

criticality alarm systems were used because the licensee desired that employees only evacuate if they would be affected by the criticality event detected as defined by horn audibility. Detector and annunciator (horn) coverage of exterior areas was not fully redundant, resulting in the necessity for individual systems to be able to annunciate events in their area of coverage without the assistance of other systems. Four out of five horns on one exterior system became inoperable over time so that an alarm from that system could not be heard in a large portion of its area of coverage, including locations with high ambient noise levels and the interior of two buildings containing non-fissile operations.

## **DISCUSSION**

The criticality alarm concern arises when licensees fail to detect inoperable criticality alarm system annunciators (horns) during routine testing, and an inaudible criticality alarm situation is not corrected. Two factors contributed to the problem. First, the test procedure sounded horns in groups and did not routinely check individual horns for operability. Inoperable horns were not always detected during the criticality alarm routine tests and, in fact, could go undetected until many horns were inaudible and a large part of the facility was not receiving an audible alarm. Second, the licensee relied on all employees to report inaudibility, but employees did not fully understand requirements for criticality alarm horn response during system audibility testing. In fact, employees were trained to react only to audible alarms. The affected buildings involved intermittent work operations so that, even though the criticality alarm system horns involved were rated at approximately 100 decibels, employees working in the area did not recognize that the horns never sounded.

The NRC concern about this issue is that failure to adequately test a criticality alarm system for audibility may cause an inaudible condition to go undetected for an indefinite amount of time. This event likely occurred because licensee training did not result in employees understanding that inoperable horns in a work area were required to be reported and testing procedures did not result in detection and correction of inoperable horns.

Failure to maintain audibility of the criticality alarm system exposes licensees to the possibility that affected employees will not evacuate during an actual criticality event. NRC inspections of criticality alarm systems typically include review of criticality accident alarm audibility test procedures, employee emergency response training, criticality accident alarm detector/annunciator coverage, and criticality accident alarm outage procedures.
