot Standby	
	Hot Shutdown	

Example-EmergencyEmergency Action Level:

SA2.1. Indication(s) exist that a Reactor Protection System setpoint was exceeded AND

RPS automatic trip did not reduce power to LESS THAN 5%

AND

Any of the following operator actions are successful in reducing power to LESS THAN 5%:

- Use of Manual Reactor Trip push buttons
- De-energizing Busses 33 AND 43

Indication(s) exist that indicate that reactor-protection system setpoint was exceeded and automatic scram did-not-occur. and a successful manual scram occurred.

Basis:

This condition indicates failure of the automatic protection system to scram-trip the reactor. This condition is more than a potential degradation of a safety system in that a front line automatic protection system did not function in response to a plant transient and thus the plant safety has been compromised, and design limits of the fuel may have been exceeded. An Alert is indicated because conditions exist that lead to potential loss of fuel clad or RCS. Reactor protection system setpoint being exceeded, rather than limiting safety system setpoint being exceeded, is specified here because failure of the automatic protection system is the issue. A manual scram-trip is any set of actions by the reactor operator(s) at the reactor-control room consoles which causes control rods to be rapidly inserted into the core and brings the reactor subcritical (e.g., reactor trip button, Alternate-Rod-Insertion). Failure of manual scram-trip would escalate the event to a Site Area Emergency.

Following a successful reactor trip, nuclear power promptly drops to only a few percent of nominal, and then decays away to a level some 8 decades less. Reactor power levels resulting from radioactive fission product decay are never more than a few percent of nominal power and also lower in time. Heat removal safety systems are sized to remove only decay heat and not significant core power. Reactor power levels at or above 5% (in a core that is supposed to be shutdown) are considered an extreme challenge to the Fuel Cladding barrier and warrant a Critical Safety Function Status Tree (CSFST) Subcriticality-Red path priority. The setpoint has been chosen because it is clearly readable on the power range meters. Reactor power levels in the power range are indicated on Mechanical Control Console "B" nuclear instruments NI-41, 42, 43 and 44. KNPP

Following any automatic reactor trip signal, plant procedures prescribe operator insertion of redundant manual trip signals to ensure reactor shutdown is achieved. A successful manual trip is any set of actions by the reactor operator(s) in the Control Room that causes control rods to be rapidly inserted into the core and brings the reactor subcritical. Manual trip includes the procedural direction to deenergize Busses 33 and 43 to ensure rod insertion. Control rod insertion completed from the Rod Drive Equipment Room is not considered a successful manual trip as action is required outside the Control Room. Manual insertion of control rods from the Control Room is not considered rapid insertion that brings the reactor sub-critical.

Note: This EAL is SA2 following SU8. SA1 is not used in NEI 99-01 Revision 4 and that convention is carried forward here.

- 1. E-0 Reactor Trip or Safety Injection, Rev. V
- 2. ES-0.1 Reactor Trip Response, Rev. P

Initiating Condition - ALERT

UNPLANNED Loss of Most or All Safety System Annunciation or Indication in Control Room With Either (1) a SIGNIFICANT TRANSIENT in Progress, or (2) Compensatory Non-Alarming Indicators are Unavailable.

Operating Mode Applicability:	Power Operation	
	Startup	
	Hot Standby Hot Shutdown Intermediate Shutdown	

Example-EmergencyEmergency Action Level:

SA4.1. UNPLANNED loss of most or all (site-specific) annunciators or indicators associated with safety systems for greater-thanGREATER THAN 15 minutes on Mechanical Vertical Panels A, B and C, Mechanical Control Consoles A, B and C, Electrical Vertical Panel and Electrical Control Console

AND

Either of the following: (a or b)

a. A SIGNIFICANT TRANSIENT is in progress.

OR

b. COMPENSATORY NON-ALARMING INDICATIONS are unavailable.

Basis:

This IC and its associated EAL are intended to recognize the difficulty associated with monitoring changing plant conditions without the use of a major portion of the annunciation or indication equipment during a transient. Recognition of the availability of computer based indication equipment is considered (e.g., SPDS, plant computer, etc.).

SIGNIFICANT TRANSIENT includes response to automatic or manually initiated functions such as scramsreactor trips, runbacks involving greater than 25% thermal power change, ECCS injections, or thermal power oscillations of 10% or greater.

COMPENSATORY NON-ALARMING INDICATIONS include the plant process computer (PPCS), SPDS, plant recorders, or plant instrument displays in the control room. If both a major portion of the annunciation system and all computer monitoring are unavailable, the Alert is required.

"Planned" loss of annunciators or indicators includes scheduled maintenance and testing activities.

KNPP

SA4

Quantification of "Most" is arbitrary, however, it is estimated that if approximately 75% of the safety system annunciators or indicators are lost, there is an increased risk that a degraded plant condition could go undetected. It is not intended that plant personnel perform a detailed count of the instrumentation lost but use the value as a judgment threshold for determining the severity of the plant conditions. It is also not intended that the Shift Supervisor-Manager be tasked with a making a judgment decision as to whether additional personnel are required to provide increased monitoring of system operation.

It is further recognized that most-plant designs provides redundant safety system indication powered from separate uninterruptable power supplies. While failure of a large portion of annunciators is more likely than a failure of a large portion of indications, the concern is included in this EAL due to difficulty associated with assessment of plant conditions. The loss of specific, or several, safety system indicators should remain a function of that specific system or component operability status. This will be addressed by the specific Technical Specification. The initiation of a Technical Specification imposed plant shutdown related to the instrument loss will be reported via 10- CFR-CFR 50.72. If the shutdown is not in compliance with the Technical Specification action, the NOUE is based on SU2 "Inability to Reach Required Shutdown Within Technical Specification Limits."

Site-specificThe specified panels for this EAL include annunciators or-and indicators for-this EAL must include those-identified in the Abnormal Operating Procedures, in the Emergency Operating Procedures, and in other EALs (e.g., area, process, and/or effluent rad monitors, etc.).

"Compensatory-non-alarming-indications"-in-this-context-includes-computer-based-information such-as-SPDS. This should include-all-computer-systems-available-for-this-use-depending-on specific-plant-design-and-subsequent-retrofits. If both-a-major-portion-of-the-annunciation-system and all-computer-monitoring are-unavailable, the Alert is required.

Due to the limited number of safety systems in operation during cold shutdown, refueling and defueled modes, no IC is indicated during these modes of operation.

This Alert will be escalated to a Site Area Emergency if the operating crew cannot monitor the transient in progress.

Note: This EAL is SA4 following SA2. SA3 is not used in NEI 99-01 Revision 4 and that convention is carried forward here.

SA5

Initiating Condition - ALERT

AC power capability to essential busses reduced to a single power source for greater thanGREATER THAN 15 minutes such that any additional single failure would result in station blackout.

Operating Mode Applicability:	Power Operation	
	Startup	
·	——Hot Standby	
	Hot Shutdown	
	Intermediate Shutdown	

Example-EmergencyEmergency Action Level:

SA5.1. AC power capability to Bus 5 AND Bus 6 reduced to only one of the following sourcesa single power source for greater than GREATER THAN 15 minutes:

- One emergency diesel generator (A or B)
- TAT
- RAT
- MAT on backfeed

AND

Any additional single failure will result in station blackout.

Basis:

This IC and the associated EALs are intended to provide an escalation from IC SU1, "Loss of All Offsite Power To Essential Busses for Greater Than 15 Minutes." The condition indicated by this IC is the degradation of the offsite and onsite power systems such that any additional single failure would result in a station blackout. This condition could occur due to a loss of offsite power with a concurrent failure of one emergency diesel generator to supply power to its emergency busses. Another related condition could be the-loss-of-all-offsite-power-and-loss-of onsite-emergency diesels with only one train of emergency busses being backfed from the unit main generator, or the loss of onsite emergency diesels with only one train of emergency busses being backfed from offsite power. Offsite power sources include the 345 kVAC system or 138 kVAC system to the Tertiary Auxiliary Transformer (TAT), the 345 kVAC system or 138 kVAC system to the Reserve Auxiliary Transformer (RAT), and the 345 kVAC system to the Main Auxiliary Transformer (MAT) on backfeed through the main transformers. Note that the time required to effect a backfeed to the MAT is likely longer than the fifteen-minute interval. If off--normal plant conditions have already established the backfeed, however, its power to the ESF busses may be considered an offsite power source. Onsite power sources consist of 1A Diesel Generator to Bus 5 and 1B Diesel Generator to Bus 6. Several combinations of power failures could therefore satisfy this EAL. The subsequent loss of this-the single remaining power source would escalate the event to a Site Area

Emergency in accordance with IC SS1, "Loss of All Offsite and Loss of All Onsite AC Power to Essential Busses."

KNPP Basis Reference(s):

- 1. ECA-0.0 Loss of All AC Power, Rev. AB
- 2. USAR Figure 8.2-2, Rev. 16
- 3. USAR Section 8.2.3, Rev. 18
- 4. USAR Section 8.2.4, Rev. 18
- 5. GNP-08.04.01 Shutdown Safety Assessment, Rev. K

At-multi-unit-stations, the EALs should allow credit for operation of installed design features, such as cross-ties or swing diesels, provided that abnormal or emergency operating procedures address their use. However, these stations must also consider the impact of this condition on other shared safety functions in developing the site specific EAL.

SS1

Initiating Condition -- SITE AREA EMERGENCY

Loss of All Offsite Power and Loss of All Onsite AC Power to Essential Busses.

Operating Mode Applicability:

Power Operation Startup –Hot Standby Hot Shutdown Intermediate Shutdown

Example-EmergencyEmergency Action Level:

SS1.1. Loss of ALL offsite-power to Bus 5 AND Bus 6 for GREATER THAN 15 minutes. power-to-(site-specific) transformers.

AND

------Failure of all (site-specific) emergency diesel generators to supply power to Bus 5 AND Bus 6emergency busses.

AND

Failure to restore power to at least one Bus 5 OR Bus 6 emergency bus within 15 (sitespecific) minutes from the time of loss of both offsite and onsite AC power.

Basis:

Loss of all AC power compromises all plant safety systems requiring electric power including RHR, ECCS, Containment Heat Removal and the Ultimate-Heat-SinkService Water System. Prolonged loss of all AC power will cause core uncovering and loss of containment integrity, thus this event can escalate to a General Emergency. The (site-specific)-time-duration-should-be-selected-to exclude transient or momentary power-losses, but should not exceed 15 minutes.

Offsite power sources include the 345 kVAC system or 138 kVAC system to the Tertiary Auxiliary Transformer (TAT), the 345 kVAC or 138 kVAC system to the Reserve Auxiliary Transformer (RAT), and the 345 kVAC system to the Main Auxiliary Transformer (MAT) on backfeed through the main transformers. Note that the time required to effect a backfeed to the MAT is likely longer than the fifteen-minute interval. If off-normal plant conditions have already established the backfeed, however, its power to the ESF busses may be considered an offsite power source. Onsite power sources consist of 1A Diesel Generator to Bus 5 and 1B Diesel Generator to Bus 6.

Escalation to General Emergency is via Fission Product Barrier Degradation or IC SG1, "Prolonged Loss of All Offsite Power and Prolonged Loss of All Onsite AC Power."

Consideration should be given to operable loads necessary to remove decay heat or provide Reactor Vessel makeup capability when evaluating loss of AC power to safety-related 4160 VAC essential-busses. Even though an safety-related 4160 VAC essential-bus may be energized, if necessary loads (i.e., loads that if lost would inhibit decay heat removal capability or Reactor KNPP 6-S-21 10/22/04

Vessel makeup capability) are not operable on the energized bus then the bus should not be considered operable. If this bus was the only energized bus then a Site Area Emergency per SS1 should be declared.

5.GNP-08.04.01-Shutdown Safety-Assessment, Rev.-K

SS2

Initiating Condition -- SITE AREA EMERGENCY

Failure of Reactor Protection System Instrumentation to Complete or Initiate an Automatic Reactor Scram-Trip Once a Reactor Protection System Setpoint Has Been Exceeded and Manual Scram-Reactor Trip Was NOT Successful.

Operating Mode Applicability:	Power Operation
	StartupHot Standby

Example-EmergencyEmergency Action Level:

SS2.1. Indication(s) exist that automatic and manual scram were not successful.Indication(s) exist that automatic and manual trip were NOT successful in reducing power to LESS THAN 5%. Manual Reactor Trips include use of Manual Reactor Trip push buttons or De-energizing Busses 33 AND 43.

Basis:

Automatic and manual scram-trip are not considered successful if action away from the reactor Ceontrol Roomconsole was required to scram-trip the reactor.

Under these conditions, the reactor is producing more heat than the maximum decay heat load for which the safety systems are designed. A Site Area Emergency is indicated because conditions exist that lead to imminent loss or potential loss of both fuel clad and RCS. Although this IC may be viewed as redundant to the Fission Product Barrier Degradation IC, its inclusion is necessary to better assure timely recognition and emergency response. Escalation of this event to a General Emergency would be via Fission Product Barrier Degradation or Emergency Director Judgment ICs.

Automatic or manual reactor trip is considered successful if actions taken (use of Manual Reactor Trip push buttons or De-energizing Busses 33 AND 43) result in reducing reactor power less than 5%. Reactor power levels in the power range are indicated on N-41, 42, 43 and 44. Automatic and manual trips are not considered successful if action away from the Control Room (e.g., Rod Drive Equipment Room) is required to trip the reactor. Manual insertion of control rods from the Control Room is not considered rapid insertion that brings the reactor sub-critical.

KNPP Basis Reference(s):

- 1. E-0 Reactor Trip or Safety Injection, Rev. V
- 2. ES-0.1 Reactor Trip Response, Rev. P
- 3. F-0.1 Subcriticality, Rev. C

SS3

Initiating Condition -- SITE AREA EMERGENCY

Loss of All Vital DC Power.

Operating Mode Applicability:

Power Operation Startup Hot Standby Hot Shutdown Intermediate Shutdown

Example-EmergencyEmergency Action Level:

SS3.1. Loss of aAll vVital DC pPower based on LESS THAN 105 VDC on Train A AND Train B Safeguards DC Distribution Systems for greater-thanGREATER THAN 15 minutes.

Basis:

Loss of all DC power compromises ability to monitor and control plant safety functions. Prolonged loss of all DC power will cause core uncovering and loss of containment integrity when there is significant decay heat and sensible heat in the reactor system. Escalation to a General Emergency would occur by Abnormal Rad Levels/Radiological Effluent, Fission Product Barrier Degradation, or Emergency Director Judgment ICs. Fifteen minutes was selected as a threshold to exclude transient or momentary power losses.

The loss of a safeguards DC train consists of a combination of loss of power to specified DC distribution panels. These panels include: BRA (BRB)-102, and BRA (BRB)-104. In all cases, BRA (BRB)-102 panel indicating less than 105 VDC constitutes a loss of the associated DC distribution train. However, a loss of power to the BRA (BRB) -104 panel, which does not have voltage indication, also constitutes a loss of the associated DC distribution train.

125 VDC safeguard main distribution cabinets (BRA-102 and BRB-102) supply two safeguard subdistribution cabinets (BRA-104 and BRB-104) and provide for connection of safeguard batteries (BRA-101 and BRB-101) to their associated battery chargers (BRA-108 and BRB-108). The combination of low voltages on the specified distribution cabinets results in a total loss of vital 125 VDC power. The 125 VDC safeguards distribution system supplies circuit breaker control power, Control Room alarms, Control Room controls, diesel generator controls, and the Reactor Protection System. The 125 VDC safeguard system is also the standby power source to the AC inverters. BRA-102 and BRB-102 voltage is displayed on Control Room indicators 4494001 and 4494002, respectively. Undervoltage is alarmed on Control Room Sequence of Event Recorder (SER) points 490011196 and 490011200 and annunciators 447101A and 47101B, respectively.

Each of the 125 VDC batteries has been sized to carry the expected shutdown loads following a reactor trip and a loss of all AC power for a period of eight hours without battery terminal voltage falling below 105 VDC. This voltage value therefore incorporates a margin of at least 15 minutes of operation before the onset of inability to operate loads. The nominal battery cell voltage is 2.20 VDC. Low battery terminal voltage activates Control Room SER point 49001832 and annunciator 47105A. The batteries are located in Battery Rooms A and B on the Turbine Building Mezzanine Floor (606 ft el.).

.

:

SS4

Initiating Condition -- SITE AREA EMERGENCY

Complete Loss of Heat Removal Capability.

Operating Mode Applicability:

Power Operation Startup —Hot Standby Hot Shutdown Intermediate Shutdown

Example-EmergencyEmergency Action Level:

SS4.1. Loss of core cooling and heat sink-(PWR).

SS4.1. -- Heat-Capacity-Temperature Limit-Curve exceeded (BWR).

Basis:

This EAL addresses complete loss of functions, including ultimate heat-sinkService Water System, required for hot shutdown with the reactor at pressure and temperature. Reactivity control is addressed in other EALs. For BWRs the loss of heat removal function is indicated by the Heat Removal Capability Temperature Limit Curve being exceeded.

Under these conditions, there is an actual major failure of a system intended for protection of the public. Thus, declaration of a Site Area Emergency is warranted. Escalation to General Emergency would be via Abnormal Rad Levels / Radiological Effluent, Emergency Director Judgment, or Fission Product Barrier Degradation ICs.

KNPP Basis Reference(s):

None

SS6

Initiating Condition -- SITE AREA EMERGENCY

Inability to Monitor a SIGNIFICANT TRANSIENT in Progress.

Operating Mode Applicability:

Power Operation Startup -Hot Standby Hot Shutdown Intermediate Shutdown

Example-EmergencyEmergency Action Level:

SS6.1. a.-Loss of most or all -(site-specific)-annunciators associated with safety systems on Mechanical Vertical Panels A, B and C, Mechanical Control Consoles A, B and C, Electrical Vertical Panel and Electrical Control Console.

AND

SIGNIFICANT TRANSIENT in progress.

AND

b.-COMPENSATORY NON-ALARMING INDICATIONSCompensatory-non-alarming indications are unavailable.

AND

e.-Indications needed to monitor the ability to shut down the reactor, maintain the core cooled, maintain the reactor coolant system intact, and maintain containment intactmonitor-(site-specific) safety functions are unavailable.

AND

d. SIGNIFICANT TRANSIENT in progress.

Basis:

This IC and its associated EAL are intended to recognize the inability of the control room staff to monitor the plant response to a transient. A Site Area Emergency is considered to exist if the control room staff cannot monitor safety functions needed for protection of the public.

SIGNIFICANT TRANSIENT includes response to automatic or manually initiated functions such as reactor trips, runbacks involving greater than 25% thermal power change, ECCS injections, or thermal power oscillations of 10% or greater.

COMPENSATORY NON-ALARMING INDICATIONS include the plant process computer (PPCS), SPDS, plant recorders, or plant instrument displays in the control room.

(Site-specific) annunciators for this EAL should be limited to include those identified in the Abnormal Operating Procedures, in the Emergency Operating Procedures, and in other EALs (e.g., rad monitors, etc.)

"Compensatory non-alarming-indications"-in-this-context-includes-computer-based-information such-as-SPDS. This-should-include-all-computer-systems-available-for-this-use-depending-on specific plant design and subsequent retrofits.

-(Site-specific)-iIndications needed to monitor safety functions necessary for protection of the public must-include control room indications, computer generated indications and dedicated annunciation capability. The specific indications should-beare those used to determine-such functions asmonitor the ability to shut down the reactor, maintain the core cooled, to maintain the reactor coolant system intact, and to maintain containment intact.

"Planned" and "UNPLANNED" actions are not differentiated since the loss of instrumentation of this magnitude is of such significance during a transient that the cause of the loss is not an ameliorating factor.

Quantification of "Most" is arbitrary, however, it is estimated that if approximately 75% of the safety system annunciators or indicators are lost, there is an increased risk that a degraded plant condition could go undetected. It is not intended that plant personnel perform a detailed count of the instrumentation lost but use the value as a judgment threshold for determining the severity of the plant conditions. It is also not intended that the Shift Supervisor be tasked with making a judgment decision as to whether additional personnel are required to provide increased monitoring of system operation.

SYSTEM MALFUNCTION

SG1

Initiating Condition -- GENERAL EMERGENCY

Prolonged Loss of All Offsite Power and Prolonged Loss of All Onsite AC Power to Essential Busses.

Operating	Mode A	pplical	bility:
-----------	--------	---------	---------

Power Operation Startup Hot Standby Hot Shutdown Intermediate Shutdown

Example-EmergencyEmergency Action Level:

SG1.1. Loss of all offsite power to Bus 5 AND Bus 6(site-specific)-transformers

AND

Failure of (site-specific) all emergency diesel generators to supply power to Bus 5 AND Bus 6-emergency busses.

AND

Either of the following: (a or b)

a. Restoration of at least either Bus 5 OR Bus 6 one-within (site-specific) 4 hours is not likely

OR

 b. (Site-Specific) Indication of cContinuing degradation of core cooling based on Fission Product Barrier monitoring- as indicated by a Core Cooling-RED or Core Cooling-ORANGE

Basis:

Loss of all AC power compromises all plant safety systems requiring electric power including RHR, ECCS, Containment Heat Removal and the Ultimate-Heat-SinkService Water System. Prolonged loss of all AC power will lead to loss of fuel clad, RCS, and containment. The (site-specific)4 hours to restore AC power can-beis based on a-the site blackout coping analysis performed in conformance with 10 CFR 50.63 and Regulatory Guide-Guide 1.155, "Station Blackout,"-as available. Four hours includes aAppropriate allowance for offsite emergency response including evacuation of surrounding areas-should-be-considered. Although this IC may be viewed as redundant to the Fission Product Barrier Degradation IC, its inclusion is necessary to better assure timely recognition and emergency response.

KNPP

10/22/04

This IC is specified to assure that in the unlikely event of a prolonged station blackout, timely recognition of the seriousness of the event occurs and that declaration of a General Emergency occurs as early as is appropriate, based on a reasonable assessment of the event trajectory.

Offsite power sources include the 345 kVAC system or 138 kVAC system to the Tertiary Auxiliary Transformer (TAT), the 345 kVAC system or 138 kVAC system to the Reserve Auxiliary Transformer (RAT), and the 345 kVAC system to the Main Auxiliary Transformer (MAT) on backfeed through the main transformers. Time required to effect a backfeed to the MAT is likely longer than the four hours. If shutddown plant conditions have already established the backfeed, however, its power to the ESF busses may be considered an offsite power source. Onsite power sources consist of Diesel Generator A to Bus 5 and Diesel Generator B to Bus 6.

The likelihood of restoring at least one emergency bus should be based on a realistic appraisal of the situation since a delay in an upgrade decision based on only a chance of mitigating the event could result in a loss of valuable time in preparing and implementing public protective actions. In addition, under these conditions, fission product barrier monitoring capability may be degraded. Although it may be difficult to predict when power can be restored, it is necessary to give the Emergency Director a reasonable idea of how quickly (s)he may need to declare a General Emergency based on two major considerations:

- Are there any present indications that core cooling is already degraded to the point that Loss or Potential Loss of Fission Product Barriers is imminent? (Refer to Table s-3-and-4F-1 for | more information.)
- 2. If there are no present indications of such core cooling degradation, how likely is it that power can be restored in time to assure that a loss of two barriers with a potential loss of the third barrier can be prevented?

Thus, indication of continuing core cooling degradation must be based on Fission Product Barrier monitoring with particular emphasis on Emergency Director judgment as it relates to imminent Loss or Potential Loss of fission product barriers and degraded ability to monitor fission product barriers.

SYSTEM MALFUNCTION

SG2

Initiating Condition -- GENERAL EMERGENCY

Failure of the Reactor Protection System to Complete an Automatic Scram-Reactor Trip and Manual Scram-Reactor Trip was NOT Successful and There is Indication of an Extreme Challenge to the Ability to Cool the Core.

Operating Mode Applicability:

Power Operation StartupHot Standby

Example-EmergencyEmergency Action Level:

SG2.1. Indication(s) exist that automatic and manual scram-reactor trip were NOT successful in reducing power to LESS THAN 5%.

Indications exist that automatic and manual scram were not successful.

AND

Either of the following: (a or b)

—a. Indication(s) exists that the core cooling is extremely challenged as indicated by conditions exist for entry into-Core Cooling - RED.

OR

----b. Indication(s) exists that heat removal is extremely challenged as indicated by Heat Sink - RED.

Basis:

Automatic and manual scram-reactor trips are not considered successful if action away from the reactor control console is required to scram-trip the reactor.

Under the conditions of this IC and its associated EALs, the efforts to bring the reactor subcritical have been unsuccessful and, as a result, the reactor is producing more heat than the maximum decay heat load for which the safety systems were designed. Although there are capabilities away from the reactor control-consoleto reduce reactor power, such as emergency boration-in-PWRs, or standby-liquid-control-in-BWRs, the continuing temperature rise indicates that these capabilities are not effective. This situation could be a precursor for a core melt sequence.

For PWRs, the extreme challenge to the ability to cool the core is intended to mean that the core exit temperatures are at or approaching 1200 degrees F or that the reactor vessel water level is below the top of active fuel. For plants using CSFSTs, this EAL equates to a Core Cooling RED condition and an entry into function restoration procedure FR-SC.1. For BWRs, the extreme challenge to the ability to cool the core is intended to mean that the reactor vessel water level cannot be restored and maintained above Minimum Steam Cooling RPV Water Level as described in the EOP bases.

Another consideration is the inability to initially remove heat during the early stages of this sequence. For PWRs, ilf emergency feedwater flow is insufficient to remove the amount of heat required by design from at least one steam generator, an extreme challenge should be considered to exist. For plants using CSFSTs, tThis EAL equates to a Heat Sink RED condition. For BWRs, considerations include inability to remove heat via the main condenser, or via the suppression pool or torus (e.g., due to high pool water temperature).

In the event either of these challenges exist at a time that the reactor has not been brought below the power associated with the safety system design (typically_3_to_5% power) a core melt sequence exists. In this situation, core degradation can occur rapidly. For this reason, the General Emergency declaration is intended to be anticipatory of the fission product barrier matrix declaration to permit maximum offsite intervention time.

Automatic or manual reactor trip is considered successful if actions taken (use of Manual Reactor Trip push buttons or De-energizing Busses 33 AND 43) result in reducing reactor power less than 5%. Reactor power levels in the power range are indicated on N-41, 42, 43 and 44. Automatic and manual trips are not considered successful if action away from the Control Room (e.g., Rod Drive Equipment Room) is required to trip the reactor. Manual insertion of control rods from the Control Room is not considered rapid insertion that brings the reactor sub-critical.

1. PURPOSE

This document provides the detailed set of Emergency Action Levels (EALs) applicable to the Kewaunee Nuclear Plant (KNP) and the associated Technical Bases using the EAL development methodology found in NEI 99-01 Revision 4 [Ref. 2.1]. Personnel responsible for implementation of EPIP-AD-02 "Emergency Class Determination" [Ref. 2.2], and the Emergency Action Level Matrix [Ref. 2.3] may use this document as a technical reference and an aid in EAL interpretation.

The primary tool for determining the emergency classification level is the Emergency Action Level Matrix. The user of the Emergency Action Level Matrix may (but is not required to) consult the EAL Technical Basis Document in order to obtain additional information concerning the EALs under classification consideration.

2. **REFERENCES**

- 2.1 NEI 99-01 Revision 4, Methodology for Development of Emergency Action Levels, January 2003
- 2.2 KNPP Technical Specifications, Section 1.0 Definitions, Amendments 162, 172 and 176.

3. **DISCUSSION**

3.1 Background

EALs are the plant-specific indications, conditions or instrument readings that are utilized to classify emergency conditions defined in the KNPP Emergency Plan.

In 1992, the NRC endorsed NUMARC/NESP-007 "Methodology for Development of Emergency Action Levels" as an alternative to NUREG 0654 EAL guidance.

NEI 99-01 (NUMARC/NESP-007) Revision 4 represents the most recent NRC endorsed methodology per RG 1.101 Rev 4, "Emergency Planning and Preparedness for Nuclear Power Reactors." Enhancements over earlier revisions included:

- Consolidating the system malfunction initiating conditions and example emergency action levels which address conditions that may be postulated to occur during plant shutdown conditions.
- Addressing initiating conditions and example emergency action levels that fully address conditions that may be postulated to occur at permanently Defueled Stations and Independent Spent Fuel Storage Installations.
- Simplifying the fission product barrier EAL threshold for a Site Area Emergency.

Using NEI 99-01 Rev. 4, KNPP conducted an EAL implementation upgrade project that produced the EALs discussed herein. While the upgraded EALs are site-specific, an objective of the project was to ensure to the extent possible EAL conformity and consistency between the NMC plant sites.

3.2 Key Definitions in EAL Methodology

The following definitions apply to the generic EAL methodology:

EMERGENCY CLASS: One of a minimum set of names or titles, established by the Nuclear Regulatory Commission (NRC), for grouping of normal nuclear power plant conditions according to (1) their relative radiological seriousness, and (2) the time sensitive onsite and off site radiological emergency preparedness actions necessary to respond to such conditions. The existing radiological emergency classes, in ascending order of seriousness, are called:

- Unusual Event (UE)
- Alert
- Site Area Emergency (SAE)
- General Emergency (GE)

Section 3.3 provides further discussion of the emergency classes.

INITIATING CONDITION (IC): One of a predetermined subset of nuclear power plant conditions when either the potential exists for a radiological emergency, or such an emergency has occurred.

- An IC is an emergency condition which sets it apart from the broad class of conditions that may or may not have the potential to escalate into a radiological emergency.
- It can be a continuous, measurable function that is outside technical specifications, such as elevated RCS temperature or falling reactor coolant level (a symptom).
- It also encompasses occurrences such as FIRE (an event) or reactor coolant pipe failure (an event or a barrier breach).

EMERGENCY ACTION LEVEL (EAL): A pre determined, site-specific, observable threshold for a plant Initiating Condition that places the plant in a given emergency class. An EAL can be: an instrument reading; an equipment status indicator; a measurable parameter (onsite or offsite); a discrete, observable event; results of analyses; entry into specific emergency operating procedures; or another phenomenon which, if it occurs, indicates entry into a particular emergency class.

- There are times when an EAL will be a threshold point on a measurable continuous function, such as a primary system coolant leak that has exceeded technical specifications.
- At other times, the EAL and the IC will coincide, both identified by a discrete event that places the plant in a particular emergency class.
- 3.3 Recognition Categories

ICs and EALs are grouped in one of several categories. This classification scheme incorporates symptom-based, event-based, and barrier-based ICs and EALs.

- R Abnormal Rad Levels/Radiological Effluent
- C Cold Shutdown./ Refueling System Malfunction
- F Fission Product Barrier Degradation
- H Hazards
- S System Malfunction

Some recognition categories are further divided into one or more subcategories depending on the types and number of plant conditions that dictate emergency classifications. An EAL may or may not exist for each subcategory at all four classification levels. Similarly, more than one EAL may exist for a subcategory in a given emergency classification when appropriate (i.e., no EAL at the General Emergency level but three EALs at the Unusual Event level).

3.4 Emergency Class Descriptions

There are three considerations related to the emergency classes. These are:

- The potential impact on radiological safety, either as now known or as can be reasonably projected.
- How far the plant is beyond its predefined design, safety and operating envelopes.
- Whether or not conditions that threaten health are expected to be confined to within the site boundary.

The ICs deal explicitly with radiological safety affect by escalating from levels corresponding to releases within regulatory limits to releases beyond EPA Protective Action Guideline (PAG) plume exposure levels.

UNUSUAL EVENT: Events are in process or have occurred which indicate a potential degradation of the level of safety of the plant. No releases of radioactive material requiring offsite response or monitoring are expected unless further degradation of safety systems occurs.

- Potential degradation of the level of safety of the plant is indicated primarily by exceeding plant technical specification Limiting Condition of Operation (LCO) allowable action statement time for achieving required mode change.
- Precursors of more serious events may be included because precursors represent a potential degradation in the level of safety of the plant.
- Minor releases of radioactive materials are included. In this emergency class, however, releases do not require monitoring or offsite response (e.g., dose consequences of less than 10 millirem).

ALERT: Events are in process or have occurred which involve an actual or potential substantial degradation of the level of safety of the plant. Any releases are expected to be limited to small fractions of the EPA Protective Action Guideline exposure levels.

SITE AREA EMERGENCY: Events are in progress or have occurred which involve actual or likely major failures of plant functions needed for protection of the public. Any releases are not expected to result in exposure levels which exceed EPA Protective Action Guideline (PAG) exposure levels beyond the site boundary.

- The discriminator (threshold) between Site Area Emergency and General Emergency is whether or not the EPA PAG plume exposure levels are expected to be exceeded outside the site boundary.
- This threshold, in addition to dynamic dose assessment considerations discussed in the EAL guidelines, clearly addresses NRC and offsite emergency response agency concerns as to timely declaration of a General Emergency.

GENERAL EMERGENCY: Events are in process or have occurred which involve actual or imminent substantial core degradation or melting with potential for loss of containment integrity. Releases can be reasonably expected to exceed EPA Protective Action Guideline exposure levels offsite for more than the immediate site area.

- The bottom line for the General Emergency is whether evacuation or sheltering of the general public is indicated based on EPA PAGs and, therefore, should be interpreted to include radionuclide release regardless of cause.
- To better assure timely notification, EALs in this category are primarily expressed in terms of plant function status, with secondary reliance on dose projection. In terms of fission product barriers, loss of two barriers with loss or potential loss of the third barrier constitutes a General Emergency.
- 3.5 Operating Mode Applicability

Technical Specifications [Ref. 2.4] provides definitions for the following operating modes:

1 Operating (OP)

Reactivity $\Delta k/k$ is LESS THAN Technical Specification minimum required (0.25%) and EQUAL TO OR GREATER than 2% fission power.

2 Hot Standby (HSB)

Reactivity $\Delta k/k$ is LESS THAN Technical Specification minimum required (0.25%) and LESS THAN 2% fission power.

3 Hot Shutdown (HSD)

Reactivity $\Delta k/k$ as specified in the Core Operating Limits Report with coolant temperature (Tavg) GREATER THAN OR EQUAL TO 540°F.

4 Intermediate Shutdown (ISD)

Reactivity $\Delta k/k$ as specified in the Core Operating Limits Report with coolant temperature (Tavg) LESS THAN 540°F and GREATER THAN 200°F.

5 Cold Shutdown (CSD)

Reactivity $\Delta k/k$ GREATER THAN OR EQUAL TO Technical Specification minimum required (-1%) with coolant temperature (Tavg) LESS THAN OR EQUAL TO 200°F.

6 <u>Refueling (REF)</u>

Reactivity $\Delta k/k$ GREATER THAN OR EQUAL TO Technical Specification minimum required for refueling operations (-5%) and coolant temperature (Tavg) LESS THAN OR EQUAL TO 140°F.

In addition to the Technical Specification operating modes, NEI 99-01 [Ref. 1] defines the following additional mode:

D <u>Defueled</u>

All reactor fuel removed from Reactor Vessel (full core off load during refueling or extended outage)

The plant operating mode that exists at the time that the event occurs (prior to any protective system or operator action is initiated in response to the condition) should be compared to the mode applicability of the EALs. If a lower or higher plant operating mode is reached before the emergency classification is made, the declaration shall be based on the mode that existed at the time the event occurred.

Recognition categories are associated with the operating modes listed in the following matrix:

	Recognition Category				
Mode	R	С	F	н	S
Operations	Х		X	X	Х
Hot Standby	Х		X	X	Х
Hot Shutdown	x		X	X	Х
Intermediate Shutdown	Х		X	X	х
Cold Shutdown	Х	X		x	
Refueling	х	x		X	
Defueled	Х	x		X	

3.6 Fission Product Barriers

Many of the EALs derived from the NEI methodology are fission product barrier based. That is, the conditions that define the EALs are based upon loss of or potential loss of one or more of the three fission product barriers. "Loss" and "potential loss" signify the relative damage and threat of damage to the barrier. "Loss" means the barrier no longer assures containment of radioactive materials and "potential loss" means imminent loss of the barrier.

The primary fission product barriers are:

- <u>Fuel Cladding (FC)</u>: Zirconium tubes which house the ceramic uranium oxide pellets along with the end plugs which are welded into each end of the fuel rods comprise the FC barrier.
- <u>Reactor Coolant System (RCS)</u>: The reactor vessel shell, vessel head, vessel nozzles and penetrations and all primary systems directly connected to the reactor vessel up to the first containment isolation valve comprise the RCS barrier.
- <u>Containment (CMT)</u>: The vapor containment structure and all isolation valves required to maintain containment integrity under accident conditions comprise the Containment barrier.
- 3.7 Emergency Classification Based on Fission Product Barrier Degradation

The following criteria are the bases for event classification related to fission product barrier loss or challenge:

• Unusual Event:

Any loss or any potential loss of Containment

• <u>Alert</u>:

Any loss or any potential loss of either Fuel Cladding or RCS

• <u>Site Area Emergency</u>:

Loss or potential loss of any two barriers

• <u>General Emergency</u>:

Loss of any two barriers and loss or potential loss of third barrier

3.8 EAL Relationship to EOPs and Critical Safety Function Status

Where possible, the EALs have been made consistent with and utilize the conditions defined in the Critical Safety Function Status Trees (CSFSTs). While the symptoms that drive operator actions specified in the CSFSTs are not indicative of <u>all</u> possible conditions which warrant emergency classification, they define the symptoms, independent of initiating events, for which reactor plant safety and/or fission product barrier integrity are threatened. Where these symptoms are clearly representative of one of the NEI Initiating Conditions, they have been utilized as an EAL. This permits rapid classification of emergency situations based on plant conditions without the need for additional evaluation or event diagnosis. Although some of the EALs presented here are based on conditions defined in the CSFSTs, classification of emergencies using these EALs is not dependent upon Emergency Operating Procedures (EOP) entry or execution. The EALs can be utilized independently or in conjunction with the EOPs.

3.9 Symptom Based vs. Event Based Approach

To the extent possible, the EALs are symptom based. That is, the action level is defined by values of key plant operating parameters that identify emergency or potential emergency conditions. This approach is appropriate because it allows the full scope of variations in the types of events to be classified as emergencies. But, a purely symptom based approach is not sufficient to address all events for which emergency classification is appropriate. Particular events to which no predetermined symptoms can be ascribed have also been utilized as EALs since they may be indicative of potentially more serious conditions not yet fully realized.

Category R - Abnormal Rad Levels/Radiological Effluent and Category F - Fission Product Barrier Degradation are primarily symptom-based. The symptoms are indicative of actual or potential degradation of either fission product barriers or personnel safety.

Other categories tend to be event-based. For example, System Malfunctions are abnormal and emergency events associated with vital plant system failures, while Hazards are those non-plant system related events that have affected or may affect plant safety.

3.10 Treatment of Emergency Class Upgrading

The emergency class is based on the highest EAL reached. For example, two Alerts remain in the Alert category. Or, an Alert and a Site Area Emergency is a Site Area Emergency.

3.11 Classifying Transient Events

For some events, the condition may be corrected before a declaration has been made. For example, an emergency classification is warranted when automatic and manual actions taken within the control room do not result in a required reactor trip. However, it is likely that actions taken outside of the control room will be successful, probably before the Emergency Director classifies the event. The key consideration in this situation is to determine whether or not further plant damage occurred while the corrective actions were being taken. In some situations, this can be readily determined. In other situations, further analyses (e.g., coolant sampling) may be necessary. In general, observe the following guidance: Classify the event as indicated and terminate the emergency once assessment shows that there were no consequences from the event and other termination criteria are met. For example, a momentary event, such as an ATWS or an earthquake, requires declaration even though the condition may have been resolved by the time the declaration is made.

- An ATWS represents a failure of a front line Reactor Protection System (RPS) designed to protect the health and safety of the public.
- The affect of an earthquake on plant equipment and structures may not be readily apparent until investigations are conducted.

There may be cases in which a plant condition that exceeded an EAL threshold was not recognized at the time of occurrence, but is identified well after the condition has occurred (e.g., as a result of routine log or record review) and the condition no longer exists. In these cases, an emergency should not be declared. Reporting requirements of 10 CFR 50.72 are applicable and the guidance of NUREG-1022, Rev. 1, Section 3 should be applied.

3.12 Imminent EAL Thresholds

Although the majority of the EALs provide very specific thresholds, the Emergency Director must remain alert to events or conditions that lead to the conclusion that exceeding the EAL threshold is imminent. If, in the judgment of the Emergency Director, an imminent situation is at hand, the classification should be made as if the thresholds has been exceeded. While this is particularly prudent at the higher emergency classes (as the early classification may provide for more effective implementation of protective measures), it is nonetheless applicable to all emergency classes. Explicit EALs, specifying use of Emergency Director judgment, are given in the Hazards and Fission Product Barrier Degradation categories.

4. TECHNICAL BASES INFORMATION

4.1 Recognition Category Organization

The technical bases of the EALs are provided under Recognition Categories R, C, F, H and S of this document. A table summarizing the Initiating Conditions introduces each category. The tables provide an overview of how the ICs are related under each emergency class. ICs within each category are listed according to classification (as applicable) in the following order: Unusual Event, Alert, Site Area Emergency, and General Emergency.

For Recognition Category F, Table F-0 defines the emergency classifications associated with barrier loss and potential loss. Table F-1 lists the thresholds associated with the loss and potential loss of each fission product barrier. The presentation method shown for Table F-1 was chosen to clearly show the synergism among the EALs and to support more accurate dynamic assessments. Basis discussion of the thresholds immediately follows Table F-1.

4.2 Initiating Condition Structure

ICs in Recognition Categories R, C, H and S are structured in the following manner:

- Recognition Category Title
- IC Identifier:
 - o First character identifies the category by letter (R, C, H and S)
 - Second character identifies the emergency classification level (U for Unusual Event, A for Alert, S for Site Area Emergency, and G for General Emergency)
 - Third character is the numerical sequence as given in Revision 4 of NEI 99-01 [Ref. 1] (e.g., SA2). Due to document revisions, certain NEI ICs have been deleted, leaving gaps in the numerical sequence.
- Emergency Class: Unusual Event, Alert, Site Area Emergency, or General Emergency
- IC Description
- Operating Mode Applicability: Refers to the operating mode during which the IC/EAL is applicable

- Emergency Action Level(s): EALs are the conditions applicable to the criteria of the IC and are used to determine the need to classify an event/condition. If more than one EAL is applicable to an IC, emergency classification is required when any EAL within the IC reaches the EAL threshold. To clarify this intent, ICs with multiple EALs include a parenthetical phrase in the EAL title line, indicating that each constitutes an emergency classification. For example, the phrase "(RA1.1 or RA1.2)" indicates that either EAL is a Notification of Unusual Event.
- Basis: Provides information that explains the IC and EAL(s). Plant source document references are provided as needed to substantiate site-specific information included in the EALs and bases.

4.3 EAL Identification

The EAL identifier is the IC identifier followed by a period and sequence number (e.g., RU1.1, RU1.2, etc.). If only one EAL is assigned to an IC, the EAL is given the number one.

The primary purpose of the EAL identifier is to uniquely distinguish each classifiable condition. Secondary purposes are to assist location of an EAL within the EAL classification scheme and to announce the emergency classification level.

5. **DEFINITIONS**

In the ICs and EALs, selected words are in uppercase print. These words are defined terms. Definitions are provided below.

AFFECTING SAFE SHUTDOWN: event in progress has adversely affected functions that are necessary to bring the plant to and maintain it in the applicable HOT or COLD SHUTDOWN condition. Plant condition applicability is determined by Technical Specification LCOs in effect.

Example 1: Event causes damage that results in entry into an LCO that requires the plant to be placed in HOT SHUTDOWN. HOT SHUTDOWN is achievable, but COLD SHUTDOWN is not. This event is not "AFFECTING SAFE SHUTDOWN."

Example 2: Event causes damage that results in entry into an LCO that requires the plant to be placed in COLD SHUTDOWN. HOT SHUTDOWN is achievable, but COLD SHUTDOWN is not. This event is "AFFECTING SAFE SHUTDOWN."

BOMB: an explosive device suspected of having sufficient force to damage plant systems or structures.

CIVIL DISTURBANCE: a group of unexpected or unauthorized individuals violently protesting station operations or activities at the site.

CONFINEMENT BOUNDARY: the barrier(s) between areas containing radioactive substances and the environment.

CONTAINMENT CLOSURE: defined by N-CCI-56A, "Open Containment Boundary Tracking".

EXPLOSION: a rapid, violent, unconfined combustion, or catastrophic failure of pressurized equipment that imparts energy of sufficient force to potentially damage permanent structures, systems, or components.

EXTORTION: an attempt to cause an action at the station by threat of force.

FAULTED: a steam generator, the existence of secondary side leakage that results in an uncontrolled decrease in steam generator pressure or the steam generator being completely depressurized.

FIRE: combustion characterized by heat and light. Sources of smoke such as slipping drive belts or overheated electrical equipment do not constitute FIREs. Observation of flame is preferred but is NOT required if large quantities of smoke and heat are observed.

HOSTAGE: a person(s) held as leverage against the station to ensure that demands will be met by the station.

HOSTILE FORCE: one or more individuals who are engaged in a determined assault, overtly or by stealth and deception, equipped with suitable weapons capable of killing, maiming, or causing destruction.

KNPP

IMMEDIATELY DANGEROUS TO LIFE AND HEALTH (IDLH): A condition that either poses an immediate threat to life and health or an immediate threat of severe exposure to contaminants which are likely to have adverse delayed effects on health.

INTRUSION / INTRUDER: person(s) present in a specified area without authorization. Discovery of a BOMB in a specified area is indication of INTRUSION into that area by a HOSTILE FORCE.

LOWER FLAMMABILITY LIMIT (LFL): The minimum concentration of a combustible substance that is capable of propagating a flame through a homogenous mixture of the combustible and a gaseous oxidizer.

NORMAL PLANT OPERATIONS: activities at the plant site associated with routine testing, maintenance, or equipment operations, in accordance with normal operating or administrative procedures. Entry into abnormal or emergency operating procedures, or deviation from normal security or radiological controls posture, is a departure from NORMAL PLANT OPERATIONS.

PROTECTED AREA: boundary within the security isolation zone.

RUPTURED: In a steam generator, existence of primary-to-secondary leakage of a magnitude sufficient to require or cause a reactor trip and safety injection.

SABOTAGE: deliberate damage, misalignment, or mis-operation of plant equipment with the intent to render the equipment inoperable. Equipment found tampered with or damaged due to malicious mischief may NOT meet the definition of SABOTAGE until this determination is made by security supervision.

SIGNIFICANT TRANSIENT: an UNPLANNED event involving one or more of the following: (1) automatic turbine runback >25% thermal reactor power, (2) electrical load rejection >25% full electrical load, (3) Reactor Trip, (4) Safety Injection Activation, or (5) thermal power oscillations >10%.

STRIKE ACTION: a work stoppage within the PROTECTED AREA by a body of workers to enforce compliance with demands. The STRIKE ACTION must threaten to interrupt NORMAL PLANT OPERATIONS.

UNPLANNED: A parameter change or an event that is not the result of an intended evolution and requires corrective or mitigative actions.

VALID: An indication, report, or condition is considered to be VALID when it is verified by (1) an instrument channel check, or (2) indications on related or redundant indicators, or (3) by direct observation by plant personnel, such that doubt related to the indicator operability, the condition existence, or the report accuracy is removed. Implicit in this definition is the need for timely assessment.

VISIBLE DAMAGE: damage to equipment or structure that is readily observable without measurements, testing, or analysis. Damage is sufficient to cause concern regarding the continued operability or reliability of affected safety structure, system, or component. Example damage includes: deformation due to heat or impact, denting, penetration, rupture, cracking, paint blistering. Surface blemishes (e.g., paint chipping, scratches) should not be included.

VITAL AREA: Area within the PROTECTED AREA, which contains equipment, systems, components, or material; the failure, destruction, or release of which could directly or indirectly endanger the public health and safety by exposure to radiation.

6. EMERGENCY ACTION LEVEL CATEGORIES

R - Abnormal Rad Levels/Radiological Effluent

C - Cold Shutdown / Refueling System Malfunction

ABNORMAL RAD LEVELS/RADIOLOGICAL EFFLUENT

RU1

Initiating Condition -- UNUSUAL EVENT

Any UNPLANNED Release of Gaseous or Liquid Radioactivity to the Environment that Exceeds Two Times the Offsite Dose Calculation Manual for 60 Minutes or Longer.

Operating Mode Applicability: All

Emergency Action Levels: (RU1.1 or RU1.2 or RU1.3)

RU1.1. VALID reading on any effluent monitor that is GREATER THAN two times the alarm setpoint established by a current radioactivity discharge permit for 60 minutes or longer.

Auxiliary Building	Action Value
R-13 Aux. Bldg. Vent Exhaust	2.61E+05 cpm
R-14 Aux. Bidg. Vent Exhaust	2.62E+05 cpm
Reactor Building	
R-12 Containment Gas	4.41E+05 cpm
R-21 Containment Vent	4.40E+05 cpm
Liquid Radwaste	
R-18 Waste Disposal System Liquid	2 X Calculated ODCM Setpoint

RU1.2. VALID reading on one or more of the following radiation monitors that is GREATER THAN the reading shown for 60 minutes or longer.

Liquid Radwaste	Action Value
R-16 Containment FCU SW Return	3.38E+05 cpm
R-19 S/Ġ Blowdown Liquid	2.58E+06 cpm
R-20 Aux Bldg SW Return	1.03E+05 cpm

RU1.3. Confirmed sample analyses for gaseous or liquid release indicates concentrations or release rates, with a release duration of 60 minutes or longer, in excess of two times the ODCM limit.

Basis:

This IC addresses a potential or actual decrease in the level of safety of the plant as indicated by a radiological release that exceeds regulatory commitments for an extended period of time. KNPP incorporates features intended to control the release of radioactive effluents to the environment. Further, there are administrative controls established to prevent unintentional releases, or control and monitor intentional releases. These controls are located in the Offsite Dose Calculation

KNPP

Manual (ODCM) [Ref. 2, 3]. The occurrence of extended, uncontrolled radioactive releases to the environment is indicative of a degradation in these features and/or controls.

The ODCM multiples are specified in ICs RU1 and RA1 only to distinguish between non-emergency conditions, and from each other. While these multiples obviously correspond to an offsite dose or dose rate, the emphasis in classifying these events is the degradation in the level of safety of the plant, NOT the magnitude of the associated dose or dose rate. Releases should not be prorated or averaged. For example, a release exceeding 4x ODCM for 30 minutes does not meet the threshold for this IC.

UNPLANNED, as used in this context, includes any release for which a radioactivity discharge permit was not prepared, or a release that exceeds the conditions (e.g., minimum dilution flow, maximum discharge flow, alarm setpoints, etc.) on the applicable permit. The Emergency Director should not wait until 60 minutes has elapsed, but should declare the event as soon as it is determined that the release duration has or will likely exceed 60 minutes. Also, if an ongoing release is detected and the starting time for that release is unknown, the Emergency Director should, in the absence of data to the contrary, assume that the release has exceeded 60 minutes.

RU1.1 addresses radioactivity releases, that for whatever reason, cause effluent radiation monitor readings to exceed two times the ODCM limit and releases are not terminated within 60 minutes. The "UE" values are two times the monitor high alarm setpoints or ODCM release limits. The setpoints are established to ensure the ODCM release limits are not exceeded [Ref. 2, 3]. These alarm setpoints may be associated with a planned batch release, or a continuous release path. In either case, the setpoint is established by the ODCM to warn of a release that is not in compliance with the ODCM. Indexing the EAL threshold to the ODCM setpoints in this manner insures that the EAL threshold will never be less than the setpoint established by a specific discharge permit. Each liquid discharge permit includes a value for R-18, calculated in accordance with the ODCM that will vary based on the discharge flow rate. Therefore 2 X Calculated ODCM Setpoint was used as the threshold. Escalation will be based on radiation readings increasing per the following:

Normal Effluent Release Monitor Classification Thresholds					
Monitor	GE	SAE	Alert	UE	
Auxiliary Building			•		
01-05 Aux. Bldg. SPING Lo Range					
01-07 Aux. Bldg. SPING Mid Range	1.00E+05 cpm	1.00E+04 cpm			
01-09 Aux. Bldg. SPING Hi Range	1.00E+02 cpm	1.00E+01 cpm			
R-13 Aux. Bldg. Vent Exhaust			2.61E+07 cpm	2.61E+05 cpm	
R-14 Aux. Bldg. Vent Exhaust			2.62E+07 cpm	2.62E+05 cpm	
Reactor Building		•			
02-05 Rx Bldg. Vent SPING Lo Range					
02-07 Rx Bldg. Vent SPING Mid Range	2.00E+04 cpm	2.00E+03 cpm			
02-09 Rx Bldg. Vent SPING Hi Range	2.00E+01 cpm		· - ·		
R-12 Containment Gas		 ·	4.41E+07 cpm	4.41E+05 cpm	
R-21 Containment Vent			4.40E+07 cpm	4.40E+05 cpm	
Liguid Radwaste					
R-18 Waste Disposal System Liquid	N/A	N/A	200 X Calculated ODCM Setpoint	2 X Calculated ODCM Setpoint	

RU1.2 is intended for effluent monitoring on non-routine release pathways for which a discharge permit would not normally be prepared. The ODCM establishes a methodology for determining effluent radiation monitor setpoints. The ODCM specifies default source terms and, for gaseous releases, prescribes the use of pre-determined annual average meteorology in the most limiting downwind sector for showing compliance with the regulatory commitments. These monitor reading EALs have been determined using this methodology. The "UE" values are two times the monitor high alarm setpoints or ODCM release limits. The setpoints are established to ensure the ODCM release limits are not exceeded [Ref. 2, 3]. Escalation will be based on radiation readings increasing per the following:

Abnormal Effluent Release Monitor Classification Thresholds				
Monitor	GE	SAE	Alert	UE
Main Steam Line (PORV)				
R-31 'A' Steamline Lo Range	1.77E+03 mR/hr	1.77E+02 mR/hr		
R-32 'A' Steamline High Range	1.77E+00 R/hr			
R-33 'B' Steamline Lo Range	1.77E+03 mR/hr	1.77E+02 mR/hr		
R-34 'B' Steamline High Range	1.77E+00 R/hr	—		
Main Steam Line (SG Safety)				
R-31 'A' Steamline Lo Range	8.30E+02 mR/hr	8.30E+01 mR/hr		
R-32 'A' Steamline High Range				
R-33 'B' Steamline Lo Range	8.30E+02 mR/hr	8.30E+01 mR/hr		
R-34 'B' Steamline High Range		—		
Liquid Radwaste		<u>.</u>		
R-16 Containment Fcu SW Return	N/A	N/A	3.38E+07 cpm	3.38E+05 cpm
R-19 S/G Blowdown Liquid	N/A	N/A	2.58E+08 cpm	2.58E+06 cpm
R-20 Aux Bldg SW Return	N/A	N/A	1.03E+07 cpm	1.03E+05 cpm

RU1.3 addresses uncontrolled releases that are detected by sample analyses, particularly on unmonitored pathways, e.g., spills of radioactive liquids into storm drains, heat exchanger leakage in lake water systems, etc.

RU1.1 and RU1.2 directly correlate with the IC since annual average meteorology is required to be used in showing compliance with the ODCM and is used in calculating the alarm setpoints. The fundamental basis of this IC is NOT a dose or dose rate, but rather the degradation in the level of safety of the plant implied by the uncontrolled release.

ABNORMAL RAD LEVELS/RADIOLOGICAL EFFLUENT

RU2

Initiating Condition -- UNUSUAL EVENT

Unexpected Rise in Plant Radiation.

Operating Mode Applicability: All

Emergency Action Levels: (RU2.1 or RU2.2)

RU2.1. VALID indication of uncontrolled water level lowering in the reactor refueling cavity, spent fuel pool, or fuel transfer canal with all irradiated fuel assemblies remaining covered by water as indicated by Spent Fuel Pool low water level alarm setpoint (3 ft 4 in. below floor, SER 159/160) **OR** visual observation

AND

Any UNPLANNED VALID Direct Area Radiation Monitor reading rises as indicated by:

- R-2 Containment Area ALERT Alarm
- R-5 Fuel Handling Area ALERT Alarm
- R-10 New Fuel Pit Area ALERT Alarm
- RU2.2. Any UNPLANNED VALID Area Radiation Monitor reading rises by a factor of 1000 over normal* levels. *Normal levels can be considered as the highest reading in the past twenty-four hours

"Normal levels can be considered as the highest reading in the past twenty-four hours excluding the current peak value.

Basis:

This IC addresses increased radiation levels as a result of water level decreases above the Reactor Vessel flange or events that have resulted, or may result, in unexpected increases in radiation dose rates within plant buildings. These radiation increases represent a loss of control over radioactive material and may represent a potential degradation in the level of safety of the plant.

In light of Reactor Cavity Seal failure incidents at two different PWRs and loss of water in the Spent Fuel Pit/Fuel Transfer Canal at a BWR, explicit coverage of these types of events via RU2.1 is appropriate given their potential for increased doses to plant staff. Classification as an UE is warranted as a precursor to a more serious event. Indications include instrumentation such as water level and local area radiation monitors, and personnel (e.g., refueling crew) reports. If available, security video cameras may allow remote observation. Depending on available level instrumentation, the declaration threshold may need to be based on indications of water makeup rate or decrease in refueling water storage tank level.

While a radiation monitor could detect an increase in dose rate due to a drop in the water level, it might not be a reliable indication of whether or not the fuel is covered. For example, the reading on an area radiation monitor located on the refueling bridge may increase due to planned evolutions such as head lift, or even a fuel assembly being raised in the manipulator mast. Generally, increased radiation monitor indications will need to combined with another indicator (or personnel report) of water loss. For refueling events where the water level drops below the Reactor Vessel flange classification would be via CU2. This event escalates to an Alert per IC RA2

if irradiated fuel outside the reactor vessel is uncovered. For events involving irradiated fuel in the reactor vessel, escalation would be via the Fission Product Barrier Matrix for events in Operating through Intermediate Shutdown operating modes.

The Spent Fuel Pool (SFP) low level alarm is actuated by LA-16640-02 (SER 159) and LA-16641-02 (SER 160) at 3 ft 4 in. below floor level. The North (A) and South (B) Spent Fuel Pools are located in the Auxiliary Building refueling area. The pools can be isolated from each other by a removable gate, which is normally removed. The top of each pool is at 649 ft 6 in. el. and the bottom is at 608 ft el. Fuel occupies the bottom 14 ft. [Ref. 3].

RU2.2 addresses UNPLANNED increases in in-plant radiation levels that represent a degradation in the control of radioactive material, and represent a potential degradation in the level of safety of the plant. This event escalates to an Alert per IC RA3 if the increase in dose rates impedes personnel access necessary for safe operation.

*Normal levels can be considered as the highest reading in the past twenty-four hours excluding the current peak value.

ABNORMAL RAD LEVELS/RADIOLOGICAL EFFLUENT

Initiating Condition -- ALERT

Any UNPLANNED Release of Gaseous or Liquid Radioactivity to the Environment that Exceeds 200 Times the Offsite Dose Calculation Manual for 15 Minutes or Longer.

Operating	Mode	Applicability:	All
-----------	------	----------------	-----

- **Emergency Action Levels:** (RA1.1 or RA1.2 or RA1.3)
- RA1.1. VALID reading on any effluent monitor GREATER THAN 200 times the alarm setpoint established by a current radioactivity discharge permit for 15 minutes or longer.

Auxiliary Building	Action Value
R-13 Aux. Bldg. Vent Exhaust	2.61E+07 cpm
R-14 Aux. Bldg. Vent Exhaust	2.62E+07 cpm
Reactor Building	
R-12 Containment Gas	4.41E+07 cpm
R-21 Containment Vent	4.40E+07 cpm
Liquid Radwaste	
R-18 Waste Disposal System Liquid	200 X Calculated ODCM Setpoint

RA1.2. VALID reading on one or more of the following radiation monitors GREATER THAN the reading shown for 15 minutes or longer:

Liquid Radwaste	Action Value
R-16 Containment FCU SW Return	3.38E+07 cpm
R-19 S/G Blowdown Liquid	2.58E+08 cpm
R-20 Aux Bldg SW Return	1.03E+07 cpm

RA1.3. Confirmed sample analyses for gaseous or liquid release indicate concentrations or release rates, with a release duration of 15 minutes or longer, in excess of 200 times ODCM limit.

Basis:

This IC addresses a potential or actual decrease in the level of safety of the plant as indicated by a radiological release that exceeds regulatory commitments for an extended period of time. KNPP incorporates features intended to control the release of radioactive effluents to the environment. Further, there are administrative controls established to prevent unintentional releases, or control and monitor intentional releases. These controls are located in the Offsite Dose Calculation

KNPP

RA1

Manual (ODCM). The occurrence of extended, uncontrolled radioactive releases to the environment is indicative of a degradation in these features and/or controls.

The ODCM multiples are specified in ICs RU1 and RA1 only to distinguish between non-emergency conditions, and from each other. While these multiples obviously correspond to an offsite dose or dose rate, the emphasis in classifying these events is the degradation in the level of safety of the plant, NOT the magnitude of the associated dose or dose rate. Releases should not be prorated or averaged.

UNPLANNED, as used in this context, includes any release for which a radioactivity discharge permit was not prepared, or a release that exceeds the conditions (e.g., minimum dilution flow, maximum discharge flow, alarm setpoints, etc.) on the applicable permit. The Emergency Director should not wait until 15 minutes has elapsed, but should declare the event as soon as it is determined that the release duration has or will likely exceed 15 minutes. Also, if an ongoing release is detected and the starting time for that release is unknown, the Emergency Director should, in the absence of data to the contrary, assume that the release has exceeded 15 minutes. RA1.1 addresses radioactivity releases that for whatever reason cause effluent radiation monitor readings that exceed two hundred times the alarm setpoint established by the radioactivity discharge permit. The "Alert" values shown for each monitor are two hundred times the alarm setpoints or calculated ODCM release limits as specified in Reference 4. The setpoints are established to ensure the ODCM release limits are not exceeded [Ref. 2, 3]. The alarm setpoints may be associated with a planned batch release, or a continuous release path. In either case, the setpoint is established by the ODCM to warn of a release that is not in compliance with the ODCM. Indexing the EAL threshold to the ODCM setpoints in this manner insures that the EAL threshold will never be less than the setpoint established by a specific discharge permit. Each liquid discharge permit includes a value for R-18, calculated in accordance with the ODCM, that will vary based on the discharge flow rate, therefore "200 X Calculated ODCM Setpoint" was used as the threshold. Escalation will be based on radiation readings increasing per the following:

Normal Effluent Release Monitor Classification Thresholds					
Monitor	GE	SAE	Alert	UE	
Auxiliary Building					
01-05 Aux. Bldg. SPING Lo Range					
01-07 Aux. Bldg. SPING Mid Range	1.00E+05 cpm	1.00E+04 cpm			
01-09 Aux. Bldg. SPING Hi Range	1.00E+02 cpm	1.00E+01 cpm	*	·	
R-13 Aux. Bldg. Vent Exhaust			2.61E+07 cpm	2.61E+05 cpm	
R-14 Aux. Bldg. Vent Exhaust		. 	2.62E+07 cpm	2.62E+05 cpm	
Reactor Building					
02-05 Rx Bldg. Vent SPING Lo Range					
02-07 Rx Bldg. Vent SPING Mid Range	2.00E+04 cpm	2.00E+03 cpm		'	
02-09 Rx Bldg. Vent SPING Hi Range	2.00E+01 cpm	•		· ·	
R-12 Containment Gas		• 	4.41E+07 cpm	4.41E+05 cpm	
R-21 Containment Vent			4.40E+07 cpm	4.40E+05 cpm -	
Liquid Radwaste		· · · ·			
R-18 Waste Disposal System Liquid	N/A	N/A	200 X Calculated ODCM Setpoint	2 X Calculated ODCM Setpoint	

RA1.2 addresses effluent or accident radiation monitors on non-routine release pathways (i.e., for which a discharge permit would not normally be prepared) [Ref. 1]. The ODCM establishes a methodology for determining effluent radiation monitor setpoints. The ODCM specifies default

source terms and, for gaseous releases, prescribes the use of pre-determined annual average meteorology in the most limiting downwind sector for showing compliance with the regulatory commitments. These monitor reading EALs have been determined using this methodology. The "Alert" values for each monitor are two hundred times the alarm setpoints or calculated ODCM release limits as specified in Reference 4. The setpoints are established to ensure the ODCM release limits are not exceeded [Ref. 2, 3]. Escalation will be on based radiation readings increasing per the following:

Abnormal Effluent Release Monitor Classification Thresholds						
Monitor	GE	SAE	Alert	UE		
Main Steam Line (PORV)						
R-31 'A' Steamline Lo Range	1.77E+03 mR/hr	1.77E+02 mR/hr				
R-32 'A' Steamline High Range	1.77E+00 R/hr			 .		
R-33 'B' Steamline Lo Range	1.77E+03 mR/hr	1.77E+02 mR/hr				
R-34 'B' Steamline High Range	1.77E+00 R/hr					
Main Steam Line (SG Safety)						
R-31 'A' Steamline Lo Range	8.30E+02 mR/hr	8.30E+01 mR/hr		[:]		
R-32 'A' Steamline High Range						
R-33 'B' Steamline Lo Range	8.30E+02 mR/hr	8.30E+01 mR/hr	-	·		
R-34 'B' Steamline High Range				· ·		
Liquid Radwaste						
R-16 Containment Fcu SW Return	N/A	N/A	3.38E+07 cpm	3.38E+05 cpm		
R-19 S/G Blowdown Liquid	N/A	N/A	2.58E+08 cpm	2.58E+06 cpm		
R-20 Aux Bldg SW Return	N/A	N/A	1.03E+07 cpm	1.03E+05 cpm		

RA1.3 addresses uncontrolled releases that are detected by sample analyses, particularly on unmonitored pathways, e.g., spills of radioactive liquids into storm drains, heat exchanger leakage in lake water systems, etc.

RA1.1 and RA1.2 directly correlate with the IC since annual average meteorology is required to be used in showing compliance with the ODCM and is used in calculating the alarm setpoints. The fundamental basis of this IC is NOT a dose or dose rate, but rather the degradation in the level of safety of the plant implied by the uncontrolled release.

Due to the uncertainty associated with meteorology, emergency implementing procedures call for the timely performance of dose assessments using actual (real-time) meteorology in the event of a gaseous radioactivity release of this magnitude. The results of these assessments should be compared to the ICs RS1 and RG1 to determine if the event classification should be escalated.

ABNORMAL RAD LEVELS/RADIOLOGICAL EFFLUENT

Initiating Condition-- ALERT

Damage to Irradiated Fuel or Loss of Water Level that Has or Will Result in the Uncovering of Irradiated Fuel Outside the Reactor Vessel.

Operating Mode Applicability: All

Emergency Action Levels: (RA2.1 or RA2.2)

- RA2.1. A VALID radiation indication high alarm or reading on one or more of the following radiation monitors resulting from damage to irradiated fuel or loss of water level:
 - R-2 Containment Area
 - R-5 Fuel Handling Area
 - R-13 or R-14 Aux Bldg Vent Exhaust
 - R-11 or R-12 Containment Particulate / Gas Ventilation
 - R-21 Containment Vent
- RA2.2. Water level LESS THAN 50% Wide Range Refueling Water Level OR GREATER THAN 14 feet below top of Spent Fuel Pool that will result in irradiated fuel uncovering.

Basis:

This IC addresses specific events that have resulted, or may result, in unexpected increases in radiation dose rates within plant buildings, and may be a precursor to a radioactivity release to the environment. These events represent a loss of control over radioactive material and represent a degradation in the level of safety of the plant. These events escalate from IC RU2 in that fuel activity has been released, or is anticipated due to fuel heatup. This IC applies to spent fuel requiring water coverage and is not intended to address spent fuel which is licensed for dry storage, which is discussed in IC EU1.

RA2.1 addresses radiation monitor indications [Ref. 1, 2, 3] of fuel uncovery and/or fuel damage. Increased readings on ventilation monitors may be indication of a radioactivity release from the fuel, confirming that damage has occurred. Increased background at the monitor due to water level decrease may mask increased ventilation exhaust airborne activity and needs to be considered. While a radiation monitor could detect an increase in dose rate due to a drop in the water level, it might not be a reliable indication of whether or not the fuel is covered. For example, the monitor could in fact be properly responding to a known event involving transfer or relocation of a source, stored in or near the fuel pool or responding to a planned evolution such as removal of the reactor head. Application of these Initiating Conditions requires understanding of the actual radiological conditions present in the vicinity of the monitor. Information Notice No. 90-08, *"KR-85 Hazards from Decayed Fuel"* was considered in establishing radiation monitor EAL thresholds and there is no impact on this EAL.

In RA2.2, indications include instrumentation such as water level and local area radiation monitors, and personnel (e.g., refueling crew) reports. Wide Range Refueling Water Level is measured by L9053A for channel A and L9054A for channel B. If available, security video cameras may allow remote observation. The top of each pool is at 649 ft 6 in. el. and the bottom is at 608 ft el. Fuel occupies the bottom 14 ft. [Ref. 4]. Declaration may need to be based on indications of water makeup rate or decrease in refueling water storage tank level.

RA2

Escalation, if appropriate, would occur via IC RS1 or RG1 or Emergency Director judgment.

ABNORMAL RAD LEVELS/RADIOLOGICAL EFFLUENT

RA3

Initiating Condition -- ALERT

Release of Radioactive Material or Rise in Radiation Levels Within the Facility That Impedes Operation of Systems Required to Maintain Safe Operations or to Establish or Maintain Cold Shutdown

Operating Mode Applicability: All

Emergency Action Levels: (RA3.1 or RA3.2)

RA3.1. VALID radiation monitor readings GREATER THAN 15 mR/hr in areas requiring continuous occupancy to maintain plant safety functions:

Control Room (Rad monitor R-1) OR Central Alarm Station (Rad monitor R-1) OR Secondary Alarm Station (by survey)

- RA3.2. Any VALID radiation monitor reading GREATER THAN 6 R/hr in areas requiring infrequent access to maintain plant safety functions.
 - Auxiliary Building
 - Safeguards Alley
 - Diesel Generator Rooms (includes "A" Diesel Room to Screen House Tunnel)
 - Screenhouse/Forebay
 - Relay Room
 - Safeguard Battery Room

Basis:

This IC addresses increased radiation levels that impede necessary access to operating stations, or other areas containing equipment that must be operated manually or that requires local monitoring, in order to maintain safe operation or perform a safe shutdown. It is this impaired ability to operate the plant that results in the actual or potential substantial degradation of the level of safety of the plant. The cause and/or magnitude of the increase in radiation levels is not a concern of this IC. The Emergency Director must consider the source or cause of the increased radiation levels and determine if any other IC may be involved. For example, a dose rate of 15 mR/hr in the control room may be a problem in itself. However, the increase may also be indicative of high dose rates in the containment due to a LOCA. In this latter case, an SE or GE may be indicated by the fission product barrier matrix ICs.

This IC is not meant to apply to increases in the containment radiation monitors, as these are events which are addressed in the fission product barrier matrix ICs. Nor is it intended to apply to anticipated temporary increases due to planned events (e.g., radwaste container movement, depleted resin transfers, etc.)

For RA3.1 areas requiring continuous occupancy include the Control Room and the central alarm station (CAS). The CAS has no installed radiation monitoring capability [Ref. 3]. The value of 15mR/hr is derived from the GDC 19 value of 5 rem in 30 days with adjustment for expected occupancy times. Although Section III.D.3 of NUREG-0737, *"Clarification of TMI Action Plan Requirements"* [Ref. 1, 2], provides that the 15 mR/hr value can be averaged over the 30 days, the value is used here without averaging, as a 30 day duration implies an event potentially more significant than an Alert.

For RA3.2 areas requiring infrequent access, the basis of the 6 R/hr value is as follows:

The KNPP annual administrative personnel exposure limit is 2 Rem/Year. Assuming an emergency worker is at his administrative limit, any emergency worker needing access to a plant area for the safe shutdown of the plant could receive up to an additional 3 Rem without exceeding the legal 10CFR20 annual exposure limit of 5 Rem [Ref. 4] and thus the need for emergency exposure authorization. Assuming that an activity required to be performed in the plant would, on average, require a 30 minute stay time in that area, an area exposure rate of 6 R/hr would not unduly impede access to areas necessary for safe plant shutdown.

As used here, *impede*, includes hindering or interfering provided that the interference or delay is sufficient to significantly threaten the safe operation of the plant. RA3.2 provides the list of safe shutdown areas requiring infrequent access. The listed areas contain functions and systems required for the safe shutdown of the plant. KNPP safe shutdown analyses were consulted for equipment and plant areas required for the applicable mode [Ref 5].

In-plant radiation surveys and Area Radiation Monitor (ARM) readings are methods available to assess this EAL. Radiation monitors are not specified in the EAL wording because portable monitoring devices may be used to determine area accessibility. It would then be possible to erroneously exclude information gained from portable monitor surveys when interpreting the EAL.

R-33 'B' Steamline Lo Range	1.77E+02 mR/hr
Main Steam Line (SG Safety)	
R-31 'A' Steamline Lo Range	8.30E+01 mR/hr
R-33 'B' Steamline Lo Range	8.30E+01 mR/hr

- RS1.2. Dose assessment using actual meteorology indicates doses GREATER THAN 100 mRem TEDE or 500 mRem thyroid CDE at or beyond the site boundary.
- RS1.3. Field survey results indicate closed window dose rates exceeding 100 mRem/hr expected to continue for more than one hour, at or beyond the site boundary; OR Analyses of field survey samples indicate thyroid CDE of 500 mRem for one hour of

inhalation, at or beyond the site boundary.

Basis:

This IC addresses radioactivity releases that result in doses at or beyond the site boundary that exceed a small fraction of the EPA Protective Action Guides (PAGs). Releases of this magnitude are associated with the failure of plant systems needed for the protection of the public. While these

failures are addressed by other ICs, this IC provides appropriate diversity and addresses events which may not be able to be classified on the basis of plant status alone, e.g., fuel handling accident in spent fuel building.

The TEDE dose is set at 10% of the EPA PAG, while the 500 mRem thyroid CDE was established in consideration of the 1:5 ratio of the EPA PAG for TEDE and thyroid CDE.

The Emergency Director should not wait until 15 minutes has elapsed, but should declare the event as soon as it is determined that the release duration has or will likely exceed 15 minutes. The monitor list in RS1.1 includes monitors on all potential release pathways [Ref. 1, 3, 4].

The "SAE" effluent monitor readings are derived from Reference 2.

Since dose assessment is based on actual meteorology, whereas the monitor reading EALs are not, the results from these assessments may indicate that the classification is not warranted, or may indicate that a higher classification is warranted. For this reason, emergency implementing procedures call for the timely performance of dose assessments using actual meteorology and release information. If the results of these dose assessments are available when the classification is made (e.g., initiated at a lower classification level), the dose assessment results override the monitor reading EALs.

- RG1.2. Dose assessment using actual meteorology indicates doses GREATER THAN 1000 mRem TEDE or 5000 mRem thyroid CDE at or beyond the site boundary.
- RG1.3. Field survey results indicate closed window dose rates exceeding 1000 mRem/hr expected to continue for more than one hour, at or beyond site boundary. OR

Analyses of field survey samples indicate thyroid CDE of 5000 mRem for one hour of inhalation, at or beyond site boundary.

Basis:

This IC addresses radioactivity releases that result in doses at or beyond the site boundary that exceed the EPA Protective Action Guides (PAGs). Public protective actions will be necessary. Releases of this magnitude are associated with the failure of plant systems needed for the protection of the public and likely involve fuel damage. While these failures are addressed by other ICs, this IC provides appropriate diversity and addresses events which may not be able to be classified on the basis of plant status alone. It is important to note that, for the more severe accidents, the release may be unmonitored or there may be large uncertainties associated with the source term and/or meteorology.

The Emergency Director should not wait until 15 minutes has elapsed, but should declare the event as soon as it is determined that the release duration has or will likely exceed 15 minutes. The monitor list in RG1.1 includes monitors on all potential release pathways [Ref. 1, 3, 4].

The "GE" effluent monitor readings are derived from Reference 2.

Since dose assessment is based on actual meteorology, whereas the monitor reading EALs are not, the results from these assessments may indicate that the classification is not warranted, or may indicate that a higher classification is warranted. For this reason, emergency implementing procedures call for the timely performance of dose assessments using actual meteorology and release information. If the results of these dose assessments are available when the classification is made (e.g., initiated at a lower classification level), the dose assessment results override the monitor reading EALs.

CU1

Initiating Condition -- UNUSUAL EVENT

RCS Leakage.

Operating Mode Applicability: Cold Shutdown

Emergency Action Levels: (CU1.1 or CU1.2)

CU1.1. Unidentified or pressure boundary leakage GREATER THAN 10 gpm.

CU1.2. Identified leakage GREATER THAN 25 gpm.

Basis:

This IC is included as a UE because it is considered to be a potential degradation of the level of safety of the plant. Positive indications in the Control Room of Reactor Coolant System (RCS) leakage to the containment are provided by equipment that monitors:

- Charging/Letdown flow mismatch
- Containment air activity
- Containment humidity
- Containment Sump A In-leakage

[Ref. 1, 2]

The 10 gpm value for the unidentified and pressure boundary leakage was selected as it is sufficiently large to be observable via normally installed instrumentation (e.g., Pressurizer level, RCS loop level instrumentation, etc.) or reduced inventory instrumentation such as tygon level indication. Lesser values must generally be determined through time-consuming surveillance tests (e.g., mass balances). The EAL for identified leakage is set at a higher value due to the lesser significance of identified leakage in comparison to unidentified or pressure boundary leakage. Prolonged loss of RCS Inventory may result in escalation to the Alert level via either IC CA1 (Loss of RCS Inventory with Irradiated Fuel in the Reactor Vessel) or CA4 (Inability to Maintain Plant in Cold Shutdown with Irradiated Fuel in the Reactor Vessel).

The difference between CU1 and CU2 deals with the RCS conditions that exist between cold shutdown and refueling mode applicability. In cold shutdown the RCS will normally be intact and RCS inventory and level monitoring means such as Pressurizer level indication and makeup volume control tank levels are normally available. In the refueling mode the RCS is not intact and Reactor Vessel level and inventory are monitored by different means.

- 1. Technical Specifications LCO 3.1.d, Amendment No. 165
- 2. SP-36-82 Reactor Coolant System Leak Rate Check, Rev. AE

CU2

Initiating Condition -- UNUSUAL EVENT

UNPLANNED Loss of RCS Inventory with Irradiated Fuel in the Reactor Vessel.

Operating Mode Applicability: Refueling

Emergency Action Levels: (CU2.1 or CU2.2)

- CU2.1. UNPLANNED RCS level lowering below the Reactor Vessel flange (21.5%) for GREATER THAN OR EQUAL TO 15 minutes
- CU2.2. Loss of Reactor Vessel inventory as indicated by unexplained Containment Sump A, Containment Sump C or Liquid Waste Disposal System level rise

AND

Reactor Vessel level cannot be monitored

Basis:

This IC is included as an UE because it may be a precursor of more serious conditions and, as result, is considered to be a potential degradation of the level of safety of the plant. Refueling evolutions that decrease RCS water level below the Reactor Vessel flange are carefully planned and procedurally controlled. An UNPLANNED event that results in water level decreasing below the Reactor Vessel flange warrants declaration of an Unusual Event due to the reduced RCS inventory that is available to keep the core covered. The allowance of 15 minutes was chosen because it is reasonable to assume that level can be restored within this time frame using one or more of the redundant means of refill that should be available. If level cannot be restored in this time frame then it may indicate a more serious condition exists. Continued loss of RCS Inventory will result in escalation to the Alert level via either IC CA2 (Loss of Reactor Vessel Inventory with Irradiated Fuel in the Reactor Vessel) or CA4 (Inability to Maintain Plant in Cold Shutdown with Irradiated Fuel in the Reactor Vessel).

The difference between CU1 and CU2 deals with the RCS conditions that exist between cold shutdown and refueling modes. In cold shutdown the RCS will normally be intact and standard RCS inventory and level monitoring means are available. In the refueling mode the RCS is not intact and Reactor Vessel level and inventory are monitored by different means.

In the refueling shutdown mode, normal means of core temperature indication and RCS level indication may not be available. Redundant means of Reactor Vessel level indication will normally be installed (including the ability to monitor level visually) to assure that the ability to monitor level will not be interrupted. However, if all level indication were to be lost during a loss of RCS inventory event, the operators would need to determine that Reactor Vessel inventory loss was occurring by observing Containment Sump A, Containment Sump C and Liquid Waste Disposal System level changes [Ref. 1, 2]. Sump and tank level rises must be evaluated against other potential sources of leakage such as cooling water sources inside the containment to ensure they are indicative of RCS leakage. When CONTAINMENT SUMP A LEVEL HIGH is received, the corresponding

leakrate within containment is calculated from sump pump run history. Escalation to Alert would be via either CA2 or RCS heatup via CA4.

CU2.1 involves a decrease in RCS level below the top of the Reactor Vessel flange that continues for 15 minutes due to an UNPLANNED event. The level at the Reactor Vessel flange is monitored by:

- Wide Range Refueling Water Level (L9053A for channel A and L9054A for channel B) indication: 21.5%
- RVLIS: 52.8%
- Sightglass/Tygon: 340 in. WC

[Ref. 3]

This EAL is not applicable to decreases in flooded reactor cavity level (covered by RU2.1) until such time as the level decreases to the level of the vessel flange. If Reactor Vessel level continues to decrease and reaches the Bottom ID of the RCS Loop (Refueling Level, 0% RVLIS, 252 in. sightglass), then escalation to CA2 would be appropriate. Note that the Bottom ID of the RCS Loop Setpoint corresponds to the bottom of the Reactor Vessel loop penetration (not the low point of the loop).

CU3

Initiating Condition -- UNUSUAL EVENT

Loss of All Offsite Power to Essential Busses for GREATER THAN 15 Minutes.

Operating Mode Applicability:

Cold Shutdown Refueling

Emergency Action Level:

CU3.1. Loss of all offsite power to Bus 5 AND Bus 6 for GREATER THAN 15 minutes.

AND

At least one emergency diesel generator is supplying power to Bus 5 or Bus 6.

Basis:

Prolonged loss of AC power reduces required redundancy and potentially degrades the level of safety of the plant by rendering the plant more vulnerable to a complete Loss of AC Power (e.g., Station Blackout). Fifteen minutes was selected as a threshold to exclude transient or momentary power losses.

The 4160 VAC system is divided into six busses, two of which are Engineered Safety Function (ESF) Busses 5 and 6. The ESF busses supply power to Safety Injection (SI) pumps, Residual Heat Removal (RHR) pumps, containment heat removal equipment, etc.

Offsite power is available from the 345 kVAC and 138 kVAC systems. The 345 kVAC system is connected to the North Appleton line, the Point Beach line, the main transformers, and transformer T-10. The 345 kVAC is the normal supply to the 13.8 kVAC system through transformer T-10, which feeds the Tertiary Auxiliary Transformer (TAT). The TAT normally provides power to ESF bus 5. The TAT is not considered available to power both ESF busses in an emergency situation due to its size. As a contingency, however, it is acceptable to use the TAT to power both ESF busses when guidance for sequencing and monitoring TAT loads is available in the Control Room. The Reserve Auxiliary Transformer (RAT) and Main Auxiliary Transformer (MAT) provide backup sources to bus 5, in that order.

The 138 kVAC system is connected to the Shoto/Mishicot line, the East Krok line and transformer T-10. The 138 kVAC system is the normal supply to the Reserve Auxiliary Transformer (RAT) via the East and West substation busses. (When the 345 kVAC system is unavailable, the 138 kVAC system can supply power to transformer T-10 and the TAT.) The RAT normally provides power to ESF bus 6. The TAT and MAT provide backup sources to bus 6 in that order.

When the main turbine generator is on line, generator output supplies power to the Main Auxiliary Transformer (MAT) and the 4160 VAC busses. When the main turbine generator is off line, the 345 kVAC system can be aligned to backfeed the MAT. Note that the time required to effect the backfeed is likely longer than the fifteen-minute interval associated with this EAL. If shutdown plant conditions have already established the backfeed, however, its power to the ESF busses may be considered an offsite power source.

Following a loss of power, ECA 0.0 provides guidance to restore power to ESF busses. For the purpose of classification under this EAL, offsite power sources include any of the following:

- 345 kVAC system supplying power to transformer T-10 and the TAT
- 138 kVAC system supplying power to transformer T-10 and the TAT
- 138 kVAC system supplying power to the RAT
- 345 kVAC system supplying power to the MAT on backfeed through the main transformers when the main turbine generator is off line

CU4

Initiating Condition -- UNUSUAL EVENT

UNPLANNED Loss of Decay Heat Removal Capability with Irradiated Fuel in the Reactor Vessel.

Operating Mode Applicability:

Cold Shutdown Refueling

(CU4.1 or CU4.2)

Emergency Action Levels:

- CU4.1. An UNPLANNED event results in RCS temperature GREATER THAN 200°F
- CU4.2. Loss of all RCS temperature and Reactor Vessel level indication for GREATER THAN 15 minutes.

Basis:

This IC is included as an UE because it may be a precursor of more serious conditions and, as a result, is considered to be a potential degradation of the level of safety of the plant. In cold shutdown the ability to remove decay heat relies primarily on forced cooling flow. Operation of the systems that provide this forced cooling may be jeopardized due to the unlikely loss of electrical power or RCS inventory. Since the RCS usually remains intact in the cold shutdown mode a large inventory of water is available to keep the core covered. In cold shutdown the decay heat available to raise RCS temperature during a loss of inventory or heat removal event may be significantly greater than in the refueling mode. Entry into cold shutdown conditions may be attained within hours of operating at power. Entry into the refueling mode procedurally may not occur for typically 100 hours or longer after the reactor has been shutdown. Thus the heatup threat and therefore the threat to damaging the fuel clad may be lower for events that occur in the refueling mode with irradiated fuel in the Reactor Vessel (note that the heatup threat could be lower for cold shutdown conditions if the entry into cold shutdown was following a refueling). In addition, the operators should be able to monitor RCS temperature and Reactor Vessel level so that escalation to the alert level via CA4 or CA1 will occur if required.

During refueling the level in the Reactor Vessel will normally be maintained above the Reactor Vessel flange. Refueling evolutions that decrease water level below the Reactor Vessel flange are carefully planned and procedurally controlled. Loss of forced decay heat removal at reduced inventory may result in more rapid rises in RCS/Reactor Vessel temperatures depending on the time since shutdown. Escalation to the Alert level via CA4.

Unlike the cold shutdown mode, normal means of core temperature indication and RCS level indication may not be available in the refueling mode. Redundant means of Reactor Vessel level indication are therefore procedurally installed to assure that the ability to monitor level will not be interrupted. However, if all level and temperature indication were to be lost in either the cold shutdown of refueling modes, CU4.2 would result in declaration of an Unusual Event if either temperature or level indication cannot be restored within 15 minutes from the loss of both means of indication. Escalation to Alert would be via CA2 based on an inventory loss or CA4 based on exceeding its temperature criteria (200°F) [Ref. 1].

Reactor Vessel water level is normally monitored using the following instruments:

- 21158 Refueling Water Level Narrow Range (L9055A)
- 21159 Refueling Water Level B Wide Range (L9054A)
- 24068 Refueling Water Level A Wide Range (L9053A)
- LI-41337 Reactor Cavity Lvl
- Local Rx Vessel Level Sightglass/Tygon (252 in. to 645 in.)
- RVLIS 41622 Train A
- RVLIS 41623 Train B

Refueling Water Level B Wide Range instrument is calibrated to provide indication from the top of active fuel (0% or 200 in. WC) to the refueling floor (68.5% or 645 in. WC). The Reactor Vessel Level Indicating System (RVLIS) is part of the Post Accident Monitoring Instrumentation. RVLIS is provided for verification and long term surveillance of core cooling and indicates from the bottom of the RCS hot leg penetration (0% or 252 in. WC) to above the high point of the Reactor Vessel head (100% or 419 in.). Procedures N-RC-36E, Draining the Reactor Coolant System, and N-RHR-34C, RHR Operation at a Reduced Inventory Condition, provide a cross-reference table of indicated water levels and sightglass readings.

[Ref. 2, 3, 4]

Several instruments are capable of providing indication of RCS temperature with respect to the Technical Specification cold shutdown temperature limit (200°F). N-0-01, Plant Startup from Cold Shutdown Condition to Hot Shutdown Condition, specifies the use of the highest of the wide range, RHR inlet, or Core Exit Thermocouples to monitor RCS temperature in the Cold Shutdown or Refueling Mode.

The Emergency Director must remain attentive to events or conditions that lead to the conclusion that exceeding the EAL threshold is imminent. If, in the judgment of the Emergency Director, an imminent situation is at hand, the classification should be made as if the threshold has been exceeded.

- 1. Technical Specifications, Modes Definition for Cold Shutdown, Amendment No. 172

CU5

Initiating Condition -- UNUSUAL EVENT

Fuel Clad Degradation.

Operating Mode Applicability:

Cold Shutdown Refueling

Emergency Action Levels: (CU5.1or CU5.2)

- CU5.1. RCS Letdown Line (R-9) radiation monitor GREATER THAN 2000 mR/hr indicating fuel clad degradation.
- CU5.2. Coolant sample activity GREATER THAN ANY of the following indicating fuel clad degradation:
 - 1.0 µCi/gram dose equivalent lodine-131 for more than 48 hours in one continuous time interval
 - 60 µCi/gram dose equivalent lodine-131.
 - 91/Ē µCi/cc gross radioactivity

Basis:

This IC is included as a UE because it is considered to be a potential degradation in the level of safety of the plant and a potential precursor of more serious problems. CU5.1 addresses RCS Letdown Line (R-9) radiation monitor readings that provide indication of fuel clad integrity [Ref. 4 & 5]. CU5.2 addresses coolant samples exceeding coolant technical specifications for iodine spike [Ref. 1].

2000 mR/hr was calculated using the following:

0.01% fuel cladding defect equals 7.2E+1 mR/hr increase on R-9 [Ref. 4] 0.2745% fuel cladding defect equals 1.0 μCi/gram dose equivalent lodine-131 [Ref. 5].

Therefore 1976.4 mR/hr increase on R-9 is equal to 1.0 μ Ci/gram dose equivalent lodine-131

R-9 background is equivalent to 56 mR/hr [Ref. 4], which is added to the calculated dose rate above.

With the addition of background R-9 will read 2032.4 mR/hr (rounded to 2000 mR/hr) equal to 1.0 μ Ci/gram dose equivalent lodine-131.

Although the Technical Specification is applicable when average reactor coolant temperature is GREATER THAN 500°F, it is appropriate that this EAL be applicable in cold shutdown and refueling modes, as it indicates a potential degradation in the level of safety of the plant.

CU6

Initiating Condition -- UNUSUAL EVENT

UNPLANNED Loss of All Onsite or Offsite Communications Capabilities.

Operating Mode Applicability:	Cold Shutdown Refueling

Emergency Action Levels:

CU6.1. Loss of all Table C-1 onsite communications capability affecting the ability to perform routine operations.

(CU6.1 or CU6.2)

Table C-1 Onsite Communications Systems	
Intraplant Paging (Gai-tronics)	
Sound powered phones	
PBX telephone system	
 Personal communications system (PCS phones) 	
 Portable radio communications system 	

CU6.2. Loss of all Table C-2 offsite communications capability.

Table C-2 Offsite Communications Systems

- PBX telephone system
- NRC FTS System (including ENS and HPN)
- Dial select phones

Basis:

The purpose of this IC and its associated EALs is to recognize a loss of communications capability that either defeats the plant operations staff ability to perform routine tasks necessary for plant operations or the ability to communicate problems with offsite authorities. The loss of offsite communications ability is expected to be significantly more comprehensive than the condition addressed by 10 CFR 50.72.

The availability of one method of ordinary offsite communications is sufficient to inform state and local authorities of plant problems. This EAL is intended to be used only when extraordinary means (e.g., relaying of information from radio transmissions, individuals being sent to offsite locations, etc.) are being utilized to make communications possible.

Table C-1 onsite communications loss encompasses the loss of all means of routine communications (e.g., commercial telephones, sound powered phone systems, page party system and radios / walkie talkies). Due to its limited capability, the emergency gai-tronics is not listed in Table C-1.

Table C-2 offsite communications loss encompasses the loss of all means of communications with offsite authorities. This includes the NRC FTS System (including Emergency Notification System - ENS and Health Physics Network – HPN), commercial telephone lines, telecopy transmissions, and dedicated phone systems.

KNPP Basis Reference(s):

CU7

Initiating Condition - UNUSUAL EVENT

UNPLANNED Loss of Required DC Power for GREATER THAN 15 Minutes.

Operating Mode Applicability:

Cold Shutdown Refueling

Emergency Action Level:

CU7.1 UNPLANNED Loss of Vital DC power based on LESS THAN 105 VDC on Train A AND Train B Safeguards DC Distribution System.

AND

Failure to restore power to at least one required Train of the Safeguards DC Distribution System within 15 minutes from the time of loss.

Basis:

The purpose of this IC and its associated EALs is to recognize a loss of DC power compromising the ability to monitor and control the removal of decay heat during Cold Shutdown or Refueling operations. This EAL is intended to be anticipatory in as much as the operating crew may not have necessary indication and control of equipment needed to respond to the loss.

UNPLANNED is included in this IC and EAL to preclude the declaration of an emergency as a result of planned maintenance activities. Routinely plants will perform maintenance on a Train related basis during shutdown periods. It is intended that the loss of the operating (operable) train is to be considered. If this loss results in the inability to maintain cold shutdown, the escalation to an Alert will be per EAL CA4 "Inability to Maintain Plant in Cold Shutdown with Irradiated Fuel in the Reactor Vessel."

LESS THAN 105 VDC bus voltage is based on the minimum bus voltage necessary for the operation of safety related equipment [Ref. 1, 2]. The loss of a safeguards DC train consists of a combination of loss of power to specified DC distribution panels. These panels include: BRA (BRB)-102, and BRA (BRB)-104. In all cases, BRA (BRB)-102 panel indicating less than 105 VDC constitutes a loss of the associated DC distribution train. However, a loss of power to the BRA (BRB) -104 panel, which does not have voltage indication, also constitutes a loss of the associated DC distribution train.

125 VDC safeguard main distribution cabinets (BRA-102 and BRB-102) supply two safeguard sub-distribution cabinets (BRA-104 and BRB-104) and provide for connection of safeguard batteries (BRA-101 and BRB-101) to their associated battery chargers (BRA-108 and BRB-108). The combination of low voltages on the specified distribution cabinets results in a total loss of vital 125 VDC power. The 125 VDC safeguards system powers circuit breaker control, Control Room alarms, Control Room controls, diesel generator controls, and the Reactor Protection System. It is also the standby power source to the AC inverters. BRA-102 and BRB-102 voltage is displayed on Control Room indicators 4494001 and 4494002, respectively. Undervoltage is alarmed on Control

Room Sequence of Event Recorder (SER) points 490011196 and 490011200 and annunciators 447101A and 47101B, respectively.

Each of the 125 VDC batteries has been sized to carry the expected shutdown loads following a reactor trip and a loss of all AC power for a period of eight hours without battery terminal voltage falling below 105 VDC. This voltage value therefore incorporates a margin of at least 15 minutes of operation before the onset of inability to operate loads. The nominal battery cell voltage is 2.20 VDC. Low battery terminal voltage activates Control Room SER point 49001832 and annunciator 47105A. The batteries are located in Battery Rooms A and B on the Turbine Building Mezzanine Floor (606 ft el.).

CU8

Initiating Condition – UNUSUAL EVENT

Inadvertent Criticality.

Operating Mode Applicability:

Cold Shutdown Refueling

Emergency Action Level:

CU8.1. An UNPLANNED sustained positive startup rate observed on nuclear instrumentation.

Basis:

This IC addresses criticality events that occur in Cold Shutdown or Refueling modes (NUREG 1449, Shutdown and Low-Power Operation at Commercial Nuclear Power Plants in the United States) such as fuel mis-loading events and inadvertent dilution events. This IC indicates a potential degradation of the level of safety of the plant, warranting an Unusual Event classification. This IC excludes inadvertent criticalities that occur during planned reactivity changes associated with reactor startups (e.g., criticality earlier than estimated) which are addressed in the companion IC SU8.

This condition can be identified using startup rate meters. The term "sustained" is used in order to allow exclusion of expected short term positive startup rates from planned fuel bundle or control rod movements during core alteration. These short term positive startup rates are the result of the rise in neutron population due to subcritical multiplication.

This condition can be identified using startup rate meters (NI-31D/32D - Source Range Startup Rate).

Escalation would be by Emergency Director Judgment.

KNPP Basis Reference(s):

CA1

Initiating Condition – ALERT

Loss of RCS Inventory.

Operating Mode Applicability: Cold Shutdown

Emergency Action Levels: (CA1.1 or CA1.2)

CA1.1. Loss of RCS inventory as indicated by one or more of the following:

- Wide Range Refueling Water Level LESS THAN 8%
 - RVLIS at 0%
 - Sightglass water level LESS THAN 252 in
- CA1.2. Loss of RCS inventory as indicated by unexplained level rise in any of the following:
 - Containment Sump A
 - Containment Sump C
 - Liquid Waste Disposal System

AND

RCS level cannot be monitored for GREATER THAN 15 minutes

Basis:

These EALs serve as precursors to a loss of ability to adequately cool the fuel. The magnitude of this loss of water indicates that makeup systems have not been effective and may not be capable of preventing further Reactor Vessel level decrease and potential core uncovery. The 8% Refueling Level (0% RVLIS, 252 in. sightglass) threshold corresponds to the bottom inside diameter of the RCS hot leg [Ref. 2]. This condition will result in a minimum classification of Alert. The Bottom ID of the RCS hot leg Setpoint was chosen because at this level remote RCS level indication may be lost and loss of suction to decay heat removal systems has occurred. The Bottom ID of the RCS hot leg Setpoint is the level equal to the bottom of the Reactor Vessel loop penetration (not the low point of the loop). The inability to restore and maintain level after reaching this setpoint would therefore be indicative of a failure of the RCS barrier.

The elevation of the bottom of the RCS hot leg can be monitored by:

- Wide Range Refueling Water Level (L9053A for channel A and L9054A for channel B) indication: 7.95% rounded to 8% for readability
- RVLIS: 0%
- Sightglass/Tygon: 252 in. WC

Reactor Vessel water level is normally monitored using the following instruments:

- 21158 Refueling Water Level Narrow Range (L9055A)
- 21159 Refueling Water Level B Wide Range (L9054A)
- 24068 Refueling Water Level A Wide Range (L9053A)
- LI-41337 Reactor Cavity LvI
- Local Rx Vessel Level Sightglass/Tygon (252 in. to 645 in.)
- RVLIS 41622 Train A
- RVLIS 41623

[Ref 2]

In cold shutdown the decay heat available to raise RCS temperature during a loss of inventory or heat removal event may be significantly greater than in the refueling mode. Entry into cold shutdown conditions may be attained within hours of operating at power or hours after refueling is completed. Entry into the refueling mode procedurally may not occur for typically 100 hours or longer after the reactor has been shutdown. Thus the heatup threat and therefore the threat to damaging the fuel clad may be lower for events that occur in the refueling mode with irradiated fuel in the Reactor Vessel (note that the heatup threat could be lower for cold shutdown conditions if the entry into cold shutdown was following a refueling). The above forms the basis for needing both a cold shutdown specific IC (CA1) and a refueling specific IC (CA2).

In the cold shutdown mode, if the RCS is pressurized, then the refueling water level indication (including sightglass / tygon) will not be in service. In this case, RVLIS will serve as the means for declaration of this EAL. However, if all level indication were to be lost during a loss of RCS inventory event, the operators would need to determine that Reactor Vessel inventory loss was occurring by observing Containment Sump A, Containment Sump C and Liquid Waste Disposal System level changes [Ref. 1, 5]. Each time annunciator CONTAINMENT SUMP A LEVEL HIGH is received, the corresponding leakrate within containment is calculated from sump pump run history. Sump and tank level rises must be evaluated against other potential sources of leakage such as cooling water sources inside the containment to ensure they are indicative of RCS leakage [Ref. 1, 2,]. The 15-minute duration for the loss of level indication was chosen because it is half of the CS1 Site Area Emergency EAL duration. The 15-minute duration allows CA1 to be an effective precursor to CS1. Significant fuel damage is not expected to occur until the core has been uncovered for greater than 1 hour per the analysis referenced in the CS1 basis. Therefore this EAL meets the definition for an Alert emergency.

The difference between CA1 and CA2 deals with the RCS conditions that exist between cold shutdown and refueling mode applicability. In cold shutdown the RCS will normally be intact and standard RCS inventory and level monitoring means are available. In the refueling mode the RCS is not intact and Reactor Vessel level and inventory are monitored by different means.

If Reactor Vessel level continues to decrease then escalation to Site Area Emergency will be via CS1 (Loss of Inventory Affecting Core Decay Heat Removal Capability with Irradiated Fuel in the Reactor Vessel).

Initiating Condition -- ALERT

Loss of Reactor Vessel Inventory with Irradiated Fuel in the Reactor Vessel.

Operating Mode Applicability: Refueling

Emergency Action Levels: (CA2.1 or CA2.2)

- CA2.1. Loss of RCS inventory as indicated by Wide Range Refueling Water Level LESS THAN 8% (0% RVLIS, 252 in. sightglass)
- CA2.2. Loss of Reactor Vessel inventory as indicated by unexplained level rise in any of the following:
 - Containment Sump A
 - Containment Sump C
 - Liquid Waste Disposal System

AND

Reactor Vessel level cannot be monitored for GREATER THAN 15 minutes

Basis:

These example EALs serve as precursors to a loss of heat removal. The magnitude of this loss of water indicates that makeup systems have not been effective and may not be capable of preventing further Reactor Vessel level decrease and potential core uncovery. The 8% Refueling Level (0% RVLIS, 252 in. sightglass) threshold corresponds to the bottom inside diameter of the RCS loop [Ref. 2]. This condition will result in a minimum classification of Alert. The Bottom ID of the RCS hot leg Setpoint was chosen because at this level remote RCS level indication may be lost and loss of suction to decay heat removal systems may occur. The Bottom ID of the RCS hot leg Setpoint is the level equal to the bottom of the Reactor Vessel loop penetration (not the low point of the loop). The inability to restore and maintain level after reaching this setpoint would therefore be indicative of a failure of the RCS barrier.

The elevation of the bottom of the RCS hot leg can be monitored by:

- Wide Range Refueling Water Level (L9053A for channel A and L9054A for channel B) indication: 7.95% rounded to 8% for readability
- RVLIS: 0%
- Sightglass/Tygon: 252 in. WC

Reactor Vessel water level is normally monitored using the following instruments:

- 21158 Refueling Water Level Narrow Range (L9055A)
- 21159 Refueling Water Level B Wide Range (L9054A)
- 24068 Refueling Water Level A Wide Range (L9053A)
- LI-41337 Reactor Cavity Lvl
- Local Rx Vessel Level Sightglass/Tygon (252 in. to 645 in.)
- RVLIS 41622 Train A
- RVLIS 41623 Train B

[Ref. 2]

In cold shutdown the decay heat available to raise RCS temperature during a loss of inventory or heat removal event may be significantly greater than in the refueling mode. Entry into cold shutdown conditions may be attained within hours of operating at power or hours after refueling is completed. Entry into the refueling mode procedurally may not occur for typically 100 hours or longer after the reactor has been shutdown. Thus the heatup threat and therefore the threat to damaging the fuel clad may be lower for events that occur in the refueling mode with irradiated fuel in the Reactor Vessel (note that the heatup threat could be lower for cold shutdown conditions if the entry into cold shutdown was following a refueling). The above forms the basis for needing both a cold shutdown specific IC (CA1) and a refueling specific IC (CA2).

In the refueling mode, normal means of Reactor Vessel level indication may not be available. Redundant means of Reactor Vessel level indication will be normally installed (including the ability to monitor level visually) to assure that the ability to monitor level will not be interrupted. However, if all level indication were to be lost during a loss of RCS inventory event, the operators would need to determine that Reactor Vessel inventory loss was occurring by observing Containment Sump A, Containment Sump C and Liquid Waste Disposal System level changes [Ref. 1, 5]. Each time annunciator CONTAINMENT SUMP A LEVEL HIGH is received, the corresponding leakrate within containment is calculated from sump pump run history. [Ref. 1, 2, 3] Sump and tank level rises must be evaluated against other potential sources of leakage such as cooling water sources inside the containment to ensure they are indicative of RCS leakage. The 15-minute duration for the loss of level indication was chosen because it is half of the CS2 Site Area Emergency EAL duration. The 15-minute duration allows CA2 to be an effective precursor to CS2. Significant fuel damage is not expected to occur until the core has been uncovered for greater than 1 hour per the analysis referenced in the CS2 basis. Therefore this EAL meets the definition for an Alert.

The difference between CA1 and CA2 deals with the RCS conditions that exist between cold shutdown and refueling mode applicability. In cold shutdown the RCS will normally be intact and standard RCS inventory and level monitoring means are available. In the refueling mode the RCS is not intact and Reactor Vessel level and inventory are monitored by different means.

If Reactor Vessel level continues to decrease then escalation to Site Area Emergency will be via CS1 (Loss of Inventory Affecting Core Decay Heat Removal Capability with Irradiated Fuel in the Reactor Vessel).

CA3

Initiating Condition -- ALERT

Loss of All Offsite Power and Loss of All Onsite AC Power to Essential Busses.

Operating Mode Applicability:

Cold Shutdown Refueling Defueled

Emergency Action Level:

CA3.1. Loss of ALL power to Bus 5 AND Bus 6 for GREATER THAN 15 minutes.

Basis:

Loss of all AC power compromises all plant safety systems requiring electric power including RHR, ECCS, Containment Heat Removal, Spent Fuel Heat Removal and the Service Water System. When in cold shutdown, refueling, or defueled mode the event can be classified as an Alert, because of the significantly reduced decay heat, lower temperature and pressure, increasing the time to restore one of the emergency busses, relative to that specified for the Site Area Emergency EAL. Escalating to Site Area Emergency, if appropriate, is by Abnormal Rad Levels / Radiological Effluent, or Emergency Director Judgment ICs. Fifteen minutes was selected as a threshold to exclude transient or momentary power losses.

This EAL is indicated by the loss of all offsite and onsite AC power to the 4160 VAC ESF busses. Offsite power sources include the 345 kVAC system or 138 kVAC system to the Tertiary Auxiliary Transformer (TAT), the 345 kVAC system or 138 kVAC system to the Reserve Auxiliary Transformer (RAT), and the 345 kVAC system to the Main Auxiliary Transformer (MAT) on backfeed through the main transformers. Note that the time required to effect a backfeed to the MAT is likely longer than the fifteen-minute interval. If shutdown plant conditions have already established the backfeed, however, its power to the ESF busses may be considered an offsite power source. Onsite power sources consist of Diesel Generator A to Bus 5 and Diesel Generator B to Bus 6. [Ref. 1, 2, 3, 4, 5].

Consideration should be given to operable loads necessary to remove decay heat or provide Reactor Vessel makeup capability when evaluating loss of AC power to essential busses. Even though an essential bus may be energized, if necessary loads (i.e., loads that if lost would inhibit decay heat removal capability or Reactor Vessel makeup capability) are not operable on the energized bus then the bus should not be considered operable.

CA4

Initiating Condition -- ALERT

Inability to Maintain Plant in Cold Shutdown with Irradiated Fuel in the Reactor Vessel.

Cold Shutdown Refueling

Emergency Action Levels:

(EAL CA4.1 or CA4.2 or CA4.3)

- CA4.1. With CONTAINMENT CLOSURE NOT established AND RCS integrity NOT established, An UNPLANNED event results in RCS temperature GREATER THAN 200°F.
- CA4.2. With CONTAINMENT CLOSURE established AND RCS integrity NOT established OR Wide Range Refueling Water Level LESS THAN 17.0%,

An UNPLANNED event results in RCS temperature GREATER THAN 200°F for GREATER THAN 20 minutes*.

***NOTE:** If RHR system is in operation within this time frame and RCS temperature is being reduced then this EAL is not applicable.

CA4.3. An UNPLANNED event results in RCS temperature GREATER THAN 200°F for GREATER THAN 60 minutes*.

Results in an RCS pressure increase of GREATER THAN 10 psig.

***NOTE :** If RHR system is in operation within this time frame and RCS temperature is being reduced then this EAL is not applicable.

Basis:

CA4.1 addresses complete loss of functions required for core cooling during refueling and cold shutdown modes when neither CONTAINMENT CLOSURE nor RCS integrity are established. RCS integrity is in place when the RCS pressure boundary is in its normal condition for the cold shutdown mode of operation (e.g., reactor head on with studs tensioned, S/G and PRZR manways installed, PRZR safety valves installed, no freeze seals or nozzle dams). No delay time is allowed for CA4.1 because the evaporated reactor coolant that may be released into the Containment during this heatup condition could also be directly released to the environment.

CA4.2 addresses the complete loss of functions required for core cooling for GREATER THAN 20 minutes during refueling and cold shutdown modes when CONTAINMENT CLOSURE is

established but RCS integrity is not established or RCS inventory is reduced (e.g., mid loop operation). As in CA4.1, RCS integrity should be assumed to be in place when the RCS pressure boundary is in its normal condition for the cold shutdown mode of operation (e.g., reactor head on with studs tensioned, S/G and PRZR man-ways installed, PRZR safety valves installed, no freeze seals or nozzle dams). The allowed 20 minute time frame was included to allow operator action to restore the heat removal function, if possible. The allowed time frame is consistent with the guidance provided by Generic Letter 88-17, "Loss of Decay Heat Removal" (discussed later in this basis) and is believed to be conservative given that a low pressure Containment barrier to fission product release is established. The Note for CA4.2 indicates that CA4.2 is not applicable if actions are successful in restoring an RCS heat removal system to operation and RCS temperature is being reduced within the 20 minute time frame. Wide Range Refueling Water Level is measured by L9053A for channel A and L9054A for channel B.

CA4.3 addresses complete loss of functions required for core cooling for GREATER THAN 60 minutes during refueling and cold shutdown modes when RCS integrity is established. As in CA4.1 and CA4.2, RCS integrity should be considered to be in place when the RCS pressure boundary is in its normal condition for the cold shutdown mode of operation (e.g., reactor head on with studs tensioned, S/G and PRZR man-ways installed, PRZR safety valves installed, no freeze seals or nozzle dams). The status of CONTAINMENT CLOSURE in this EAL is immaterial given that the RCS is providing a high pressure barrier to fission product release to the environment. The 60 minute time frame should allow sufficient time to restore cooling without there being a substantial degradation in plant safety. The 10 psig pressure rise covers situations where, due to high decay heat loads, the time provided to restore temperature control, should be less than 60 minutes. RCS Pressure Narrow Range instrument PI-420 and PPCS/SPDS point P0420A are capable of measuring pressure to less than 10 psig. [Ref. 3, 7]. The Note for CA4.3 indicates that CA4.3 is not applicable if actions are successful in restoring the RHR system to operation and RCS temperature is being reduced within the 60 minute time frame assuming that the RCS pressure rise has remained less than the site specific pressure value.

Several instruments are capable of providing indication of RCS temperature with respect to the Technical Specification cold shutdown temperature limit (200°F). N-0-01, Plant Startup from Cold Shutdown Condition to Hot Shutdown Condition, specifies the use of the highest of the wide range, RHR inlet, or Core Exit Thermocouples to monitor RCS temperature in the Cold Shutdown or Refueling Mode.

[Ref. 2, 3,]

Escalation to Site Area Emergency would be via CS1 or CS2 should boiling result in significant Reactor Vessel level loss leading to core uncovery.

A loss of Technical Specification components alone is not intended to constitute an Alert. The same is true of a momentary UNPLANNED excursion above 200 degrees F when the heat removal function is available.

The Emergency Director must remain alert to events or conditions that lead to the conclusion that exceeding the EAL threshold is imminent. If, in the judgment of the Emergency Director, an imminent situation is at hand, the classification should be made as if the threshold has been exceeded.

SYSTEM MALFUNCTION

CS1

Initiating Condition -- SITE AREA EMERGENCY

Loss of Reactor Vessel Inventory Affecting Core Decay Heat Removal Capability.

Operating Mode Applicability:	Cold Shutdown
Emergency Action Levels:	(CS1.1 or CS1.2)

CS1.1. With CONTAINMENT CLOSURE <u>NOT</u> established:

a. Reactor Vessel inventory as indicated by Wide Range Refueling Water Level LESS THAN 7%

OR

- b. Reactor Vessel level cannot be monitored for GREATER THAN 30 minutes with a loss of Reactor Vessel inventory as indicated by unexplained level rise in any of the following:
 - Containment Sump A
 - Containment Sump C
 - Liquid Waste Disposal System
- CS1.2. With CONTAINMENT CLOSURE established:
 - a. Reactor Vessel inventory as indicated by Wide Range Refueling Water Level EQUAL TO 0%

OR

- b. Reactor Vessel level cannot be monitored for GREATER THAN 30 minutes with a loss of Reactor Vessel inventory as indicated by either:
 - Unexplained Containment Sump A, Containment Sump C, OR Liquid Waste Disposal System level rise
 - Erratic Source Range Monitor Indication

Basis:

Under the conditions specified by this IC, continued decrease in Reactor Vessel level is indicative of a loss of inventory control. Inventory loss may be due to a Reactor Vessel breach, pressure boundary leakage, or continued boiling in the Reactor Vessel.

In cold shutdown the decay heat available to raise RCS temperature during a loss of inventory or heat removal event may be significantly greater than in the refueling mode. Entry into cold shutdown conditions may be attained within hours of operating at power or hours after refueling is KNPP 6-C-28 10/22/04

completed. Entry into the refueling mode procedurally may not occur for typically 100 hours or longer after the reactor has been shutdown. Thus the heatup threat and therefore the threat to damaging the fuel clad may be lower for events that occur in the refueling mode with irradiated fuel in the Reactor Vessel (note that the heatup threat could be lower for cold shutdown conditions if the entry into cold shutdown was following a refueling). The above forms the basis for needing both a cold shutdown specific IC (CS1) and a refueling specific IC (CS2).

In the cold shutdown mode, normal RCS level and reactor vessel level indication systems (RVLIS) will normally be available. If the RCS is pressurized, then the Wide Range Refueling Water Level indication will not be in service. However, if all level indication were to be lost during a loss of RCS inventory event, the operators would need to determine that Reactor Vessel inventory loss was occurring by observing sump and tank level changes. <u>RVLIS indication is considered lost if leakage reduces RCS level below its indicating range</u>. Each time annunciator CONTAINMENT SUMP A LEVEL HIGH is received, the corresponding leakrate within containment is calculated from sump pump run history. [Ref. 1, 5] Sump and tank level increases must be evaluated against other potential sources of leakage such as cooling water sources inside the containment to ensure they are indicative of RCS leakage.

When Reactor Vessel water level drops to 616 ft 4 in. el., the level associated without CONTAINMENT CLOSURE established, level is six inches below the bottom of the RCS hot leg vessel penetration. This level can be monitored by Wide Range Refueling Water Level (L9053A for channel A and L9054A for channel B) indication at 7.1% (rounded to 7% for readability). The following indications are off scale low and as such are not available:

- RVLIS: <0%
- Sightglass/Tygon level equal to 246 in. WC.

When Reactor Vessel water level drops to 612 ft 4 in. el., the level associated with CONTAINMENT CLOSURE established, core uncovery is about to occur. Wide Range Refueling Water Level indication of 0% is approximately the top of active fuel.

[Ref. 1, 2]

The 30-minute duration allowed when CONTAINMENT CLOSURE is established allows sufficient time for actions to be performed to recover needed cooling equipment and is considered to be conservative given that level is being monitored via CS1 and CS2. Effluent release is not expected with closure established.

Thus, declaration of a Site Area Emergency is warranted under the conditions specified by the IC. Escalation to a General Emergency is via CG1 (Loss of Reactor Vessel Inventory Affecting Fuel Clad Integrity with Containment Challenged with Irradiated Fuel in the Reactor Vessel) or radiological effluent IC AG1 (Offsite Dose Resulting from an Actual or Imminent Release of Gaseous Radioactivity Exceeds 1000 mRem TEDE or 5000 mRem Thyroid CDE for the Actual or Projected Duration of the Release Using Actual Meteorology).

SYSTEM MALFUNCTION

CS2

Initiating Condition - SITE AREA EMERGENCY

Loss of Reactor Vessel Inventory Affecting Core Decay Heat Removal Capability with Irradiated Fuel in the Reactor Vessel.

Operating Mode Applicability: Refueling

Emergency Action Levels: (CS2.1 or CS2.2)

CS2.1. With CONTAINMENT CLOSURE NOT established:

a. Reactor Vessel inventory as indicated by Wide Range Refueling Water Level LESS THAN 7%

OR

- b. Reactor Vessel level cannot be monitored with Indication of core uncovery as evidenced by one or more of the following:
 - Containment Area Radiation Monitor (R-2) reading GREATER THAN 100 mRem/hr
 - Erratic Source Range Monitor Indication

CS2.2. With CONTAINMENT CLOSURE established

a. Reactor Vessel inventory as indicated by Wide Range Refueling Water Level EQUAL TO 0%

OR

- b. Reactor Vessel level cannot be monitored with Indication of core uncovery as evidenced by one or more of the following:
 - Containment Area Radiation Monitor (R-2) reading GREATER THAN 100 mRem/hr
 - Erratic Source Range Monitor Indication

Basis:

Under the conditions specified by this IC, continued decrease in Reactor Vessel level is indicative of a loss of inventory control. Inventory loss may be due to an Reactor Vessel breach or continued boiling in the Reactor Vessel.

In cold shutdown the decay heat available to raise RCS temperature during a loss of inventory or heat removal event may be significantly greater than in the refueling mode Entry into cold shutdown conditions may be attained within hours of operating at power or hours after refueling is completed. Entry into the refueling mode procedurally may not occur for typically 100 or longer after the reactor has been shutdown. Thus the heatup threat and therefore the threat to damaging the fuel clad may be lower for events that occur in the refueling mode with irradiated fuel in the KNPP 6-C-31 10/22/04

Reactor Vessel (note that the heatup threat could be lower for cold shutdown conditions if the entry into cold shutdown was following a refueling). The above forms the basis for needing both a cold shutdown specific IC (CS1) and a refueling specific IC (CS2).

When Reactor Vessel water level drops to 616 ft 4 in. el., the level associated without CONTAINMENT CLOSURE established, level is six inches below the bottom of the RCS hot leg vessel penetration. This level can be monitored by Wide Range Refueling Water Level (L9053A for channel A and L9054A for channel B) indication at 7.1% (rounded to 7% for readability). The following indications are off scale low and as such are not available:

- RVLIS: <0%
- Sightglass/Tygon level equal to 246 in. WC.

When Reactor Vessel water level drops to 612 ft 4 in. el., the level associated with CONTAINMENT CLOSURE established, core uncovery is about to occur. Wide Range Refueling Water Level indication of 0% is approximately the top of active fuel.

[Ref. 1, 2]

In Refuel mode at the levels of interest, RVLIS is unavailable but alternate means of level indication (refueling level) are installed to assure that the ability to monitor level will not be interrupted. If all means of level monitoring are not available, however, the Reactor Vessel inventory loss may be detected by the following indirect methods:

- As water level in the Reactor Vessel lowers, the dose rate above the core will rise. The
 dose rate due to this core shine should result in an unplanned alarm on the Containment
 Area Monitor (R-2). R-2 is used instead of the high range containment monitors because if
 a small amount of fuel was uncovered, the location of the high range monitors would
 preclude them reading on scale. Therefore the alarm setpoint of R-2 was selected to
 indicate a rise in containment radiation resulting from the conditions of this EAL [Ref. 8].
- Post-TMI studies indicated that the installed nuclear instrumentation will operate erratically when the core is uncovered and Source Range Monitors (SRM) N-31B and N-32B can be used as a tool for making such determinations. SRM count rate can also be indicated in the Control Room by the audible SRM count rate monitor.

Effluent release is not expected with CONTAINMENT CLOSURE established.

Thus, declaration of a Site Area Emergency is warranted under the conditions specified by the IC. Escalation to a General Emergency is via CG1 (Loss of Reactor Vessel Inventory Affecting Fuel Clad Integrity with Containment Challenged with Irradiated Fuel in the Reactor Vessel) or radiological effluent IC AG1 (Offsite Dose Resulting from an Actual or Imminent Release of Gaseous Radioactivity Exceeds 1000 mRem TEDE or 5000 mRem Thyroid CDE for the Actual or Projected Duration of the Release Using Actual Meteorology).

SYSTEM MALFUNCTION

CG1

Initiating Condition - GENERAL EMERGENCY

Loss of Reactor Vessel Inventory Affecting Fuel Clad Integrity with Containment Challenged with Irradiated Fuel in the Reactor Vessel.

Operating Mode Applicability:

Cold Shutdown Refueling

Emergency Action Level:

CG1.1. Loss of Reactor Vessel inventory as indicated by unexplained level rise in Containment Sump A, Containment Sump C <u>OR</u> Liquid Waste Disposal System

AND

Reactor Vessel Level (a or b):

a. EQUAL TO 0% Wide Range Refueling Water Level for GREATER THAN 30 minutes

OR

- b. cannot be monitored with indication of core uncovery for GREATER THAN 30 minutes as evidenced by one or more of the following:
 - Containment Area Radiation Monitor (R-2) reading GREATER THAN 100 mRem/hr
 - Erratic Source Range Monitor Indication

AND

Indication of CONTAINMENT challenged as indicated by one or more of the following:

- GREATER THAN OR EQUAL TO 6% hydrogen in containment
- CONTAINMENT CLOSURE NOT established
- CONTAINMENT pressure above:
 - 46 psig <u>IF</u> Containment Integrity or Reduced Inventory Containment Integrity is established

OR

• 46 psig <u>IF</u> Refueling Containment Integrity is established with no loop seal penetrations installed at Penetration 42N or 43N.

OR

• 0.6 psig <u>IF</u> Refueling Containment Integrity is established with loop seal penetration installed at either Penetration 42N or 43N.

Basis:

In the cold shutdown mode, normal RCS level and Reactor Vessel level instrumentation systems will normally be available. If the RCS is pressurized, then the Wide Range Refueling Water Level indication will not be in service. However, if all level indication were to be lost during a loss of RCS inventory event, the operators would need to determine that Reactor Vessel inventory loss was occurring by observing sump and tank level changes. <u>RVLIS indication is considered lost if leakage reduces RCS level below its indicating range.</u>

In the refueling mode, normal means of Reactor Vessel level indication may not be available. Redundant means of Reactor Vessel level indication will be normally installed (including the ability to monitor level visually) to assure that the ability to monitor level will not be interrupted. However, if all level indication were to be lost during a loss of RCS inventory event, the operators would need to determine that Reactor Vessel inventory loss was occurring by observing sump and tank level changes. Wide Range Refueling Water Level is measured by L9053A for channel A and L9054A for channel B.

Containment Sump A, Containment Sump C or Liquid Waste Disposal System level changes may be indicative of a loss of RCS inventory. Containment Sump A receives all liquid waste from floor and equipment drains inside containment including that from Containment Sump C. Each time annunciator CONTAINMENT SUMP A LEVEL HIGH is received, the corresponding leakrate within containment is calculated from sump pump run history. [Ref. 1, 8] Sump level rises must be evaluated against other potential sources of leakage such as cooling water sources inside the containment to ensure they are indicative of RCS leakage. [Ref. 19]

This EAL represents the inability to restore and maintain Reactor Vessel level to above the top of active fuel. Fuel damage is probable if Reactor Vessel level cannot be restored, as available decay heat will cause boiling, further reducing the Reactor Vessel level. When Reactor Vessel water level drops to 612 ft 4 in. el., core uncovery is about to occur. Wide Range Refueling Water Level indication of 0% is approximately the top of active fuel. [Ref. 2]

If all means of level monitoring are not available, the Reactor Vessel inventory loss may be detected by the following indirect methods:

- As water level in the Reactor Vessel lowers, the dose rate above the core will rise. The
 dose rate due to this core shine should result in an unplanned alarm on the Containment
 Area Monitor (R-2). R-2 is used instead of the high range containment monitors because if
 a small amount of fuel was uncovered, the location of the high range monitors would
 preclude them reading on scale. Therefore the alarm setpoint of R-2 was selected to
 indicate a rise in containment radiation resulting from the conditions of this EAL [Ref. 3].
- Post-TMI studies indicated that the installed nuclear instrumentation will operate erratically when the core is uncovered and Source Range Monitors (N-31 and N-32) can be used as a tool for making such determinations.

The GE is declared on the occurrence of the loss or imminent loss of function of <u>all three</u> barriers. Based on the above discussion, RCS barrier failure resulting in core uncovery for 30 minutes or more may cause fuel clad failure. With the CONTAINMENT breached or challenged then the potential for unmonitored fission product release to the environment is high. This represents a direct path for radioactive inventory to be released to the environment. This is consistent with the definition of a GE. CONTAINMENT CLOSURE is the action taken to secure containment and its associated structures, systems, and components as a functional barrier to fission product release under existing plant conditions. CONTAINMENT CLOSURE should not be confused with Refueling Containment Integrity as described in N-FH-53-CLA or CLB [Ref 6, 7]. Reduced Inventory Containment Integrity is described in N-CCI-56A–CLA or CLB [Ref 9, 10]. Site shutdown contingency plans typically provide for re-establishing CONTAINMENT CLOSURE following a loss of heat removal or RCS inventory functions. If the closure is re-established prior to exceeding the temperature or level thresholds of the RCS Barrier and Fuel Clad Barrier EALs, escalation to GE would not occur.

The pressure at which CONTAINMENT is considered challenged is based on the condition of the CONTAINMENT. When the Unit is in the cold shutdown mode and the CONTAINMENT is fully intact, Containment is considered challenged at CONTAINMENT design pressure of 46 psig. Refueling CONTAINMENT Integrity establishes normal CONTAINMENT isolation except that penetrations 42N and 43N may have loop seal penetrations installed. When a loop seal penetration is installed, CONTAINMENT is considered challenged when CONTAINMENT pressure exceeds 0.6 psig. If fiber optic penetration is installed with no loop seal penetration installed, CONTAINMENT is considered at full CONTAINMENT design pressure of 46 psig. [Ref. 20 and 21].

In the early stages of a core uncovery event, it is unlikely that hydrogen buildup due to a core uncovery could result in an explosive mixture of dissolved gasses in CONTAINMENT. However, CONTAINMENT monitoring and/or sampling should be performed to verify this assumption and a General Emergency declared if it is determined that an explosive mixture exists. When hydrogen and oxygen concentrations reach or exceed the deflagration limits (equal to or greater than 6% hydrogen), loss of the containment barrier is possible [Ref. 13, 15, 16]. Containment hydrogen concentration can be obtained from PPCS/SPDS point X8001A and X8002A, or Control Room meters 41615 and 41616.

NOTES

- 1. The logic used for these initiating conditions reflects the following considerations:
 - The Fuel Clad Barrier and the RCS Barrier are weighted more heavily than the Containment Barrier. UE ICs associated with RCS and Fuel Clad Barriers are addressed under System Malfunction ICs.
 - At the Site Area Emergency level, there must be some ability to dynamically assess how far present conditions are from the threshold for a General
 Emergency. For example, if Fuel Clad and RCS Barrier "Loss" EALs existed, that, in addition to offsite dose assessments, would require continual
 assessments of radioactive inventory and containment integrity. Alternatively, if both Fuel Clad and RCS Barrier "Potential Loss" EALs existed, the
 Emergency Director would have more assurance that there was no immediate need to escalate to a General Emergency.
 - The ability to escalate to higher emergency classes as an event deteriorates must be maintained. For example, RCS leakage steadily increasing would represent an increasing risk to public health and safety.
- 2. Fission Product Barrier ICs must be capable of addressing event dynamics. Thus, the EAL Reference Table F-1 states that imminent (i.e., within 2 hours) Loss or Potential Loss should result in a classification as if the affected threshold(s) are already exceeded, particularly for the higher emergency classes.

TABLE F-1 KNPP Emergency Action Level Fission Product Barrier Reference Table Thresholds For LOSS or POTENTIAL LOSS of Barriers*

*Determine which combination of the three barriers are lost or have a potential loss and use the following key to classify the event. barrier

Basis Information For Table F-1 KNPP Emergency Action Level Fission Product Barrier Reference Table

FUEL CLAD BARRIER EALs: (1 or 2 or 3 or 4 or 5 or 6)

The Fuel Clad Barrier is the zircalloy or stainless steel tubes that contain the fuel pellets.

1. Critical Safety Function Status

RED path indicates an extreme challenge to the safety function. ORANGE path indicates a severe challenge to the safety function.

Core Cooling - ORANGE indicates subcooling has been lost and that some clad damage may occur. Core Cooling-ORANGE path is entered if:

- RCS subcooling based on CETs is equal to or less than 30°F [65°F] and
- No RCPs are running, and
- Core Exit Thermocouples (CETs) are reading between 700°F and 1200°F

OR

- RCS subcooling based on CETs is equal to or less than 30°F [65°F], and
- At least one RCP is running, and
- RVLIS Void Fraction is Rising

[Ref. 1, 2]

Heat Sink - RED indicates the ultimate heat sink function is under extreme challenge and thus these two items (Core Cooling – ORANGE or Heat Sink – RED) indicate potential loss of the Fuel Clad Barrier. Heat Sink-Red path is entered if narrow range level in both S/Gs is less than 4% [15%] and total feedwater flow to S/Gs is less than 200 gpm.

[Ref. 4, 5]

Core Cooling - RED indicates significant superheating and core uncovery and is considered to indicate loss of the Fuel Clad Barrier. Core Cooling-RED path is entered if Core Exit Thermocouples (CETs) are equal to or greater than 1200°F.

CSFST setpoints enclosed in brackets (e.g., [65°F], etc.) are used under adverse containment conditions. Adverse containment condition thresholds apply when containment pressure is greater than 4 psig or containment radiation exceeds 10E+05 R/hr.

2. Primary Coolant Activity Level

This value is 300 μ Ci/gm I₁₃₁ equivalent. Assessment by the NUMARC EAL Task Force indicates that this amount of coolant activity is well above that expected for iodine spikes and corresponds to less than 5% fuel clad damage. This amount of radioactivity indicates significant clad damage and thus the Fuel Clad Barrier is considered lost.

There is no equivalent "Potential Loss" EAL for this item.

3. Core Exit Thermocouple Readings

Core Exit Thermocouple Readings are included in addition to the Critical Safety Functions to include conditions when the CSFs may not be in use (initiation after SI is blocked).

The "Loss" EAL 1200 degrees F reading should correspond to significant superheating of the coolant. This value corresponds to the temperature reading that indicates core cooling - RED in Fuel Clad Barrier EAL #1 which is 1200 degrees F. [Ref. 1, 6]

The "Potential Loss" EAL 700 degrees F reading should correspond to loss of subcooling. This value corresponds to the temperature reading that indicates core cooling - ORANGE in Fuel Clad Barrier EAL #1 which is 700 degrees F. [Ref.1, 2]

4. Reactor Vessel Water Level

There is no "Loss" EAL corresponding to this item because it is better covered by the other Fuel Clad Barrier "Loss" EALs.

The "Potential Loss" EAL is indicative of core uncovery but, when the reactor is at pressure and temperature, RVLIS should not be used for a quantitative value (i.e., top of active fuel). Functional restoration procedure FR-C.2 specifies monitoring of RVLIS void fraction trend and RCS subcooling instead of the water level corresponding to the top of active fuel.

The "Potential Loss" EAL is therefore defined by the Core Cooling - ORANGE path. The trend in RVLIS RCS void fraction is used to check the effectiveness of safety injection in restoring RCS inventory. If void fraction percent is decreasing and RCS subcooling based on Core Exit Thermocouples (CETs) is greater than 30°F [65°F], safety injection has been successful in restoring RCS inventory and core cooling. In the event that RCS void fraction is increasing and subcooling requirements are not met, core cooling continues to be degraded and some fuel cladding damage may occur. Setpoints enclosed in brackets are used under adverse containment conditions. Adverse containment condition thresholds apply when containment pressure is greater than 4 psig or containment radiation exceeds 10E+05 R/hr. [Ref. 7]

5. Containment Radiation Monitoring

The 1000 R/hr reading is a value which indicates the release of reactor coolant, with elevated activity indicative of fuel damage, into the containment. The reading is calculated assuming the instantaneous release and dispersal of the reactor coolant noble gas and iodine inventory associated with a concentration of 300 μ Ci/gm dose equivalent I-131 into the containment atmosphere. [Ref. 8, 9, 10] Reactor coolant concentrations of this magnitude are several times larger than the maximum concentrations (including iodine spiking) allowed within technical specifications and are therefore indicative of fuel damage. This value is higher than that specified for RCS barrier Loss EAL #4. Thus, this EAL indicates a loss of both the fuel clad barrier and a loss of RCS barrier.

Monitors used for this fission product barrier loss threshold are the containment high-range area monitors R-40 and R-41.

There is no "Potential Loss" EAL associated with this item.

6. Emergency Director Judgment

This EAL addresses any other factors that are to be used by the Emergency Director in determining whether the Fuel Clad barrier is lost or potentially lost. Such a determination should include imminent barrier degradation, barrier monitoring capability and dominant accident sequences.

- <u>Imminent barrier degradation</u> exists if the degradation will likely occur within two hours based on a projection of current safety system performance. The term "imminent" refers to recognition of the inability to reach safety acceptance criteria before completion of all checks.
- <u>Barrier monitoring</u> capability is decreased if there is a loss or lack of reliable indicators. This assessment should include instrumentation operability concerns, readings from portable instrumentation and consideration of offsite monitoring results.
- <u>Dominant accident sequences</u> lead to degradation of all fission product barriers and likely entry to the CSFSTs. The Emergency Director should be mindful of the Loss of AC power (Station Blackout) and ATWS EALs to assure timely emergency classification declarations.

In addition, the inability to monitor the barrier should also be incorporated in this EAL as a factor in Emergency Director judgment that the barrier may be considered lost or potentially lost.

RCS BARRIER EALs: (1 or 2 or 3 or 4 or 5)

The RCS Barrier includes the RCS primary side and its connections up to and including the pressurizer safety and relief valves, and other connections up to and including isolation valves.

1. Critical Safety Function Status

RED path indicates an extreme challenge to the safety function derived from appropriate instrument readings, and these CSFs indicate a potential loss of RCS barrier.

RCS Integrity-Red path is entered if:

- Temperature decrease in both RCS cold legs is equal to or greater than 100°F in the last 60 minutes, and
- Any RCS cold leg temperatures are equal to or less than 274°F.

The combination of these two conditions indicates the RCS barrier is under extreme challenge and should be considered a Potential Loss of the RCS barrier. [Ref. 11, 12]

Heat Sink-Red path is entered if:

- Narrow range level in both S/Gs is less than 4% [15%]
- Total feedwater flow to S/Gs is less than 200 gpm.

The combination of these two conditions indicates the heat sink function is under extreme challenge. This condition addresses loss of functions required for hot shutdown with the reactor at pressure and temperature and should be considered a Potential Loss of the RCS barrier. [Ref. 4, 5]

Critical Safety Function Status Tree (CSFST) setpoints enclosed in brackets are used under adverse containment conditions. Adverse containment condition thresholds apply when containment pressure is greater than 4 psig or containment radiation exceeds 10E+05 R/hr.

There is no "Loss" EAL associated with this item.

2. RCS Leak Rate

The "Loss" EAL addresses conditions where leakage from the RCS is greater than available inventory control capacity such that a loss of subcooling has occurred. The loss of subcooling is the fundamental indication that the inventory control systems are inadequate in maintaining RCS pressure and inventory against the mass loss through the leak. Loss of subcooling is defined by:

- LESS THAN 20°F if the reactor is critical
- LESS THAN 30°F if the reactor is sub-critical

Core exit thermocouples LESS THAN 20°F is the subcooling margin threshold while critical. This is based on the minimum subcooling allowed for normal operation defined in Operating Procedure A-RC-36-D. [Ref. 23]

Core exit thermocouples LESS THAN 30°F is the subcooling margin threshold while subcritical. This is the level specified in Critical Safety Function Status Trees. IPEOPs define this value as a loss of RCS subcooling. [Ref. 1]

The "Potential Loss" EAL is based on the inability to maintain normal liquid inventory within the Reactor Coolant System (RCS) by normal operation of the Chemical and Volume Control System which is considered as one variable-speed, positive displacement charging pump discharging to the charging header. A second charging pump being required is indicative of a substantial RCS leak. 60 gpm is the design flow rate for each charging pump. [Ref. 13]

3. SG Tube Rupture

This EAL is intended to address the full spectrum of Steam Generator (SG) tube rupture events in conjunction with Containment Barrier "Loss" EAL #4 and Fuel Clad Barrier EALs. The "Loss" EAL addresses RUPTURED SG(s) for which the leakage is large enough to cause actuation of ECCS (SI). ECCS (SI) actuation is caused by:

- PRZR pressure less than 1815 psig
- S/G pressure less than 500 psig
- Containment pressure greater than 4 psig

Per IPEOP E-0, Reactor Trip or Safety Injection, the Operators are directed to perform a manual Safety Injection actuation if PRZR level is less than 5% or RCS subcooling based on Core Exit Thermocouples (CETs) is less than 30°F.

By itself, this EAL will result in the declaration of an Alert. However, if the SG is also FAULTED (i.e., two barriers failed), the declaration escalates to a Site Emergency per Containment Barrier "Loss" EAL #4. [Ref. 13, 14]

There is no "Potential Loss" EAL.

4. Containment Radiation Monitoring

The 30 R/hr reading is a value which indicates the release of reactor coolant to the containment. The reading is calculated assuming the instantaneous release and dispersal of the reactor coolant noble gas and iodine inventory associated with normal operating concentrations (i.e., within Technical Specifications) into the containment atmosphere. [Ref. 8, 9, 10] This reading is less than that specified for Fuel Clad Barrier EAL #5. Thus, this EAL would be indicative of a RCS leak only. If the radiation monitor reading increased to that specified by Fuel Clad Barrier EAL #5, fuel damage would also be indicated.

Monitors used for this fission product barrier loss threshold are the containment high-range area monitors R-40 and R-41.

There is no "Potential Loss" EAL associated with this item.

5. Emergency Director Judgment

This EAL addresses any other factors that are to be used by the Emergency Director in determining whether the RCS barrier is lost or potentially lost. Such a determination should include imminent barrier degradation, barrier monitoring capability and dominant accident sequences.

- <u>Imminent barrier degradation</u> exists if the degradation will likely occur within two hours based on a projection of current safety system performance. The term "imminent" refers to recognition of the inability to reach safety acceptance criteria before completion of all checks.
- <u>Barrier monitoring</u> capability is decreased if there is a loss or lack of reliable indicators. This assessment should include instrumentation operability concerns, readings from portable instrumentation and consideration of offsite monitoring results.
- <u>Dominant accident sequences</u> lead to degradation of all fission product barriers and likely entry to the CSFSTs. The Emergency Director should be mindful of the Loss of AC power (Station Blackout) and ATWS EALs to assure timely emergency classification declarations.

In addition, the inability to monitor the barrier should also be incorporated in this EAL as a factor in Emergency Director judgment that the barrier may be considered lost or potentially lost.

CONTAINMENT BARRIER EALs: (1 or 2 or 3 or 4 or 5 or 6 or 7)

The Containment Barrier includes the Shield Building and Containment and its connections up to and including the outermost containment isolation valves. This barrier also includes the main steam, feedwater, and blowdown lines +outside the Containment up to and including the isolation valve(s).

1. Critical Safety Function Status

There is no "Loss" EAL associated with this item.

RED path indicates an extreme challenge to the safety function. Containment-Red path is entered if containment pressure is equal to or greater than 46 psig. This pressure is the containment design pressure and is in excess of that expected from the design basis loss of coolant accident, and thus represents a potential loss of containment. Conditions leading to a containment RED path result from RCS barrier and/or Fuel Clad Barrier Loss. Thus, this EAL is primarily a discriminator between Site Emergency and General Emergency representing a potential loss of the third barrier. [Ref. 15, 16, 17]

2. Containment Pressure

Rapid unexplained loss of pressure (i.e., not attributable to containment spray or condensation effects) following an initial pressure rise indicates a loss of containment integrity. USAR Section 14.3.4.2 describes containment pressure response for a bounding LOCA. [Ref. 17]

Containment pressure and sump levels should rise as a result of the mass and energy release into containment from a LOCA. Thus, sump level or pressure not increasing indicates containment bypass and a loss of containment integrity.

The 46 PSIG for potential loss of containment is based on the containment design pressure. [Ref. 15, 16, 17]

If hydrogen concentration reaches or exceeds 6% in an oxygen rich environment, an explosive mixture exists. If the combustible mixture ignites inside containment, loss of the Containment barrier could occur. To generate such levels of combustible gas, loss of the Fuel Cladding and RCS barriers must also have occurred As described above, this EAL is primarily a discriminator between Site Emergency and General Emergency representing a potential loss of the third barrier. [Ref. 6, 18]

The third potential loss EAL represents a potential loss of containment in that the containment heat removal/depressurization system (but not including containment venting strategies) are either lost or performing in a degraded manner, as indicated by containment pressure greater than the setpoint (23 psig) at which the equipment was supposed to have actuated. One internal containment spray pump and two containment fan cooler units comprise one train of depressurization equipment. This equipment will provide 100% of the required cooling capacity during post-accident conditions. Each internal containment spray system consists of a spray pump, spray header, nozzles, valves, piping, instruments, and controls to ensure an operable flow path capable of taking suction from the RWST upon an ESF actuation signal. Each containment fan cooler unit consists of cooling coils, accident backdraft damper, accident fan, service water outlet valves, and controls necessary to ensure an operable service water flow path. [Ref. 15, 16, 19, 20, 21]

3. Core Exit Thermocouples

There is no "Loss" EAL associated with this item.

In this EAL, the function restoration procedures are those emergency operating procedures that address the recovery of the core cooling critical safety functions. The procedure is considered effective if the temperature is decreasing or if the vessel water level is increasing.

Severe accident analyses (e.g., NUREG-1150) have concluded that function restoration procedures can arrest core degradation within the reactor vessel in a significant fraction of the core damage scenarios, and that the likelihood of containment failure is very small in these events. Given this, it is appropriate to provide a reasonable period to allow function restoration procedures to arrest the core melt sequence. Whether or not the procedures will be effective should be apparent within 15 minutes. The Emergency Director should make the declaration as soon as it is determined that the procedures have been, or will be ineffective.

RVLIS void fraction increasing and RCS subcooling less than or equal to 30°F [65°F] is indicative of core uncovery. When the reactor is at pressure and temperature, RVLIS should not be used for a quantitative value (i.e., top of active fuel). Function restoration procedure FR-C.2 specifies monitoring of RVLIS void fraction trend and RCS subcooling instead of the water level corresponding to the top of active fuel. This is defined by the Core Cooling - ORANGE path. The trend in RVLIS RCS void fraction is used to check the effectiveness of safety injection in restoring RCS inventory. If void fraction percent is decreasing and RCS subcooling based on Core Exit Thermocouples (CETs) is greater than 30°F [65°F], safety injection has been successful in restoring RCS inventory and core cooling. In the event that RCS void fraction is increasing and subcooling requirements are not met, core cooling continues to be degraded and some fuel cladding damage may occur. Setpoints enclosed in brackets are used under adverse containment conditions. Adverse containment condition thresholds apply when containment pressure is greater than 4 psig or containment radiation exceeds 10E+05 R/hr.

The conditions in this potential loss EAL represent an imminent core melt sequence which, if not corrected, could lead to vessel failure and an increased potential for containment failure. In conjunction with the Core Cooling and Heat Sink criteria in the Fuel and RCS barrier columns, this EAL would result in the declaration of a General Emergency -- loss of two barriers and the potential loss of a third. If the function restoration procedures are ineffective, the Operating Crew will be directed to go to Severe Accident Management Guidelines (SACRG-1). [Ref. 1, 6, 7]

There is no "Loss" EAL associated with this item.

4. SG Secondary Side Release With Primary To Secondary Leakage

This "loss" EAL recognizes that SG tube leakage can represent a bypass of the containment barrier as well as a loss of the RCS barrier. The first "loss" EAL addresses the condition in which a RUPTURED steam generator is also FAULTED. This condition represents a bypass of the RCS and containment barriers. In conjunction with RCS Barrier "loss" EAL #3, this would always result in the declaration of a Site Emergency. A faulted S/G means the existence of secondary side leakage that results in an uncontrolled lowering in steam generator pressure or the steam generator being completely depressurized. A ruptured S/G means the existence of primary-to-secondary leakage of a magnitude sufficient to require or cause a reactor trip and safety injection. Confirmation should be based on diagnostic activities consistent with E-0, Reactor Trip or Safety Injection. [Ref. 14]

The second "loss" EAL addresses SG tube leaks that exceed 10 gpm in conjunction with a nonisolable release path to the environment from the affected steam generator. The threshold for establishing the nonisolable secondary side release is intended to be a prolonged release of radioactivity from the RUPTURED steam generator directly to the environment. This could be expected to occur when the main condenser is unavailable to accept the contaminated steam (i.e., SGTR with concurrent loss of offsite power and the RUPTURED steam generator is required for plant cooldown or a stuck open relief valve). If the main condenser is available, there may be releases via air ejectors, gland seal exhausters, and other similar controlled, and often monitored, pathways. These pathways do not meet the intent of a nonisolable release path to the environment. These minor releases are assessed using Abnormal Rad Levels / Radiological Effluent ICs.

A pressure boundary leakage of 10 gpm is used as the threshold in IC SU5.1, RCS Leakage, and is deemed appropriate for this EAL. For smaller breaks, not exceeding the normal charging capacity threshold in RCS Barrier "Potential Loss" EAL #2 (RCS Leak Rate) or not resulting in ECCS actuation in EAL #3 (SG Tube Rupture), this EAL results in a UE. For larger breaks, RCS barrier EALs #2 and #3 would result in an Alert. For SG tube ruptures which may involve multiple steam generators or unisolable secondary line breaks, this EAL would exist in conjunction with RCS barrier "Loss" EAL #3 and would result in a Site Emergency. Escalation to General Emergency would be based on "Potential Loss" of the Fuel Clad Barrier.

5. Containment Isolation Valve Status After Containment Isolation

This EAL is intended to address incomplete containment isolation that allows direct release to the environment. It represents a loss of the containment barrier.

The use of the modifier "direct" in defining the release path clarifies that release paths through interfacing liquid systems is not applicable to this EAL. The existence of an in-line charcoal filter does not make a release path indirect since the filter is not effective at removing fission noble gases. Typical filters have an efficiency of 95-99% removal of iodine. Given the magnitude of the core inventory of iodine, significant releases could still occur. In addition, since the fission product release would be driven by boiling in the reactor vessel, the high humidity in the release stream can be expected to render the filters ineffective in a short period.

There is no "Potential Loss" EAL associated with this item.

6. Significant Radioactive Inventory in Containment

There is no "Loss" EAL associated with this item.

The4000 R/hr reading is a value which indicates significant fuel damage well in excess of the EALs associated with both loss of Fuel Clad and loss of RCS Barriers. [Ref. 8, 9, 10] A major release of radioactivity requiring offsite protective actions from core damage is not possible unless a major failure of fuel cladding allows radioactive material to be released from the core into the reactor coolant.

Regardless of whether containment is challenged, this amount of activity in containment, if released, could have such severe consequences that it is prudent to treat this as a potential loss of containment, such that a General Emergency declaration is warranted. NUREG-1228, "Source Estimations During Incident Response to Severe Nuclear Power Plant Accidents," indicates that such conditions do not exist when the amount of clad damage is less than 20%.

Monitors used for this fission product barrier loss threshold are the containment high-range area monitors R-40 and R-41.

7. Emergency Director Judgment

This EAL addresses any other factors that are to be used by the Emergency Director in determining whether the Containment barrier is lost or potentially lost. Such a determination should include imminent barrier degradation, barrier monitoring capability and dominant accident sequences.

- <u>Imminent barrier degradation</u> exists if the degradation will likely occur within two hours based on a projection of current safety system performance. The term "imminent" refers to recognition of the inability to reach safety acceptance criteria before completion of all checks.
- <u>Barrier monitoring</u> capability is decreased if there is a loss or lack of reliable indicators. This assessment should include instrumentation operability concerns, readings from portable instrumentation and consideration of offsite monitoring results.
- <u>Dominant accident sequences</u> lead to degradation of all fission product barriers and likely entry to the CSFSTs. The Emergency Director should be mindful of the Loss of AC power (Station Blackout) and ATWS EALs to assure timely emergency classification declarations.

In addition, the inability to monitor the barrier should also be incorporated in this EAL as a factor in Emergency Director judgment that the barrier may be considered lost or potentially lost.

Initiating Condition – UNUSUAL EVENT

Natural and Destructive Phenomena Affecting the PROTECTED AREA.

Operating Mode Applicability: All

Emergency Action Level: (HU1.1 or HU1.2 or HU1.3 or HU1.4 or HU1.5 or HU1.6 or HU1.7)

HU1.1. Earthquake felt in plant as indicated by:

Consensus of Control Room operators on duty **AND** Activation of seismic monitor with Trigger light lit in Relay Room on RR159 (SER 330 Seismic Monitor Event)

- HU1.2. Report by plant personnel of tornado or high winds GREATER THAN 100 mph striking within PROTECTED AREA boundary.
- HU1.3. Vehicle crash into plant structures containing functions and systems required for safe shutdown of the plant within the PROTECTED AREA boundary.
- HU1.4. Report by plant personnel of an unanticipated EXPLOSION within PROTECTED AREA boundary resulting in VISIBLE DAMAGE to permanent structure or equipment.
- HU1.5. Report of turbine failure resulting in casing penetration or damage to turbine or generator seals.
- HU1.6. Uncontrolled flooding in the following areas of the plant that has the potential to affect safety related equipment needed for the current operating mode:
 - Diesel Generator A Room
 - Diesel Generator B Room
 - Safeguards Alley
 - Relay Room
 - CRDM Equipment Room
 - RHR Pump Pits
 - Auxiliary Building Basement
 - Screen House
- HU1.7. High or low lake level in excess of column "Unusual Event", Lake-Forebay Level Thresholds, Table H-2 for GREATER THAN 15 minutes.

KNPP

Т	Table H-2 Lake-Forebay Level Thresholds (GREATER THAN 15 min.)									
Unusual Event					Ale	rt				
Level	Number of Running Circulating Water Pumps			Level	Number of Running Circulating Water Pumps					
	0	1	2		0	1	2

* Computer point L9075A

Basis:

UEs in this IC are categorized on the basis of the occurrence of an event of sufficient magnitude to be of concern to plant operators. Areas identified in the EALs define the location of the event based on the potential for damage to equipment contained therein. Escalation of the event to an Alert occurs when the magnitude of the event is sufficient to result in damage to equipment contained in the specified location.

HU1.1. Damage may be caused to some portions of the site, but should not affect ability of safety functions to operate. Method of detection is based on instrumentation, or operator assessment [Ref. 1, 2]. Consensus of the Control Room operators with respect to ground motion helps avoid unnecessary classification if the seismic switches inadvertently trip or detect vibrations not related to an earthquake. As defined in the EPRI-sponsored "Guidelines for Nuclear Plant Response to an Earthquake", dated October 1989, a *"felt earthquake"* is:

An earthquake of sufficient intensity such that: (a) the vibratory ground motion is felt at the nuclear plant site and recognized as an earthquake based on a consensus of control room operators on duty at the time, and (b) for plants with operable seismic instrumentation, the seismic switches of the plant are activated. For most plants with seismic instrumentation, the seismic switches are set at an acceleration of about 0.01g.

HU1.2 is based on the assumption that a tornado striking (touching down) or high winds within the PROTECTED AREA may have potentially damaged plant structures containing functions or systems required for safe shutdown of the plant. The high wind value is based on site-specific FSAR design basis [Ref. 3]. If such damage is confirmed visually or by other in-plant indications, the event may be escalated to Alert. Even though the meteorological towers are outside of the Protected Area, winds in excess of 100 mph detected there can be assumed to be inside of the Protected Area.

HU1.3 is intended to address crashes of vehicle types large enough to cause significant damage to plant structures containing functions and systems required for safe shutdown of the plant [Ref. 4]. If the crash is confirmed to affect a plant VITAL AREA, the event may be escalated to Alert.

For HU1.4 only those EXPLOSIONs of sufficient force to damage permanent structures or equipment within the PROTECTED AREA should be considered [Ref. 4]. No attempt is made in this EAL to assess the actual magnitude of the damage. The occurrence of the EXPLOSION with reports of evidence of damage is sufficient for declaration. The Emergency director also needs to consider any security aspects of the EXPLOSION, if applicable.

HU1.5 is intended to address main turbine rotating component failures of sufficient magnitude to cause observable damage to the turbine casing or to the seals of the turbine generator. Of major concern is the potential for leakage of combustible fluids (lubricating oils) and gases (hydrogen cooling) to the plant environs. Actual FIREs and flammable gas build up are appropriately classified via HU2 and HU3. Generator seal damage observed after generator purge does not meet the intent of this EAL because it did not impact normal operation of the plant. This EAL is consistent with the definition of a UE while maintaining the anticipatory nature desired and recognizing the risk to non-safety related equipment. Escalation of the emergency classification is based on potential damage done by missiles generated by the failure or in conjunction with a steam generator tube rupture. These latter events would be classified by the radiological ICs or Fission Product Barrier ICs.

HU1.6 addresses the effect of flooding caused by internal events such as component failures, equipment misalignment, or outage activity mishaps. The listed internal flooding areas are those vulnerable areas indicated in the KNPP PRA that, should significant internal flooding occur (such as a Service Water or Circulating Water pipe rupture), could impact areas that contain systems required for safe shutdown of the plant that are not designed to be wetted or submerged [Ref. 5]. Escalation of the emergency classification is based on the damage caused or by access restrictions that prevent necessary plant operations or systems monitoring.

HU1.7 covers high lake (forebay) water level conditions that could be a precursor of more serious events as well as low lake (forebay) water level conditions which may threaten operability of plant cooling systems. Lake water level greater than or equal to 586 ft. International Great Lakes Datum (IGLD) corresponds to the floor elevation of the Service Water Pump Room and access tunnel. Lake water level less than 569.5 ft IGLD corresponds to one foot below the Alert (design) threshold [Ref. 6, 7, 8].

KNPP does not have instrumentation for taking direct readings of the lake level. However the intake forebay level is monitored for this purpose. When no circulating water pumps are operating, the intake forebay level is equal to lake level. However, when the Circulating Water Pumps are operating forebay level is reduced compared to actual lake level due to the hydraulic resistance of the plant intake. KNPP has correlated the intake forebay level with actual lake level when either one or both Circulating Water Pumps are operating, adjusting the EAL thresholds accordingly. In most cases the Circulating Water Pumps will trip (42% indicated forebay level) prior to exceeding the forebay level that corresponds to the low lake level threshold.

The classification should be declared if the threshold is exceeded for greater than 15 minutes. This allows for short duration dynamic effects associated with the KNPP forebay and will avoid unnecessary event declaration due to shifting of Circulating Water Pumps and other dynamic effects in the forebay.

The International Great Lakes Datum (IGLD 1955) is a reference used to represent water levels in the Great Lakes region.

Initiating Condition – UNUSUAL EVENT

FIRE Within PROTECTED AREA Boundary Not Extinguished Within 15 Minutes of Detection.

Operating Mode Applicability: All

Emergency Action Level:

HU2.1. FIRE in the PROTECTED AREA not extinguished within 15 minutes of control room notification or verification of a control room alarm

Basis:

The purpose of this IC is to address the magnitude and extent of FIREs that may be potentially significant precursors to damage to safety systems. As used here, detection is visual observation and report by plant personnel or sensor alarm indication. The 15 minute time period begins with a credible notification that a FIRE is occurring, or indication of a VALID fire detection system alarm. An alarm is assumed to be an indication of a FIRE unless it is disproved within the 15 minute period by personnel dispatched to the scene. In other words, a personnel report from the scene may be used to disprove a sensor alarm if received within 15 minutes of the alarm, but shall not be required to verify the alarm.

The intent of this 15 minute duration is to size the FIRE and to discriminate against small FIREs that are readily extinguished (e.g., smoldering waste paper basket). The applicable areas are limited and apply to buildings and areas contiguous (in actual contact with or immediately adjacent) to plant VITAL AREAs or other significant buildings or areas.

Escalation to a higher emergency class is by IC HA2, "FIRE or EXPLOSION Affecting the Operability of Plant Safety Systems Required to Establish or Maintain Safe Shutdown".

KNPP Basis Reference(s):

Initiating Condition – UNUSUAL EVENT

Release of Toxic or Flammable Gases Deemed Detrimental to Normal Operation of the Plant.

Operating Mode Applicability: All

Emergency Action Levels: (HU3.1 or HU3.2)

- HU3.1. Report or detection of toxic or flammable gases that has or could enter the site area boundary in amounts that can affect NORMAL PLANT OPERATIONS.
- HU3.2. Report by Local, County or State Officials for evacuation or sheltering of site personnel based on an offsite event.

Basis:

This IC is based on the existence of uncontrolled releases of toxic or flammable gas that may enter the site boundary and affect normal plant operations. It is intended that releases of toxic or flammable gases are of sufficient quantity, and the release point of such gases is such that normal plant operations would be affected. This would preclude small or incidental releases, or releases that do not impact structures needed for plant operation. The EALs are intended to not require significant assessment or quantification. The IC assumes an uncontrolled process that has the potential to affect plant operations, or personnel safety.

Escalation of this EAL is via HA3, which involves a quantified release of toxic or flammable gas affecting VITAL AREAs.

KNPP Basis Reference(s):

None

Initiating Condition – UNUSUAL EVENT

Confirmed Security Event Which Indicates a Potential Degradation in the Level of Safety of the Plant.

Operating Mode Applicability: All

Emergency Action Levels: (HU4.1 or HU4.2)

HU4.1. Security Shift Supervisor reports ANY of the following:

- Suspected sabotage device discovered within the plant PROTECTED AREA
- Suspected sabotage device discovered outside the PROTECTED AREA or in the plant switchyard
- Confirmed tampering with safety-related equipment
- A hostage or extortion situation that disrupts NORMAL PLANT OPERATIONS
- Civil disturbance or strike which disrupts NORMAL PLANT OPERATIONS
- Internal disturbance that is <u>not</u> a short lived or that is not a harmless outburst involving ANY individuals within the PROTECTED AREA
- Malevolent use of a vehicle outside the PROTECTED AREA which disrupts normal plant operations

HU4.2 A credible site specific security threat notification

Basis:

Reference is made to the Security Shift Supervisor because this individual is the designated person on-site qualified and trained to confirm that a security event is occurring or has occurred. Training on security event classification confirmation is closely controlled due to the strict secrecy controls placed on the plant Safeguards Contingency Plan.

HU4.1 is based on the Security And Safeguards Contingency Plan. Security events which do not represent a potential degradation in the level of safety of the plant, are reported under 10 CFR 73.71 or in some cases under 10 CFR 50.72. Examples of security events that indicate Potential Degradation in the Level of Safety of the Plant are provided below for consideration.

INTRUSION into the plant PROTECTED AREA by a HOSTILE FORCE would result in EAL escalation to an ALERT or higher.

The intent of HU4.2 is to ensure that appropriate notifications for the security threat are made in a timely manner. Only the plant to which the specific threat is made need declare the Unusual Event.

The determination of "credible" is made through use of information found in the Security And Safeguards Contingency Plan.
A credible site specific security threat is a threat of physical attack to the plant that represents a potential degradation of the level of safety to the plant.

A higher initial classification could be made based upon the nature and timing of the threat and potential consequences. The licensee shall consider upgrading the emergency response status and emergency classification in accordance with the Security And Safeguards Contingency Plan and Emergency Plans.

- 1. NRC Safeguards Advisory 10/6/01
- 2. Security And Safeguards Contingency Plan
- 3. Letter from Mr. B. A. Boger (NRC) to Ms. Lynette Hendricks (NEI) dated 2/4/02

Initiating Condition – UNUSUAL EVENT

Other Conditions Existing Which in the Judgment of the Emergency Director Warrant Declaration of a UE.

Operating Mode Applicability: All

Emergency Action Level:

HU5.1. Other conditions exist which in the judgment of the Emergency Director indicate that events are in process or have occurred which indicate a potential degradation of the level of safety of the plant. No releases of radioactive material requiring offsite response or monitoring are expected unless further degradation of safety systems occurs.

Basis:

This EAL is intended to address unanticipated conditions not addressed explicitly elsewhere but that warrant declaration of an emergency because conditions exist which are believed by the Emergency Director to fall under the UE emergency class.

From a broad perspective, one area that may warrant Emergency Director judgment is related to likely or actual breakdown of site-specific event mitigating actions. Examples to consider include inadequate emergency response procedures, transient response either unexpected or not understood, failure or unavailability of emergency systems during an accident in excess of that assumed in accident analysis, or insufficient availability of equipment and/or support personnel.

KNPP Basis Reference(s):

HA1

Initiating Condition – ALERT

Natural and Destructive Phenomena Affecting the Plant VITAL AREA.

Operating Mode Applicability:	All
Emergency Action Levels:	(HA1.1 or HA1.2 or HA1.3 or HA1.4 or HA1.5)

- HA1.1. Seismic event GREATER THAN Operating Basis Earthquake (OBE) as indicated by activation of seismic monitor with OBE Limit Exceeded light lit in Relay Room on RR159 (SER 331 Seismic Monitor Operational Basis Earthquake)
- HA1.2. Tornado or high winds GREATER THAN 100 mph within PROTECTED AREA boundary and resulting in VISIBLE DAMAGE to any plant structures or equipment located in Table H-1 areas or Control Room indication of degraded performance of those systems located within Table H-1 areas.

	Table H-1 Safe Shutdown/VITAL Areas
•	Shield Building (Reactor Building)
٠	Auxiliary Building
•	Safeguards Alley
•	Diesel Generator Rooms (includes "A" Diesel Room to Screen House Tunnel)
•	Screenhouse/Forebay
•	Technical Support Center Basement
•	Control Room
•	Control Room AC Equipment Room
•	Relay Room
•	Safeguards Battery Rooms

- HA1.3. Vehicle crash within PROTECTED AREA boundary and resulting in VISIBLE DAMAGE to any plant structures or equipment located in Table H-1 areas or Control Room indication of degraded performance of those systems located within Table H-1 areas.
- HA1.4. Turbine failure-generated missiles result in any VISIBLE DAMAGE to or penetration of any plant areas listed in Table H-1:
- HA1.5. Uncontrolled flooding in the following areas of the plant that results in degraded safety system performance as indicated in the control room or that creates industrial safety

hazards (e.g., electric shock) that precludes access necessary to operate or monitor safety equipment:

- Diesel Generator A Room
- Diesel Generator B Room
- Safeguards Alley
- Relay Room
- CRDM Equipment Room
- RHR Pump Pits
- Auxiliary Building basement
- Screen House

HA1.6. High or low lake level in excess of column "Alert", Lake-Forebay Level Thresholds, Table H-2 for GREATER THAN 15 minutes.

]	Table H-2	Lake-Fore	bay Level '	Thresholds (C	GREATER TH	HAN 15 min.

* Computer point L9075A

Basis:

The EALs in this IC escalate from the UE EALs in HU1 in that the occurrence of the event has resulted in VISIBLE DAMAGE to plant structures or areas containing equipment necessary for a safe shutdown, or has caused damage to the safety systems in those structures evidenced by control indications of degraded system response or performance. The occurrence of VISIBLE DAMAGE and/or degraded system response is intended to discriminate against lesser events. The initial "report" should not be interpreted as mandating a lengthy damage assessment prior to classification. No attempt is made in this EAL to assess the actual magnitude of the damage. The significance here is not that a particular system or structure was damaged, but rather, that the event was of sufficient magnitude to cause this degradation. Escalation to higher classifications occurs on the basis of other ICs (e.g., System Malfunction).

HA1.1 is based on the USAR design basis operating earthquake of 0.06 g horizontal or 0.04 g vertical acceleration. Seismic events of this magnitude can result in a plant VITAL AREA being

KNPP

subjected to forces beyond design limits, and thus damage may be assumed to have occurred to plant safety systems. [Ref. 1, 2]

HA1.2 is based on the FSAR design basis wind speed of 100 mph [Ref. 3, 4, 5]. Wind loads of this magnitude can cause damage to safety functions.

HA1.3 is intended to address crashes of vehicle types large enough to cause significant damage to plant structures containing functions and systems required for safe shutdown of the plant.

HA1.4 is intended to address the threat to safety related equipment imposed by missiles generated by main turbine rotating component failures. Table H-1 lists areas that contain systems and components required for the safe shutdown functions of the plant.. This EAL is, therefore, consistent with the definition of an ALERT in that if missiles have damaged or penetrated areas containing safety-related equipment the potential exists for substantial degradation of the level of safety of the plant.

HA1.5 addresses the effect of internal flooding that has resulted in degraded performance of systems affected by the flooding, or has created industrial safety hazards (e.g., electrical shock) that preclude necessary access to operate or monitor safety equipment. The inability to operate or monitor safety equipment represents a potential for substantial degradation of the level of safety of the plant. This flooding may have been caused by internal events such as component failures, equipment misalignment, or outage activity mishaps. The listed internal flooding areas are those vulnerable areas indicated in the KNPP PRA that should significant internal flooding occur (such as a Service Water or Circulating Water pipe rupture), could impact areas that contain systems required for safe shutdown of the plant that are not designed to be wetted or submerged. [Ref. 6, 7]. . HA1.6 covers flooding or seiche. This EAL can be a precursor of more serious events. Lake water level greater than or equal to 588 ft International Great Lakes Datum (IGLD) corresponds to levels approaching design limits which if exceeded threatens operability of safety related equipment. Lake water level less than 568.5 ft IGLD corresponds to design levels (with added conservatism) to ensure Service Water Pumps have adequate NPSH and that vortexing does not occur [Ref. 8, 9].

KNPP does not have instrumentation for taking direct readings of the lake level. However the intake forebay level is monitored for this purpose. When no circulating water pumps are operating, the intake forebay level is equivalent to lake level. However, when the Circulating Water Pumps are operating forebay level is reduced compared to actual lake level due to the hydraulic resistance of the plant intake. KNPP has correlated the intake forebay level with actual lake level when either one or both Circulating Water Pumps are operating, adjusting the EAL thresholds accordingly. In most cases the Circulating Water Pumps will trip (42% indicated forebay level) prior to exceeding the forebay level that corresponds to the low lake level threshold.

The classification should be declared if the threshold is exceeded for greater than 15 minutes. This allows for short duration dynamic effects associated with the KNPP forebay and will avoid unnecessary event declaration due to shifting of Circulating Water Pumps and other dynamic effects in the forebay.

The International Great Lakes Datum (IGLD 1955) is a reference used to represent water levels in the Great Lakes region.

Initiating Condition – ALERT

FIRE or EXPLOSION Affecting the Operability of Plant Safety Systems Required to Establish or Maintain Safe Shutdown.

Operating Mode Applicability: All

Emergency Action Level:

HA2.1. FIRE or EXPLOSION in any of the following areas (Table H-1):

Table I	H-1 Safe Shutdown/VITAL Areas
Shield	d Building (Reactor Building)
Auxili	ary Building
Safeg	juards Alley
Diese Scree	el Generator Rooms (includes "A" Diesel Room to en House Tunnel)
Scree	enhouse/Forebay
Techr	nical Support Center Basement
Contr	ol Room
Contr	ol Room AC Equipment Room
Relay	/ Room
Safeg	guards Battery Rooms

AND

Affected safety system parameter indications show degraded performance or plant personnel report VISIBLE DAMAGE to permanent structures or equipment needed for safe shutdown.

Basis:

These areas contain systems and components required for the safe shutdown functions of the plant. The KNPP safe shutdown analyses were consulted for equipment and plant areas required for the applicable mode. This will make it easier to determine if the FIRE or EXPLOSION is potentially affecting one or more redundant trains of safety systems [Ref. 1, 2]. Escalation to a higher emergency class, if appropriate, will be based on System Malfunction, Fission Product Barrier Degradation, Abnormal Rad Levels / Radiological Effluent, or Emergency Director Judgment ICs.

KNPP

10/22/04

This EAL addresses a FIRE / EXPLOSION and not the degradation in performance of affected systems. System degradation is addressed in the System Malfunction EALs. The reference to damage of systems is used to identify the magnitude of the FIRE / EXPLOSION and to discriminate against minor FIREs / EXPLOSIONs. The reference to safety systems is included to discriminate against FIREs / EXPLOSIONs in areas having a low probability of affecting safe operation. The significance here is not that a safety system was degraded but the fact that the FIRE / EXPLOSION was large enough to cause damage to these systems. Thus, the designation of a single train was intentional and is appropriate when the FIRE / EXPLOSION is large enough to affect more than one component.

This situation is not the same as removing equipment for maintenance that is covered by a plant's Technical Specifications. Removal of equipment for maintenance is a planned activity controlled in accordance with procedures and, as such, does not constitute a substantial degradation in the level of safety of the plant. A FIRE / EXPLOSION is an UNPLANNED activity and, as such, does constitute a substantial degradation in the level of safety of the plant. In this situation, an Alert classification is warranted.

The inclusion of a "report of VISIBLE DAMAGE" should not be interpreted as mandating a lengthy damage assessment prior to classification. No attempt is made in this EAL to assess the actual magnitude of the damage. The occurrence of the EXPLOSION with reports of evidence of damage is sufficient for declaration. The declaration of an Alert and the activation of the Technical Support Center will provide the Emergency Director with the resources needed to perform these damage assessments. The Emergency Director also needs to consider any security aspects of the EXPLOSIONs, if applicable.

HA3

Initiating Condition -- ALERT

Release of Toxic or Flammable Gases Within or Contiguous to a VITAL AREA Which Jeopardizes Operation of Systems Required to Maintain Safe Operations or Establish or Maintain Safe Shutdown.

Operating Mode Applicability: All

Emergency Action Levels: (HA3.1 or HA3.2)

HA3.1. Report or detection of toxic gases within or contiguous to a Safe Shutdown/VITAL AREA (Table H-1) in concentrations that may result in an atmosphere IMMEDIATELY DANGEROUS TO LIFE AND HEALTH (IDLH).

	Table H-1 Safe Shutdown/VITAL Areas	
•	Shield Building (Reactor Building)	
•	Auxiliary Building	
•	Safeguards Alley	
•	Diesel Generator Rooms (includes "A" Diesel Room to Screen House Tunnel)	
•	Screenhouse/Forebay	
•	Technical Support Center Basement	
•	Control Room	
•	Control Room AC Equipment Room	
•	Relay Room	
•	Safeguards Battery Rooms	

HA3.2. Report or detection of gases in concentration greater than the LOWER FLAMMABILITY LIMIT within or contiguous to a Safe Shutdown/VITAL AREA (Table H-1).

Basis:

This IC is based on gases that affect the safe operation of the plant. This IC applies to buildings and areas contiguous (in actual contact with or immediately adjacent) to plant Safe Shutdown/VITAL AREAs or other significant buildings or areas [Ref. 1, 2]. The intent of this IC is not to include buildings (e.g., warehouses) or other areas that are not contiguous or immediately adjacent to plant Safe Shutdown/VITAL AREAs. It is appropriate that increased monitoring be done to ascertain whether consequential damage has occurred. Escalation to a higher emergency class, if appropriate, will be based on System Malfunction, Fission Product Barrier Degradation, Abnormal Rad Levels / Radioactive Effluent, or Emergency Director Judgment ICs.

KNPP

10/22/04

HA3.1 is met if measurement of toxic gas concentration results in an atmosphere that is IDLH within a Safe Shutdown/VITAL AREA or any area or building contiguous to Safe Shutdown/VITAL AREA. Exposure to an IDLH atmosphere will result in immediate harm to unprotected personnel, and would preclude access to any such affected areas.

HA3.2 is met when the flammable gas concentration in a Safe Shutdown/VITAL AREA or any building or area contiguous to a Safe Shutdown/VITAL AREA exceed the LOWER FLAMMABILITY LIMIT. Flammable gasses, such as hydrogen and acetylene, are routinely used to maintain plant systems (hydrogen) or to repair equipment/components (acetylene - used in welding). This EAL addresses concentrations at which gases can ignite/support combustion. An uncontrolled release of flammable gasses within a facility structure has the potential to affect safe operation of the plant by limiting either operator or equipment operations due to the potential for ignition and resulting equipment damage/personnel injury. Once it has been determined that an uncontrolled release is occurring, then sampling must be done to determine if the concentration of the released gas is within this range.

HA4

Initiating Condition -- ALERT

Confirmed Security Event in a Plant PROTECTED AREA.

Operating Mode Applicability: All

Emergency Action Levels: (HA4.1 or HA4.2)

HA4.1. INTRUSION into the plant PROTECTED AREA by a HOSTILE FORCE.

- HA4.2. Security Shift Supervisor reports any of the following:
 - Sabotage device discovered in the plant PROTECTED AREA
 - Standoff attack on the protected area by a HOSTILE FORCE (i.e., Sniper)
 - ANY Security event of increasing severity that persists for > 30 minutes:
 - Credible bomb threats
 - Hostage / Extortion
 - Suspicious Fire or Explosion
 - Significant Security System Hardware Failure
 - Loss of contact with Security Officers

Basis:

This class of security events represents an escalated threat to plant safety above that contained in the UE. A confirmed INTRUSION report is satisfied if physical evidence indicates the presence of a HOSTILE FORCE within the PROTECTED AREA.

The Security And Safeguards Contingency Plan identifies numerous events/conditions that constitute a threat/compromise to station security. Only those events that involve actual or potential substantial degradation to the level of safety of the plant need to be considered.

INTRUSION into a VITAL AREA by a HOSTILE FORCE will escalate this event to a Site Area Emergency.

Reference is made to Security Shift Supervisor because this individual is the designated person on-site qualified and trained to confirm that a security event is occurring or has occurred. Training on security event classification confirmation is closely controlled due to the strict secrecy controls placed on the plant Physical Security Plan.

HA5

Initiating Condition -- ALERT

Control Room Evacuation Has Been Initiated.

Operating Mode Applicability: All

Emergency Action Level:

HA5.1. Entry into E-O-06, Fire in Alternate Fire Zone for control room evacuation.

Basis:

With the control room evacuated, additional support, monitoring and direction through the Technical Support Center and/or other emergency response facility is necessary. E-O-06, Fire in Alternate Fire Zone, provides specific instructions for evacuating the Control Room/Building and establishing plant control at the Dedicated Shutdown Panel and in alternate locations. Inability to establish plant control from outside the control room will escalate this event to a Site Area Emergency.

KNPP Basis Reference(s):

1. E-O-06, Fire in Alternate Fire Zone, Rev. W

KNPP

ì

Initiating Condition – ALERT

Other Conditions Existing Which in the Judgment of the Emergency Director Warrant Declaration of an Alert.

Operating Mode Applicability: All

Emergency Action Level:

HA6.1. Other conditions exist which in the judgment of the Emergency Director indicate that events are in process or have occurred which involve actual or likely potential substantial degradation of the level of safety of the plant. Any releases are expected to be limited to small fractions of the EPA Protective Action Guideline exposure levels.

Basis:

This EAL is intended to address unanticipated conditions not addressed explicitly elsewhere but that warrant declaration of an emergency because conditions exist which are believed by the Emergency Director to fall under the Alert emergency class. Refer to EPIP-AD-19 for EPA Protective Action Guideline exposure levels.

- 1. EPA 400, Manual of Protective Action Guides And Protective Actions For Nuclear Incidents, October 1991
- 2. EPIP-AD-19 Determining Protective Action Recommendations, Rev. T

HS1

Initiating Condition – SITE AREA EMERGENCY

Confirmed Security Event in a Plant VITAL AREA.

Operating Mode Applicability: All

Emergency Action Levels: (HS1.1 or HS1.2)

HS1.1. INTRUSION into the plant VITAL AREA by a HOSTILE FORCE.

HS1.2. Security Supervision reports ANY of the following:

- A security event that results in the loss of control of ANY VITAL AREAS (other than Control Room)
- Imminent loss of physical control of the facility (remote shutdown capability) due to a security event
- A confirmed sabotage discovered in a VITAL AREA

Basis:

This class of security events represents an escalated threat to plant safety above that contained in the Alert IC in that a HOSTILE FORCE has progressed from the PROTECTED AREA to a VITAL AREA.

Consideration is given to the following types of events when evaluating an event against the criteria of the site specific Security Contingency Plan: SABOTAGE and HOSTAGE / EXTORTION. The Safeguards Contingency Plan identifies numerous events/conditions that constitute a threat/compromise to a Station's security. Only those events that involve Actual or Likely Major failures of plant functions needed for protection of the public need to be considered.

Loss of Plant Control would escalate this event to a GENERAL EMERGENCY.

Reference is made to Security Shift Supervisor because this individual is the designated person on-site qualified and trained to confirm that a security event is occurring or has occurred. Training on security event classification confirmation is closely controlled due to the strict secrecy controls placed on the plant Physical Security Plan.

- 1. NRC Safeguards Advisory 10/6/01
- 2. Security And Safeguards Contingency Plan
- 3. Letter from Mr. B. A. Boger (NRC) to Ms. Lynette Hendricks (NEI) dated 2/4/02
- 4. Physical Security Plan

Initiating Condition – SITE AREA EMERGENCY

Control Room Evacuation Has Been Initiated and Plant Control Cannot Be Established.

Operating Mode Applicability: All

Emergency Action Level:

HS2.1. Control room evacuation has been initiated.

AND

Control of the plant cannot be established per E-O-06, Fire in Alternate Fire Zone within 15 minutes.

Basis:

Expeditious transfer of safety systems has not occurred but fission product barrier damage may not yet be indicated. The intent of this IC is to capture those events where control of the plant cannot be reestablished in a timely manner. The determination of whether or not control is established at the Dedicated Shutdown Panel is based on Emergency Director (ED) judgment. The ED is expected to make a reasonable, informed judgment within the time for transfer that the operator has control of the plant from the Dedicated Shutdown Panel.

E-O-06, Fire in Alternate Fire Zone, provides specific instructions for evacuating the Control Room/Building and establishing plant control at the Dedicated Shutdown Panel and in alternate locations.

The intent of the EAL is to establish control of important plant equipment and knowledge of important plant parameters in a timely manner. Primary emphasis should be placed on those components and instruments that supply protection for and information about safety functions. Typically, these safety functions are reactivity control (ability to shutdown the reactor and maintain it shutdown), RCS inventory (ability to cool the core), and secondary heat removal (ability to maintain a heat sink).

Escalation of this event, if appropriate, would be by Fission Product Barrier Degradation, Abnormal Rad Levels/Radiological Effluent, or Emergency Director Judgment ICs.

KNPP Basis Reference(s):

1. E-O-06, Fire in Alternate Fire Zone, Rev. W

Initiating Condition – SITE AREA EMERGENCY

Other Conditions Existing Which in the Judgment of the Emergency Director Warrant Declaration of Site Area Emergency.

Operating Mode Applicability: All

Emergency Action Level:

HS3.1. Other conditions exist which in the judgment of the Emergency Director indicate that events are in process or have occurred which involve actual or likely major failures of plant functions needed for protection of the public. Any releases are not expected to result in exposure levels which exceed EPA Protective Action Guideline exposure levels beyond the site boundary.

Basis:

This EAL is intended to address unanticipated conditions not addressed explicitly elsewhere but that warrant declaration of an emergency because conditions exist which are believed by the Emergency Director to fall under the emergency class description for Site Area Emergency. Refer to EPIP-AD-19 for EPA Protective Action Guideline exposure levels.

- 1. EPA 400, Manual of Protective Action Guides And Protective Actions For Nuclear Incidents, October 1991
- 2. EPIP-AD-19 Determining Protective Action Recommendations, Rev. T

Initiating Condition – GENERAL EMERGENCY

Security Event Resulting in Loss Of Physical Control of the Facility.

Operating Mode Applicability: All

Emergency Action Level:

HG1.1. A HOSTILE FORCE has taken control of plant equipment such that plant personnel are unable to operate equipment required to maintain safety functions as indicated by loss of physical control of EITHER:

A VITAL AREA (including the Control Room) such that operation of equipment required for safe shutdown is lost

OR

Spent fuel pool cooling systems if imminent fuel damage is likely

Basis:

This IC encompasses conditions under which a HOSTILE FORCE has taken physical control of VITAL AREAs (containing vital equipment or controls of vital equipment, including the Control Room) required to maintain safety functions and control of that equipment cannot be transferred to and operated from another location. Typically, these safety functions are reactivity control (ability to shut down the reactor and keep it shutdown) RCS inventory (ability to cool the core), and secondary heat removal (ability to maintain a heat sink). If control of the plant equipment necessary to maintain safety functions can be transferred to another location, then the above initiating condition is not met.

This EAL should also address loss of physical control of spent fuel pool cooling systems if imminent fuel damage is likely (e.g., freshly off-loaded reactor core in pool).

Loss of physical control of the control room or remote shutdown capability may prevent the ability to maintain safety functions.

- 1. NRC Safeguards Advisory 10/6/01
- 2. Security And Safeguards Contingency Plan
- 3. Letter from Mr. B. A. Boger (NRC) to Ms. Lynette Hendricks (NEI) dated 2/4/02
- 4. Physical Security Plan

Initiating Condition – GENERAL EMERGENCY

Other Conditions Existing Which in the Judgment of the Emergency Director Warrant Declaration of General Emergency.

Operating Mode Applicability: All

Emergency Action Level:

HG2.1. Other conditions exist which in the judgment of the Emergency Director indicate that events are in process or have occurred which involve actual or imminent substantial core degradation or melting with potential for loss of containment integrity. Releases can be reasonably expected to exceed EPA Protective Action Guideline exposure levels offsite for more than the immediate site area.

Basis:

This EAL is intended to address unanticipated conditions not addressed explicitly elsewhere but that warrant declaration of an emergency because conditions exist which are believed by the Emergency Director to fall under the General Emergency class. Refer to EPIP-AD-19 for EPA Protective Action Guideline exposure levels.

- 1. EPA 400, Manual of Protective Action Guides And Protective Actions For Nuclear Incidents, October 1991
- 2. EPIP-AD-19 Determining Protective Action Recommendations, Rev. T

SU1

Initiating Condition -- UNUSUAL EVENT

Loss of All Offsite Power to Essential Busses for GREATER THAN 15 Minutes.

Operating Mode Applicability:

Power Operation Hot Standby Hot Shutdown Intermediate Shutdown

Emergency Action Level:

SU1.1. Loss of all offsite power to Bus 5 AND Bus 6 for GREATER THAN 15 minutes.

AND

Emergency diesel generators are supplying power to Bus 5 AND Bus 6.

Basis:

Prolonged loss of AC power reduces required redundancy and potentially degrades the level of safety of the plant by rendering the plant more vulnerable to a complete Loss of AC Power (e.g., Station Blackout). Fifteen minutes was selected as a threshold to exclude transient or momentary power losses.

The 4160 VAC system is divided into six busses, two of which are Engineered Safety Features (ESF) busses 5 and 6. The ESF busses supply power to Safety Injection (SI) pumps, Residual Heat Removal (RHR) pumps, containment heat removal equipment, etc.

Offsite power is available from the 345 kVAC and 138 kVAC systems. The 345 kVAC system is connected to the North Appleton line, the Point Beach line, the main transformers, and transformer T-10. The 345 kVAC is the normal supply to the 13.8 kVAC system through transformer T-10, which feeds the Tertiary Auxiliary Transformer (TAT). The TAT normally provides power to ESF bus 5. The TAT is not considered available to power both ESF busses in an emergency situation due to its size. As a contingency, however, it is acceptable to use the TAT to power both ESF busses when guidance for sequencing and monitoring TAT loads is available in the Control Room. The Reserve Auxiliary Transformer (RAT) and Main Auxiliary Transformer (MAT) provide backup sources to bus 5, in that order.

The 138 kVAC system is connected to the Shoto/Mishicot line, the East Krok line and transformer T-10. The 138 kVAC system is the normal supply to the Reserve Auxiliary Transformer (RAT) via the East and West substation busses. (When the 345 kVAC system is unavailable, the 138 kVAC system can supply power to transformer T-10 and the TAT.) The RAT normally provides power to ESF bus 6. The TAT and MAT provide backup sources to bus 6 in that order.

When the main turbine generator is on line, generator output supplies power to the Main Auxiliary Transformer (MAT) and the 4160 VAC busses. When the main turbine generator is off line, the 345 kVAC system can be aligned to backfeed the MAT. Note that the time required to effect the backfeed is likely longer than the fifteen-minute interval associated with this EAL. If off-normal KNPP 6-S-3 10/22/04

plant conditions have already established the backfeed, however, its power to the ESF busses may be considered an offsite power source.

Following a loss of power, ECA 0.0 provides guidance to restore power to ESF busses. For the purpose of classification under this EAL, offsite power sources include any of the following:

- 345 kVAC system supplying power to transformer T-10 and the TAT
- 138 kVAC system supplying power to transformer T-10 and the TAT
- 138 kVAC system supplying power to the RAT
- 345 kVAC system supplying power to the MAT on backfeed through the main transformers when the main turbine generator is off line

SU2

Initiating Condition -- UNUSUAL EVENT

Inability to Reach Required Shutdown Within Technical Specification Limits.

Operating Mode Applicability:

Power Operation Hot Standby Hot Shutdown Intermediate Shutdown

Emergency Action Level:

SU2.1. Plant is not brought to required operating mode within Technical Specifications LCO Action Statement Time.

Basis:

Limiting Conditions of Operation (LCOs) require the plant to be brought to a required shutdown mode when the Technical Specification required configuration cannot be restored. Depending on the circumstances, this may or may not be an emergency or precursor to a more severe condition. In any case, the initiation of plant shutdown required by the KNPP Technical Specifications requires a one hour report under 10 CFR 50.72 (b) Non-emergency events. The plant is within its safety envelope when being shut down within the allowable action statement time in the Technical Specifications. An immediate UE is required when the plant is not brought to the required operating mode within the allowable action statement time in the Technical Specifications. Declaration of a UE is based on the time at which the LCO-specified action statement time period elapses under the site Technical Specifications and is not related to how long a condition may have existed. Other required Technical Specification shutdowns that involve precursors to more serious events are addressed by other System Malfunction, Hazards, or Fission Product Barrier Degradation ICs.

KNPP Basis Reference(s):

1. KNPP Technical Specifications

SU3

Initiating Condition -- UNUSUAL EVENT

UNPLANNED Loss of Most or All Safety System Annunciation or Indication in The Control Room for GREATER THAN 15 Minutes

Operating Mode Applicability:

Power Operation Hot Standby Hot Shutdown Intermediate Shutdown

Emergency Action Level:

SU3.1. UNPLANNED loss of most or all annunciators or indicators associated with safety systems for GREATER THAN 15 minutes on Mechanical Vertical Panels A, B and C, Mechanical Control Consoles A, B and C, Electrical Vertical Panel and Electrical Control Console

Basis:

This IC and its associated EAL are intended to recognize the difficulty associated with monitoring changing plant conditions without the use of a major portion of the annunciation or indication equipment.

Recognition of the availability of computer based indication equipment is considered (e.g., PPCS, SER or SPDS).

Quantification of "Most" is arbitrary, however, it is estimated that if approximately 75% of the safety system annunciators or indicators are lost, there is an increased risk that a degraded plant condition could go undetected. It is not intended that plant personnel perform a detailed count of the instrumentation lost but use the value as a judgment threshold for determining the severity of the plant conditions.

It is further recognized that plant design provides redundant safety system indication powered from separate uninterruptable power supplies. While failure of a large portion of annunciators is more likely than a failure of a large portion of indications, the concern is included in this EAL due to difficulty associated with assessment of plant conditions. The loss of specific, or several, safety system indicators should remain a function of that specific system or component operability status. This is addressed by the specific Technical Specification. The initiation of a Technical Specification imposed plant shutdown related to the instrument loss will be reported via 10 CFR 50.72. If the shutdown is not in compliance with the Technical Specification action, the UE is based on SU2 "Inability to Reach Required Shutdown Within Technical Specification Limits."

The specified panels for this EAL include annunciators and indicators identified in the Abnormal Operating Procedures, in the Emergency Operating Procedures, and in other EALs (e.g., area, process, and/or effluent rad monitors, etc.).

Fifteen minutes was selected as a threshold to exclude transient or momentary power losses.

Due to the limited number of safety systems in operation during cold shutdown, refueling, and defueled modes, no IC is indicated during these modes of operation.

This UE will be escalated to an Alert if a transient is in progress during the loss of annunciation or indication.

SU4

Initiating Condition -- UNUSUAL EVENT

Fuel Clad Degradation.

Operating Mode Applicability:

Power Operation Hot Standby Hot Shutdown Intermediate Shutdown

Emergency Action Levels: (SU4.1 or SU4.2)

- SU4.1. RCS Letdown Line (R-9) radiation monitor GREATER THAN 2000 mR/hr indicating fuel clad degradation.
- SU4.2. Coolant sample activity GREATER THAN ANY of the following indicating fuel clad degradation:
 - 1.0 µCi/gram dose equivalent lodine-131 for more than 48 hours in one continuous time interval
 - 60 µCi/gram dose equivalent lodine-131
 - 91/Ē µCi/cc gross radioactivity

Basis:

This IC is included as a UE because it is considered to be a potential degradation in the level of safety of the plant and a potential precursor of more serious problems. SU5.1 addresses RCS Letdown Line (R-9) radiation monitor readings that provide indication of fuel clad integrity. [Ref. 4 & 5] SU4.2 addresses coolant samples exceeding coolant technical specifications [Ref. 1].

2000 mR/hr was calculated using the following:

0.01% fuel cladding defect equals 7.2E+1 mR/hr increase on R-9 [Ref. 4] 0.2745% fuel cladding defect equals 1.0 μCi/gram dose equivalent lodine-131 [Ref. 5].

Therefore 1976.4 mR/hr increase on R-9 is equal to 1.0 μ Ci/gram dose equivalent lodine-131

R-9 background is equivalent to 56 mR/hr [Ref. 4], which is added to the calculated dose rate above.

With the addition of background R-9 will read 2032.4 mR/hr (rounded to 2000 mR/hr) equal to 1.0 μ Ci/gram dose equivalent lodine-131.

Escalation of this IC to the Alert level is via the Fission Product Barrier Degradation Monitoring ICs. Though the referenced Technical Specification limits are applicable when average reactor coolant temperature is GREATER THAN 500°F, it is appropriate that the EAL's be applicable in all modes, as they indicate a potential degradation in the level of safety of the plant. The companion IC to SU4 for the Cold Shutdown/Refueling modes is CU5.

SU5

Initiating Condition -- UNUSUAL EVENT

RCS Leakage.

Operating Mode Applicability:

Power Operation Hot Standby Hot Shutdown Intermediate Shutdown

Emergency Action Levels:

(SU5.1 or SU5.2)

SU5.1. Unidentified or pressure boundary leakage GREATER THAN 10 gpm.

SU5.2. Identified leakage GREATER THAN 25 gpm.

Basis:

This IC is included as a UE because it may be a precursor of more serious conditions and, as result, is considered to be a potential degradation of the level of safety of the plant. Positive indications in the Control Room of Reactor Coolant System (RCS) leakage to the containment are provided by equipment that monitors:

- Charging/Letdown flow mismatch
- Containment air activity
- Containment atmosphere humidity
- Containment Sump A in leakage

[Ref. 1, 2]

The 10 gpm value for the unidentified and pressure boundary leakage was selected as it is observable with normal control room indications. Lesser values must generally be determined through time-consuming surveillance tests (e.g., mass balances). SP-36-82 provides instructions for calculating primary system leak rate by water inventory balances for off-normal events and for operations troubleshooting [Ref, 2]. The EAL for identified leakage is set at a higher value due to the lesser significance of identified leakage in comparison to unidentified or pressure boundary leakage. In either case, escalation of this IC to the Alert level is via Fission Product Barrier Degradation ICs.

- 2. SP-36-82 Reactor Coolant System Leak Rate Check, Rev. AE

SU6

Initiating Condition -- UNUSUAL EVENT

UNPLANNED Loss of All Onsite or Offsite Communications Capabilities.

Operating Mode Applicability:	Power Operation
	Hot Standby
	Hot Shutdown
	Intermediate Shutdown

Emergency Action Levels: (SU6.1 or SU6.2)

SU6.1. Loss of all Table C-1 onsite communications capability affecting the ability to perform routine operations.

	Table C-1 Onsite Communications Systems	
•	Intraplant Paging (Gai-tronics)	
•	Sound powered phones	
•	PBX telephone system	
•	 Personal communications system (PCS phones) 	
•	Portable radio communications system	

SU6.2. Loss of all Table C-2 offsite communications capability.

Table C-2 Offsite Communications Systems

- PBX telephone system
- NRC FTS System (including ENS and HPN)
- Dial select phones

Basis:

The purpose of this IC and its associated EALs is to recognize a loss of communications capability that either defeats the plant operations staff ability to perform routine tasks necessary for plant operations or the ability to communicate problems with offsite authorities. The loss of offsite communications ability is expected to be significantly more comprehensive than the condition addressed by 10 CFR 50.72.

The availability of one method of ordinary offsite communications is sufficient to inform state and local authorities of plant problems. This EAL is intended to be used only when extraordinary means (e.g., relaying of information from radio transmissions, individuals being sent to offsite locations, etc.) are being utilized to make communications possible.

Table C-1 onsite communications loss encompasses the loss of all means of routine communications (e.g., commercial telephones, sound powered phone systems, page party system (Gaitronics) and radios / walkie talkies). Due to its limited capability, the emergency gai-tronics is not listed in Table C-1.

Table C-2 offsite communications loss encompasses the loss of all means of communications with offsite authorities. This includes the NRC FTS System (including Emergency Notification System - ENS and Health Physics Network – HPN), commercial telephone lines, telecopy transmissions, and dedicated phone systems.

SU8

Initiating Condition – UNUSUAL EVENT

Inadvertent Criticality.

Operating Mode Applicability:

Hot Shutdown Intermediate Shutdown

Emergency Action Level:

SU8.1. An UNPLANNED sustained positive startup rate observed on nuclear instrumentation.

Basis:

This IC addresses inadvertent criticality events. While the primary concern of this IC is criticality events that occur in Cold Shutdown or Refueling modes (NUREG 1449, Shutdown and Low-Power Operation at Commercial Nuclear Power Plants in the United States), the IC is applicable in other modes in which inadvertent criticalities are possible. This IC indicates a potential degradation of the level of safety of the plant, warranting an Unusual Event classification. This IC excludes inadvertent criticalities that occur during planned reactivity changes associated with reactor startups (e.g., criticality earlier than estimated). The Cold Shutdown/Refueling IC is CU8.

This condition can be identified using the startup rate monitor. The term "sustained" is used in order to allow exclusion of expected short term positive startup rates from planned control rod movements such as shutdown bank withdrawal. These short term positive startup rates are the result of the rise in neutron population due to subcritical multiplication.

This condition can be identified using startup rate monitors (NI-31D/32D - Source Range Startup Rate).

Escalation would be by the Fission Product Barrier Matrix, as appropriate to the operating mode at the time of the event, or by Emergency Director Judgment.

Note: This EAL is SU8 following SU6. SU7 is not used in NEI 99-01 Revision 4 and that convention is carried forward here.

KNPP Basis Reference(s):

1. N-0-02 Plant Startup from Hot Shutdown to 35% Power, Rev. AN

Initiating Condition -- ALERT

Failure of Reactor Protection System Instrumentation to Complete or Initiate an Automatic Reactor Trip Once a Reactor Protection System Setpoint Has Been Exceeded and Manual Reactor Trip Was Successful.

Operating Mode Applicability:

Power Operation Hot Standby Hot Shutdown

Emergency Action Level:

SA2.1. Indication(s) exist that a Reactor Protection System setpoint was exceeded AND

RPS automatic trip did <u>not</u> reduce power to LESS THAN 5% AND

Any of the following operator actions are successful in reducing power to LESS THAN 5%:

- Use of Manual Reactor Trip push buttons
- De-energizing Busses 33 AND 43

Basis:

This condition indicates failure of the automatic protection system to trip the reactor. This condition is more than a potential degradation of a safety system in that a front line automatic protection system did not function in response to a plant transient and thus the plant safety has been compromised, and design limits of the fuel may have been exceeded. An Alert is indicated because conditions exist that lead to potential loss of fuel clad or RCS. Reactor protection system setpoint being exceeded, rather than limiting safety system setpoint being exceeded, is specified here because failure of the automatic protection system is the issue. A manual trip is any set of actions by the reactor operator(s) at the control room consoles which causes control rods to be rapidly inserted into the core and brings the reactor subcritical (e.g., reactor trip button). Failure of manual trip would escalate the event to a Site Area Emergency.

Following a successful reactor trip, nuclear power promptly drops to only a few percent of nominal, and then decays away to a level some 8 decades less. Reactor power levels resulting from radioactive fission product decay are never more than a few percent of nominal power and also lower in time. Heat removal safety systems are sized to remove only decay heat and not significant core power. Reactor power levels at or above 5% (in a core that is supposed to be shutdown) are considered an extreme challenge to the Fuel Cladding barrier and warrant a Critical Safety Function Status Tree (CSFST) Subcriticality-Red path priority. The setpoint has been chosen because it is clearly readable on the power range meters. Reactor power levels in the power range are indicated on Mechanical Control Console "B" nuclear instruments NI-41, 42, 43 and 44.

Following any automatic reactor trip signal, plant procedures prescribe operator insertion of redundant manual trip signals to ensure reactor shutdown is achieved. A successful manual trip is any set of actions by the reactor operator(s) in the Control Room that causes control rods to be KNPP 6-S-14 10/22/04

rapidly inserted into the core and brings the reactor subcritical. Manual trip includes the procedural direction to deenergize Busses 33 and 43 to ensure rod insertion. Control rod insertion completed from the Rod Drive Equipment Room is not considered a successful manual trip as action is required outside the Control Room. Manual insertion of control rods from the Control Room is not considered rapid insertion that brings the reactor sub-critical.

Note: This EAL is SA2 following SU8. SA1 is not used in NEI 99-01 Revision 4 and that convention is carried forward here.

SA4

Initiating Condition -- ALERT

UNPLANNED Loss of Most or All Safety System Annunciation or Indication in Control Room With Either (1) a SIGNIFICANT TRANSIENT in Progress, or (2) Compensatory Non-Alarming Indicators are Unavailable.

Operating Mode Applicability:

Power Operation Hot Standby Hot Shutdown Intermediate Shutdown

Emergency Action Level:

SA4.1. UNPLANNED loss of most or all annunciators or indicators associated with safety systems for GREATER THAN 15 minutes on Mechanical Vertical Panels A, B and C, Mechanical Control Consoles A, B and C, Electrical Vertical Panel and Electrical Control Console

AND

Either of the following: (a or b)

a. A SIGNIFICANT TRANSIENT is in progress.

OR

b. COMPENSATORY NON-ALARMING INDICATIONS are unavailable.

Basis:

This IC and its associated EAL are intended to recognize the difficulty associated with monitoring changing plant conditions without the use of a major portion of the annunciation or indication equipment during a transient. Recognition of the availability of computer based indication equipment is considered (e.g., SPDS, plant computer, etc.).

SIGNIFICANT TRANSIENT includes response to automatic or manually initiated functions such as reactor trips, runbacks involving greater than 25% thermal power change, ECCS injections, or thermal power oscillations of 10% or greater.

COMPENSATORY NON-ALARMING INDICATIONS include the plant process computer (PPCS), SPDS, plant recorders, or plant instrument displays in the control room. If both a major portion of the annunciation system and all computer monitoring are unavailable, the Alert is required.

"Planned" loss of annunciators or indicators includes scheduled maintenance and testing activities.

Quantification of "Most" is arbitrary, however, it is estimated that if approximately 75% of the safety system annunciators or indicators are lost, there is an increased risk that a degraded plant condition could go undetected. It is not intended that plant personnel perform a detailed count of the instrumentation lost but use the value as a judgment threshold for determining the severity of the plant conditions. It is also not intended that the Shift Manager be tasked with making a judgment decision as to whether additional personnel are required to provide increased monitoring of system operation.

It is further recognized that plant design provides redundant safety system indication powered from separate uninterruptable power supplies. While failure of a large portion of annunciators is more likely than a failure of a large portion of indications, the concern is included in this EAL due to difficulty associated with assessment of plant conditions. The loss of specific, or several, safety system indicators should remain a function of that specific system or component operability status. This will be addressed by the specific Technical Specification. The initiation of a Technical Specification imposed plant shutdown related to the instrument loss will be reported via 10 CFR 50.72. If the shutdown is not in compliance with the Technical Specification action, the UE is based on SU2 "Inability to Reach Required Shutdown Within Technical Specification Limits."

The specified panels for this EAL include annunciators and indicators identified in the Abnormal Operating Procedures, in the Emergency Operating Procedures, and in other EALs (e.g., area, process, and/or effluent rad monitors, etc.).

Due to the limited number of safety systems in operation during cold shutdown, refueling and defueled modes, no IC is indicated during these modes of operation.

This Alert will be escalated to a Site Area Emergency if the operating crew cannot monitor the transient in progress.

Note: This EAL is SA4 following SA2. SA3 is not used in NEI 99-01 Revision 4 and that convention is carried forward here.

Initiating Condition -- ALERT

AC power capability to essential busses reduced to a single power source for GREATER THAN 15 minutes such that any additional single failure would result in station blackout.

Operating Mode Applicability:

Power Operation Hot Standby Hot Shutdown Intermediate Shutdown

Emergency Action Level:

- SA5.1. AC power capability to Bus 5 AND Bus 6 reduced to only one of the following sources for GREATER THAN 15 minutes:
 - One emergency diesel generator (A or B)
 - TAT
 - RAT
 - MAT on backfeed

AND

Any additional single failure will result in station blackout.

Basis:

This IC and the associated EALs are intended to provide an escalation from IC SU1, "Loss of All Offsite Power To Essential Busses for Greater Than 15 Minutes." The condition indicated by this IC is the degradation of the offsite and onsite power systems such that any additional single failure would result in a station blackout. This condition could occur due to a loss of offsite power with a concurrent failure of one emergency diesel generator to supply power to its emergency busses. Another related condition could be the loss of onsite emergency diesels with only one train of emergency busses being backfed from offsite power. Offsite power sources include the 345 kVAC system or 138 kVAC system to the Tertiary Auxiliary Transformer (TAT), the 345 kVAC system or 138 kVAC system to the Reserve Auxiliary Transformer (RAT), and the 345 kVAC system to the Main Auxiliary Transformer (MAT) on backfeed through the main transformers. Note that the time required to effect a backfeed to the MAT is likely longer than the fifteen-minute interval. If off-normal plant conditions have already established the backfeed, however, its power to the ESF busses may be considered an offsite power source. Onsite power sources consist of 1A Diesel Generator to Bus 5 and 1B Diesel Generator to Bus 6. Several combinations of power failures could therefore satisfy this EAL. The subsequent loss of the single remaining power source would escalate the event to a Site Area Emergency in accordance with IC SS1, "Loss of All Offsite and Loss of All Onsite AC Power to Essential Busses."
KNPP Basis Reference(s):

- 1. ECA-0.0 Loss of All AC Power, Rev. AB
- 2. USAR Figure 8.2-2, Rev. 16

- 4. USAR Section 8.2.4, Rev. 18
- 5. GNP-08.04.01 Shutdown Safety Assessment, Rev. K

SYSTEM MALFUNCTION

SS1

Initiating Condition -- SITE AREA EMERGENCY

Loss of All Offsite Power and Loss of All Onsite AC Power to Essential Busses.

Operating Mode Applicability:

Power Operation Hot Standby Hot Shutdown Intermediate Shutdown

Emergency Action Level:

SS1.1. Loss of ALL power to Bus 5 AND Bus 6 for GREATER THAN 15 minutes.

Basis:

Loss of all AC power compromises all plant safety systems requiring electric power including RHR, ECCS, Containment Heat Removal and the Service Water System. Prolonged loss of all AC power will cause core uncovering and loss of containment integrity, thus this event can escalate to a General Emergency.

Offsite power sources include the 345 kVAC system or 138 kVAC system to the Tertiary Auxiliary Transformer (TAT), the 345 kVAC or 138 kVAC system to the Reserve Auxiliary Transformer (RAT), and the 345 kVAC system to the Main Auxiliary Transformer (MAT) on backfeed through the main transformers. Note that the time required to effect a backfeed to the MAT is likely longer than the fifteen-minute interval. If off-normal plant conditions have already established the backfeed, however, its power to the ESF busses may be considered an offsite power source. Onsite power sources consist of 1A Diesel Generator to Bus 5 and 1B Diesel Generator to Bus 6.

Escalation to General Emergency is via Fission Product Barrier Degradation or IC SG1, "Prolonged Loss of All Offsite Power and Prolonged Loss of All Onsite AC Power."

Consideration should be given to operable loads necessary to remove decay heat or provide Reactor Vessel makeup capability when evaluating loss of AC power to safety-related 4160 VAC busses. Even though a safety-related 4160 VAC bus may be energized, if necessary loads (i.e., loads that if lost would inhibit decay heat removal capability or Reactor Vessel makeup capability) are not operable on the energized bus then the bus should not be considered operable. If this bus was the only energized bus then a Site Area Emergency per SS1 should be declared.

SYSTEM MALFUNCTION

SS2

Initiating Condition -- SITE AREA EMERGENCY

Failure of Reactor Protection System Instrumentation to Complete or Initiate an Automatic Reactor Trip Once a Reactor Protection System Setpoint Has Been Exceeded and Manual Reactor Trip Was NOT Successful.

Operating Mode Applicability:	[•] Power Operation
	Hot Standby

Emergency Action Level:

SS2.1. Indication(s) exist that automatic and manual trip were NOT successful in reducing power to LESS THAN 5%. Manual Reactor Trips include use of Manual Reactor Trip push buttons or De-energizing Busses 33 AND 43.

Basis:

Automatic and manual trip are not considered successful if action away from the Control Room was required to trip the reactor.

Under these conditions, the reactor is producing more heat than the maximum decay heat load for which the safety systems are designed. A Site Area Emergency is indicated because conditions exist that lead to imminent loss or potential loss of both fuel clad and RCS. Although this IC may be viewed as redundant to the Fission Product Barrier Degradation IC, its inclusion is necessary to better assure timely recognition and emergency response. Escalation of this event to a General Emergency would be via Fission Product Barrier Degradation or Emergency Director Judgment ICs.

Automatic or manual reactor trip is considered successful if actions taken (use of Manual Reactor Trip push buttons or De-energizing Busses 33 AND 43) result in reducing reactor power less than 5%. Reactor power levels in the power range are indicated on N-41, 42, 43 and 44. Automatic and manual trips are not considered successful if action away from the Control Room (e.g., Rod Drive Equipment Room) is required to trip the reactor. Manual insertion of control rods from the Control Room is not considered rapid insertion that brings the reactor sub-critical.

KNPP Basis Reference(s):

- 1. E-0 Reactor Trip or Safety Injection, Rev. V

SYSTEM MALFUNCTION

SS3

Initiating Condition -- SITE AREA EMERGENCY

Loss of All Vital DC Power.

Operating Mode Applicability:

Power Operation Hot Standby Hot Shutdown Intermediate Shutdown

Emergency Action Level:

SS3.1. Loss of all vital DC power based on LESS THAN 105 VDC on Train A AND Train B Safeguards DC Distribution Systems for GREATER THAN 15 minutes.

Basis:

Loss of all DC power compromises ability to monitor and control plant safety functions. Prolonged loss of all DC power will cause core uncovering and loss of containment integrity when there is significant decay heat and sensible heat in the reactor system. Escalation to a General Emergency would occur by Abnormal Rad Levels/Radiological Effluent, Fission Product Barrier Degradation, or Emergency Director Judgment ICs. Fifteen minutes was selected as a threshold to exclude transient or momentary power losses.

The loss of a safeguards DC train consists of a combination of loss of power to specified DC distribution panels. These panels include: BRA (BRB)-102, and BRA (BRB)-104. In all cases, BRA (BRB)-102 panel indicating less than 105 VDC constitutes a loss of the associated DC distribution train. However, a loss of power to the BRA (BRB) -104 panel, which does not have voltage indication, also constitutes a loss of the associated DC distribution train.

125 VDC safeguard main distribution cabinets (BRA-102 and BRB-102) supply two safeguard sub-distribution cabinets (BRA-104 and BRB-104) and provide for connection of safeguard batteries (BRA-101 and BRB-101) to their associated battery chargers (BRA-108 and BRB-108). The combination of low voltages on the specified distribution cabinets results in a total loss of vital 125 VDC power. The 125 VDC safeguards distribution system supplies circuit breaker control power, Control Room alarms, Control Room controls, diesel generator controls, and the Reactor Protection System. The 125 VDC safeguard system is also the standby power source to the AC inverters. BRA-102 and BRB-102 voltage is displayed on Control Room indicators 4494001 and 4494002, respectively. Undervoltage is alarmed on Control Room Sequence of Event Recorder (SER) points 490011196 and 490011200 and annunciators 447101A and 47101B, respectively.

Each of the 125 VDC batteries has been sized to carry the expected shutdown loads following a reactor trip and a loss of all AC power for a period of eight hours without battery terminal voltage falling below 105 VDC. This voltage value therefore incorporates a margin of at least 15 minutes of operation before the onset of inability to operate loads. The nominal battery cell voltage is 2.20 VDC. Low battery terminal voltage activates Control Room SER point 49001832 and annunciator 47105A. The batteries are located in Battery Rooms A and B on the Turbine Building Mezzanine Floor (606 ft el.).

SYSTEM MALFUNCTION

SS4

Initiating Condition -- SITE AREA EMERGENCY

Complete Loss of Heat Removal Capability.

Operating Mode Applicability:

Power Operation Hot Standby Hot Shutdown Intermediate Shutdown

Emergency Action Level:

SS4.1. Loss of core cooling and heat sink.

Basis:

This EAL addresses complete loss of functions, including Service Water System, required for hot shutdown with the reactor at pressure and temperature. Reactivity control is addressed in other EALs.

Under these conditions, there is an actual major failure of a system intended for protection of the public. Thus, declaration of a Site Area Emergency is warranted. Escalation to General Emergency would be via Abnormal Rad Levels / Radiological Effluent, Emergency Director Judgment, or Fission Product Barrier Degradation ICs.

KNPP Basis Reference(s):

None

SYSTEM MALFUNCTION

SS6

Initiating Condition -- SITE AREA EMERGENCY

Inability to Monitor a SIGNIFICANT TRANSIENT in Progress.

Operating Mode Applicability:

Power Operation Hot Standby Hot Shutdown Intermediate Shutdown

Emergency Action Level:

SS6.1. Loss of most or all annunciators associated with safety systems on Mechanical Vertical Panels A, B and C, Mechanical Control Consoles A, B and C, Electrical Vertical Panel and Electrical Control Console.

AND

SIGNIFICANT TRANSIENT in progress.

AND

COMPENSATORY NON-ALARMING INDICATIONS are unavailable.

AND

Indications needed to monitor the ability to shut down the reactor, maintain the core cooled, maintain the reactor coolant system intact, and maintain containment intact are unavailable.

Basis:

This IC and its associated EAL are intended to recognize the inability of the control room staff to monitor the plant response to a transient. A Site Area Emergency is considered to exist if the control room staff cannot monitor safety functions needed for protection of the public.

SIGNIFICANT TRANSIENT includes response to automatic or manually initiated functions such as reactor trips, runbacks involving greater than 25% thermal power change, ECCS injections, or thermal power oscillations of 10% or greater.

COMPENSATORY NON-ALARMING INDICATIONS include the plant process computer (PPCS), SPDS, plant recorders, or plant instrument displays in the control room.

Indications needed to monitor safety functions necessary for protection of the public include control room indications, computer generated indications and dedicated annunciation capability. The specific indications are those used to monitor the ability to shut down the reactor, maintain the core cooled, to maintain the reactor coolant system intact, and to maintain containment intact.

"Planned" and "UNPLANNED" actions are not differentiated since the loss of instrumentation of this magnitude is of such significance during a transient that the cause of the loss is not an ameliorating factor.

Quantification of "Most" is arbitrary, however, it is estimated that if approximately 75% of the safety system annunciators or indicators are lost, there is an increased risk that a degraded plant condition could go undetected. It is not intended that plant personnel perform a detailed count of the instrumentation lost but use the value as a judgment threshold for determining the severity of the plant conditions. It is also not intended that the Shift Supervisor be tasked with making a judgment decision as to whether additional personnel are required to provide increased monitoring of system operation.

Note: This EAL is SS6 following SS4. SS5 is not used in NEI 99-01 Revision 4 and that convention is carried forward here.

SYSTEM MALFUNCTION

SG1

Initiating Condition – GENERAL EMERGENCY

Prolonged Loss of All Offsite Power and Prolonged Loss of All Onsite AC Power to Essential Busses.

Operating Mode Applicability:

Power Operation Hot Standby Hot Shutdown Intermediate Shutdown

Emergency Action Level:

SG1.1. Loss of all offsite power to Bus 5 AND Bus 6

AND

Failure of all emergency diesel generators to supply power to Bus 5 AND Bus 6.

AND

Either of the following: (a or b)

a. Restoration of either Bus 5 OR Bus 6 within 4 hours is not likely

OR

b. Continuing degradation of core cooling based on Fission Product Barrier monitoring as indicated by a Core Cooling-RED or Core Cooling-ORANGE

Basis:

Loss of all AC power compromises all plant safety systems requiring electric power including RHR, ECCS, Containment Heat Removal and the Service Water System. Prolonged loss of all AC power will lead to loss of fuel clad, RCS, and containment. The 4 hours to restore AC power is based on the site blackout coping analysis performed in conformance with 10 CFR 50.63 and Regulatory Guide 1.155, "Station Blackout,". Four hours includes appropriate allowance for offsite emergency response including evacuation of surrounding areas. Although this IC may be viewed as redundant to the Fission Product Barrier Degradation IC, its inclusion is necessary to better assure timely recognition and emergency response.

This IC is specified to assure that in the unlikely event of a prolonged station blackout, timely recognition of the seriousness of the event occurs and that declaration of a General Emergency occurs as early as is appropriate, based on a reasonable assessment of the event trajectory.

Offsite power sources include the 345 kVAC system or 138 kVAC system to the Tertiary Auxiliary Transformer (TAT), the 345 kVAC system or 138 kVAC system to the Reserve Auxiliary

Transformer (RAT), and the 345 kVAC system to the Main Auxiliary Transformer (MAT) on backfeed through the main transformers. Time required to effect a backfeed to the MAT is likely longer than the four hours. If shutddown plant conditions have already established the backfeed, however, its power to the ESF busses may be considered an offsite power source. Onsite power sources consist of Diesel Generator A to Bus 5 and Diesel Generator B to Bus 6.

The likelihood of restoring at least one emergency bus should be based on a realistic appraisal of the situation since a delay in an upgrade decision based on only a chance of mitigating the event could result in a loss of valuable time in preparing and implementing public protective actions. In addition, under these conditions, fission product barrier monitoring capability may be degraded. Although it may be difficult to predict when power can be restored, it is necessary to give the Emergency Director a reasonable idea of how quickly (s)he may need to declare a General Emergency based on two major considerations:

- 1. Are there any present indications that core cooling is already degraded to the point that Loss or Potential Loss of Fission Product Barriers is imminent? (Refer to Table F-1 for more information.)
- 2. If there are no present indications of such core cooling degradation, how likely is it that power can be restored in time to assure that a loss of two barriers with a potential loss of the third barrier can be prevented?

Thus, indication of continuing core cooling degradation must be based on Fission Product Barrier monitoring with particular emphasis on Emergency Director judgment as it relates to imminent Loss or Potential Loss of fission product barriers and degraded ability to monitor fission product barriers.

SYSTEM MALFUNCTION

SG2

Initiating Condition - GENERAL EMERGENCY

Failure of the Reactor Protection System to Complete an Automatic Reactor Trip and Manual Reactor Trip was NOT Successful and There is Indication of an Extreme Challenge to the Ability to Cool the Core.

Operating Mode Applicability:

Power Operation Hot Standby

Emergency Action Level:

SG2.1. Indication(s) exist that automatic and manual reactor trip were NOT successful in reducing power to LESS THAN 5%.

AND

Either of the following: (a or b)

a. Indication(s) exists that the core cooling is extremely challenged as indicated by Core Cooling - RED.

OR

b. Indication(s) exists that heat removal is extremely challenged as indicated by Heat Sink - RED.

Basis:

Automatic and manual reactor trips are not considered successful if action away from the reactor control console is required to trip the reactor.

Under the conditions of this IC and its associated EALs, the efforts to bring the reactor subcritical have been unsuccessful and, as a result, the reactor is producing more heat than the maximum decay heat load for which the safety systems were designed. Although there are capabilities to reduce reactor power, such as emergency boration, the continuing temperature rise indicates that these capabilities are not effective. This situation could be a precursor for a core melt sequence.

The extreme challenge to the ability to cool the core is intended to mean that the core exit temperatures are at or approaching 1200 degrees F or that the reactor vessel water level is below the top of active fuel. This EAL equates to a Core Cooling RED condition and an entry into function restoration procedure FR-C.1.

Another consideration is the inability to initially remove heat during the early stages of this sequence. If emergency feedwater flow is insufficient to remove the amount of heat required by design from at least one steam generator, an extreme challenge should be considered to exist. This EAL equates to a Heat Sink RED condition.

In the event either of these challenges exist at a time that the reactor has not been brought below the power associated with the safety system design (5% power) a core melt sequence exists. In this situation, core degradation can occur rapidly. For this reason, the General Emergency declaration is intended to be anticipatory of the fission product barrier matrix declaration to permit maximum offsite intervention time.

Automatic or manual reactor trip is considered successful if actions taken (use of Manual Reactor Trip push buttons or De-energizing Busses 33 AND 43) result in reducing reactor power less than 5%. Reactor power levels in the power range are indicated on N-41, 42, 43 and 44. Automatic and manual trips are not considered successful if action away from the Control Room (e.g., Rod Drive Equipment Room) is required to trip the reactor. Manual insertion of control rods from the Control Room is not considered rapid insertion that brings the reactor sub-critical.

Kewaunee Nuclear Power Plant EALs vs NEI 99-01 rev 4 EALs Differences / Deviations / Site Specific Information

Kewaunee Nuclear Power Plant EALs vs NEI 99-01 rev 4 EALs

Definitions

The following definitions were used from RIS 2003-18 Sup 1 to define Differences and Deviations contained in this submittal:

Difference: An EAL change where the basis scheme guidance differs in wording but agrees in meaning and intent, such that classification of an event would be the same, whether using the basis scheme guidance or the site-specific proposed EAL

Deviation: An EAL change where the basis scheme guidance differs in wording and is altered in meaning or intent, such that classification of the event could be different between the basis scheme guidance and the site-specific proposed EAL.

Generic Differences

The generic changes listed below are not deviation because they do not alter the meaning or intent of associated EAL's, such that classification of the event could be different between the NEI guidance and the plant EAL:

- Each EAL was numbered sequentially in the subgroups. In example: "RU1.1" is the first EAL in subgroup RU1. This was done to improve communication at the KNPP emergency facilities and with offsite agencies.
- ISFSI and Permanently Defueled NEI EAL section are not applicable to KNPP and have been deleted.
- The symbols <, >, etc. were replaced with "LESS THAN", "GREATER THAN", etc. is to be consistent with other KNPP documents (Procedures Writer Guide GNP-03.01.04) and for human factors.
- The "LESS THAN", "GREATER THAN", etc wording is capitalized to be consistent with other KNPP documents (Procedures Writer Guide GNP-03.01.04) and for human factors.
- "Reactor Scram" was replaced with "Reactor Trip" to be consistent with KNPP wording.
- Capitalization and Bold of logic "AND" / "OR" is to be consistent with other KNPP documents and for human factors.
- NEI Operating Mode Applicability "Startup" was deleted and "Intermediate Shutdown" was added to conform to KNPP's Operating Modes. Also, Power Operation was changed to Operating to conform to KNPP's Operating Modes. Refer to Technical Specification page TS 1.0-4.
- NOUE (Notice of Unusual Event) was changed to KNPP wording of UE (Unusual Event).
- The words "increase" and "decrease" has been replaced with "raise" / "rise" and "lowering". This change was done to be consistent with KNPP communication standards

and for human factors. The words 'increase' and 'decrease' are not normally used because they are easily misunderstood.

- "Reactor Vessel" was used in place of "RPV" to match site procedure verbiage and PWR terminology.
- "Exceeds" was replaced with "GREATER THAN" to allow consistency between other KNPP documents.
- Words that are defined in the EAL Bases were capitalized to indicate define words.

General Development Information

Unless otherwise documented in the EAL bases, values and setpoints contained with in the EAL's were made in accordance with NEI 99-01 rev 4 guidelines and are not addressed separately in the Difference and Deviation Matrix.

5	VALID indication on automatic real- time dose assessment capability greater than (site-specific value) for 15 minutes or longer [for sites having such capability]	N/A	N/A	
Site specific	N/A			
Difference	• Deleted NEI 99-01 Example EAL #5 because the plant is not equipped with automatic real-time dose assessment capability.			
Deviation	None			

RA1 – Basi	RA1 – Basis Justification					
KNPP	Specific Additions/Deletions		Justification			
1. Adde the ra for th	d specific information pertaining to idiation monitors listed and the basis ie values listed.	1.	This information was added to explain the monitor values.			
2. Deleted reference to EAL#4		2.	KNPP is not equipped with perimeter radiation monitors.			
3. Deleted reference to EAL#5		3.	KNPP is not equipped with automatic real-time dose assessment capabilities.			
4. Development information contained in the NEI Basis was deleted.		4.	Development information is not necessary after the site specific information has been developed. The basis would be very confusing if these statements were left in along with the site specific information.			
Difference	• Information was added to explain the basis for the monitor values.					
• "2 X Calculated ODCM Setpoint" was used for R-18 due to setpoint being calculated discharge permit and is dependent upon flow rate of discharge.						
	• EAL #4 and #5 Basis information	on is not a	applicable to KNPP and was deleted.			
Deviations	None

Mode App.	All		All		
Site specific	None				
Difference	None				
Deviation	None				

NEI EAL#	NEI EAL Wording	KNPP EAL#(s)	KNPP EAL Wording	
1	A VALID (site-specific) alarm or reading on one or more of the following radiation monitors: (site-specific monitors) Refuel Floor Area Radiation Monitor Fuel Handling Building Ventilation Monitor Refueling Bridge Area Radiation Monitor	RA2.1	 A VALID radiation indication high alarm or reading on one or more of the following radiation monitor resulting from damage to irradiated fuel or loss of water level: R-2, Containment Area R-5, Fuel Handling Area R-13 or R-14, Aux Bldg Vent Exhaust R-11 or R-12, Containment Particulate/Gas Ventilation R-21, Containment Vent 	
Site specific	 The listed radiation monitors represent the site-specific equivalents of Refuel Floor Area Radiation Monitor, Auxiliary Building Ventilation Monitor, Containment Ventilation Monitors, and Spent Fuel Pool Area Radiation Monitor. "Radiation Indication High" is the appropriate terminology for KNPP. 			
Difference	 Added the wording: "resulting from damage to irradiated fuel or loss of water level" to be consistent with NEI basis. This change is not a deviation because it does not alter the meaning or intent, such that classification of the event could be different between the NEI guidance and the plant EAL. 			
Deviation	None

NEI EAL#	NEI EAL Wording	KNPP EAL#(s)	KNPP EAL Wording
2	Water level less than (site-specific) feet for the reactor refueling cavity, spent fuel pool and fuel transfer canal that will result in irradiated fuel uncovering	RA2.2	Water level LESS THAN 50% Wide Range Refueling Water Level <u>OR</u> GREATER THAN 14 ft. below top of Spent Fuel Pool that will result in irradiated fuel uncovering.
Site specific	• Added site specific indications of 50% Wide Range Refueling Water Level and 14 ft. below top of Spent Fuel Pool. The values inserted are the maximum height the fuel could be during refueling. This would be bounding and conservative for all conditions. Since there is no remote level indication for corresponding Spent Fuel Pool Level, KNPP would rely on visual observation for the Spent Fuel Pool (a installed ruler on side).		
Difference	 The Fuel Transfer Canal was removed because there is no level indication and when fuel is located in the canal it is lined-up to the cavity and fuel pool. 		
	• Replaced "and" with " <u>OR</u> " since either level lowering can result in irradiated fuel uncovery.		
	 These changes are not a deviation because they do not alter the meaning or intent, such that classification of the event could be different between the NEI guidance and the plant EAL. 		
Deviation	• None		

RA2 – Basis Justification				
KNP S	pecific Additions/Deletions	Justification		
Added the fol each pool is a at 608 ft el. F [Ref. 4].	lowing statement - The top of at 649 ft 6 in. el. and the bottom is uel occupies the bottom 14 ft.	This statement was added to provide clear reference to site specific information.		
Difference	Site specific information was added for clarity.

____......

NEI EAL#	NEI EAL Wording	KNPP EAL#(s)	KNPP EAL Wording
1	 a. Loss of power to (site-specific) transformers for greater than 15 minutes. AND b. At least (site-specific) emergency generators are supplying power to emergency busses 	CU3.1	Loss of all offsite power to Bus 5 AND Bus 6 for GREATER THAN 15 minutes <u>AND</u> At least one emergency diesel generator is supplying power to Bus 5 or Bus 6
Site specific	 "all offsite power to Bus 5 and Bus 6" – has been used in place of "transformers" to focus the classification on the loss of offsite power capability rather than the status of one or more transformers that may or may not be capable of powering the essential buses Safety related Bus 5 and Bus 6 identifies the site specific ESF busses "One diesel generator" is the site specific number needed to power one ESF bus. 		
Difference	 The NEI example EAL condition "Loss of power to (site-specific) transformers for greater than 15 minutes" has been changed to "Loss of offsite power to Bus 5 and Bus 6 for GREATER THAN 15 min." The KNPP wording focuses the classification on the loss of offsite power capability rather than the status of one or more transformers that may or may not be capable of powering the essential buses. This simplifies the EAL wording and meets the intent of the NEI IC. This change is not a deviation because it does not alter the meaning or intent, such that classification of the event could be different between the NEI guidance and the plant EAL 		
Deviation	None		

CU3 – Basis Justification				
KNPP	Specific Additions/Deletions	Justification		
1. Added site informatic purpose o	e specific system description on on offsite power sources for the f classification under this EAL.	1. This information was added to clarify the conditions under which this EAL would apply.		
2. Removed	the companion unit paragraph.	2. KNPP is a single unit site.		
Difference	Added site specific information on offsite power sources.

	a. Loss of power to (site-specific) transformers.		Loss of ALL power to Bus 5 AND Bus 6 for GREATER THAN 15 minutes
1	b. Failure of (site-specific) emergency generators to supply power to emergency busses.	CA3.1	
	AND c. Failure to restore power to at least one emergency bus within 15 minutes from the time of loss of both offsite and onsite AC power.		
Site specific	 "all offsite power to Bus 5 and Bus 6 classification on the loss of offsite po transformers that may or may not be and Bus 6 identifies the site specific 	5" – has beer ower capabil capable of p ESF buses.	used in place of "transformers" to focus the ity rather than the status of one or more owering the essential buses. Safety related Bus 5
	 Emergency diesel generators A and I 	B are site spe	cific generators that would supply the ESF buses.

.

Difference	 The NEI example EAL condition "Loss of power to (site-specific) transformers" has been changed to "Loss of offsite power to Bus 5 and Bus 6." The KNPP wording focuses the classification on the loss of offsite power capability rather than the status of one or more transformers that may or may not be capable of powering the essential buses. This simplifies the EAL wording and concisely meets the intent of the NEI IC.
	 KNPP EAL was reformatted from three NEI conditions to an encompassing one condition. This was done to simplify the classification and the economy of words. Stating that "ALL power" is lost to Bus 5 and Bus 6 covers the first two NEI conditions (loss of power to the transformers and failure of the emergency diesel generators). "For GREATER THAN 15 minutes" is equivalent to the third NEI condition (time to restore power to at least one emergency bus).
	 These changes are not deviations because it does not alter the meaning or intent, such that classification of the event could be different between the NEI guidance and the plant EAL
Deviation	None

CA3 – Basis Justification			
KNPP S	Specific Additions/Deletions	Justification

| Difference       | • Due to NEI Examples EAL 1, 2 & 3 being "and" logic, combined into a single EAL.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|                  | • R-2 is used instead of the high range containment monitors because if a small amount of fuel was uncovered, the location of the high range monitors would preclude them reading on scale. Therefore the alarm setpoint of R-2 was selected to indicate a rise in containment radiation resulting from the conditions of this EAL.                                                                                                                                                                                                                                                                                                                           |
|                  | • These change is not a deviation because it dose not alter the meaning or intent, such that classification of the event could be different between the NEI guidance and the plant EAL.                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

#### General Difference for section:

BWR Fission Product Barrier is not applicable to KNPP and was deleted.

Format change to Emergency Action Levels on the top of the tables, EALs were reordered so from left to right the EALs are listed GE, SAE, Alert and UE. This corresponds to the KNPP wallchart.

| Deviation        | The NEI phrase "greater than" has been changed to "GREATER THAN OR EQUAL TO" so that the EAL threshold agrees with the level specified in CSF-ST Critical Safety Function Status Trees. Using "greater than or equal to" is conservative deviation. Therefore, this deviation does not decrease the effectiveness of the NEI EAL and does not adversely effects the health/safety of the public. |                |                                                                           |

| Site<br>specific | 1000 R/hr is the site-specific containment rad monitor reading that has been calculated assuming the instantaneous release and dispersal of the reactor coolant noble gas and iodine inventory associated with a concentration of 300 $\mu$ Ci/gm dose equivalent I-131 into the containment atmosphere. Refer to Calc. C11617 |                |                                                                                                                |

| Deviation         | Used "GREATER THAN OR EQUAL TO" wording to be consistent with the CSFST definition of the KNPP Core Cooling-Orange path, which is entered if CET readings are equal to or greater than 700°F. Using "greater than or equal to" is conservative deviation. Therefore, this deviation does not decrease the effectiveness of the NEI EAL and does not adversely effects the health/safety of the public. |                   |                                                                          |

| Site<br>specific  | <ul> <li>RVLIS void fraction rising and at least one RCP running and RCS Subcooling less than 30 °F [65°F] indicates a potential loss of the fuel clad barrier. This combination is an indication of inadequate coolant inventory and is used in the Core Cooling-ORANGE path and indicates subcooling has been lost and that some fuel cladding damage may occur. The value in brackets is for adverse containment conditions.</li> </ul>                                                                                                                                                                                                                                                                                                                                 |                   |                                                                                                                          |
| Difference        | <ul> <li>KNPP RVLIS does not extend down to the top of active fuel. It only measures as low as the bottom of the hot legs. The NEI methodology states that the Core Cooling orange path should define the potential loss EAL. This is defined in two ways. If RCS subcooling is less than 30°F with one or more reactor coolant pumps running, then RVLIS void fraction rising defines the Core Cooling orange path. If RCS subcooling is less than 30°F with no reactor coolant pumps running, then core exit thermocouples above 700°F defines the Core Cooling orange path. Since the fuel clad potential loss for core exit thermocouples uses 700°F for its potential loss, the latter path is not used for the reactor vessel water level potential loss.</li> </ul> |                   |                                                                                                                          |

| Site<br>specific | 60 gpm: This threshold is based on the inability to maintain normal liquid inventory within the RCS by normal operation of the Chemical and Volume Control System, which is considered as one charging pump discharging to the charging header. The need for a second charging pump would be indicative of a substantial RCS leak. |                 |                                                                                                                                          |  |

Hazards and Other Conditions Affecting Plant Safety

--

#### NEI KNPP KNPP EAL Wording **NEI EAL Wording** EAL# EAL#(s) Security Supervision reports ANY of the Other security events as determined following: from (site-specific) Safeguards • A security event that results in the loss of Contingency Plan and reported by the control of ANY VITAL AREAS (other than (site-specific) security shift supervision Control Room) • Imminent loss of physical control of the HS1.2 2 facility (remote shutdown capability) due to a security event A confirmed sabotage discovered in a ٠ VITAL AREA Site . The "Security Shift Supervisor" is the title of the site-specific security supervision specific . Addition of security events to cover the following: loss of control of any vital area, imminent lose of physical control and sabotage in vital area. Difference Reworded EAL for readability. • This change is not a deviation because it meets the intent of NEI 99-01. . Deviation None

| 1                | Loss of power to (site specific)<br>transformers for greater than 15<br>minutes<br>AND<br>At least (site specific) emergency<br>generators are supplying power to<br>emergency busses.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | SU1.1           | Loss of all offsite power to Bus 5 <u>AND</u> Bus 6<br>for GREATER THAN 15 minutes<br><u>AND</u><br>Emergency diesel generators are supplying<br>power to Bus 5 <u>AND</u> Bus 6 |
| Site<br>specific | <ul> <li>"Loss of all offsite power to Bus 5 <u>AND</u> Bus 6" has been used in place of "Loss of power to (site specific) transformers" to focus the classification on the loss of offsite power capability rather than the status of one or more transformers that may or may not be capable of powering the essential buses</li> <li>Bus 5 and Bus 6 are the KNPP emergency safeguards buses.</li> <li>"Emergency diesel generators are supplying power to Bus 5 <u>AND</u> Bus 6" was added to describe the emergency diesel generator configuration at KNPP.</li> </ul>                                                                                                                                          |                 |                                                                                                                                                                                  |
| Difference       | <ul> <li>The NEI example EAL condition "Loss of power to (site-specific) transformers for greater than 15 minutes" has been changed to "Loss of all offsite power to Bus 5 <u>AND</u> Bus 6 for GREATER THAN 15 minutes." The KNPP wording focuses the classification on the loss of offsite power capability rather than the status of one or more transformers that may or may not be capable of powering the essential buses. This simplifies the EAL wording and concisely meets the intent of the NEI IC</li> <li>This change is not a deviation because it does not alter the meaning or intent, such that classification of the event could be different between the NEI guidance and the plant EAL</li> </ul> |                 |                                                                                                                                                                                  |
| Deviation        | None                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                 |                                                                                                                                                                                  |

| Difference  | <ul> <li>The NEI example EAL condition "Loss of power to (site-specific) transformers" has been<br/>changed to "Loss of ALL power to Bus 5 <u>AND</u> Bus 6" The plant EAL wording focuses the<br/>classification on the loss of power capability rather than the status of one or more transformers that<br/>may or may not be capable powering the essential buses. This simplifies the EAL wording and<br/>concisely meets the intent of the NEI IC.</li> </ul>                        |                               |                                                                                          |
|             | <ul> <li>KNPP EAL was reformatted from three NEI conditions to an encompassing one condition. This was done to simplify the classification and the economy of words. Stating that "ALL power" is lost to Bus 5 and Bus 6 covers the first two NEI conditions (loss of power to the transformers and failure of the emergency diesel generators). "For GREATER THAN 15 minutes" is equivalent to the third NEI condition (time to restore power to at least one emergency bus).</li> </ul> |                               |                                                                                          |

| <b>OPERATING</b> | PROCEDURE |
|------------------|-----------|
|------------------|-----------|

### 4.2.6.b CONTINUED

- 4. INITIATE Containment Isolation.
  - A. VERIFY CI Active status panel lights, ON.
- c. Maintain Containment habitability.
  - 1. START Containment Fan Coil Units.
  - 2. ESTABLISH Service Water to Containment Fan Coil Units.
  - 3. MONITOR containment radiation levels.
- d. <u>GO</u> <u>TO</u> Step 4.6.

#### 4.3 Decreasing RCS Level or Pressure:

- 1. VERIFY RCS temperature stable or increasing, <u>IF NOT</u>, STOP cooldown.
- 2. VERIFY following:
  - Pressurizer PORVs, CLOSED.
  - Normal Przr Spray Valves, CLOSED.
  - CVC-15/CV-31230, Przr Auxiliary Spray Valve, CLOSED.
- 3. ESTABLISH maximum Charging flow.
- 4. ISOLATE RHR to CVCS:
  - a. Locally, CLOSE RHR-210, RHR/CVC Inlet Isolation.
  - b. CLOSE LD-60/MV-32099, RHR To CVCS Letdown Line.
  - c. CLOSE LD-6/CV-31234, Letdown Line Isolation.
- 5. CLOSE LD-2/CV-31108, Letdown Isolation.
- 6. ENERGIZE Przr Heaters as required.

#### **CONTINUED**

4.3 CONTINUED

# <u>CAUTION</u>

"Surge Line Flooding" will cause RCS level to increase at a rate far in excess of rate attributed to pumped flow.

- 7. VERIFY RCS level and pressure stable or increasing, <u>IF NOT</u>:
  - a. INITIATE Containment Closure:
    - 1. INITIATE closure of open containment boundaries.
    - 2. EVACUATE unnecessary personnel from containment.
    - 3. VERIFY at least one door CLOSED in each airlock.
    - 4. INITIATE Containment Isolation.
      - A. VERIFY CI Active status panel lights, ON.
  - b. Maintain Containment habitability.
    - 1. START Containment Fan Coil Units.
    - 2. ESTABLISH Service Water to Containment Fan Coil Units.
    - 3. MONITOR containment radiation levels.
  - c. STOP RHR Pumps.
    - <u>IF</u> both RCS Cold Leg temperatures increase to >200°F, CLOSE RHR-1A, RCS Loop A Supply to RHR Pumps <u>AND</u> RHR-1B, RCS Loop B Supply to RHR Pumps.
  - d. CHECK if RXCPs should be stopped:
    - 1. IF #1 Seal  $\Delta P$  <200 psig, STOP affected RXCP.
    - 2. IF #1 Seal leakoff flow <0.2 gpm, STOP affected RXCP.

#### 1. INTRODUCTION

Function Restoration Procedure FR-C.2. RESPONSE TO DEGRADED CORE COOLING. has been developed to address the symptoms for degraded core cooling. These symptoms are: 1) core exit TC temperatures greater than 700°F, or 2) core exit TC temperatures less than 700°F and a RVLIS RXCPs OFF indication less than 0%, i.e., below the bottom of the hot leg nozzles.

This procedure is entered from CSF Status Tree F-0.2. on an ORANGE priority. The major actions to be performed in this procedure include:

1 Reinitiation of high pressure safety injection

2 Controlled secondary depressurization

These actions are to be performed sequentially. Success, as indicated by improved core cooling, is evaluated prior to performing the next action in the sequence if no RXCP is running. If, for example, the operator is successful in restoring core cooling via high pressure safety injection, then he is returned to the procedure and step in effect. If not, he continues with this procedure. Once core cooling has been restored and adequate makeup flow has been established and verified, the operator is directed to E-1, LOSS OF REACTOR OR SECONDARY COOLANT, Step 17. Since the KNPP RVLIS VOID FRACTION indication cannot be used for a quantitative value of RCS voiding and core exit TCs will not indicate superheated conditions when RXCPs are running, the operator is directed to continue with the second actions if any RXCP is running when this procedure is entered.

#### 2. DESCRIPTION

Degraded core cooling is caused by a substantial loss of primary coolant. The RXCPs may or may not be running when degraded core cooling is indicated. If the RXCPs are not running, the degraded core cooling symptoms indicate the core is partially uncovered. If the RXCPs are running, the symptoms indicate that the potential for core uncovery exists should the RXCPs fail or be manually tripped. Operator action is required to restore RCS inventory in either case.

Reinitiation of high pressure safety injection is the most effective method to restore RCS inventory and core cooling. If some form of high pressure injection cannot be established or is ineffective in restoring core cooling, then the operator must take actions to reduce the RCS pressure in order for the SI accumulators and low-head SI (RHR) pumps to inject. A controlled secondary depressurization is an effective method for achieving this, while at the same time avoiding a rapid RCS cooldown that could cause problems with pressurized thermal shock.

The expected system response to both of the recovery techniques listed above, will be described below.

## 2.1 <u>Reinitiation of High Pressure Safety Injection</u>

This procedure uses the trends in core exit TC temperatures and indicated vessel level to determine appropriate operation actions. When no RXCP is running, the effectiveness of safety injection in restoring core cooling is determined by the trend in core exit TC temperatures. If the RXCPs are off and core exit TC temperatures are decreasing, no further action may be necessary. Core exit TC temperatures less than 700°F with no RXCP running indicates success in restoring core cooling. allowing the operator to return to the procedure and step in effect. The expected system response from reinitiation of high pressure safety injection with RXCPs either tripped or running is given below.

### RXCPs Tripped

The introduction of subcooled safety injection will cause steam in the cold legs to condense. Steam flow throughout the RCS will increase as a result of this condensation effect. Superheated steam forced out of the core may initially cause the core exit TC temperatures to increase. As the vessel begins to refill, heat transfer from the fuel will cause the fluid entering the core to boil vigorously. This will create a frothy two phase mixture which will eventually recover the entire core and cause the core exit TC temperatures to quickly decrease to the saturation temperature of the RCS. The RVLIS indication, which is an indirect measure of vessel level based on local pressure differences within the vessel, may fluctuate as the core recovers; however, the general trend in RVLIS indication should increase as the vessel is refilled.

### RXCPs\_Running

The only indication of degraded core cooling with the RXCPs running is the RVLIS VOID FRACTION reading. The RVLIS VOID FRACTION indication provides an indirect measure of relative vessel void fraction. When safety injection is reinitiated, the actual vessel void fraction and the RVLIS VOID FRACTION indication should decrease. The KNPP RVLIS VOID FRACTION indication has been determined to be usable only for trending and should not be used as a quantitative indication of actual percent void fraction in the RCS: therefore, RVLIS VOID FRACTION indication decreasing and RCS subcooling are used to determine if RCS inventory is being restored.

If a degraded core cooling condition is reached with RXCPs running, then the RXCPs should not be stopped, even if RXCP support requirements are lost or if RXCP pump trip criteria are met.

### 2.2 Secondary Depressurization

If attempts to reinitiate high pressure safety injection were unsuccessful. or were ineffective in restoring core cooling, then a controlled SG depressurization, similar to the one in ES-1.2. POST LOCA COOLDOWN AND DEPRESSURIZATION. must be performed. A controlled secondary depressurization will increase primary-to-secondary heat transfer and cause steam in the primary side of the steam generator U-tubes to condense. When the condensation rate exceeds the steam creation rate, the RCS will begin to depressurize. The continued RCS depressurization will eventually cause SI accumulator injection. To prevent nitrogen injection from the SI accumulators, the operator must isolate them when the RCS pressure reaches approximately 210 psig.

After the SI accumulators have been isolated and the RXCPs have been tripped, the secondary should be depressurized to atmospheric pressure. The RCS pressure should follow secondary pressure until the RHR pumps begin to inject. Adequate core cooling has been restored and preparations for long term plant recovery can be started, once RHR flow has been established and the core is completely recovered.

### 3. <u>RECOVERY/RESTORATION\_TECHNIQUES</u>

The objective of the recovery/restoration technique incorporated into IPEOP FR-C.2 is directed toward preventing core damage due to degraded core cooling as detected by the Core Cooling Status Tree.

### 3.1 <u>High Level Action Summary</u>

A summary of the high level actions performed in FR-C.2 is given in the following subsections.

### 3.1.1 Establish Safety Injection Flow to the RCS

The operator must properly align emergency SI valves. start the SI pumps. and then check for flow through the SI lines to the RCS. If no RXCP is running, core exit TC temperatures are checked to determine the effectiveness of safety injection in restoring core cooling and vessel inventory. If a RXCP is running, the operator must continue in the procedure to SG depressurization because the KNPP RVLIS VOID FRACTION indication cannot be used for a quantitative value of RCS inventory on which to base a decision of restored core cooling.

## 3.1.2 <u>Initiate a Controlled SG Depressurization to Cool Down and</u> <u>Depressurize the RCS</u>

The operator must maintain a 100°F/hr cooldown of the RCS by dumping steam or opening the SG PORVs while maintaining adequate feedwater to the SGs. The SI accumulators must be isolated and the RXCPs tripped once the SGs have been depressurized to the point where the RCS has been depressurized to 210 psig. The RCS cooldown and depressurization is continued until low-head safety injection (RHR) flow to the RCS has been established and verified. RCS Hot Leg temperatures and the RVLIS RXCPs OFF indication are checked to determine the effectiveness of accumulator and/or low-head safety injection in restoring core cooling and vessel inventory.

### 4. DETAILED\_DESCRIPTION OF STEPS, NOTES, AND CAUTIONS

This section contains a one-page (or more) step description table for each separate procedure step, note, and caution. Notes and cautions are always presented relative to the step they precede.

The Step Description Tables for the steps and associated notes and cautions of IPEOP FR-C.2 are presented on the following pages.

**KEWAUNEE NUCLEAR POWER PLANT** 

TITLE RESPONSE TO DEGRADED CORE COOLING

IPEOP BACKGROUND DOCUMENT

DATE MAR 21 2004

BKG FR-C.2

NO.

STEP 5

of 34

**PAGE** 13

STEP: Check Core Cooling:

<u>PURPOSE</u>: To check if an RCS inventory condition symptomatic of a degraded core cooling condition still exists

STEP DESCRIPTION TABLE FOR FR-C.2

**BASIS**:

KNPP RVLIS Void Fraction indication does not have the same capabilities as the WOG generic RVLIS and can not be used for a quantitative value. Therefore, the step is modified from the WOG ERG to monitor KNPP-RVLIS Void Fraction for trends and RCS subcooling.

The trend in RVLIS RCS Void Fraction % is used to check the effectiveness of safety injection in restoring RCS inventory. If void fraction percent is decreasing and RCS subcooling based on core exit TCs is greater than 30°F [65°F for adverse containment], then safety injection has been successful in restoring RCS inventory and core cooling. This step will then transfer the operator to procedure and step in effect. This guidance is consistant with addressing the entry conditions for FR-C.2 from Status Tree F-0.2.

In the event RCS Void Fraction % is decreasing, but subcooling requirements are not met, no further actions may be necessary. The operator is instructed to return to the beginning of this procedure and repeat the initial procedure steps until the subcooling requirements are met.

If the RVLIS Void Fraction % is not decreasing, then the operator must continue with this procedure.

ACTIONS:

- o
- Determine if RVLIS Void Fraction % is decreasing Determine if RCS subcooling is greater than 30°F[65°F for adverse 0 containment]

**INSTRUMENTATION:** 

**RVLIS Void Fraction % indication** RCS subcooling

CONTROL/EQUIPMENT:

N/A

KNOWLEDGE:

Understanding of RVLIS Void Fraction % function and interpretation

| <u>PURPOSE</u> : To determine if symptoms of degra<br>when the RXCPs are not running                                                                                                                                                                                                                                                                                                                                                        | aded core cooling still        | exist                |  |  |
| BASIS:                                                                                                                                                                                                                                                                                                                                                                                                                                      |                                |                      |  |  |
| The core exit TC temperatures are used to check the effectiveness of<br>safety injection in restoring core cooling when the RXCPs are not<br>running. If the trend in core exit TC temperatures is decreasing, then<br>no further action may be necessary. The operator is instructed to return<br>to the beginning of the procedure and repeat the initial procedure steps<br>until the the core exit TC temperatures are less than 700°F. |                                |                      |  |  |
| If core exit TC temperatures are less than 700°F, safety injection has been successful in restoring RCS inventory and core cooling. This step will transfer the operator to the procedure and step in effect.                                                                                                                                                                                                                               |                                |                      |  |  |
| If core exit TC temperatures are greater than 700°F and not decreasing,<br>then the operator must continue with this procedure in order to perform<br>the alternative action for restoring core cooling.                                                                                                                                                                                                                                    |                                |                      |  |  |
