Electrical Design Parameters of Typical 230kv and 500kv Transmission Lines Terminating into Plant Vogtle

The following includes electrical design parameters and EMF calculations for typical 230kv and 500kv transmission lines terminated into Plant Vogtle. In addition, a 1994 IEEE conference paper is included that covers an extensive analysis and measurements of radio noise characteristic of two 500kv lines located near Atlanta, Georgia.

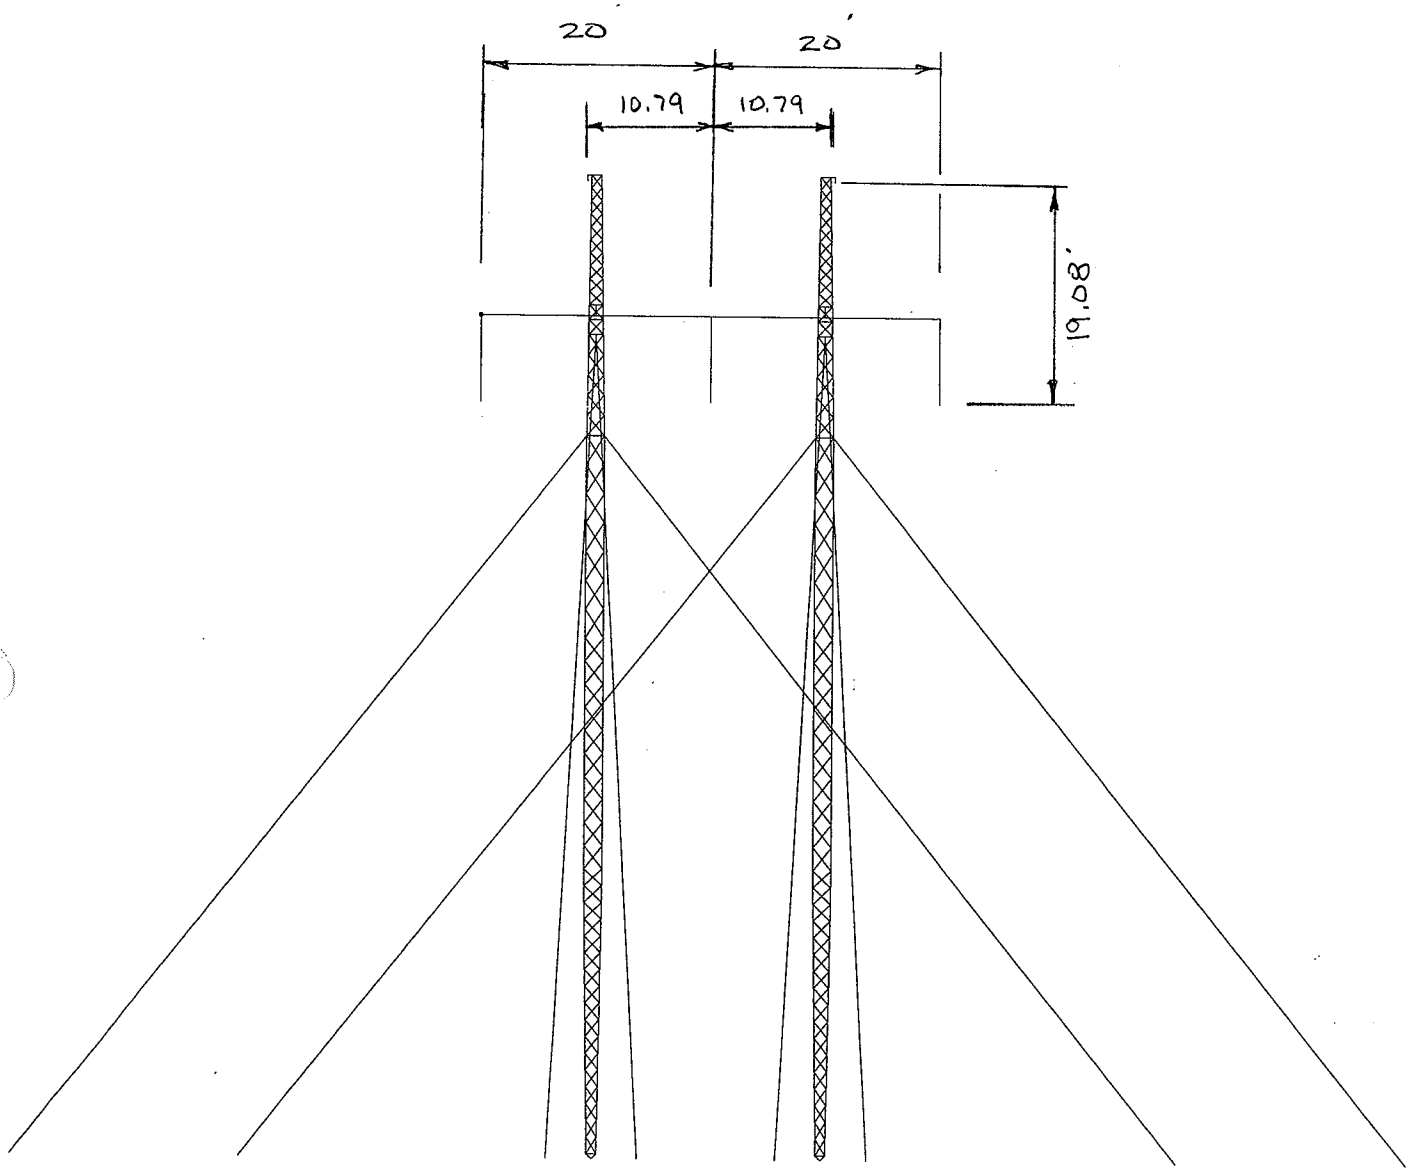
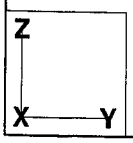
3/8"-7 STN SHIELDWIRE
125' Right-of-WAY





EMF Summary - EPRI ACDCLINE

Type Construction: **230 kv Horizontal H-Frame - (NESC Light Zone-No Sun)**

Distance From Shieldwire to Conductor Attachment (ft)	19.1
Right-of-Way Width (ft)	125.0

Overage Voltage	5 %

		Ruling Span (ft)		1300	No. 0f Sub-Cond	Sub-Cond Spacing (in)	Height to Str Attachment	H-Dist from Centerline		
		Final Sags in Ruling Span						Left	Middle	Right
Conductor Temperature (Deg F)		120	167	212						
Shieldwire:	3/8" HS Steel	26.0					94.8	-10.8	0.0	10.8
Conductor:	**Martin**	39.0	42.5	45.7	1		75.7	-20.0	0.0	20.0
Minimum Ground Clearance		36.6	33.2	30.0						

Conductor Temperature (Deg F)	**120**	**167**	**212**
Ampacity (Amps)	629	1141	1456
Power (mva)	251	455	580

Ampacity Rating Parameters	
Ambient Temp (deg F)	104
Wind Speed (ft/sec)	2
Wind Direction	90
Solar Gain	No

Audible Noise (db(A)) @ Edge of R/W				
Condition	L50 Fair	25.3	25.4	25.5
	L5 Rain	47.1	47.2	47.3
	L50 Rain	36	36.1	36.2

Radio Noise @ 500kHz (db) @ Edge of R/W				
Condition	Avg Fair Weather	40.5	40.6	40.5
	Avg Foul Weather	62.1	62.2	62.1
	Heavy Rain	70	70	69.9
	Wet Conductor	58.4	58.5	58.5

Electric Field

Edge of R/W (kv/m)	0.993	1.019	1.03
Maximum (kv/m)	2.022	2.417	2.876
Distance of Maximum Level from Center Line (ft)	30		

Electrical Coupling to Truck

Size (ft)	Height	13.5		
	Width	8.5		
	Length	65		
Short Circuit Current (ma)				
Orientation	Perpendicular	1.1	1.24	1.38
	Parallel	2.5	2.94	3.42

Magnetic Field

Edge of R/W (mg)	31.7	61.76	318.6
Maximum (mg)	98.26	211.48	82.89
Distance of Maximum from Center Line (ft)	0

Audible noise prediction methods do not apply to all line geometries, voltages, or weather conditions. If a prediction method does not apply, the appropriate output data column will be zeros.

(1) The "Average Stable Foul Weather" noise is calculated using an empirical expression for the radio noise excitation function that was derived (see REF. [A]) to best fit the long term radio noise measurements of existing lines (in the 345 kV to 765 kV range). This generation function is used also in the program RNOISE, which is applicable to AC transmission lines. If AC lines are not present, the "Average Stable Foul Weather" column contains zeros.

(2) The "Average Fair Weather" radio noise values can be obtained by subtracting 21.6 dB from the "Average Stable Foul Weather" radio noise data.

(3) The "Heavy Rain" and the "Wet Conductor" radio noise levels, are defined in the EPRI's Transmission Line Reference Book - 345 kV and Above. The equations for the excitation functions for AC conductors are derived from the Reference Book and are applicable for large ranges of surface gradients (from 10 to 25 kV/cm), subconductor diameters (2 to 8 cm) and number of subconductors (1 to 12). The equations for the excitation functions for DC and HYBRID line conductors are derived from the EPRI RP 2472-6. Heavy rain was

defined as rain with intensity of the order of 8 - 12 mm/hr. In the Northeastern climate, the "Heavy Rain" noise is exceeded only 1% of the time during periods of rain. "Wet Conductor" noise corresponds to the condition of the conductor saturated with water drops and with little noise caused by the impingement of rain droplets. Experimental data from which the equations for the "Wet Conductor" noise were derived, indicate that the "Wet Conductor" noise is exceeded 50% of the time during natural rain periods. "Wet Conductor" noise also corresponds to the maximum noise that can be produced during fog.

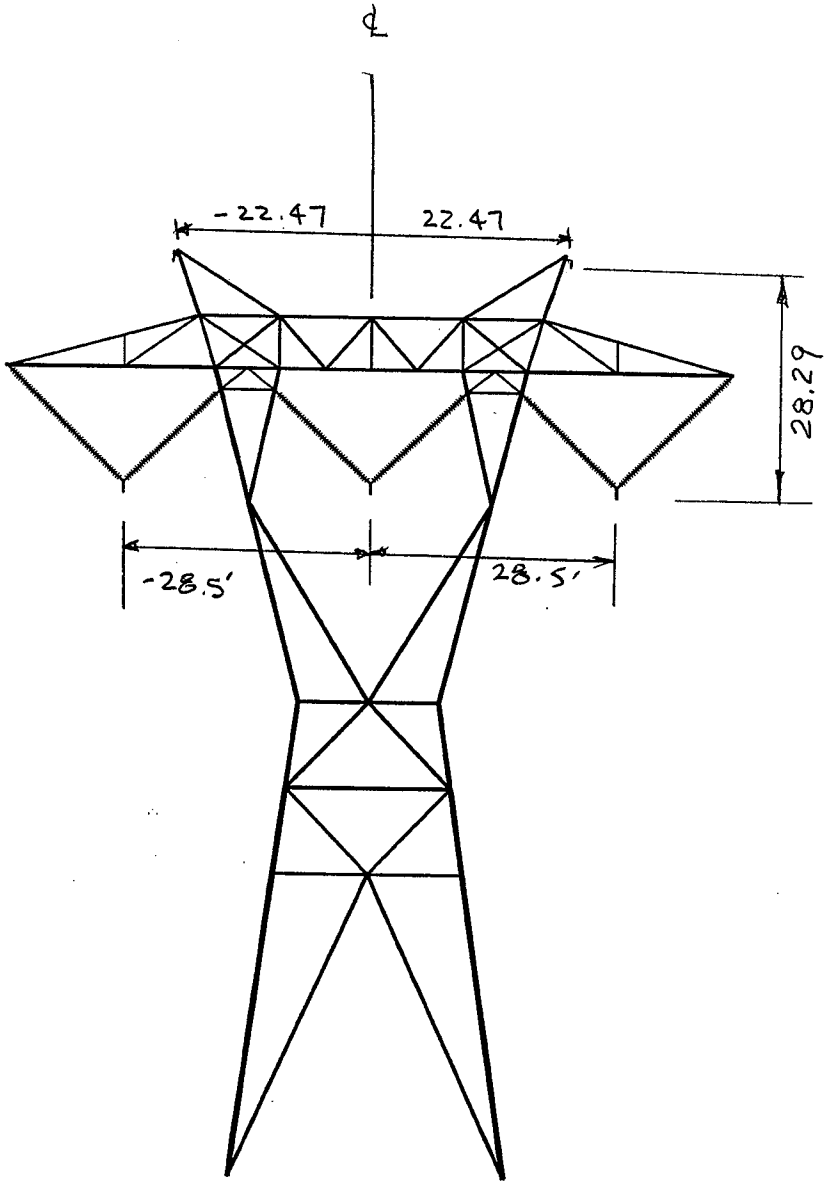
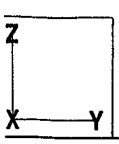
500KV Rigid Braze
Bluejay Conductor
3-sub cond per phase





EMF Summary - EPRI ACDCLINE

Type Construction: **500 kv Horizontal Rigid Base - (NESC Light Zone-No Sun)**

Distance From Shieldwire to Conductor Attachment (ft)	28.3
Right-of-Way Width (ft)	150.0

Overage Voltage	5 %

		Ruling Span (ft)		1300	No. 0f	Sub-Cond	Height to Str	H-Dist from Centerline		
		Final Sags in Ruling Span			Sub-Cond	Spacing (in)	Attachment	Left	Middle	Right
Conductor Temperature (Deg F)		120	167	212						
Shieldwire:	3/8" HS Steel	26.0					116.3	-22.5		22.5
Conductor:	**Bluejay**	43.0	46.5	49.7	3	18	88.0	-28.5	0.0	28.5
Minimum Ground Clearance		45.0	41.5	38.3						

Conductor Temperature (Deg F)	**120**	**167**	**212**
Ampacity (Amps)	1650	2991	4368
Power (mva)	1429	2590	3783

Ampacity Rating Parameters	
Ambient Temp (deg F)	104
Wind Speed (ft/sec)	2
Wind Direction	90
Solar Gain	No

Audible Noise (db(A)) @ Edge of R/W				
Condition	L50 Fair	38.3	38.4	38.7
	L5 Rain	53.4	53.5	53.8
	L50 Rain	49.6	49.7	50

Radio Noise @ 500kHz (db) @ Edge of R/W				
Condition	Avg Fair Weather	54.8	55	55.1
	Avg Foul Weather	76.4	76.6	76.7
	Heavy Rain	80.7	80.8	80.9
	Wet Conductor	73.6	73.7	73.8

Electric Field

Edge of R/W (kv/m)	2.828	2.908	2.961
Maximum (kv/m)	5.498	6.331	7.248
Distance of Maximum from Center Line (ft)	35		

Electrical Coupling to Truck

Size (ft)	Height	13.5		
	Width	8.5		
	Length	65		
Short Circuit Current (ma)				
Orientation	Perpendicular	3.82	4.26	4.71

(1) The "Average Stable Foul Weather" noise is calculated using an empirical expression for the radio noise excitation function that was derived (see REF. [A]) to best fit the long term radio noise measurements of existing lines (in the 345 kV to 765 kV range). This generation function is used also in the program RNOISE, which is applicable to AC transmission lines. If AC lines are not present, the "Average Stable Foul Weather" column contains zeros.

(2) The "Average Fair Weather" radio noise values can be obtained by subtracting 21.6 dB from the "Average Stable Foul Weather" radio noise data.

(3) The "Heavy Rain" and the "Wet Conductor" radio noise levels, are defined in the EPRI's Transmission Line Reference Book - 345 kV and Above. The equations for the excitation functions for AC conductors are derived from the Reference Book and are applicable for large ranges of surface gradients (from 10 to 25 kV/cm), subconductor diameters (2 to 8 cm) and number of subconductors (1 to 12). The equations for the excitation functions for DC and HYBRID line conductors are derived from the EPRI RP 2472-6. Heavy rain was

defined as rain with intensity of the order of 8 - 12 mm/hr. In the Northeastern climate, the "Heavy Rain" noise is exceeded only 1% of the time during periods of rain. "Wet Conductor" noise corresponds to the condition of the conductor saturated with water drops and with little noise caused by the impingement of rain droplets. Experimental data from which the equations for the "Wet Conductor" noise were derived, indicate that the "Wet Conductor" noise is exceeded 50% of the time during natural rain periods. "Wet Conductor" noise also corresponds to the maximum noise that can be produced during fog.

500 KV TRANSMISSION LINE RADIO NOISE PERFORMANCE

K. W. Priest

General Electric Company
Philadelphia, Pennsylvania

D. R. Williamson

Georgia Power Company
Atlanta, Georgia

ABSTRACT

The extensive analyses of the radio noise characteristics of two 500kV lines near Atlanta Georgia are presented. Comprehensive analytical work and an extensive series of field measurements at twenty field locations are reported. Field measurements were conducted before, during, and after construction. Unique measurements of shielding effects are included. Selected night and loop antenna measurements were recorded, also. The results have been compared and interpreted for application in the design of future 500kV lines.

INTRODUCTION

The prediction of the radio noise produced by EHV transmission lines has been discussed for many years[1.2.3.4.5.]. The Atlanta #1 and Norcross lines were considered to be excellent candidates for extensive pre and post construction radio noise field measurements. Twenty areas along these lines were chosen as relatively accessible measurement locations. The original study objectives may be listed as follows:

1. Verify prior calculations of noise levels by comparing them with field measurements using the normal prediction method and using rain cage test results from Project UHV.[4.]
2. Extend RN calculations to long term statistical predictions based on weather data from Atlanta, Georgia.[5.]
3. Present signal-to-noise (S/N) ratios for both calculated and measured RN levels.
4. Compare signal strength measurements to Radio Station predictions.
5. Compute and describe statistically the Quality of Radio Reception near the rights-of-way.[5.]

This paper summarizes the results of a complete analysis as highlighted by the flow chart shown in Figure 1.

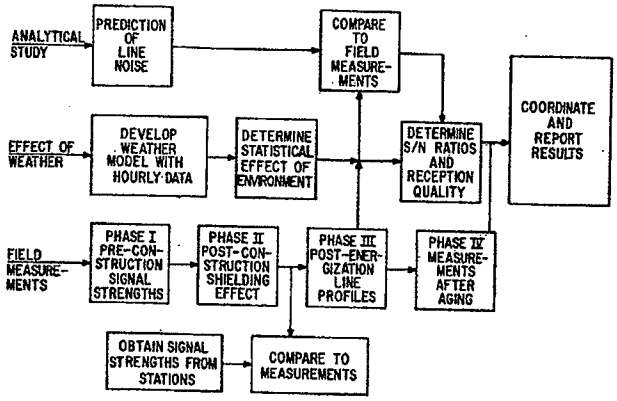

Fig. 1 500-kV line noise study program.

This program was divided into three basic areas: analytical work, the effect of weather, and the field measurements. Each of these topics is discussed in separate sections followed by the coordination of results.

Shown in Figure 2 is a sketch of the tower configuration used for the Atlanta #1 and Norcross 500kV lines of the Georgia Power Co. A triangular bundle of three 1.259" diameter (bluejay) conductors are considered. The radio noise profiles are computed using the techniques described in Reference 5. The base case profiles are based on the assumptions listed in Table I.

CONFERENCE PAPER

C 74 451-1. A paper recommended by the IEEE Transmission & Distribution Committee of the IEEE Power Engineering Society for presentation at the IEEE PES Summer Meeting & Energy Resources Conf., Anaheim, Cal., July 14-19, 1974. Manuscript submitted February 4, 1974; made available for printing May 16, 1974.

Price: Members $1.50
Nonmembers $2.00
At Meeting: $1.00

Table I. BASE CASE CONDITIONS

Variables	Value
Voltage	5 50kV
Surface Factor	0.7
Frequency	1000k Hz
Ground Resistivity	62.7 Ohmeters
Relative Humidity	50 Percent
Relative Air Density	1.0 per unit
Wind Speed	0 km/hr
Precipitation	(None (Fair Weather) (Heavy Rain (Foul Weather)

The effect of variation in the above variables is discussed in Reference 7. The results are presented in Figure 3.

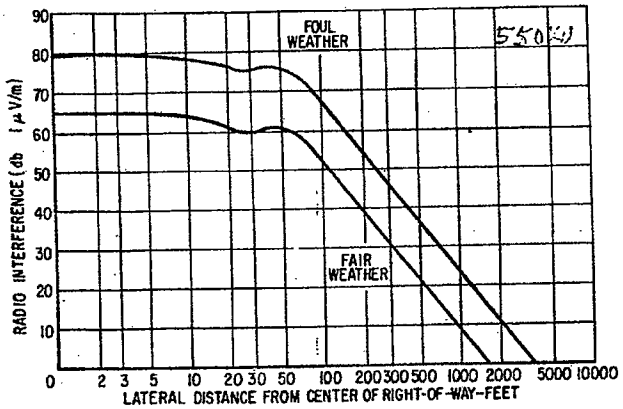

Fig. 3. Predicted radio noise profile for fair and foul weather.

These results are compared to the field measurements in the coordination of results.

EFFECT OF WEATHER

Hourly weather data from Atlanta, Georgia was obtained and processed[6] in order to determine the expected statistical variations due to changing weather patterns. For each hour over a ten (10) year period, the correction to the base case was computed based on the correction factors in Reference 7. These corrections may be displayed in a histogram as shown in Figure 4.

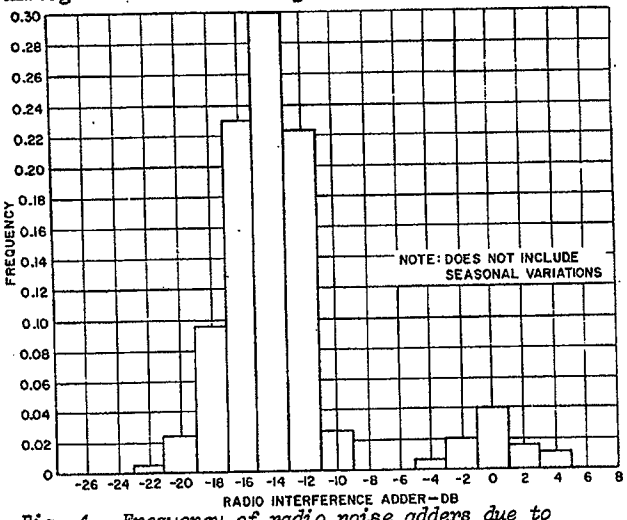

Fig. 4. Frequency of radio noise adders due to atmospheric variations in Atlanta, Georgia.

This data may be added to the foul weather base case corrected for non weather variables to produce a histogram of expected radio noise generation. Seasonal variations have not been included. They would be expected to add a variation of ± 6dB to the fair weather portion of the histogram. In foul weather the effect of droplets on the conduction tends to overwhelm the seasonal variations.[4]

FIELD MEASUREMENTS

Measurements on both transmission lines (Atlanta #1 and Norcross 500kV lines) have been made in wet and dry weather, day and night during four phases of their history.

Phase I	Pre-Construction
Phase II	Post-Construction Pre-Energization
Phase III	Post-Energization
Phase IV	After Aging

The radio noise data described were collected using the Stoddart Model NM 20B radio noise meter. Both rod and loop antena measurements have been made. The measurement locations along the line are indicated on the map in Figure 5. At each location, measurements are taken directly under the outside phase conductors. Also, appropriate spatial profiles have been measured and the measurement locations are noted. Careful attention has been given to selection of each measurement location, calibration of the instruments, the background noise level. The measurement techniques used are consistent with the guidelines described in Reference (8). During the measurement periods, the line was energized from between 495 kV to 525 kV. All measurements, unless otherwise noted, have been corrected to 500 kV using the correction technique presented in Reference 7.

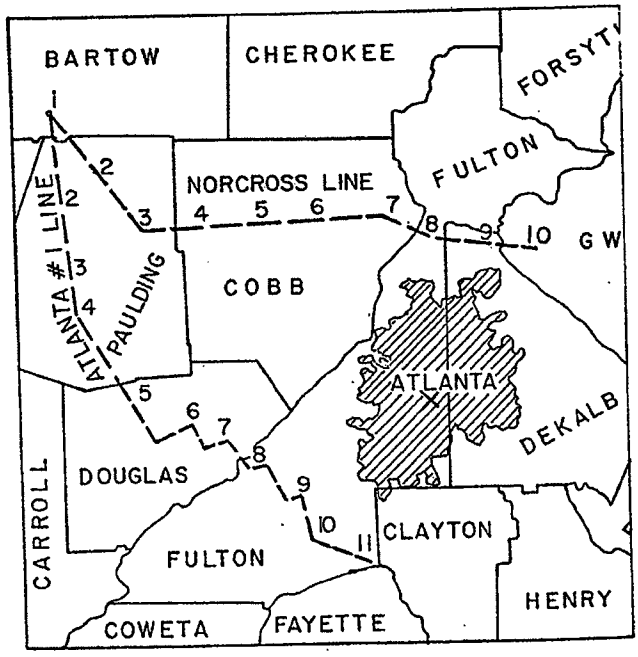

Fig. 5. Measurement locations.

A typical measurement location is illustrated by the pictures in Figure 6 and Figure 7. These pictures were taken from measurement location number 6 on the Norcross line looking east and west. Over ten thousand readings have been made during the four measurement phases at the 20 locations. Several hundred of these measurements have been made under foul weather.

Phase I - Pre-Construction

During September and November radio station signal strengths and background noise measurements were made. Typical results are shown in Tables II and III for the signal strengths and background noise respectively. Tables II and III give the measurements in decibels above 1 microvolt per meter. The measurement locations may be obtained from Figure 5. Table IV gives the results of some night measurements and Table V gives

the minimum and maximum loop antenna recordings. Due to the large volume of data taken, only typical data is presented. The conclusions are based on all the data, and the data presented is intended to show typical trends.

Phase II - Post-Construction Pre-Energization

The radio station signal strengths and background noise measurements were repeated for comparison and typical results are shown in Tables II and III, respectively. These signal strength measurements (Table II) averaged 3.7 db less. This change could be explained by a general shielding effect or a seasonal variation. Phase I measurements were made in the fall and Phase II in the Spring. Some individual changes were significant, and profiles were then taken. Typical lateral and longitudinal profiles are shown in Figures 8 and 9, respectively. These show in more detail the distortion produced by coupling to the line and reradiation. The profiles taken at midspan were generally not symmetrical, however, the major effects tend to be localized within the right-of-way.

Phase III - Post Energization

Again signal strengths were measured and the typical results are shown in Table II. The noise measurements were made in generally fair weather. However, several sets of readings were taken during rain. Noise and signal profiles were taken to estimate actual signal-to-noise ratios. Figure 10 shows a typical result.

Phase IV - After Aging

After the conductors have been permitted to age for about a year, measurments were re-made. The signal strengths are recorded in Table II and the noise measurements in Table III.

COORDINATION OF RESULTS

Since extensive data was taken, one of the most difficult tasks is to interpret general results without becoming hopelessly involved with a sea of numbers. It is with this philosphy in mind that the following summaries are presented.

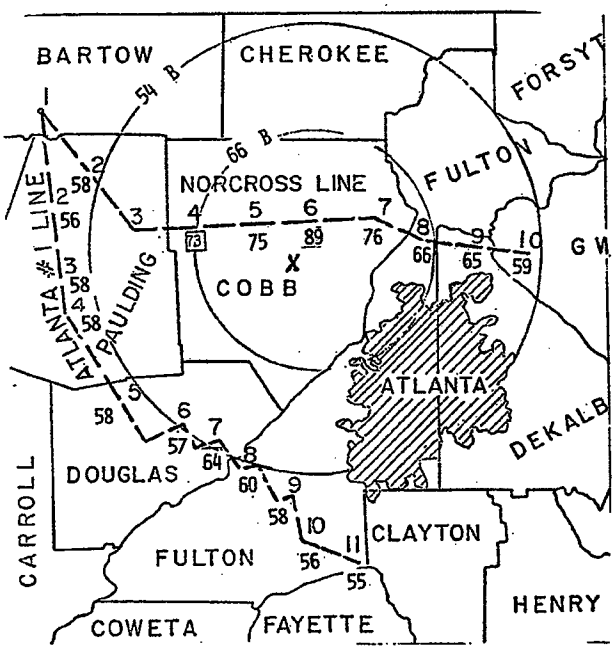

Fig. 12 Signal strength measurements.

Radio Station Signal Strengths

Several local radio stations provided data for their predicted signal strengths in the Atlanta area. A typical comparison to the field measurements is shown in Figure 11. Generally, the field measurements were consistent with the predicted signal levels. Table II indicates the typical fluctuations for the different field measurement periods.

Noise Comparisons

Table III presents noise measurements for all four phases of field measurements through a wide frequency range. An excellent example of the data is available in the history of measurements at location 6 of the Norcross line. Figure 12 shows pre-construction, after energizing, during rain and after aging measurements. The dramatic effect

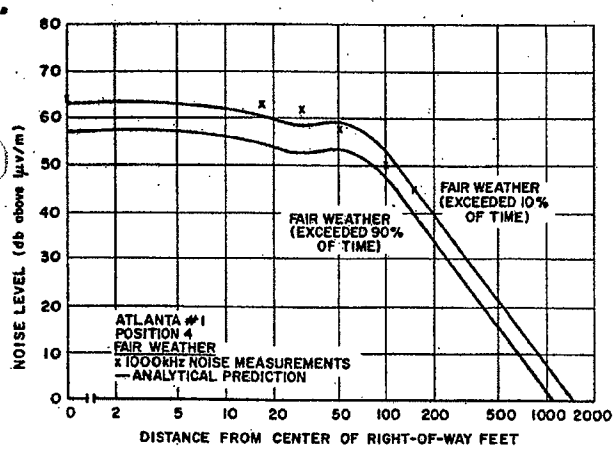

Fig. 13. Measurements compared to prediction.

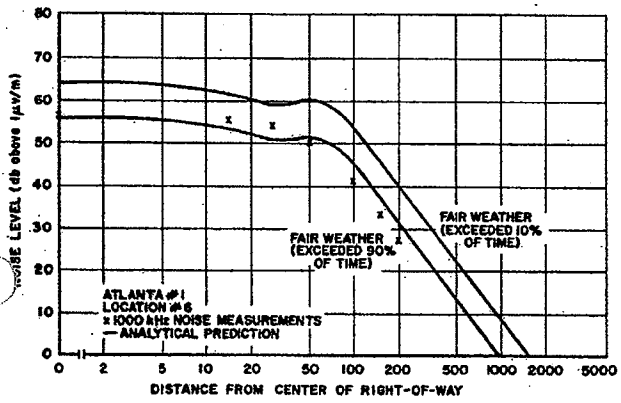

Fig. 14. Measurements compared to prediction.

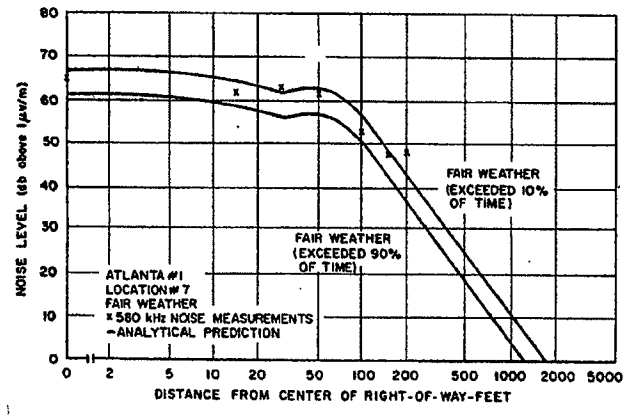

Fig. 15. Measurements compared to prediction.

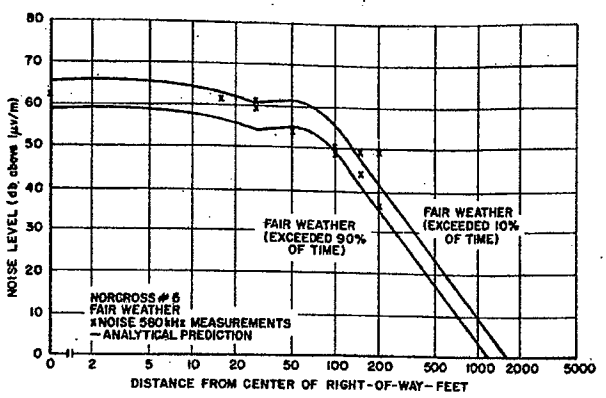

Fig. 16. Measurements compared to prediction.

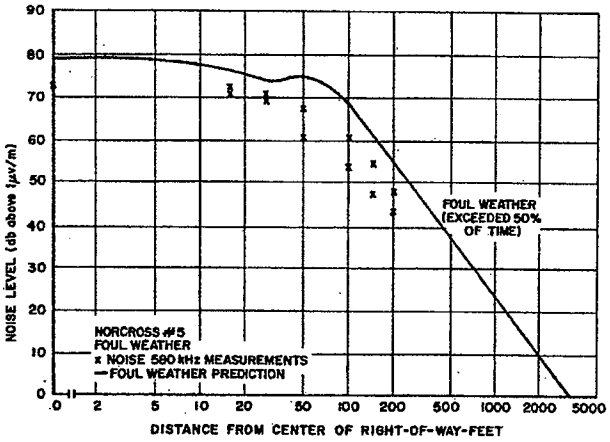

Fig. 17. Measurements compared to prediction.

after aging measurements. The dramatic effect of rain is clearly noted. An average increase of over 20dB is evident throughout the entire frequency spectrum.

Noise Profiles

One of the criteria for modern radio noise programs is to predict field measurements. During the Phase III field program, an excellent opportunity for measuring noise profiles was provided. In addition, several profiles were taken under foul weather conditions. The computed profiles shown earlier in Figure 3 must be modified before direct comparisons can be made. First the weather corrections were added to develop a statistical prediction. Then corrections for line voltage and frequency were applied.

Seasonal effects have not been included but an additional variation of ±6db might be expected.

Figures 13, 14, 15 and 16 present profile comparisons for four different measurement locations in fair weather. Agreement is excellent. Figures 17 and 18 show two foul weather profiles taken at Norcross location 5. Agreement in this case is good.

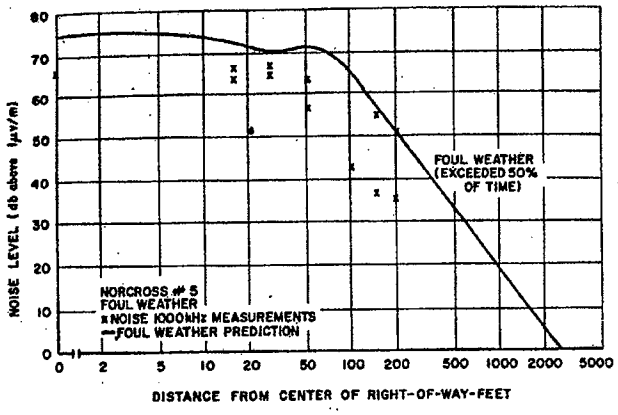

Fig. 18. Measurements compared to prediction.

CONCLUSIONS

The significant conclusions may be summarized as follows:

1. Radio station predicted field strengths agree well with measurements.
2. Noise predictions, including the statistical weather effects,[5] agree well with field measurements.
3. Fair weather conditions prevail some 91% of the time.
4. Shielding effects of transmission line may produce substantial variations in the signal pattern. However, these variations do not have a significant effect outside the right-of-way.
5. Aging has tended to reduce the line noise levels, but the effect has been minor.

This data has been applied to help select a right-of-way width. The intent is to minimize the effect on the public. That is, to acquire the smallest right-of-way width possible without introducing objectionable radio interference. After extensive considerations, it was concluded that a width greater than 150 feet would restrict public uses unnecessarily and there would not be objectionable interference at this distance.
