NEW YORK, NY 10007-1866

10/22/97

40-7102

Michael Weber, Chief
Fuel Cycle Licensing Branch
Nuclear Regulatory Commission
Washington, DC 20555-0001

Dear Mr. Weber:

This letter serves to transmit to the U.S. Nuclear Regulatory Commission (NRC) the preliminary analytical results of soil samples collected by the U.S. Environmental Protection Agency (EPA) from the Newfield Landfill (Landfill) during June 1997. It should be noted that the Landfill is located adjacent to the Shieldalloy Metallurgical Corporation (Shieldalloy) Superfund Site (Site) in the Borough of Newfield, Gloucester County, New Jersey. As you are aware, Shieldalloy is currently licensed by the NRC to possess and store uranium, thorium and their associated decay products at the Site. Further, Shieldalloy's operations have resulted in the storage of radioactive slag and baghouse dust at the Site adjacent to the Landfill.

The above-mentioned June 1997 soil sampling event was conducted by EPA in an attempt to clarify whether the Landfill had been impacted by contaminant migration from the Site. As part of this sampling event, soil samples were collected at the approximate locations displayed on Figure 1. The results of gamma, gross alpha and beta analyses of these samples have been attached. Furthermore, the gross alpha analytical results are summarized below:

Sample Number	Gross Alpha, pCi/g	Sample Number	Gross Alpha, pCi/g
1	508	6	22.3
2	335	7	14.0, 15.1
3	18.8	8	<6.36
4	23.4	9	10
5	8.13	10	<7.04

Normal gross alpha levels observed in natural soils in central New Jersey range from 5 to 20pCi/g with results usually falling within the upper end of this range. Based upon these findings, EPA has determined that soil samples 1 and 2, which were collected immediately adjacent to the Site fence line, exhibit radiological contamination well above background. Furthermore, EPA believes that this data

9710270122 971017
PDR ADDOCK 04007102
C PDR

displays probable radiological contamination in soil samples 3, 4 and 6, which were collected on a road which runs parallel to the Site fence line.

Due to the proximity of the Landfill to the Site, and the presence of elevated gross alpha levels in soil samples collected immediately adjacent to the Site, EPA believes that the radiological contamination at the Landfill may have originated from the Site. Please note that EPA is currently analyzing the above-referenced soil samples for specific radioisotopes, which should shed more light on the origin of the radiological contamination at the Landfill. Once available, the results of the isotopic analysis will be provided to the NRC.

EPA believes that it may be beneficial at this time for the agencies with regulatory authority over environmental and radiation matters at the Site to jointly discuss the implications of the attached sampling results. Therefore, EPA recommends that a conference call be scheduled between the appropriate representatives of the NRC, EPA and the New Jersey Department of Environmental Protection to discuss these sampling results.

If you have any questions regarding this matter or wish to schedule a conference call to discuss the attached sampling results, please have your staff contact Joseph Gowers, the EPA Project Manager for the Site, at (212) 637-4413.

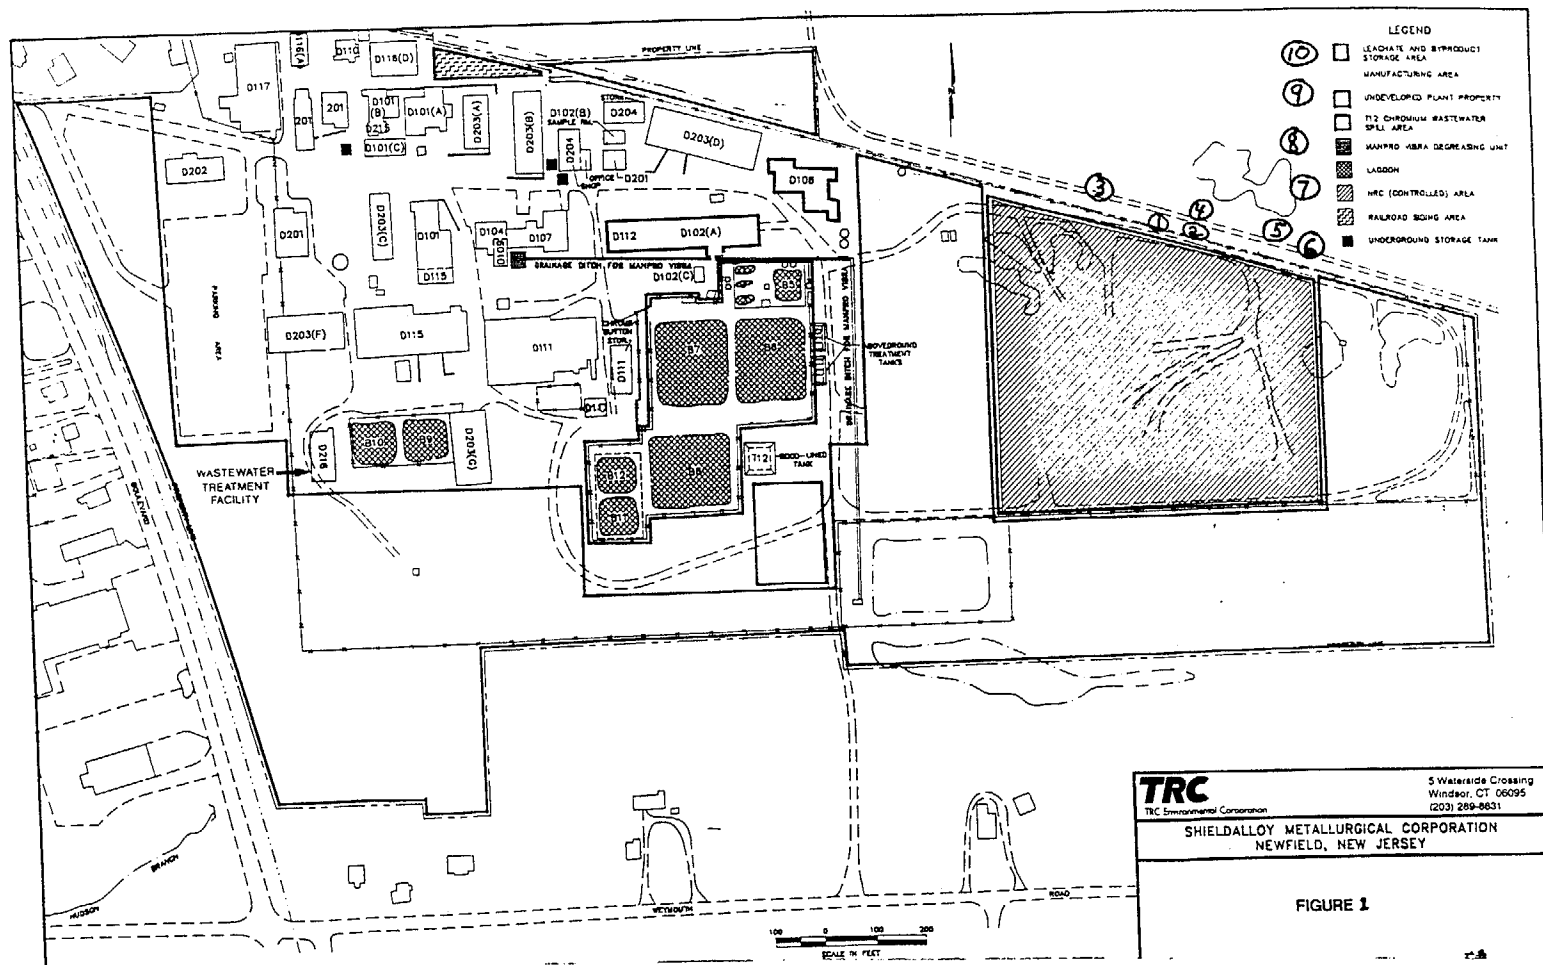

Sincerely yours,

Carole Petersen, Chief
New Jersey Remediation Branch

MEMORANDUM

SUBJECT: Radioanalytical Results for
Newfield Landfill Site
Soil Samples

FROM: John Griggs, Chief *John Griggs*
Monitoring and Analytical Services Branch

TO: Mark P. Winslow, Coordinator
Radiation Health and Safety Program

Attached are the results of gamma and gross alpha and beta analyses on soil samples collected at Newfield Landfill Site. The samples constitute NAREL batch number 97-00121. The results of further analyses will be sent as they are completed.

Radiochemical analyses usually require the subtraction of an instrument background measurement for a gross sample measurement. Both values are positive, but when the sample activity is low, random variations in the two measurements can cause the gross value to be less than the background, resulting in a measured activity less than zero. Although negative activities have no physical significance, they do have statistical significance, as for example in the evaluation of trends or the comparison of two groups of samples.

For all analyses except gamma spectroscopy, it is the policy of NAREL to report results as generated, whether positive, negative, or zero, together with the 2-sigma measurement uncertainty and a sample-specific estimate of the minimum detectable concentration (MDC). The activity, uncertainty, and MDC are given in the same units. The activity and 2-sigma uncertainty for a radionuclide measured by gamma spectroscopy are reported only if the nuclide is detected; so, the results of gamma analyses are never zero or negative. Nuclides that are not detected do not appear in the report, with the exception of Ba-140, Co-60, Cs-137, I-131, K-40, Ra-226, and Ra-228. If one of these seven nuclides is undetected, NAREL reports it as "Not Detected," or "ND," and provides a sample-specific estimate of the MDC.

Specific information concerning all aspects of the radiological analysis of the samples is contained in the batch case narratives of the data packages. If you have any questions concerning the results, please contact me at (334) 270-3450.

D. General
Information:

The reporting format lists the gamma emitters in alphabetical order. The activity and 2-sigma uncertainty for radionuclides measured by gamma spectroscopy are reported only if the nuclide is detected. Nuclides that are not detected do not appear in the report, with the exception of Ba-140, Co-60, Cs-137, I-131, K-40, Ra-226 and Ra-228. If one of these seven nuclides is undetected, NAREL reports it as "Not Detected" or "ND", and provides a sample-specific estimate of the MDC.

Due to potential spectral interferences and other possible problems associated with the determination of the activity of certain radionuclides, the activities for Th-234, Pa-234m, Ra-226, and U-235 are subject to greater possible error than other commonly reported radionuclides. It should be noted that this potential error is not included in the two-sigma counting error which is reported with each activity. Although in this report we do provide the calculated activities for these radionuclides, we recommend that the results be used only as a qualitative means of indicating the presence of these radionuclides and not as a quantitative measure of their concentration. The results for these nuclides are not used in the evaluation of quality control samples. Furthermore, because of mutual interference between Ra-226 and U-235, NAREL's gamma analysis software tends to overestimate the amounts of these nuclides whenever both are present in a sample. Lower estimates for Ra-226 activities can be obtained from the reported activities of its decay products, Pb-214 and Bi-214, which are likely to be somewhat less than the Ra-226 activity because of the potential escape of radon gas.

GAMMA

NAREL Batch #: 97-00121

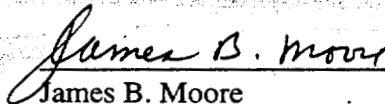

PAGE 3

NAREL's gamma spectroscopy software corrects activities and MDCs for decay between collection and analysis, but only up to a limit of ten half-lives. So, if the decay time for a sample is more than ten half-lives of a radionuclide, that nuclide will almost always be undetected and the reported MDC will be meaningless. This is usually a problem only for short-lived radionuclides, such as I-131 and Ba-140, when there is a long delay between collection and analysis.

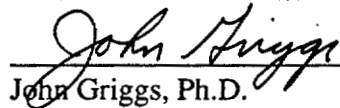

III. QUALITY CONTROL

All replicate analyses met NAREL QC criteria.

IV. I certify that this data package complies with the terms and conditions of the Quality Assurance Project Plan, both technically and for completeness, other than the exceptions detailed above. Release of the data contained in this package has been authorized by the Chief of the Monitoring and Analytical Services Branch and the NAREL Quality Assurance Coordinator, or their designees, as verified by the following signatures.
