1. PRE-EVENT PLANT CONDITIONS:

On March 16, 2007 the R.E. Ginna Nuclear Power Plant (Ginna) was in Mode 1 at approximately 100% steady state reactor power.

DESCRIPTION OF EVENT: 11.

EVENT: Α.

On March 16, 2007, at approximately 2209 EST, Ginna experienced a safety injection signal and reactor trip as the result of low steam pressure in the 'A' main steam line. The event was the result of the 'B' Main Steam Isolation Valve (MSIV) closing due to a change in the pressure balance in the actuator that keeps the valve disk out of the main steam flow path. The closure of the 'B' MSIV caused steam flow isolation from the 'B' Steam Generator. This in turn caused steam flow from 'A' Steam Generator to rapidly increase in an attempt to maintain the required full power steam flow to the High Pressure Turbine. The increase in steam flow from the 'A' Steam Generator caused a rapid decrease in 'A' steam line pressure which generated a low 'A' steam line pressure safety injection signal. The safety injection signal caused the reactor to trip. as is required by design.

The Control Room operators performed the appropriate actions of Emergency Operating Procedure E-0 (Reactor Trip or Safety Injection). The operators then transitioned to Emergency Operating Procedure ES-1.1 (SI Termination) when directed by procedure E-0.

Β. INOPERABLE STRUCTURES, COMPONENTS, OR SYSTEMS THAT CONTRIBUTED TO THE EVENT:

None

- DATES AND APPROXIMATE TIMES OF MAJOR OCCURENCES: C.
- March 16, 2007, 2209 EST: automatic safety injection signal and reactor trip due to low steam pressure from the 'A' Steam Generator.
- D. OTHER SYSTEMS OR SECONDARY FUNCTIONS AFFECTED:

None

E. METHOD OF DISCOVERY:

The safety injection signal and reactor trip were immediately apparent due to plant response, alarms, and indications in the Control Room.

F. SAFETY SYSTEM RESPONSES:

The required automatic system responses resulting from the safety injection signal were confirmed to have occurred. No injection to the reactor coolant system was required due to the system pressure. Additionally, actuation of the Turbine Driven Auxiliary Feedwater Pump occurred due to the coincident low water levels in both steam generators.

Immediately following receipt of the safety injection signal, the high flow from 'A' Steam generator in combination with the safety injection signal caused a Main Steam Isolation of the 'A' MSIV. The resulting closure of the 'A' MSIV caused the main condenser dump valves to not be available for controlling steam generator pressure for both steam generators. Steaming of both steam generators was provided by operation of the Atmospheric Relief Valves (ARVs). The peak pressure in the 'B' main steam line approached the nominal setpoint of Main Steam Safety Valve (MSSV) 3514. No MSSV actuations were apparent based on a review of computer data. Proper operation of the ARVs was able to control steam generator pressure for both steam generators.

CAUSE OF EVENT: Ш.

The immediate cause of the reactor trip was an automatic safety injection signal which actuated as the result of low steam pressure in the steam line from the 'A' Steam Generator. The low 'A' steam line pressure was an indirect result of the spurious closure of the 'B' MSIV.

The cause of this event was a lack of procedural guidance and maintenance practices, in conjunction with a lack of configuration control, which failed to identify that a solid plug was installed in the 'B' MSIV actuator exhaust vent port instead of a drilled plug. The solid plug prevented instrument air that leaked past the actuator piston seals from venting to the atmosphere. The seal leakage that accumulated in the upper chamber of the actuator over time, built up to equalize the pressure between the two sides of the piston, and allowed the spring force to overcome the instrument air pressure. This resulted in the valve disc moving into the flow stream, closing the valve.

The requirement to have a drilled plug instead of a solid plug was a preventative action that was implemented following MSIV closures in 1975. This information was not properly placed in the applicable drawings and procedures at that time. The 'B' MSIV actuator had recently been replaced in the fall 2006 refueling outage. Prior to the fall 2006 refueling outage the actuator was normally rebuilt and reinstalled. Several key steps to accurately complete the
