## **1.0 INTRODUCTION**

The Radiological Environmental Monitoring Program (REMP) is conducted in accordance with Chapter 4 of the Offsite Dose Calculation Manual (ODCM). REMP activities for 2006 are reported herein in accordance with Technical Specification (TS) 5.6.2 and ODCM 7.1.

The objectives of the REMP are to:

- 1) Determine the levels of radiation and the concentrations of radioactivity in the environs and;
- 2) Assess the radiological impact (if any) to the environment due to the operation of the Edwin I. Hatch Nuclear Plant (HNP).

The assessments include comparisons between the results of analyses of samples obtained at locations where radiological levels are not expected to be affected by plant operation (control stations) and at locations where radiological levels are more likely to be affected by plant operation (indicator stations), as well as comparisons between preoperational and operational sample results.

The pre-operational stage of the REMP began with the establishment and activation of the environmental monitoring stations in January of 1972. The operational stage of the REMP began on September 12, 1974 with Unit 1 initial criticality.

A description of the REMP is provided in Section 2 of this report. An annual summary of the results of the analyses of REMP samples is provided in Section 3. A discussion of the results, including assessments of any radiological impacts upon the environment, and the results of the land use census and the river survey, are provided in Section 4. The results of the Interlaboratory Comparison Program (ICP) are provided in Section 5. Conclusions are provided in Section 6.

## **2.0 REMP DESCRIPTION**

A summary description of the REMP is provided in Table 2-1. This table summarizes the program as it meets the requirements outlined in ODCM Table 4-1. It details the sample types to be collected and the analyses to be performed in order to monitor the airborne, direct radiation, waterborne and ingestion pathways, and also delineates the collection and analysis frequencies. The sampling locations (stations) specified by ODCM 4.2 are depicted on maps in Figures 2-1 and 2-2. These maps are keyed to Table 2-2 which delineates the direction and distance of each station from the main stack.

REMP samples are collected by Georgia Power Company's (GPC) Environmental Laboratory (EL) personnel. The same lab performs all the laboratory analyses at their headquarters in Smyrna, Georgia.

TABLE 2-1 (SHEET 1 of 3)

SUMMARY DESCRIPTION OF RADIOLOGICAL ENVIRONMENTAL MONITORING PROGRAM

| Exposure Pathway and/or Sample           | Approximate Number of Sample Locations | Sampling and Collection Frequency                                  | Type of Analysis and Frequency   |
|--|--|--|--|
| 1. Airborne Radioiodine and Particulates | 6                                      | Continuous operation of the sampler with sample collection weekly. | Radioiodine canister: I-131 analysis, weekly.<br><br>Particulate sampler: analyze for gross beta radioactivity not less than 24 hours following filter change, weekly; perform gamma isotopic analysis on affected sample when gross beta activity is 10 times the yearly mean of control samples; and composite (by location) for gamma isotopic analysis, quarterly. |
| 2. Direct Radiation                      | 37                                     | Quarterly  | Gamma dose, quarterly.   |
| 3. Ingestion                             |  |  |  |
| Milk (a)                                 | 1                                      | Biweekly   | Gamma isotopic and I-131 analysis, biweekly.   |
| Fish or Clams (b)                        | 2                                      | Semiannually   | Gamma isotopic analysis on edible portions, semiannually.  |
| Grass or Leafy Vegetation                | 3                                      | Monthly during growing season.                                     | Gamma isotopic analysis, monthly. (c)  |
| 4. Waterborne                            |  |  |  |
| Surface                                  | 2                                      | Composite sample collected monthly. (d)                            | Gamma isotopic analysis, monthly. Composite (by location) for tritium analysis, quarterly.   |
| Sediment                                 | 2                                      | Semiannually.  | Gamma isotopic analysis, semiannually.   |

TABLE 2-1 (SHEET 2 of 3)

SUMMARY DESCRIPTION OF RADIOLOGICAL ENVIRONMENTAL MONITORING PROGRAM

| Exposure Pathway and/or Sample | Approximate Number of Sample Locations  | Sampling and Collection Frequency   | Type of Analysis and Frequency  |
|--------------------------------|---|---|---|
| Drinking Water (e & f)         | One sample of river water near the intake and one sample of finished water from each of one to three of the nearest water supplies which could be affected by HNP discharges. | River water collected near the intake will be a composite sample; the finished water will be a grab sample. These samples will be collected monthly unless the calculated dose due to consumption of the water is greater than 1 mrem/year; then the collection will be biweekly. The collections may revert to monthly should the calculated doses become less than 1 mrem/year. | I-131 analysis on each sample when biweekly collections are required. Gross beta and gamma isotopic analysis on each sample; composite (by location) for tritium analysis, quarterly. |

**TABLE 2-1 (SHEET 3 of 3)**

**SUMMARY DESCRIPTION OF RADIOLOGICAL ENVIRONMENTAL MONITORING PROGRAM**

Notes:

- a. Up to three sampling locations within 5 miles and in different sectors will be used as available. In addition, one or more control locations beyond 10 miles will be used.
- b. Commercially or recreationally important fish may be sampled. Clams may be sampled if difficulties are encountered in obtaining sufficient fish samples.
- c. If gamma isotopic analysis is not sensitive enough to meet the Minimum Detectable Concentration (MDC), a separate analysis for I-131 may be performed.
- d. The composite samples shall be composed of a series of aliquots collected at intervals not exceeding a few hours.
- e. If it is found that river water downstream of the plant is used for drinking, drinking water samples will be collected and analyzed as specified herein.
- f. A survey shall be conducted annually at least 50 river miles downstream of the plant to identify those who use water from the Altamaha River for drinking.

**TABLE 2-2 (SHEET 2 of 2)**

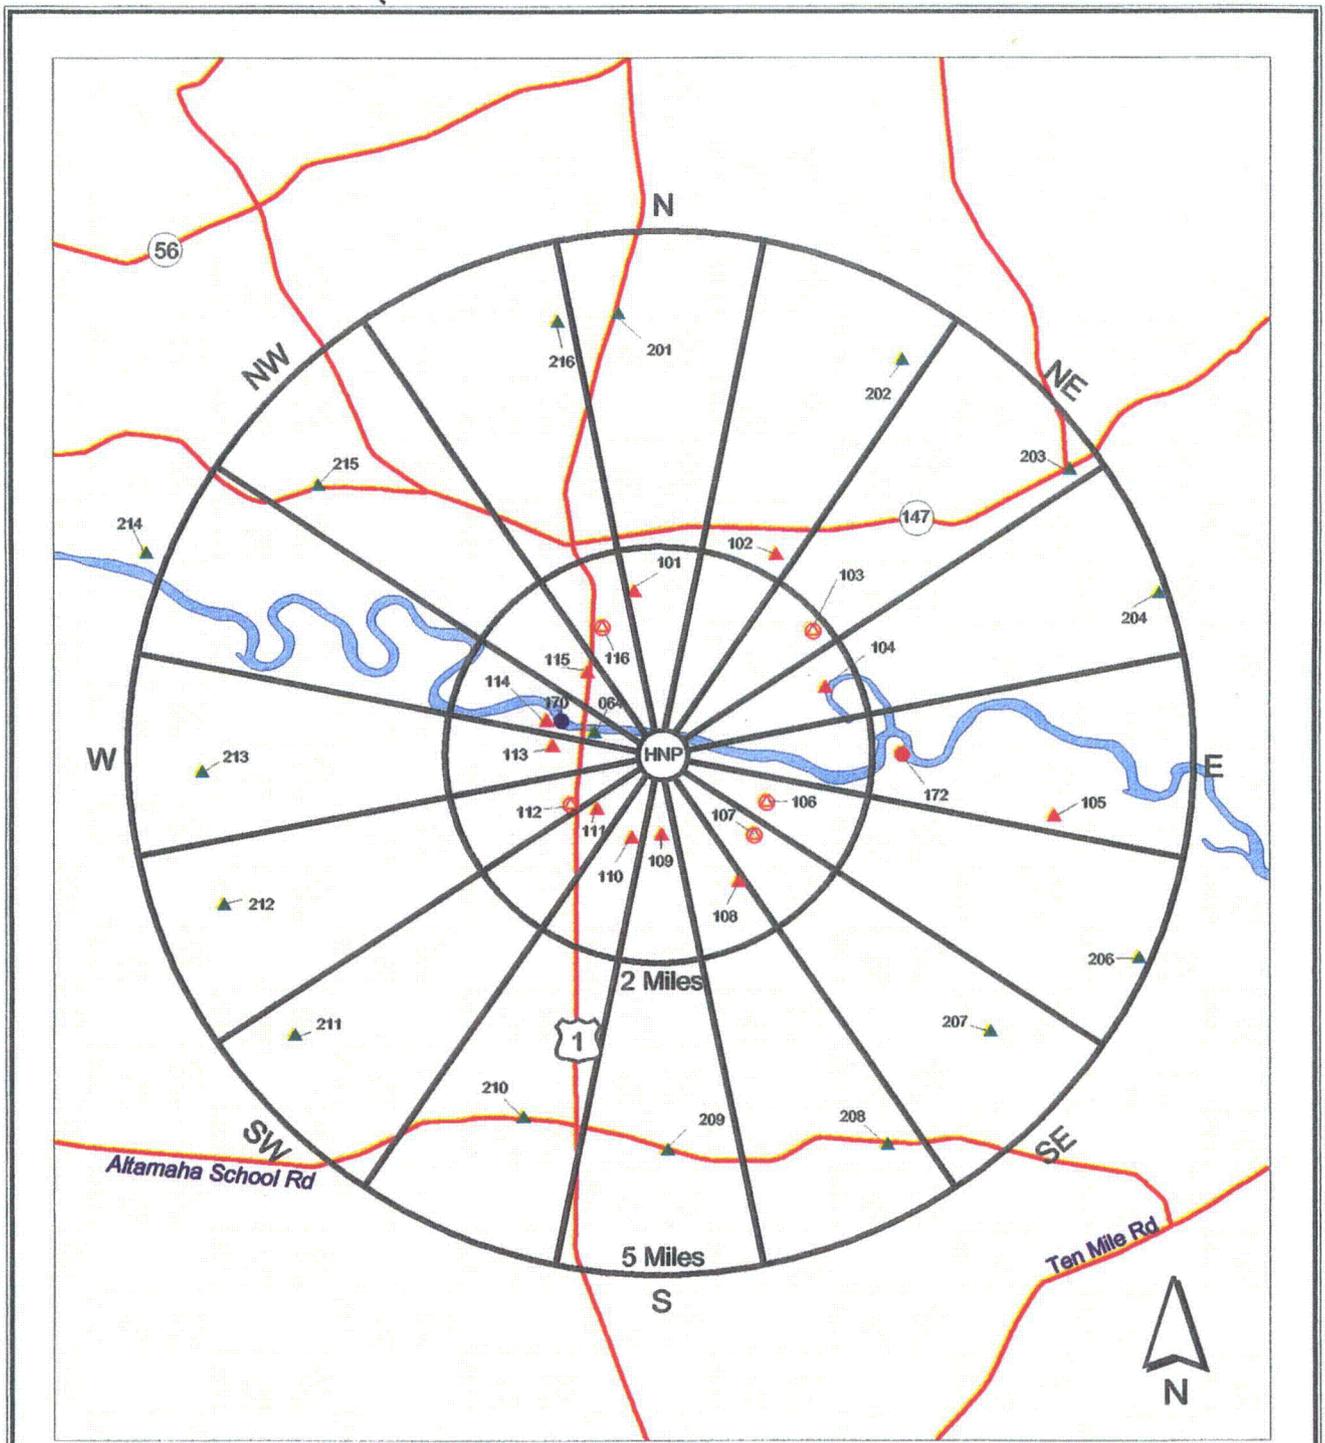

**RADIOLOGICAL ENVIRONMENTAL SAMPLING LOCATIONS**

Notes:

- a. Direction and distance are determined from the main stack.
- b. River (fish or clams, shoreline sediment, and surface water)
- c. Station 170 is located approximately 0.6 river miles upstream of the intake structure for river water, 1.1 river miles for sediment and clams, and 1.5 river miles for fish.

Station 172 is located approximately 3.0 river miles downstream of the discharge structure for river water, sediment and clams, and 1.7 river miles for fish.

The locations from which river water and sediment may be taken can be sharply defined. However, the sampling locations for clams often have to be extended over a wide area to obtain a sufficient quantity. High water adds to the difficulty in obtaining clam samples and may also make an otherwise suitable location for sediment sampling unavailable. A stretch of the river of a few miles or so is generally needed to obtain adequate fish samples. The mile locations given above represent approximations of the locations where samples are collected.

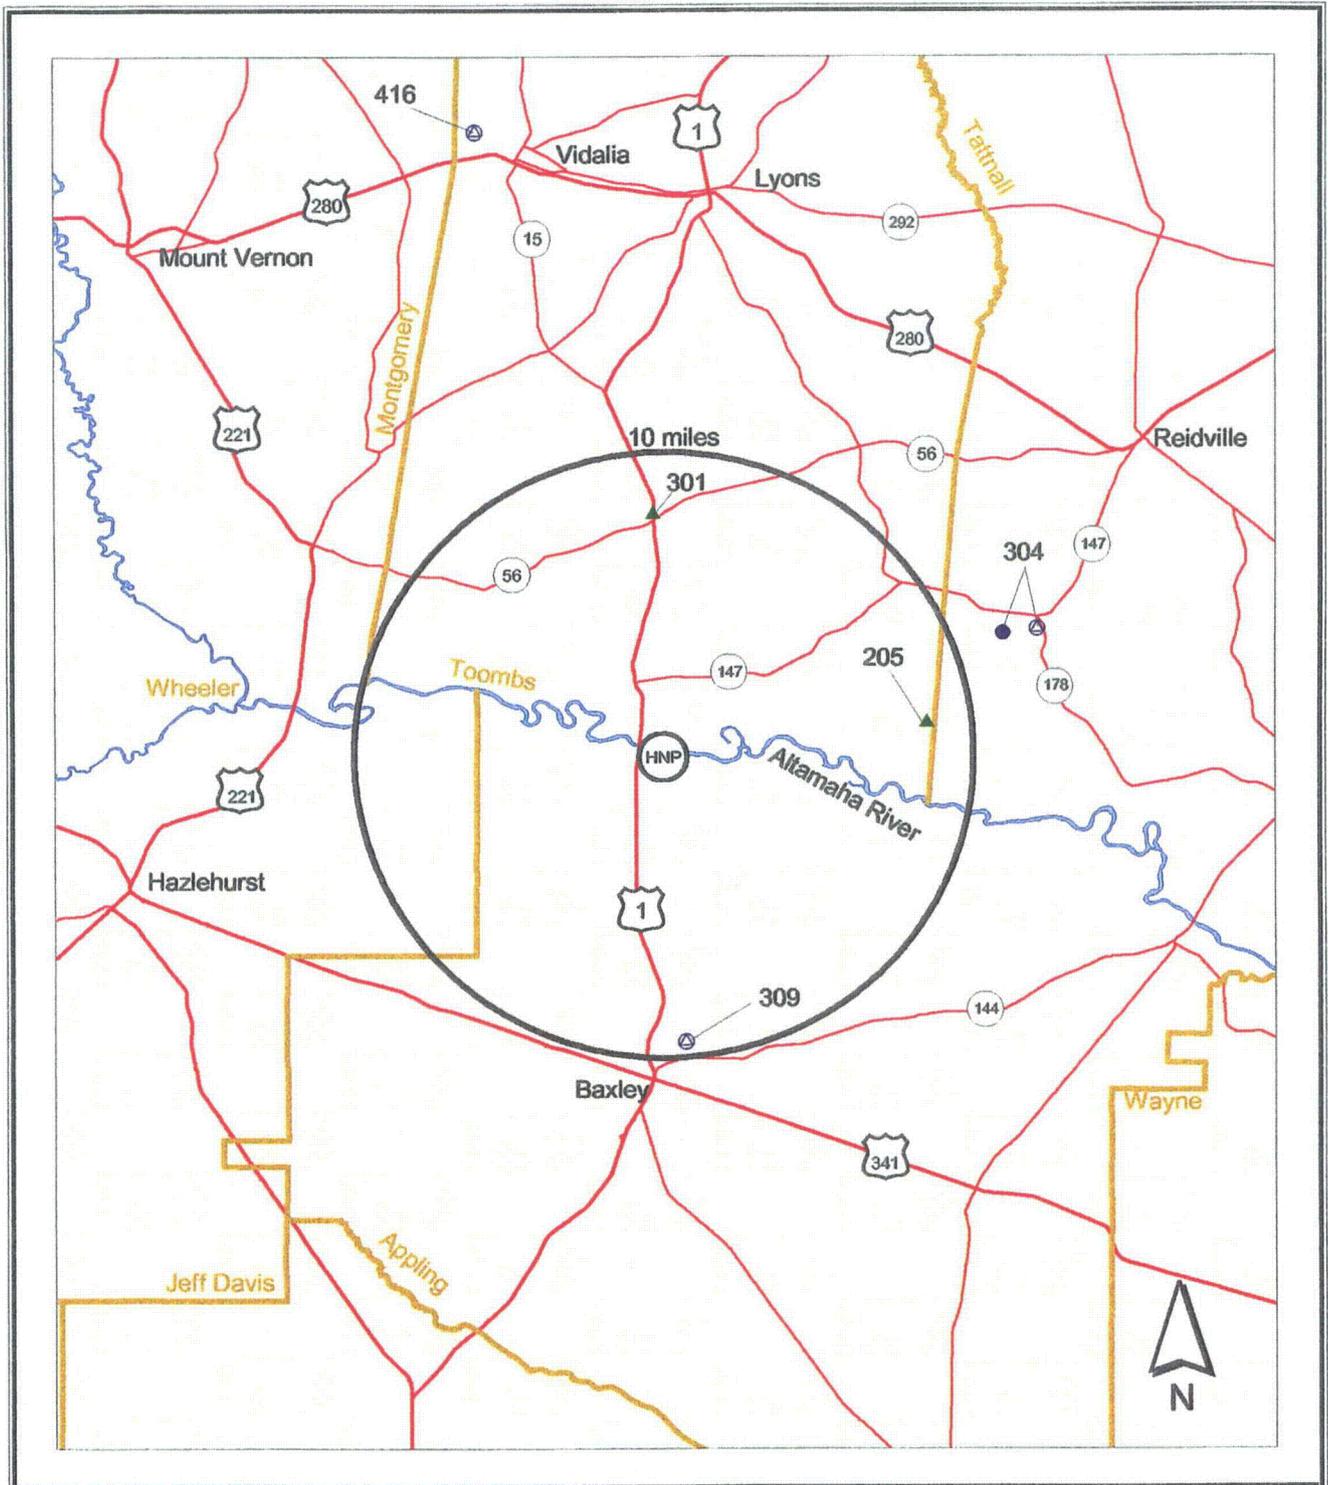

**Radiological Environmental Sampling Locations**

### **3.0 RESULTS SUMMARY**

In accordance with ODCM 7.1.2.1, the summarized and tabulated results for all of the regular samples collected for the year at the designated indicator and control stations are presented in Table 3-1. The format of Table 3-1 is similar to Table 3 of the Nuclear Regulatory Commission (NRC) Branch Technical Position, "An Acceptable Radiological Environmental Monitoring Program", Revision 1, November 1979. Since no naturally occurring radionuclides were found in the plant's effluent releases, only man-made radionuclides are reported as permitted by ODCM 7.1.2.1. Results for samples collected at locations other than control or indicator stations are discussed in Section 4 under the particular sample type.

**RADIOLOGICAL ENVIRONMENTAL MONITORING PROGRAM ANNUAL SUMMARY**

**Edwin I. Hatch Nuclear Plant, Docket Nos. 50-321 and 50-366**

**Appling County, Georgia**

**NOTATIONS**

- a. The MDC is defined in ODCM 10.1. Except as noted otherwise, the values listed in this column are the detection capabilities required by ODCM Table 4-3. The values listed in this column are a priori (before the fact) MDCs. In practice, the a posteriori (after the fact) MDCs are generally lower than the values listed. Any a posteriori MDC greater than the value listed in this column is discussed in Section 4.
- b. Mean and range are based upon detectable measurements only. The fraction of all measurements at specified locations that are detectable is placed in parenthesis.
- c. No Detectable Measurement(s).
- d. Not Applicable.
- e. If a drinking water pathway were to exist, a MDC of 1 pCi/l would have been used (see Table 4-1 of this report).
- f. If a drinking water pathway were to exist, a MDC of 2000 pCi/l would have been used (see Table 4-1 of this report).
- g. "Other" stations, identified in the "station type" column of Table 2-2, include community and special stations.

## 4.0 DISCUSSION OF RESULTS

Included in this section are evaluations of the laboratory results for the various sample types. Comparisons were made between the difference in mean values for pairs of station groups (e.g., indicator and control stations) and the calculated Minimum Detectable Difference (MDD) between these pairs at the 99% Confidence Level (CL). The MDD was determined using the standard Student's t-test. A difference in the mean values which was less than the MDD was considered to be statistically indiscernible.

The 2006 results were compared with past results, including those obtained during pre-operation. As appropriate, results were compared with their Minimum Detectable Concentrations (MDC) and Reporting Levels (RL) which are listed in Tables 4-1 and 4-2 of this report, respectively. The required MDCs were achieved during laboratory sample analyses. Any anomalous results are explained within this report.

Results of interest are graphed to show historical trends. The data points are tabulated and included in this report. The points plotted and provided in the tables represent mean values of only detectable results. Periods for which no detectable measurements (NDM) were observed or periods for which values were not applicable (e.g., milk indicator, etc.) are plotted as 0's and listed in the tables as NDM.

**Table 4-1**

### Minimum Detectable Concentrations (MDC)

| Analysis   | Water<br>(pCi/l) | Airborne<br>Particulate<br>or Gases<br>(fCi/m <sup>3</sup> ) | Fish<br>(pCi/kg-<br>wet) | Milk<br>(pCi/l) | Grass or<br>Leafy<br>Vegetation<br>(pCi/kg-wet) | Sediment<br>(pCi/kg-<br>dry) |

(a) This is the 40 CFR 141 value for drinking water samples. If no drinking water pathway exists, a value of 30,000 may be used.

(b) If no drinking water pathway exists, a value of 20 pCi/l may be used.

Atmospheric nuclear weapons tests from the mid 1940s through 1980 distributed man-made nuclides around the world. The most recent atmospheric tests in the 1970s and in 1980 had a significant impact upon the radiological concentrations found in the environment prior to and during preoperation, and the earlier years of operation. Some long lived radionuclides, such as Cs-137, continue to be detectable.

Significant upward trends also followed the Chernobyl incident which began on April 26, 1986.

In accordance with ODCM 4.1.1.2.1, deviations from the required sampling schedule are permitted, if samples are unobtainable due to hazardous conditions, unavailability, inclement weather, equipment malfunction or other just reasons. Deviations from conducting the REMP as described in Table 2-1 are summarized in Table 4-3 along with their causes and resolutions.

All results were tested for conformance to Chauvenet's criterion (G. D. Chase and J. L. Rabinowitz, Principles of Radioisotope Methodology, Burgess Publishing Company, 1962, pages 87-90) to identify values which differed from the mean of a set by a statistically significant amount. Identified outliers were investigated to determine the reason(s) for the difference. If equipment malfunction or other valid physical reasons were identified as causing the variation, the anomalous result was excluded from the data set as non-representative. No data were excluded exclusively for failing Chauvenet's criterion. Data exclusions are discussed in this section under the appropriate sample type.

**TABLE 4-3  
DEVIATIONS FROM RADIOLOGICAL ENVIRONMENTAL MONITORING PROGRAM**

| <b>COLLECTION PERIOD</b>      | <b>AFFECTED SAMPLES</b> | <b>DEVIATION</b>                                    | <b>CAUSE</b>   | <b>RESOLUTION</b>  |
|-------------------------------|-------------------------|---|--|--|
| 05/08/06-05/15/06             | AF/AC<br>Station 304    | Non-representative sample of airborne particulates. | Lost about 71.1 hours of sampling time due to blown pump fuse.   | Sample pump operated satisfactorily after fuse was replaced.                                       |
| 06/26/06-07/03/06<br>EXCLUDED | AF/AC<br>Station 103    | Non-representative sample of airborne particulates. | No sample due to blown fuse on distribution pole (Hwy. 147 and Dead River Road).                             | Altamaha EMC replaced fuse and sample station operated satisfactorily.                             |
| 09/05/06-09/11/06             | AF/AC<br>Station 304    | Non-representative sample of airborne particulates. | Lost about 15.7 hours of sampling time due to blown transformer.   | Sample station operated satisfactorily after transformer repaired.                                 |
| 09/11/06-09/18/06             | AF/AC<br>Station 103    | Non-representative sample of airborne particulates. | Lost about 2.5 hours of sampling time. Distribution pole rotted and fell.                                    | Sample station operated satisfactorily after distribution pole replaced.                           |
| 10/23/06-10/30/06             | AF/AC<br>Station 304    | Non-representative sample of airborne particulates. | Lost about 64.1 hours of sampling time due to broken power supply line.                                      | Temporary fix restored power to station and station operated satisfactorily.                       |
| 10/30/06-11/06/06             | AF/AC<br>Station 304    | Non-representative sample of airborne particulates. | Lost about 1.6 hours of sampling time while power supply line reconnected.                                   | Power line replaced.   |
| 11/06/06-11/13/06             | AF/AC<br>Station 304    | Non-representative sample of airborne particulates. | Pump not returned to service after electrical repairs done.  | Sampler station returned to service.   |
| 11/21/06-11/27/06             | AF/AC<br>Station 309    | Non-representative sample of airborne particulates. | Lost about 114.1 hours sampling time. Pump locked up.  | Sample pump was replaced and afterwards sample station operated satisfactorily                     |
| 12/18/06-12/27/06<br>EXCLUDED | AF/AC<br>Station 116    | Non-representative sample of airborne particulates. | No sample. Filter cartridge was not connected properly after the pump was exchanged for routine maintenance. | Field Services Group discussed the need to double check connections before leaving sample station. |

## 4.1 Land Use Census and River Survey

In accordance with ODCM 4.1.2, a land use census was conducted on November 27 and 28, 2006, to determine the locations of the nearest permanent residence and milk animal in each of the 16 compass sectors within a distance of 5 miles, and the locations of all milk animals within a distance of 3 miles. A milk animal is defined as a cow or goat producing milk for human consumption. The locations of beef cattle and of gardens greater than 500 square feet producing broad leaf vegetation were also included in the census. The census results are tabulated in the Table 4.1-1.

**Table 4.1-1**

### LAND USE CENSUS RESULTS

**Distance in Miles to Nearest Location in Each Sector**

| SECTOR | RESIDENCE | MILK ANIMAL | BEEF CATTLE | GARDEN |
|--------|-----------|-------------|-------------|--------|
| N      | 2.1       | None        | None        | 3.8    |
| NNE    | 2.9       | None        | None        | 2.9    |
| NE     | 3.3       | None        | 3.5         | None   |
| ENE    | 4.2       | None        | 4.1         | None   |
| E      | 3.0       | None        | None        | None   |
| ESE    | 3.8       | None        | None        | None   |
| SE     | 1.8       | None        | 2.3         | 3.3    |
| SSE    | 2.0       | None        | 2.2         | 4.3    |
| S      | 1.0       | None        | 2.3         | 2.3    |
| SSW    | 1.1       | None        | 2.0         | None   |
| SW     | 1.1       | None        | 2.3         | 1.6    |
| WSW    | 1.0       | None        | 1.6         | 1.6    |
| W      | 1.1       | None        | 2.8         | 2.1    |
| WNW    | 1.1       | None        | None        | None   |
| NW     | 3.6       | None        | 3.2         | None   |
| NNW    | 1.8       | None        | 2.8         | 2.9    |

ODCM 4.1.2.2.1 requires a new controlling receptor to be identified if the land use census identifies a location that yields a calculated receptor dose greater than the one in current use. No change in the controlling receptor was required as a result of the 2006 land use census. The current controlling receptor as described in ODCM Table 3-7 is a child in the WSW Sector at 1.2 miles

ODCM 4.1.2.2.2 requires that whenever the land use census identifies a location which would yield a calculated dose (via the same ingestion pathway) 20% greater than that of a current indicator station, the new location must become a REMP station (if samples are available). The 2006 land use census did not identify a garden which yielded a calculated dose 20% greater than that for any of the current indicator stations for vegetation. The results of the census were corroborated by inquiries to the county extension agents in the 5 counties in the vicinity of the plant.

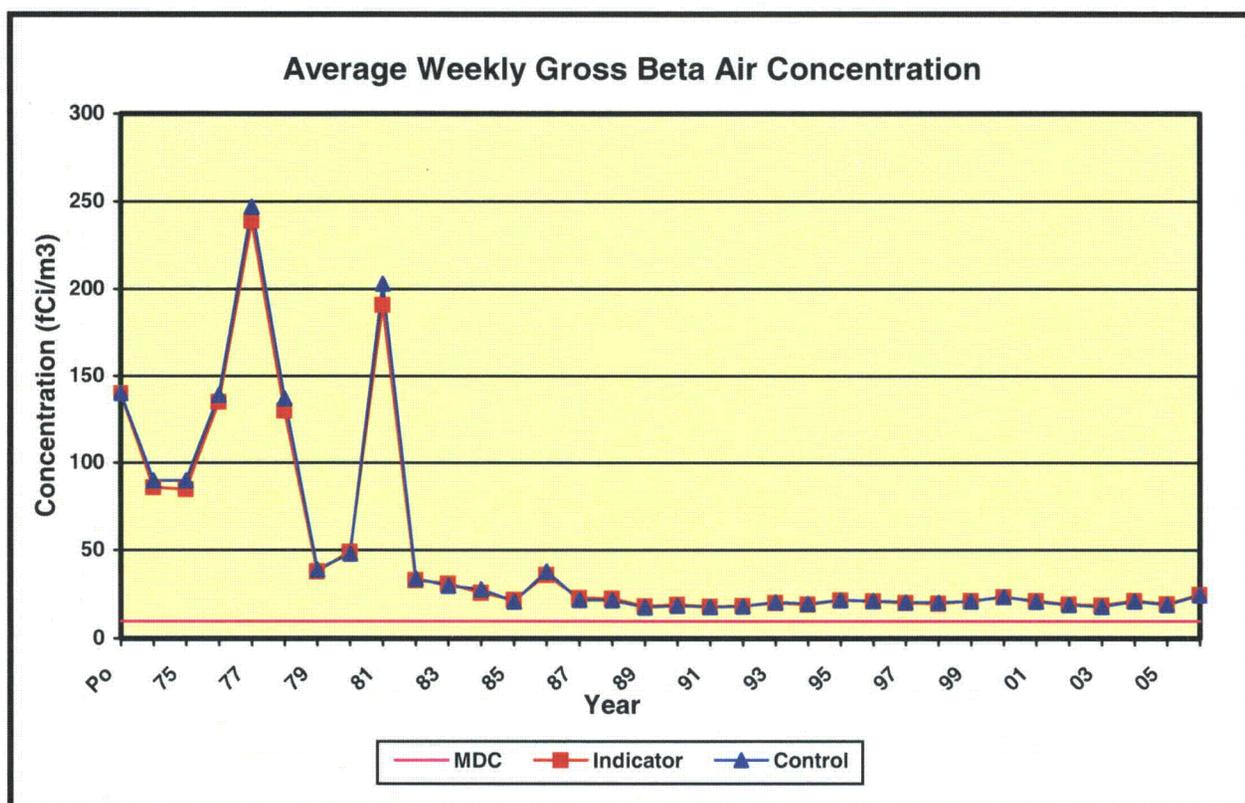

As required by Note f of Table 2-1, the annual survey of the Altamaha River for 50 miles downstream of the plant was conducted on October 30, 2006 to identify any withdrawal of river water for drinking purposes. No sources of withdrawal for drinking water or irrigation purposes were identified. Information obtained from the Georgia Department of Natural Resources on November 3, 2006 and December 28, 2006 indicated that no surface water withdrawal permits for agricultural or drinking purposes had been issued for this stretch of the Altamaha River between the 2005 survey and the 2006 survey. Should it be determined that river water downstream of the plant is being used for drinking, the sampling and analysis requirements for drinking water found in Table 2-1 would be implemented.

## 4.2 Airborne

As indicated in Table 2-2 and Figures 2-1 and 2-2, airborne particulates and airborne radioiodine are collected at 4 indicator stations (Nos. 103, 107, 112 and 116) which encircle the plant near the site periphery and at 2 control stations (Nos. 304 and 309) which are located approximately 10 miles from the main stack. At each location, air is continuously drawn through a glass fiber filter and a charcoal canister placed in series to collect airborne particulates and radioiodine. The filters and canisters are collected weekly and analyzed for gross beta and I-131, respectively. A gamma isotopic analysis is performed quarterly on a composite of the filters for each station.

The 2006 annual average weekly gross beta concentration of 24.9 fCi/m<sup>3</sup> for the indicator stations was 0.2 fCi/m<sup>3</sup> greater than that for the control stations (24.7 fCi/m<sup>3</sup>). This difference is not statistically discernible, since it is less than the calculated MDD of 1.62 fCi/m<sup>3</sup>. Figure 4.2-1 and Table 4.2-1 provide the historical trending of the average weekly gross beta concentrations in air. In general, there is close agreement between the results for the indicator and control stations. This close agreement supports the position that the plant is not contributing significantly to the gross beta concentration in air.

Figure 4.2-1

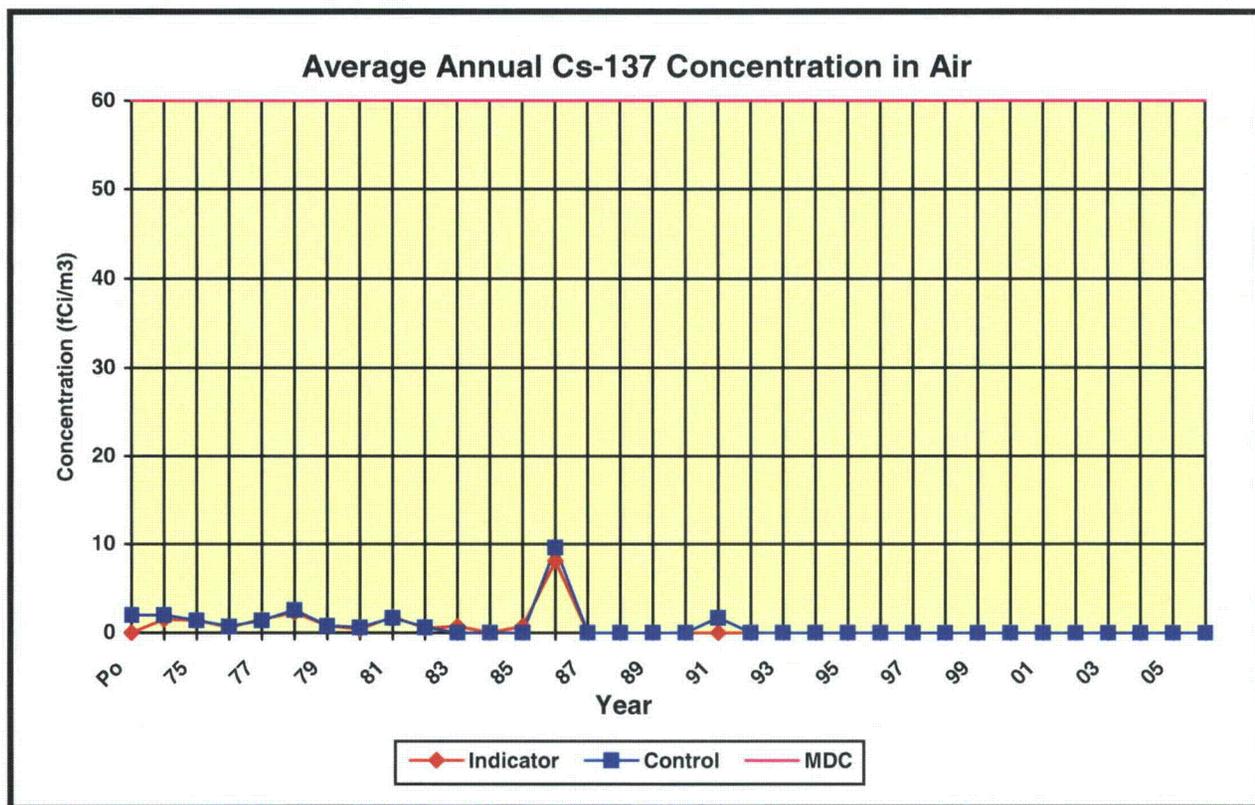

**Table 4.2-1****Average Weekly Gross Beta Air Concentration**

| <b>Year</b> | <b>Indicator<br/>(fCi/m3)</b> | <b>Control<br/>(fCi/m3)</b> |
|-------------|-------------------------------|-----------------------------|
| Pre-op      | 140                           | 140                         |
| 1974        | 87                            | 90                          |

During 2006, no man-made radionuclides were detected from the gamma isotopic analysis of the quarterly composites of the particulate air filters. During preoperation and during operation through 1986, a number of fission products and activation products were detected. These were generally attributed to the nuclear weapons tests and to the Chernobyl incident. On only one occasion since 1986, has a man-made radionuclide been detected in a quarterly composite. A small amount of Cs-137 (1.7 fCi/m<sup>3</sup>) was identified in the first quarter of 1991 at Station 304. The MDC and RL for Cs-137 in air are 60 and 20,000 fCi/m<sup>3</sup>, respectively. The historical trending of the average annual concentrations of detectable Cs-137 from quarterly air filter composites is provided in Figure 4.2-2 and Table 4.2-2.

Figure 4.2-2

No airborne I-131 was detected in the charcoal canisters in 2006. During 1976, 1977, and 1978, positive levels of I-131 were found in nearly all of the samples collected for a period of a few weeks following atmospheric nuclear weapons tests. Some of the concentrations were on the order of 70 fCi/m<sup>3</sup>. In 1986, the same phenomenon occurred following the Chernobyl incident. The highest airborne I-131 concentration found to date in an individual charcoal canister was 217 fCi/m<sup>3</sup> in 1977. The MDC and RL for airborne I-131 are 70 fCi/m<sup>3</sup> and 900 fCi/m<sup>3</sup>, respectively.

Table 4-3 lists REMP deviations that occurred in 2006. Nine deviations involved air sampling. Two of these deviations resulted in excluded data. The first incident happened 06/26/06-07/03/06 when a blown fuse resulted in no sample during the collection period. The second incident happened 12/18/06-12/27/06 and also resulted in no sample during the collection period due to the filter cartridge apparatus not being connected to the sample pump.

## 4.3 Direct Radiation

Direct (external) radiation is measured with thermoluminescent dosimeters (TLDs). Two Panasonic UD-814 TLD badges are placed at each station. Each badge contains three phosphors composed of calcium sulfate crystals (with thulium impurity). The gamma dose at each station is based upon the average readings of the phosphors from the two badges. The badges for each station are placed in thin plastic bags for protection from moisture while in the field. The badges are nominally exposed for periods of a quarter of a year (91 days). An inspection is performed near mid-quarter to assure that all badges are on-station and to replace any missing or damaged badges.

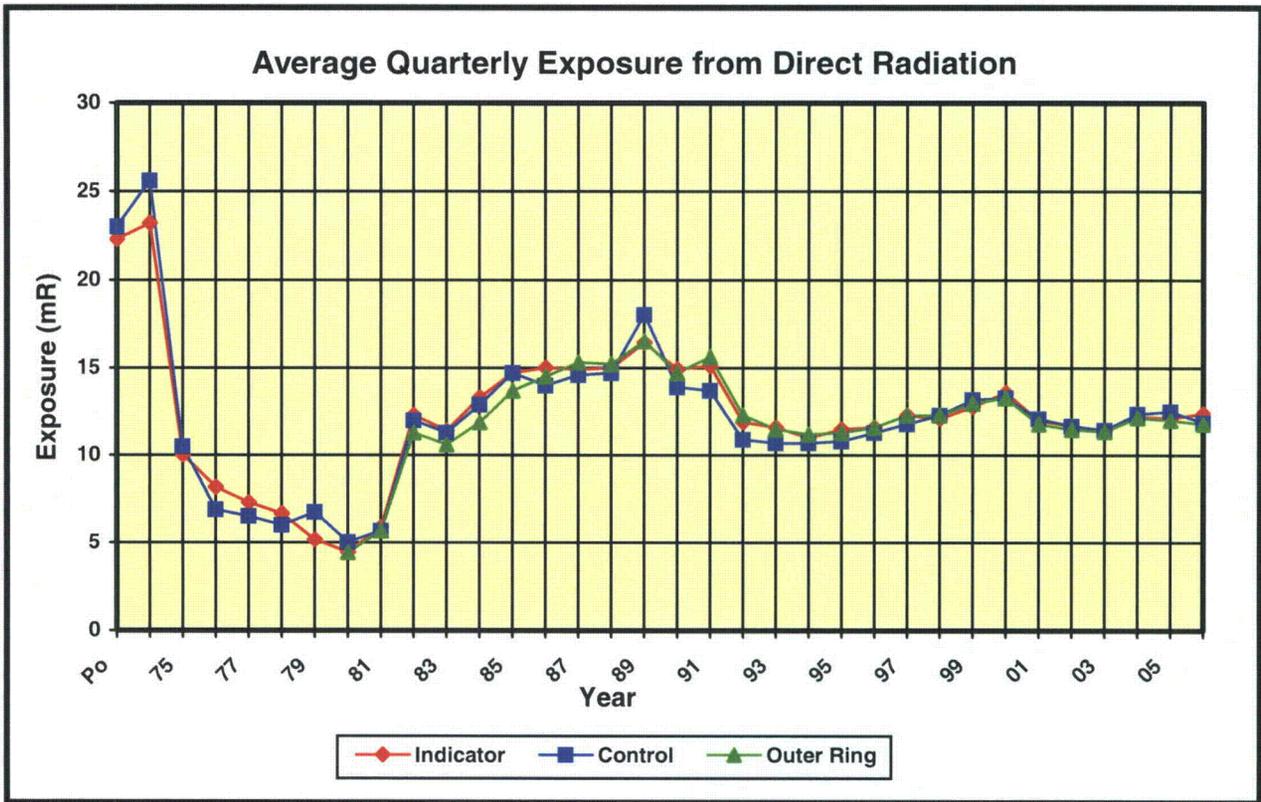

Two TLD stations are established in each of the 16 compass sectors around the plant to form 2 concentric rings, as seen in Figures 2-1 and 2-2. The two ring configuration of stations was established in 1980, in accordance with NRC Branch Technical Position "An Acceptable Radiological Environmental Monitoring Program", Revision 1, 1979. With the exception of the East sector, the inner ring stations (Nos. 101 through 116) are located near the site boundary and the outer ring stations (Nos. 201 through 216) are located at distances of 4 to 5 miles from the plant. The stations in the East sector are a few miles farther out than the other stations in their respective rings due to large swamps making normal access extremely difficult. The 16 stations forming the inner ring are designated as the indicator stations. The 3 control stations (Nos. 304, 309 and 416) are located 10 miles or more from the plant. Stations 064 and 301 monitor special interest areas. Station 064 is located at the onsite roadside park, while Station 301 is located near the Toombs Central School. Station 210, in the outer ring, is located near the Altamaha School (the only other nearby school).

As provided in Table 3-1, the average quarterly exposure measured at the indicator stations (inner ring) during 2006 was 12.4 mR. At the control stations, the average quarterly exposure was 11.9 mR. This difference (0.5 mR) is not statistically discernible since it is less than the MDD of 0.81 mR.

The quarterly exposures acquired at the outer ring stations during 2006 ranged from 8.5 to 15.8 mR, with an average of 11.8 mR. The average for the outer ring stations was 0.1 mR less than the average for the control stations. Since the results for the outer ring stations and the control stations differ by less than the MDD of 0.7 mR, there is no discernible difference between outer ring and control station results for 2006.

The historical trending of the average quarterly exposures for the indicator inner ring, outer ring, and the control stations are plotted in Figure 4.3-1 and listed in Table 4.3-1. The decrease between 1991 and 1992 values is attributed to a change in TLDs from Teledyne to Panasonic. It should be noted however that the differences between indicator and control and outer ring values did not change. The close agreement between the station groups supports the position that the plant is not contributing significantly to direct radiation in the environment.

Figure 4.3-1

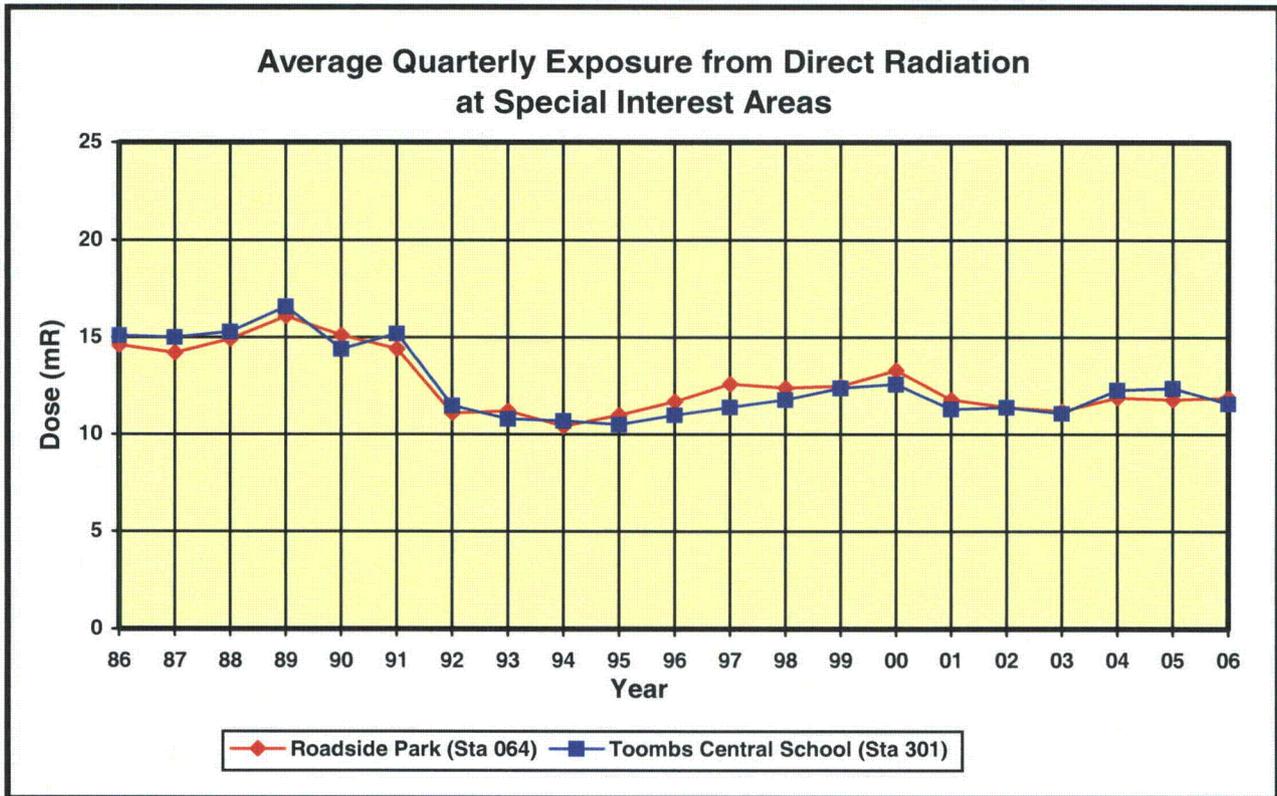

**Table 4.3-1****Average Quarterly Exposure from Direct Radiation**

| <b>Year</b> | <b>Indicator (mR)</b> | <b>Control (mR)</b> | <b>Outer Ring (mR)</b> |

| 1996        | 11.6                  | 11.3                | 11.6                   |
| 1997        | 12.3                  | 11.8                | 12.3                   |
| 1998        | 12.1                  | 12.3                | 12.3                   |
| 1999        | 12.8                  | 13.2                | 13.0                   |
| 2000        | 13.6                  | 13.3                | 13.3                   |
| 2001        | 12.0                  | 12.1                | 11.8                   |
| 2002        | 11.7                  | 11.7                | 11.5                   |
| 2003        | 11.4                  | 11.4                | 11.4                   |
| 2004        | 12.2                  | 12.4                | 12.2                   |
| 2005        | 12.1                  | 12.5                | 12.0                   |
| 2006        | 12.4                  | 11.9                | 11.8                   |

The historical trending of the average quarterly exposures at the special interest areas for the past 19 years is provided in Figure 4.3-2 and listed in Table 4.3-2. These exposures are within the range of those acquired at the other stations. They too, show that the plant is not contributing significantly to direct radiation at the special interest areas.

Figure 4.3-2

**Table 4.3-2**

**Average Quarterly Exposure from Direct Radiation  
at Special Interest Areas**

| Period | Station 064<br>(mR) | Station 301<br>(mR) |
|--------|---------------------|---------------------|
| 1986   | 14.6                | 15.1                |
| 1987   | 14.2                | 15.0                |
| 1988   | 14.9                | 15.3                |
| 1989   | 16.1                | 16.6                |
| 1990   | 15.1                | 14.4                |
| 1991   | 14.4                | 15.2                |
| 1992   | 11.1                | 11.5                |
| 1993   | 11.2                | 10.8                |
| 1994   | 10.4                | 10.7                |
| 1995   | 11.0                | 10.5                |
| 1996   | 11.7                | 11.0                |
| 1997   | 12.6                | 11.4                |
| 1998   | 12.4                | 11.8                |
| 1999   | 12.5                | 12.4                |
| 2000   | 13.3                | 12.6                |
| 2001   | 11.8                | 11.3                |
| 2002   | 11.4                | 11.4                |
| 2003   | 11.2                | 11.1                |
| 2004   | 11.9                | 12.3                |
| 2005   | 11.8                | 12.4                |
| 2006   | 11.9                | 11.6                |

In 2006, there were no field deviations involving direct radiation measurements.

The standard deviation for the quarterly result for each badge was subjected to a self imposed limit of 1.4. This limit is based upon the standard deviations obtained with the Panasonic UD-814 badges during 1992 and is calculated using a method developed by the American Society of Testing and Materials (ASTM Special Technical Publication 15D, ASTM Manual on Presentation of Data and Control Chart Analysis, Fourth Revision, Philadelphia, PA, October 1976).

The limit serves as a flag to initiate an investigation. To be conservative, readings with a standard deviation greater than 1.4 are excluded from the data set since the high standard deviation is interpreted as an indication of unacceptable variation in

TLD response. In 2006, the following TLD results were excluded from the data set because their standard deviations were greater than 1.4:

|                |                      |
|----------------|----------------------|
| First Quarter  | 064B and 101B        |
| Second Quarter | None                 |
| Third Quarter  | 114A, 204A, and 205B |
| Fourth Quarter | 204A                 |

For these stations, the reading of the companion badge at each location was used to determine the quarterly exposure.

During 2006, no direct radiation station experienced both badges having standard deviations above the self-imposed limit of 1.4. For those instances in which one badge at a station exhibited a standard deviation greater than 1.4, the other badge of the two-badge set was available to give a valid reading for the particular location.

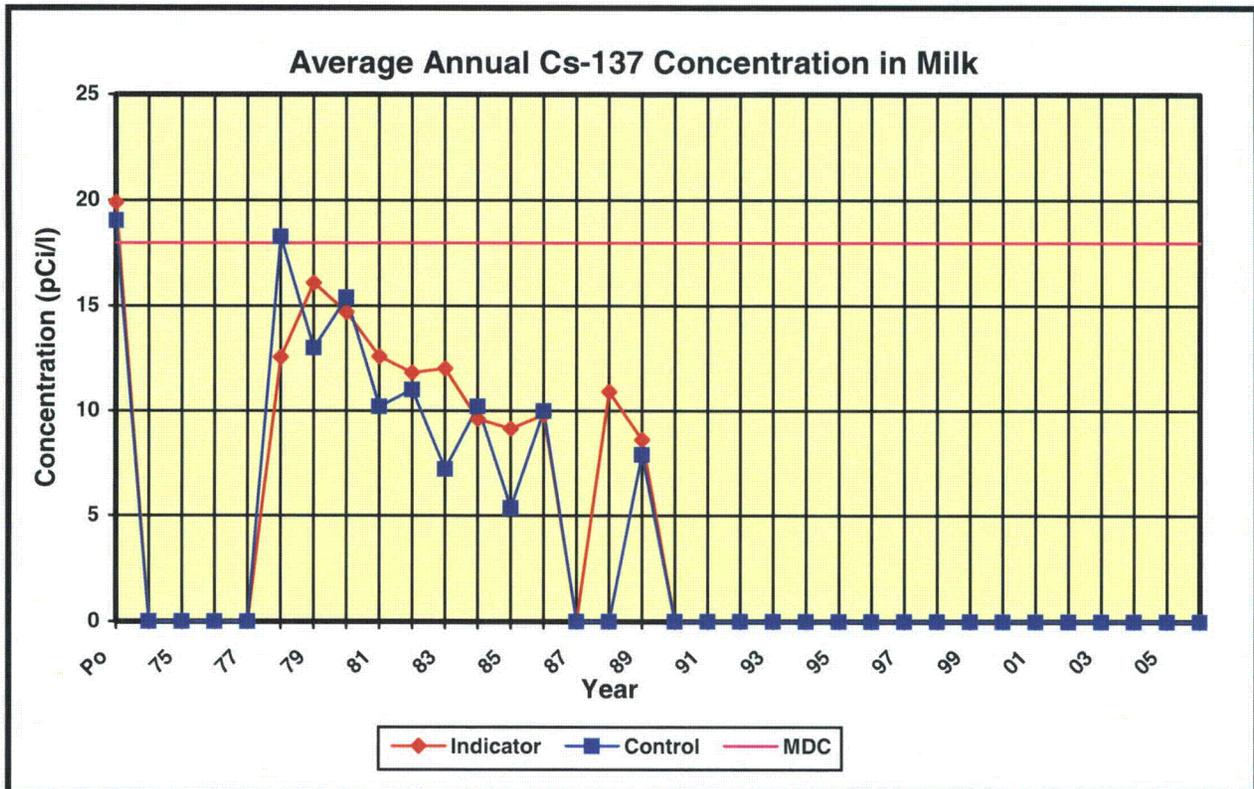

## 4.4 Milk

Milk samples are obtained biweekly from Station 304 (the state prison dairy) which is a control station located more than 10 miles from the plant. Gamma isotopic and I-131 analyses are performed on each sample as specified in Tables 2-1 and 2-2. Since 1989, efforts to locate a reliable milk sample source within 5 miles of the plant have been unsuccessful.

During 2006, no man-made radionuclides were detected from the gamma isotopic analysis of the milk samples. Cesium-137 was found in most of the samples each year from 1978 (when this analysis became a requirement) through 1989. No other man-made radionuclides have been detected by this analysis.

The MDC and RL for Cs-137 in milk are 18 and 70 pCi/l, respectively. The historical trending of the average annual detectable Cs-137 concentration in milk is provided in Figure 4.4-1 and Table 4.4-1.

Figure 4.4-1

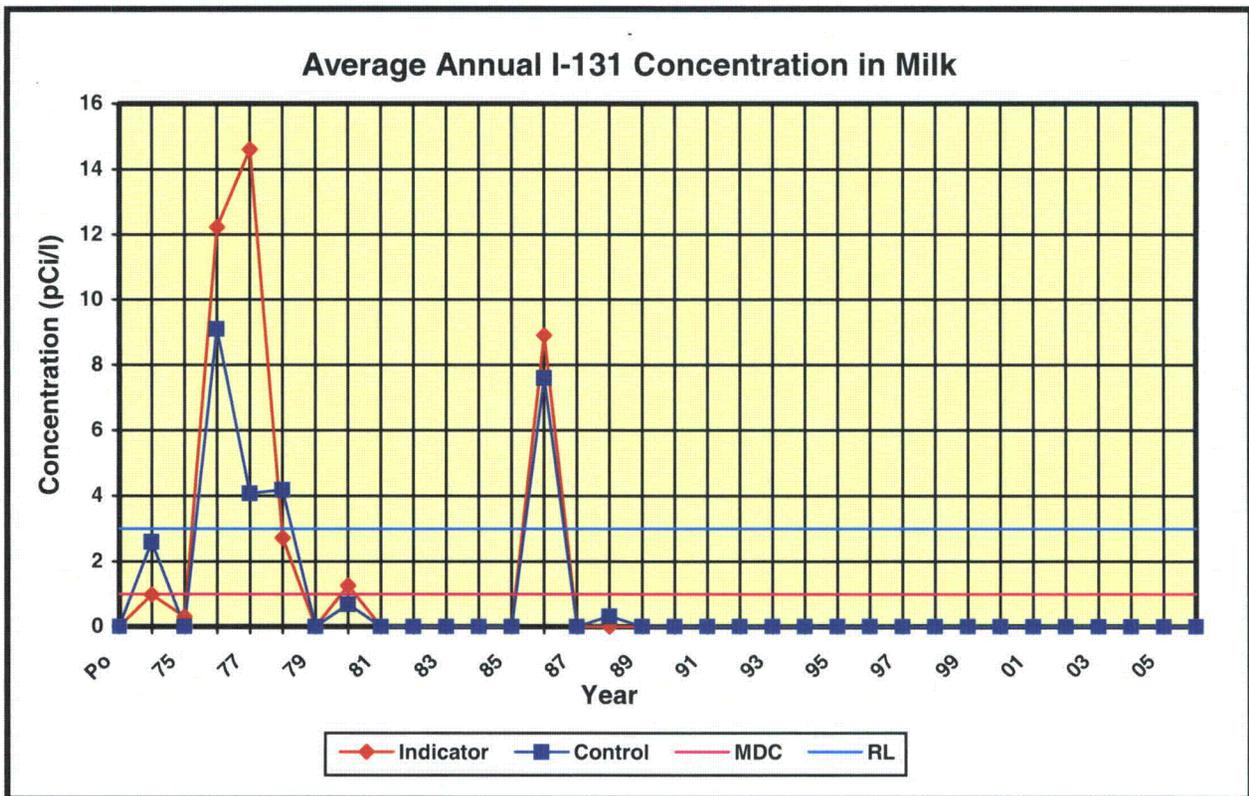

**Table 4.4-1****Average Annual Cs-137 Concentration in Milk**

| <b>Year</b> | <b>Indicator<br/>(pCi/l)</b> | <b>Control<br/>(pCi/l)</b> |
|-------------|------------------------------|----------------------------|
| Pre-op      | 19.9                         | 19.4                       |
| 1974        | NDM                          | NDM                        |
| 1975        | NDM                          | NDM                        |
| 1976        | NDM                          | NDM                        |
| 1977        | NDM                          | NDM                        |
| 1978        | 12.1                         | 18.3                       |
| 1979        | 16.1                         | 13                         |
| 1980        | 14.7                         | 15.4                       |
| 1981        | 12.57                        | 10.2                       |
| 1982        | 11.8                         | 11                         |
| 1983        | 12                           | 7.2                        |

| 2006        | NDM                          | NDM                        |

During 2006, I-131 was not detected in any of the milk samples. During preoperation, all readings were less than 2 pCi/l which was the allowed MDC at that time. Figure 4.4-2 and Table 4.4-2 provide the historical trending of the average annual detectable concentration of I-131 in milk. In 1988, a single reading of 0.32 pCi/l, which was believed to have resulted from a procedural deficiency, was reported. The MDC and RL for I-131 in milk are 1 and 3 pCi/l, respectively.

All the detectable results for Cs-137 and I-131 are attributed to fallout from the nuclear weapons tests and the Chernobyl incident.

## 4.5 Vegetation

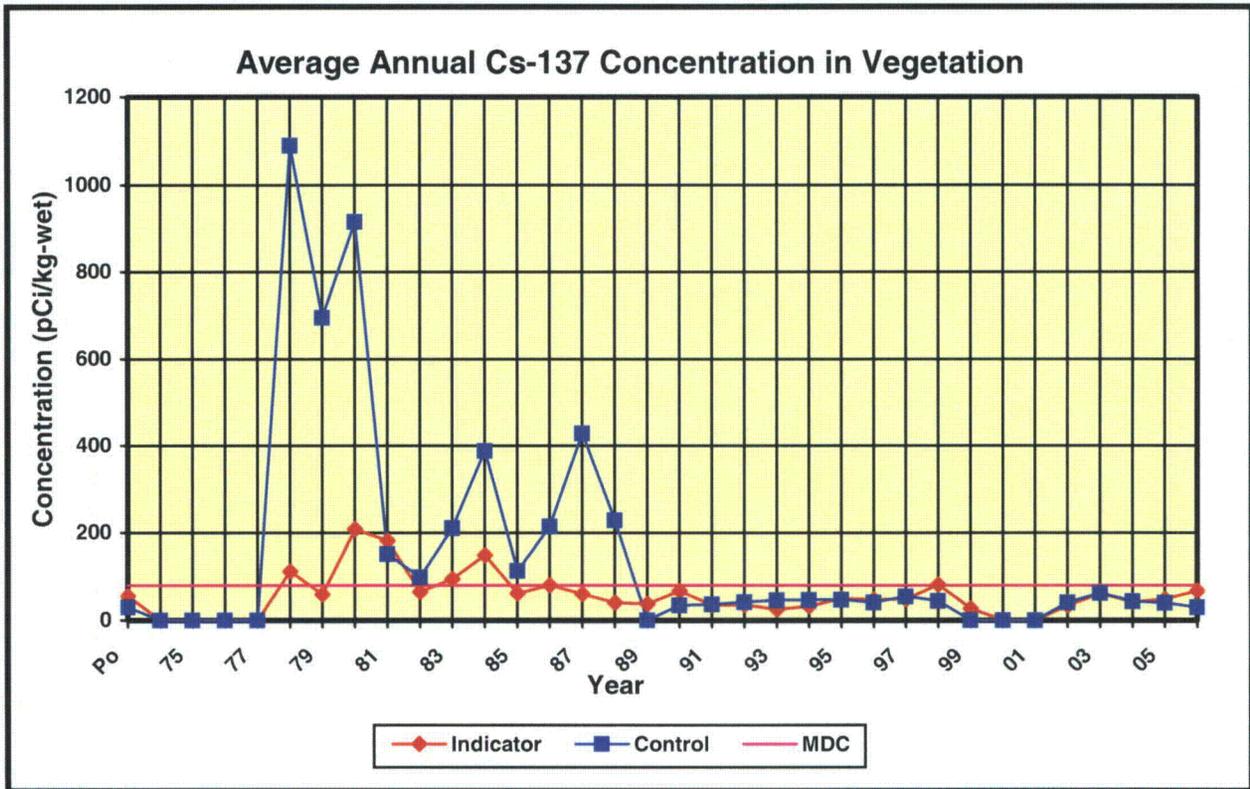

In accordance with Tables 2-1 and 2-2, grass samples are collected monthly from two indicator stations near the site boundary (Nos. 106 and 112) and at one control station located about 21 miles from the plant (No. 416). Gamma isotopic analyses are performed on each sample. Gamma isotopic analysis on vegetation samples began in 1978 when the analysis became a TS requirement.

The results presented in Table 3-1 show that Cs-137 was the only man-made radionuclide detected in vegetation samples during 2006. Cs-137 was detected in eleven samples collected at the indicator stations at an average value of 66.8 pCi/kg-wet. Two samples collected at the control station had detectable Cs-137 at an average of 29.6 pCi/kg-wet. The difference of 37.2 pCi/kg-wet between the control and the indicator averages is not statistically discernible since it is less than the MDD of 74.7 pCi/kg-wet.

Since 1986, Cs-137 has been the only man-made radionuclide found in vegetation samples. The MDC and RL for Cs-137 in vegetation samples are 80 pCi/kg-wet and 2000 pCi/kg-wet, respectively. The occasional presence of Cs-137 in vegetation samples is attributed primarily to fallout from nuclear weapons tests and the Chernobyl incident.

Figure 4.5-1 and Table 4.5-1 provide the historical trending of the average annual detectable Cs-137 concentration found in vegetation. Since 1978, the Cs-137 concentration has been on a decline, and since about 1989, generally occurring below the required MDC and very close to detectable levels.

## 4.6 River Water

Surface water from the Altamaha River is obtained at an upstream location (Station 170) and at a downstream location (Station 172) using automatic samplers. Small quantities are drawn at intervals not exceeding a few hours. The samples drawn are collected monthly and quarterly composites are produced from the monthly collections.

As specified in Table 2-1, a gamma isotopic analysis is conducted on each monthly sample. No man-made gamma emitters were detected during 2006. The only man-made gamma emitters previously detected are presented in the table below.

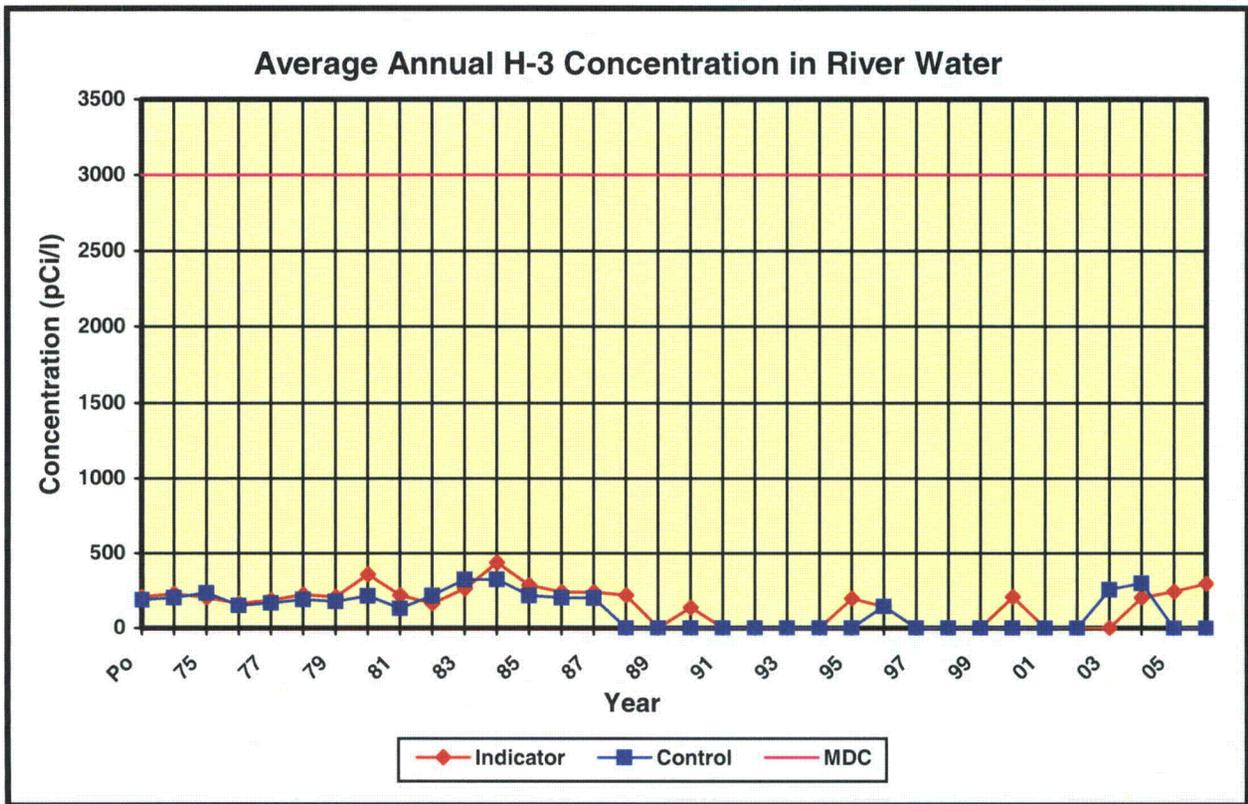

| Year | Quarter | Station | Radionuclide | Level (pCi/l) |
|------|---------|---------|--------------|---------------|
| 1975 | 4th     | 172     | Ce-141       | 78.2          |
| 1986 | 2nd     | 170     | La-140       | 18.0          |
| 1986 | 2nd     | 172     | Cs-137       | 12.0          |
| 1988 | 2nd     | 170     | Cs-137       | 6.8           |

A tritium analysis is performed on the quarterly composite. Prior to 1986, positive results were usually found in each quarterly composite at levels generally ranging from 200 and 400 pCi/l which is very close to background environmental levels (approximately 100-300 pCi/l). Subsequently, the number of positive results have diminished.

In 2006, tritium was not detected in any of the four quarterly samples at the upstream (control) location. Tritium was detected in two of the four quarterly samples at the downstream (indicator) location. The average of the two indicator samples was 299 pCi/l (the range was 264-334 pCi/l). This could be attributed to plant effluents since tritium was not detected at the control station in 2006. However, these low levels are very close to background environmental levels. The MDC and RL for tritium in river water are 3000 and 30,000 pCi/l, respectively. Figure 4.6-1 and Table 4.6-1 provide the historical trending of the annual average detectable tritium concentration in river water.

The annual 50 mile downstream survey of the Altamaha River to determine if river water is being withdrawn for drinking purposes is discussed in Section 4.1.

Figure 4.6-1

## 4.7 Fish

Gamma isotopic analyses were performed on the edible portion of the fish samples collected at the river stations on April 10, 2006 and December 20, 2006. The control station (No. 170) is located upstream of the plant while the indicator station (No. 172) is located downstream.

As shown in Table 3-1, Cs-137 was the only man-made radionuclide detected in fish during 2006. The average concentration of 10.4 pCi/kg-wet at the indicator station was 3.1 pCi/kg-wet less than the average concentration found at the control station (13.5 pCi/kg-wet). This difference is not statistically discernible since it is less than the calculated MDD of 36.4 pCi/kg-wet. Cs-137 in fish samples is attributed primarily to weapons testing and the Chernobyl incident. The MDC and RL for Cs-137 in fish are 150 and 2000 pCi/kg-wet, respectively.

The historical trending of the average annual detectable Cs-137 concentration in fish is provided in Figure 4.7-1 and Table 4.7-1. Figure 4.7-1 indicates, in general, a decline in the Cs-137 levels after 1983. (Note: From 1979 through 1982, clams were collected rather than fish.)

In the past, the only other man-made radionuclides detected in fish samples were Co-60 and Cs-134. During preoperation, Co-60 was detected in one fish sample at a very low concentration. During the period of 1983 through 1988, Cs-134 was found in about half of the samples at concentrations of the same order of magnitude as those found for Cs-137. The Co-60 and Cs-134 levels found in these samples are attributed to the nuclear weapons tests and the Chernobyl incident. Figure 4.7-2 and Table 4.7-2 show the historical trending of the annual average detectable concentration of Cs-134 in fish.

## 4.8 Sediment

Sediment was collected along the shoreline of the Altamaha River on May 1 and November 6, 2006, at the upstream control station (No. 170) and the downstream indicator station (No. 172). A gamma isotopic analysis was performed on each sample.

Co-60 was not found in sediment samples in 2006. With the exception of a few years, Co-60 has been found at either the indicator or the control station every year since 1986. There is no RL or MDC assigned to Co-60 in sediment in ODCM Tables 4-2 and 4-3 (Tables 4-2 and 4-1 of this report). The MDC assigned by the EL for Co-60 in sediment is 70 pCi/kg-dry. The historical trending of the average annual detectable Co-60 concentration in sediment is provided in Figure 4.8-1 and Table 4.8-1.

Co-60 was not detected in sediment samples near the plant until 1986, the year of the Chernobyl incident. However, because Co-60 has been detected in indicator station samples more often than in control station samples in recent years, some contribution from plant effluents cannot be ruled out.

In 2006, Cs-137 was detected in both indicator and control station sediment samples. It has been found in over 95% of all of the sediment samples collected back through preoperation, and is generally attributed to the atmospheric nuclear weapons tests or to the Chernobyl incident. As shown in Table 3-1, the average at the indicator station was 85.2 pCi/kg-dry and at the control station one of two samples was positive at 79.2 pCi/kg-dry. Using the modified Student's t-test, the difference (6.0 pCi/kg-dry) between the stations is not statistically discernible. The MDC for Cs-137 in sediment is 180 pCi/kg-dry. The historical trending of the average annual detectable Cs-137 concentration in sediment is provided in Figure 4.8-2 and Table 4.8-2.

Other man-made nuclides, besides Co-60 and Cs-137, were occasionally found in past years. Their presence was generally attributed to the nuclear weapons tests or to the Chernobyl incident, although plant releases were not ruled out. Mn-54, Co-58, and Zn-65, which have relatively short half-lives, are most likely a result of plant releases and have been plotted in Figure 4.8-3 along with their MDCs. All the man-made nuclides detected in sediment except for Co-60 and Cs-137 have been listed in Table 4.8-3. The Cs-134 MDC (150 pCi/kg-dry) is defined in ODCM Table 4-3 (Table 4-1 of this report). The MDCs for Mn-54 (42 pCi/kg-dry) and Zn-65 (129 pCi/kg-dry) were determined by the EL since no values are provided in ODCM Table 4-3.

## 4.9 Groundwater

In 2006, NEI (Nuclear Energy Institute) formed a task force to address monitoring onsite groundwater for radionuclides at nuclear facilities. The task force was formed after several plants detected radionuclides (primarily tritium) in groundwater wells off plant site. The contamination sources were found to be onsite underground piping leaks, tank leaks, storage ponds, or radioactive spills that had slowly seeped into the groundwater. These small leaks went undetected for many years and eventually led to the unexpected discovery of radionuclides off plant site. The amount of radioactivity seen in the offsite wells did not pose a significant health concern. However, NEI felt it was prudent for the industry to update site hydrology information and to develop radiological groundwater monitoring plans at each site. These groundwater protection plans would ensure that underground leaks and spills would be addressed more promptly. Additionally, NEI recommended developing a communications protocol to report radioactive leaks or spills that entered groundwater (or might eventually enter groundwater) to the NRC and State and Local government officials as needed.

Plant Hatch has monitored onsite groundwater since preoperation. Initially piezometers, which were installed prior to plant construction, were used to monitor groundwater. In the late 1970s to the early 1980s timeframe, a hydrological engineering consultant was hired to evaluate several areas where leaks had occurred and tritium had been detected in onsite wells. The consultant recommended drilling additional monitoring wells to study the groundwater movement, to determine the source of the leaks, and to track the tritium concentrations in groundwater.

In the late 1970s through the mid 1980s, Hatch reported groundwater results to the NRC. The reporting frequency was decreased for several reasons – the areas where the groundwater showed tritium were all onsite and the movement of groundwater was extremely slow (approximately 100 feet per year) and in a direction (towards the river) that was not expected to impact the public. Although the reports are no longer made on a routine basis, Plant Hatch has continued to monitor onsite groundwater wells for tritium on a scheduled frequency.

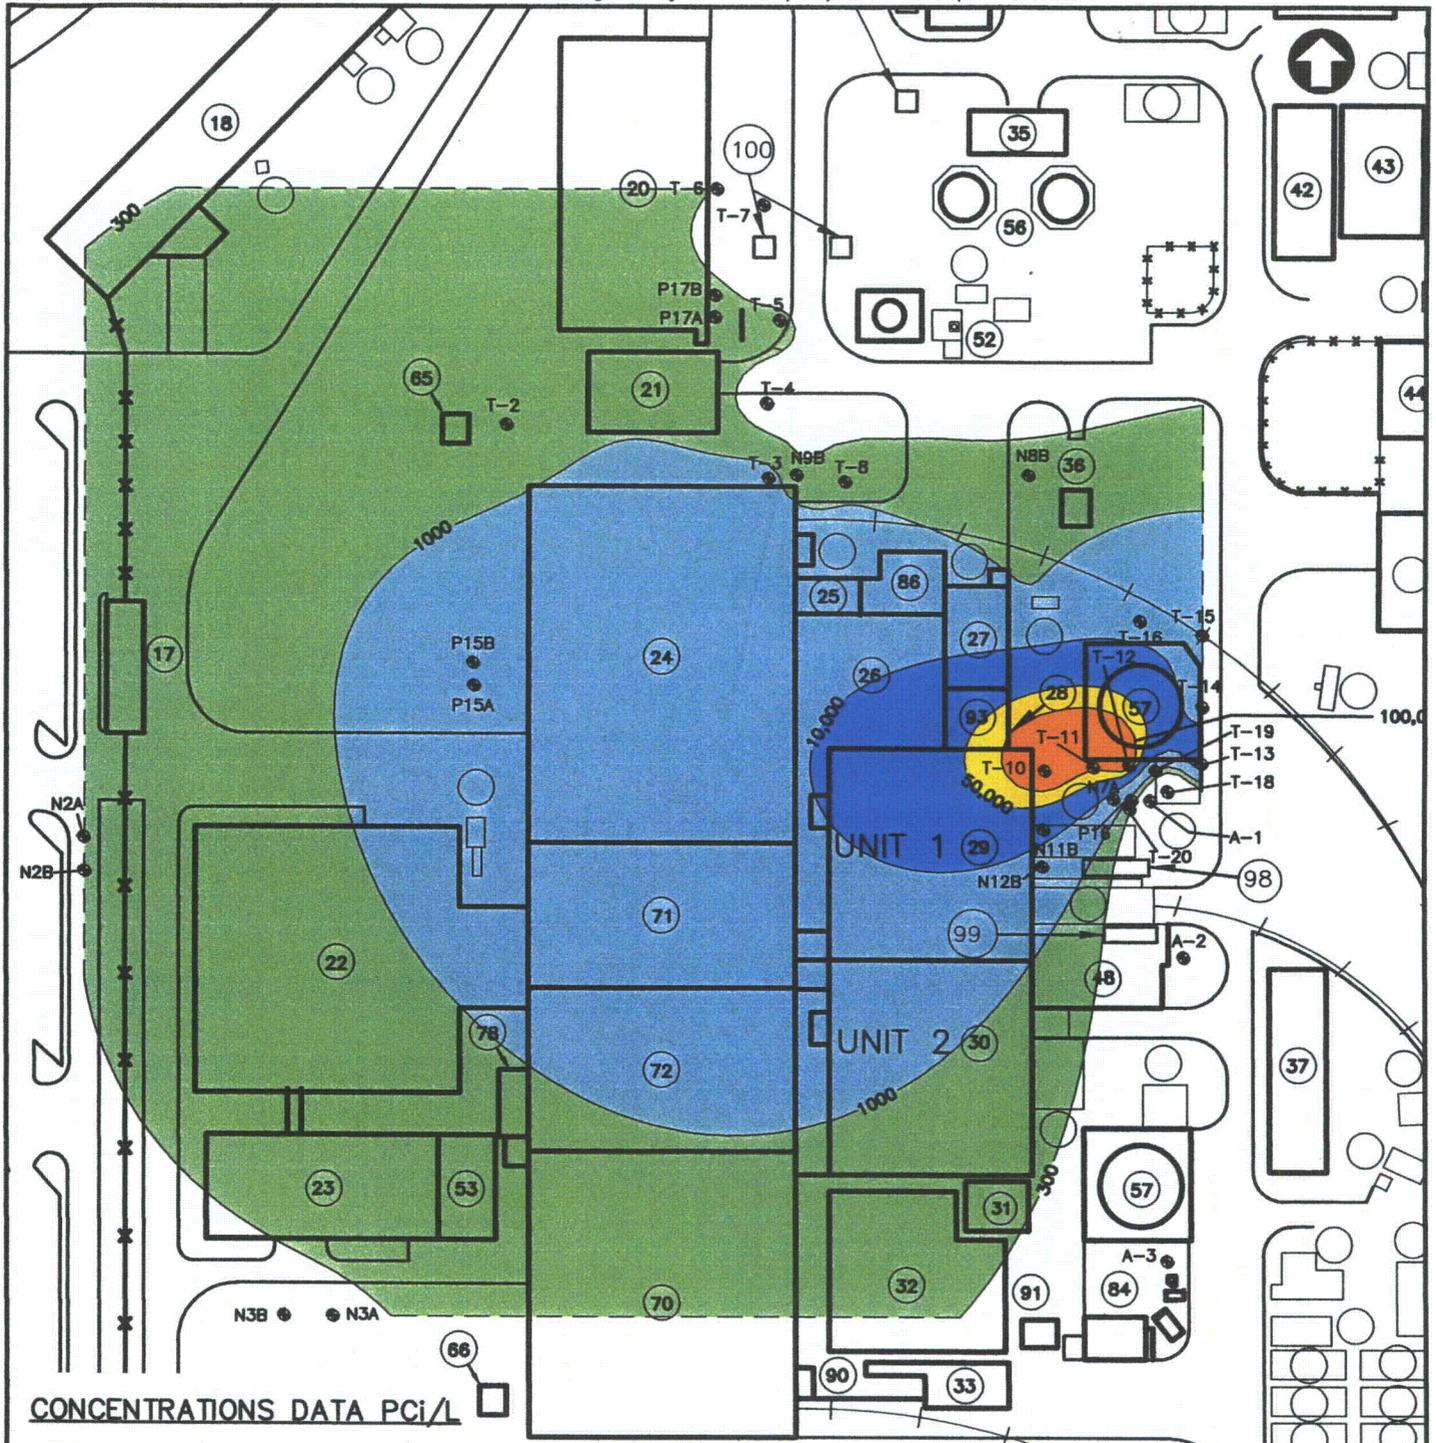

In 2006 as the nuclear industry was moving towards establishing groundwater monitoring programs, Plant Hatch hired a hydrological engineering consultant to re-evaluate the groundwater study which had been done previously. The key purpose of the new study was to evaluate the adequacy of the current monitoring program and to diagram the existing groundwater tritium plume (see map at the end of this section) to ensure that the plume had not migrated offsite. The consultant concluded that tritium was not leaving the site through the groundwater. The consultant recommended installing additional monitoring wells to better characterize the groundwater plume in areas of the site where there were no existing wells.

During the course of Plant Hatch's groundwater evaluation, some leaks were discovered that explained why the levels of tritium around CST-1 (Unit 1 Condensate Storage Tank) were not decreasing. Underground piping which carried radioactive liquids was evaluated over the plant site and replaced in some areas around CST-1. Both CST tank/pump moats (Unit 1 and Unit 2) were coated and sealed to ensure that moats would not leak in the event of transfer pump or tank leaks.

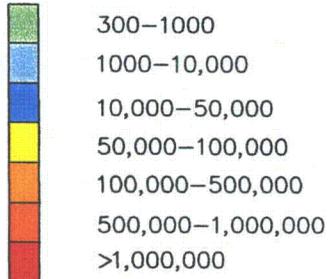

In 2006, Plant Hatch's groundwater monitoring program included over 50 points which were sampled on weekly, monthly, quarterly, or annual frequencies (see maps at the end of this section). Included in these sample points were the onsite drinking water wells. They did not contain detectable amounts of radioactivity. Surface drains or outfalls were also included as sample points. Tritium was detected in two of the outfalls which discharged to the river. These outfalls were added to the Hatch ODCM as radiological effluent release points. Permitted release point Y22N008A (by design) discharges groundwater from the site subsurface drainage system which includes the tritiated groundwater around the CST-1. The other permitted release point, Y22N003A, discharges runoff from the roof drains. The source of tritium in this outfall is more than likely from rain washout of the gaseous plant effluents. Plant Hatch sampled rainfall during two rain events in 2006 and found tritium levels as high as  $4.58E5$  pCi/l on the reactor building roof. Two other outfalls, Y22N024A and Y22N025A, which discharge into the onsite swamp show sporadic levels of tritium. The source of tritium in these outfalls is also likely to be from rain washout.

In 2007, the consultant will further update the 2006 groundwater evaluation with additional data from the existing sample points and will also include data from the new wells which were drilled and sampled in 2006. The consultant will assist in determining the need for drilling additional monitoring wells and will consider the best long-term solution for monitoring and tracking the groundwater tritium plume. The groundwater monitoring results will be reported each year in the site REMP report.

Southern Nuclear has developed a company-wide communications protocol which is contained in the Nuclear Management Procedure, *Actions for Potential Groundwater Contamination Events*, to ensure radioactive leaks and spills would be addressed and communicated appropriately.

## 5.0 INTERLABORATORY COMPARISON PROGRAM

In accordance with ODCM 4.1.3, the EL participates in an ICP that satisfies the requirements of Regulatory Guide 4.15, Revision 1, "Quality Assurance for Radiological Monitoring Programs (Normal Operations) - Effluent Streams and the Environment", February 1979. The guide indicates the ICP is to be conducted with the Environmental Protection Agency (EPA) Environmental Radioactivity Laboratory Intercomparison Studies (Cross-check) Program or an equivalent program, and the ICP should include all of the determinations (sample medium/radionuclide combinations) that are offered by the EPA and included in the REMP.

The ICP is conducted by Analytics, Inc. of Atlanta, Georgia. Analytics has a documented Quality Assurance (QA) program and the capability to prepare Quality Control (QC) materials traceable to the National Institute of Standards and Technology. The ICP is a third party blind testing program which provides a means to ensure independent checks are performed on the accuracy and precision of the measurements of radioactive materials in environmental sample matrices. Analytics supplies the crosscheck samples to the EL which performs the laboratory analyses in a normal manner. Each of the specified analyses is performed three times. The results are then sent to Analytics who performs an evaluation which may be helpful to the EL in the identification of instrument or procedural problems.

The samples offered by Analytics and included in the EL analyses are gross beta and gamma isotopic analyses of an air filter; gamma isotopic analyses of milk samples; and gross beta, tritium and gamma isotopic analyses of water samples.

The accuracy of each result is measured by the normalized deviation, which is the ratio of the reported average less the known value to the total error. The total error is the square root of the sum of the squares of the uncertainties of the known value and of the reported average. The uncertainty of the known value includes all analytical uncertainties as reported by Analytics. The uncertainty of the reported average is the propagated error of the values in the reported average by the EL. The precision of each result is measured by the coefficient of variation, which is defined as the standard deviation of the reported result divided by the reported average. An investigation is undertaken whenever the absolute value of the normalized deviation is greater than three or whenever the coefficient of variation is greater than 15% for all radionuclides other than Cr-51 and Fe-59. For Cr-51 and Fe-59, an investigation is undertaken when the coefficient of variation exceeds the values shown as follows:

| Nuclide | Concentration * | Total Sample Activity (pCi) | Percent Coefficient of Variation |
|---------|-----------------|-----------------------------|----------------------------------|
| Cr-51   | <300            | NA                          | 25                               |
| Cr-51   | NA              | >1000                       | 25                               |
| Cr-51   | >300            | <1000                       | 15                               |
| Fe-59   | <80             | NA                          | 25                               |
| Fe-59   | >80             | NA                          | 15                               |

\* For air filters, concentration units are pCi/filter. For all other media, concentration units are pCi/liter (pCi/l).

As required by ODCM 4.1.3.3 and 7.1.2.3, a summary of the results of the EL's participation in the ICP is provided in Table 5-1 for: the gross beta and gamma isotopic analyses of an air filter; gamma isotopic analyses of milk samples; and gross beta, tritium and gamma isotopic analyses of water samples. Delineated in this table for each of the media/analysis combinations, are: the specific radionuclides; Analytics' preparation dates; the known values with their uncertainties supplied by Analytics; the reported averages with their standard deviations; and the resultant normalized deviations and coefficients of variation expressed as a percentage.

The GPC EL analyzed 9 samples for 46 parameters in 2006. These analyses included tritium, gross beta, Fe-55, Sr-89/90 and gamma emitting radio-nuclides in different matrices. The attached results indicate all analyses are acceptable for accuracy. Three analyses outside the control limit for precision are discussed below. The precision deviations were for the determination of gross alpha in water, I-131 in milk and Sr-90 in an air filter.

The gross alpha in water is analyzed in triplicate with an average value reported. The high range is attributed to one of the samples not evenly mixing in the beaker during digestion. The samples were counted a second time to eliminate detector variation. The second quarter alpha sample was in control for both accuracy and precision and no further investigation will be performed.

The second quarter milk sample was analyzed by gamma spectroscopy. The sample is analyzed on three detectors with an error weighted average reported. An elevated range of values in the analysis is due to one of the detectors measuring a higher activity. No inconsistencies were found in the detectors shaping or analysis of the 364.5 keV gamma peak. No further investigation will be performed.

The third quarter air filter sample analyzed for Sr-90 had a high range of values. The low activity in the sample resulted in a high uncertainty for the measurement and is reflected in the precision for the reported values. No further investigation will be performed.

The 2005 investigation into the Fe-59 high bias using gamma spectroscopy indicated a need for the calibration curve to be evaluated. The efficiency curve was believed to be affected by summing losses for specific gamma energies of Co-60 and Y-88. A calibration standard was purchased which included nuclides that do not contribute to summing. A calibration curve was developed using the standard and the curve was compared to the calibration curve using Co-60 and Y-88. The comparison indicated only a slight difference in efficiencies, therefore there is no benefit to adjusting the calibration curve for efficiency. The analysis of Fe-59 has been investigated and a small positive bias of 13% exists in the activity recovery. No further investigation will be performed and no corrective actions are planned

## 6.0 CONCLUSIONS

This report confirms the licensee's conformance with the requirements of Chapter 4 of the ODCM. It provides a summary and discussion of the results of the laboratory analyses for each type of sample.

In 2006, there was one instance where the indicator station results were statistically discernible from the control station results. These are discussed below. No discernible radiological impact upon the environment or the public as a consequence of plant discharges to the atmosphere and to the river was established for any other REMP samples.

Two of four quarterly composite samples from the river water indicator station were positive for tritium. The average value of the two positive samples was 299 pCi/l. There were no positive values at the control station. Therefore, this tritium concentration could be attributed to plant releases. However, the levels seen are consistent with environmental background levels of approximately 100-300 pCi/l.

Although no drinking water pathway via river water exists in the plant vicinity, a potential dose from tritium due to drinking water was calculated using methodology from the HNP ODCM. This dose was calculated assuming that a person regularly consumed drinking water from the river downstream of the plant discharge near the indicator station. Under these assumed circumstances, the potential dose to such an individual would be about  $2.3 \text{ E-}2$  mrem in a year. This dose would be less than 1% of the annual dose limit (3 mrem) for the total body due to liquid effluents.

Another pathway to obtain dose from tritium in the river would be through consumption of fish. The potential total body dose for an adult who consumed fish regularly from the river would be about  $5.9\text{E-}4$  mrem in a year. This extremely small dose is approximately 0.02% of the annual limit for the total body due to liquid effluents.

The radiological levels reported in 2006 were low and are generally trending downward. The REMP trends over the course of time from preoperation to the present are decreasing or have remained fairly constant. This supports the conclusion that there is no adverse radiological impact on the environment or to the public as a result of the operation of Hatch Nuclear Plant.
