Subject: Re: Data request for PA

Vic,

I assume I am the "gentleman" mentioned in your note. I have an internal memo written to our QA Dept manager (J. V. Roberts) in 1993 on this subject. In 1993, the State Oversite group asked for fairly extensive Tank Farm related data. Some of the requested Data was how much water collects in the Tank Farm sumps, and how often do we remove it? Kelly Ribish wrote a letter documenting the Tank Farm sump transfers from 1962 through the summer of 1993 (about 30 years of data). In that letter there are 80 "flushings" of the WM-185 vault and 90 of the WM-187 vault. Perhaps the 85 mentioned in the portage memo is the average of 80 and 90. Anyway, in the referenced phone call I mentioned that we had that letter, and if necessary we could document many more flushings since 1993. A conservative estimate would be 2 per year for nearly a decade, so that would be another 20 or so and put the total flushings over 100. Also note the old historical data begin in 1962, and there were "flushings" before that time that I presume we do not have any operator data for (or at least Kelly couldn't find it as part of the original research). Anyway, I can give you a copy of the letter I have, but it is an internal letter and is not addressed to any State person. It does reference that the letter is being prepared in response to a request from the State, but it is not addressed to any State personnel. At that time, one of the CPP managers would take the internal memo and put a cover letter on it to send to the State, so the letter that went to the State would likely have been a J. M. Roberts cover letter with Kelly's letter attached.

Dan & Mike,
Could you help me out here. Thanks, Vic

Vic

Could you locate and send me the letter to the State of Idaho that documents the number of flushings of the vault/sand pad. When we had the phone conference, the gentleman (I don't recall his name) mentioned that such a letter existed that documented 85 such events.

My fax number is 970-243-5237

As requested by the INEL Oversite Manager for the State of Idaho Department of Environmental Quality, Attachment A provides all available information on the volumes of liquid removed from each High Level Liquid Waste tank sump over time. This completes WINCO's response to the two-part request detailed in References 1, 2, and 3. The first item of that request concerning tank farm composition history was issued in August, 1993.

For the years 1962-1982, most volumes were reported as liquid level in inches (References 5 and 6). When converting to gallons, the geometry of the sump and vault space must be considered. Reference 4 (attached) provides an explanation of the various sump/vault configurations and formulas from which volumes may be calculated using liquid depths. This is an accurate estimate of the volumes of liquid contained in the sump/vault spaces, but may not correctly reflect volumes transferred upon jetting. Noting level differences only, before and immediately after jetting, does not account for overflow of liquid from one sump or vault half to another, slower draining of liquid from the sand pads beneath WM-182 through -190, and level increases over time as the liquid reaches an equilibrium height. This became evident after studying the logbook records for 1962 through about 1973. After a period of time, the level readings after jetting increased significantly in many cases. Often, the final level settled back to the original level recorded before jetting, making it impossible to calculate a volume transferred from difference in level. The liquid levels, before and after, in inches, and the calculated volume estimate in gallons are included for each transfer not originally reported in gallons. The formulas in Reference 4 were used in these calculations and the values were rounded to the

nearest 10 gallons. A conservative estimate of 2 inches was added to each level value to correct to true height since the probes are about 2 inches off the bottom of each sump. For those formulas accounting for the volume in both sumps and vault halves, the quantity was divided by 2 to more closely estimate the liquid actually transferred. Greater-than (>) values indicate that the liquid was at a level higher than the level probe transmitter calibration range before jetting.

Most information for November, 1978 through February, 1983 was extracted from graphical data (Reference 6). Level decreases in the graphs of $\geq$ 100 gallons were assumed to be transfers, since only a few transfers were identified as such on the graphs.

For sump transfers from 1983 to present, volumes have been recorded in gallons (References 6, 7, and 8). Since quantities are measured at the receiving vessel, some allowance must be made for steam jet dilution (the plant average is 5% - 10%), and the volumes should be interpreted accordingly.

Tables for each HLLW tank are given in Attachment A, list transfers by date, and indicate the receiving vessel if available. The sump which was the source of the jet transfer is also identified as North, South, Cold, or Not Specified (sump identity not reported). An asterisk (*) indicates that a transfer was made but no volume information was recorded. This is the case primarily for records of WM-189 and WM-190 cold sump transfers in the early years. A double asterisk (**) identifies transfers made with both before and after level readings at or above the top of the level probe, preventing any calculation to be made from level difference.

The data given in Attachment A and the assumptions used were independently verified against the original data sources by K. M. Wendt and L. G. Olson. Other personnel who have reviewed this document have initialed beside their names.
