7 CORE DAMAGE FREQUENCY QUANTIFICATION

7.1 INTRODUCTION AND SCOPE

The purpose of this section is to document the calculation of the core damage frequency (CDF) due to events that occur when the plant is operating at full power. It covers internal events only. Sections 12 through 15 describe the CDF due to external events.

The ESBWR PRA model consists of event trees and fault trees that are quantified using a fault tree linking process. The event trees are described in Section 3, while the fault trees are described in Section 4.

The calculation of the CDF is performed as single top gate. This gate includes all sequences, but uses a sequence marker to keep all the non-minimal cutsets for that specific sequence. The sequence logic is also set up to exclude any combinations associated with the success branches in the specific sequence. The individual sequence results can then be combined as necessary for reporting, analyzing, or to be used as input for the containment performance portion of the PRA.

Section 7.2 presents the results of the quantification.

Section 7.3 is provided to further describe the details of the quantification process.

7.2 PRA RESULTS

The total core damage frequency (CDF) resulting from accident sequences is 1.07E-08/year.

7.2.1 Initiating Event Contribution

Table 7.2-1 shows the detailed contribution of initiating events to CDF. Figure 7.2-1 shows a summary contribution in the form of a pie chart.

The initiating events that have the largest contributors to CDF are identified to provide a perspective on the results.

Transients contribute approximately 85% to CDF. The most significant groups of initiators are the inadvertent stuck open relief valve (%T-IORV), loss of feedwater transient (%T-FDW), general transients (%T-GEN, and %T-IA), and initial loss of offsite power (all under gate T-LOPP) which represent 35%, 20.55%, 19.80% and 9.63% of the total CDF, respectively.

LOCAs inside containment contribute approximately 8.93%. The most significant LOCA initiator relative to CDF contribution is the large steam break in feedwater line B (%LL-S-FDWB), which represents 4.98% of the overall CDF, thus becoming the fifth most important initiating event.

Lastly, breaks outside containment (BOC) represent altogether 2.29% of the total value of the CDF.

7.2.2 Accident Class Contribution

An additional perspective on the Level 1 PRA results is provided by examining the relative contributions to the CDF of the accident classes used to define the Level 1 end states of the event trees.

Table 7.2-2 shows the CDF contribution of each of these accident classes.

Figure 7.2-2 illustrates the CDF contribution of each accident class in the form of a pie chart.

The largest accident class contributor is Class I, which involves core damage events occurring at low RPV pressures with the containment initially intact. The Class I accident sequences contribute 46.57% to CDF.

The second largest accident class contributor is Class III, which involves core damage events occurring at high RPV pressures with the containment initially intact. The Class III accident sequences contribute 34.54% to CDF.

The third largest accident class contributor is Class IV, which involves the failure to insert negative reactivity in ATWS conditions. The Class IV accident sequences contribute approximately 17.38% to CDF.

The fourth largest frequency contributing accident class is Class V, which involves the condition of the containment bypassed at the time of core damage. The Class V accident sequences contribute approximately 1.27% to CDF.

The lowest frequency contributing accident class is Class IIA, which involves loss of all decay heat removal leading to containment overpressure and failure prior to core damage. The Class IIA accident sequences contribute approximately 0.25% to CDF.

7.2.3 Accident Sequences

A total of 87 quantified accident sequences exceed the truncation value of 1E-13/year.

The sequence with the highest core damage frequency is the sequence number 63 of the IORV event tree. This sequence includes a stuck open relief valve initiator combined with failure of all high pressure injection, failure to manually depressurize using the SRV, followed by a successful automatic depressurization using the DPVs, and combined with failure of GDCS and the remaining low pressure systems (FAPCS and FPS). This Class I accident sequence has a frequency of 1.79E-9 per year, and represents 16.8% of total CDF.

Table 7.2-3 summarizes the 87 quantified accident sequences, the corresponding frequencies, and the resulting percentage contribution to CDF

Table 7.2-5 describes the top ten accident sequences from Level 1.

Figure 7.2-3 illustrates the CDF contribution for the top accident sequence (>1% CDF) in the form of a bar chart.

7.2.4 Top Cutsets Contributing to CDF

The quantified CDF results from 8,028 cutsets distributed by order of magnitude of their frequency, as follows:

Frequency (per yr)	Number. of minimal cutsets
≥ 1.00E-10	12
≥ 1.00E-11	103
≥ 1.00E-12	1131
≥ 1.00E-13	8,028

Table 7.2-6 provides the top 200 contributing cutsets to CDF. These cutsets represent approximately 62.3% of the overall CDF

The following is a description of the top ten minimal cutsets (MCs) contributing to CDF. They represent 25.4% of the overall CDF.

The highest frequency minimal cutset (MCS) stems from a loss of feedwater transient with failure of the isolation condenser due to spurious isolation (spurious common cause software error), a successful automatic depressurization due to low level, combined with common cause failure of Gravity Driven Cooling System (GDCS) check valves, and failures of Control Rod Drive System (CRD) due to perceived low GDCS level (spurious common cause software error), and operator failure to recognize the need to align Low

Pressure Coolant Injection (LPCI) systems such Fuel and Auxiliary Cooling System(FAPCS), and Firewater Injection. This is a Class I accident type cutset, and represents 4.6% of the total CDF.

Cutset number two is a loss of feedwater transient with failure of the isolation condenser due to spurious isolation (spurious common cause software error), common cause of the Depressurization (DPV) squib valves, failure of CRD due to perceived low GDCS level (spurious common cause software error), and operator failure to recognize the need to align LPCI, and Firewater Injection. This is a Class III accident type cutset.

Cutset number three is nearly identical to cutset number one, but it involves common cause of GDCS squib valves.

Cutset number four involves a large break in the feedwater line B combined with common cause failure of GDCS check valves, and operator failure to recognize the need toa lign LPCI, and Firewater Injection.

Cutset number 5 through 8, are ATWS scenarios, where the rods fail to insert combined with Standby Liquid Control (SLC) check valve failures.

Cutset number 9 (T-IORV063) involves an inadvertently stuck open relief valve with failure of all feedwater due to a consequential loop, failure of CRD due to consequential loop and failure due to a mispositioned Condensate Storage Tank (CST) valve, failure to manually depressurize followed by automatic depressurization, common cause failure of GDCS check valves. LPCI and Firewater are considered failed since the operator fail to recognize the need to manually depressurize.

Cutset number 10 is similar to cutset number one, except that LPCI and Firewater fail due to misposition of a common valve F334

Tables 7.2-7 to 7.2-16 provide the top 25 contributing cutsets from the top ten Accident Sequences listed in Table 7.2-5.

7.2.5 Accident Subclasses Based on Lower Drywell Water Level

In order to fully describe the containment state for the Level 2 analysis, Class I events must be broken down further into subclasses based on the height of the water pool in the lower drywell at the time of vessel breach.

Section 21 (NEDO 33201 rev. 1) shows that the challenge to the containment structure and systems due to steam explosions is highly dependent upon any pre-existing water pool in the lower drywell at the time the core is deposited into the containment. If the water pool is less than 0.7 m deep, the challenge to the containment structure and to the ex-vessel cooling system (BiMAC) is negligible. If the water pool is more than 1.5 m deep and is sub-cooled, there is a possibility that the containment structure will be over-stressed due to a steam explosion shortly after vessel breach. If the water pool is in the intermediate range, there is a challenge to the containment, but it is well within the containment capacity (see Section 21).

The design of the ESBWR containment reflects this unique challenge. Liquid LOCAs provide the only means for depositing a large amount of water in the lower drywell. The

rules presented in Table 7.2-4 are used to bin the Class I and Class IV sequences into these subclasses.

Table 7.2-5 contains the results of the top ten accident sequences and includes water level analysis for each of the Class I or Class IV sequences. This was done by reviewing the cutsets for all of the sequences with a contribution to Class I, or Class IV, sequences and using the rules presented in Table 7.2-4. The conditional probability for each subclass, given a Class I or Class IV core damage, is as follows:

- Low LDW Water 0.8994
- Medium LDW Water 0.0120
- High LDW Water 0.0886

CDF		1.30E-09
% of Class IV CDF		70.2%
% of total CDF		12.20%
Initiating event	General Transient (e.g. turbine trip)	
Scram fails		
Feedwater Runback is successful		
SRVs lift and overpressure protection is successful		
ADS Inhibit is successful		
One of two trains of SLC fails		
Vessel fails at low pressure		
Lower drywell water level is LOW		

Sequence	T-FDW050– Sequence No. 3	
CDF		1.12E-09
% of Class I CDF		22.55%
% of total CDF		10.50%
Initiating event	Loss of Feedwater	

Table 7.2-5

Top Ten Level 1 Accident Sequences

Scram is successful		
Isolation Condensers fail to provide overpressure protection		
SRVs lift – overpressure protection is successful		
All SRVs reclose		
ADS is successful using DPVs		
DW/WW vacuum breakers are successful - pressure suppression is successful		
GDCS fails		
Low pressure injection using FAPCS, Firewater and CRD fail		
Vessel fails at high pressure		
Lower drywell water level is LOW		
Sequence	AT-T-GEN021– Sequence No. 4	
CDF		7.46E-10
% of Class III CDF		20.27%
% of total CDF		7.00%
Initiating event	General Transient (e.g. turbine trip)	
Scram fails		
Feedwater Runback is successful		
SRVs lift – overpressure protection is successful, but one or more SRVs sticks open		
ADS Inhibit is successful		
SLC is successful		
Feedwater and CRD fail to maintain reduced level		
Sequence	T-IORV018– Sequence No. 5	
CDF		7.26E-10
% of Class III CDF		19.72%
% of total CDF		6.81%
Initiating event	Inadvertent Open Relief Valve	
Scram is successful		
Feedwater injection fails		
2 CRD fail to restore level		
Manual Depressurization using SRVs is successful		
Low pressure injection with FAPCS and Firewater fail		
ADS fails to depressurize using DPS		
Sequence	T-IORV065– Sequence No. 6	
CDF		5.75E-10

Table 7.2-5

Top Ten Level 1 Accident Sequences

% of Class III CDF		15.61%
% of total CDF		5.39%
Initiating event	Inadvertent Open Relief Valve	
Scram is Successful		
High Pressure injection fails		
Manual and ADS Depressurization fails		
Core damage starts at high pressure		
Vessel fails at low pressure		
Sequence	LL-S-FDWB045– Sequence No. 7	
CDF		5.23E-10
% of Class I CDF		10.54%
% of CDF		4.91%
Initiating event	Large LOCA in Feedwater Line B	
Scram is successful		
LOCA depressurizes		
DW/WW vacuum breakers are successful – pressure suppression is successful		
GDCS fails		
Low pressure injection using FAPCS and Firewater fail		
Lower drywell water level is HIGH		
Sequence	T-IORV017– Sequence No. 8	
CDF		4.92E-10
% of Class I CDF		9.92%
% of total CDF		4.62%
Initiating event	Inadvertent Open Relief Valve	
Scram is successful		
Feedwater Injection fails		
CRD pumps fail to restore level		
Manual Depressurization using SRVs is successful		
Low pressure injection using FAPCS and Firewater fail		
ADS depressurization using DPVs is successful		
GDCS fails		
Lower drywell water level is LOW		
Sequence	AT-T-LOPP013– Sequence No. 9	

Table 7.2-5

Top Ten Level 1 Accident Sequences

CDF		4,46E-10
% of Class I CDF		12.10%
% of total CDF		4.18%
Initiating event	Loss of Offsite power	
Scram fails		
SRVs lift – successful overpressure protection, but one or more SRV sticks open		
ADS inhibit is successful		
SLC is successful		
CRD pumps fail to maintain level (both required)		
Lower drywell water level is LOW		
Sequence	T-LOPP050 – Sequence No. 10	
CDF		3.64E-10
% of Class I		7.32%
% of CDF		3.41%
Initiating event	Loss of Offsite Power	
Scram is successful		
Isolation Condensers fail to provide overpressure protection		
SRVs lift – overpressure protection is successful		
All SRVs reclose		
ADS is successful using DPVs		
DW/WW vacuum breakers are successful - pressure suppression is successful		
GDCS fails		
Low pressure injection using FAPCS, Firewater and CRD fail		
Lower drywell water level is LOW

7.3 QUANTIFICATION PROCESS

The quantification process requires all the necessary information generated in the other PRA tasks.

7.3.1 Quantification Overview

The purpose of the core damage frequency quantification is to obtain the Boolean equation corresponding to the final event: "Core Damage". The quantification is developed in terms of minimal cutsets (MCS), which represent the minimal combinations of events that result in core damage.

The following key aspects characterize the core damage frequency quantification process:

a. Event trees to model plant response to each group of initiating events.

b. Fault trees to model the behavior of front-line and support systems.

c. Integration of event tree and fault tree structures into a single linked model.

d. Quantification of the linked Boolean model with the probabilistic database and boundary condition files (Flag files).

7.3.2 File Structure

Descriptions of the key model and quantification files are provided below.

7.3.2.1 Event Tree Files

These files contain the event tree structures for each group of initiating events. The core damage sequences of these models are converted into fault tree logic and integrated into the Master Fault Tree File along with the system fault tree logic.

7.3.2.2 Fault Tree File

A single fault tree file ("Seqmaster.caf") contains all the core damage sequences, with all the front-line and support systems linked. Each sequence subtree includes a top gate that combines the initiating event and the functional failures and successes of the sequence. In addition, logic was included for a single top of all individual subtrees combined with a sequence marker. This single top of individually marked sequences was developed to allow significant reduction in the time required for quantification of the entire model.

7.3.2.3 Database File

The database contains the probabilities and frequencies of each of the events associated with the fault tree.

7.3.2.4 Quantification File

These file contains the conditions for quantifying the different accident sequences, or a single top that combines all the sequences as described under the section 7.3.2.2. The quantification file identifies the following:

- Master fault tree file name,
- Database file name,
- Sequences to be quantified, or single top
- Quantification truncation limits for each sequence, or single top
- Flag files for each sequence, or a single master flag file (using selected configuration)
- Accident class for each sequence.
- Mutually Exclusive file
- Recovery file

7.3.2.5 "Flag" Files

"Flag" files contain boundary conditions (for example: type of initiating event, assumed plant configuration) used in the quantification of the accident sequences. Binary model elements (that have either "True" or "False" values) called "Flags" (also known as "house events") are used to identify boundary conditions in the model structure. Flag files identify the flag events and associated binary values used in the quantification of the different accident sequences. A single master flag file is used to select the equipment line-up configuration. These flags settings are provided in Section 4 under the corresponding system.

7.3.2.6 "Mutually Exclusive" Files

A cutset file is used to identify combinations that should be excluded from the results. These mutually exclusive combinations identify and delete:

- Combinations of maintenance actions in multiple trains not allowed by technical specifications.
- Combinations of failures modes for equipment that are not possible (e.g. a specific valve fails open combined with valve same fails closed)
- Eliminate cutsets that are not appropriate (e.g. human failures that are only applicable for some sequences, but not others)

7.3.2.7 "Recovery" Files

A text rule based recovery file is used to recover selected long-term decay heat removal sequences (class ii) that involve consequential loss of offsite power. Conservatively, a probability on non-recovery of loss of offsite power for 24 or more hours is applied to these sequences. In addition, the recovery file is used to update the human error probability (HEP) for long-term decay heat removal sequences associated with failure of late injection with firewater.

7.3.3 Quantification Output

Quantification of the model results in the following key outputs:

- Overall core damage frequency
- Core damage frequency as a function of:
  - Initiating event
  - Accident sequence
  - Accident class
- Importance characterization of individual events (in terms of industry standard risk importance measures, for example: Fussell-Vesely; Risk Achievement Worth, and so forth) relative to the core damage frequency.

7.3.4 Truncation Analysis

The model has been quantified at different truncations to evaluate convergence. The results indicate that the model converges as show below:

Truncation	CDF	% Change
1E-12	8.70E-09	-
1E-13	1.07E-08	2.30E-01
1E-14	1.18E-08	1.03E-01
1E-15	1.22E-08	3.39E-02
