1.0 INTRODUCTION

Hydro-Engineering was contracted by the Gas Hills, Wyoming operation of Umetco Minerals Corporation, formerly known as Union Carbide Corporation, to evaluate hydrology of the Jab 1 tract located in the Red Desert area of Sweetwater County, Wyoming. The proposed project area is shown in Exhibit D6-1.

This report addresses hydrologic analyses made and monitoring information collected between November, 1979, and November, 1982. Included are a brief geologic setting, well completion information, aquifer-test description and data, water-level data, and surface water and ground-water quality information.

D6.2.0 GROUND WATER

D6.2.1 GEOLOGIC SETTING

The Jab project area is located in the area where the Battle Springs Formation crops out. Exhibit D6-1 presents the surficial geology of Jab project and surrounding areas, as well as two faults in the area. The formation consists of mainly sandstone, being arkosic, fine to coarse grained, and green claystone. The Battle Springs Formation interfingers with the Wasatch and Green River Formation going from east to west in the Great Divide Basin.

To the north and south of the project area are deposits of gravel of Pleistocence that consist of sand and gravel, which is poorly consolidated to unconsolidated and some conglomerate. Continuing south of the gravel deposit the Laney shale and Tertiary rocks of the Green River Formation crop out. To the north and west of the Jab project area the Fort Union Formation crops out.

Two faults are presented in Exhibit D6-1. The fault to the south passes through the southwesterly corner of the project area. This fault has a vertical displacement of about 1000 ft. The fault to the north is outside of the project area. A localized fault has been defined by Umetco geologists to exist between wells OW 1301 and MW 1291. Well OW 1303 on the north side of the fault is on the uplifted side with a displacement of 39 ft. Exhibit D6-2 presents Geologic Cross-Section A-A' which runs in a north-south direction through the localized fault. The cross-section

presents the mudstone bed that is used to indicate the base of the ore zone and to show the generalized geologic structure. From well MW 1300 to the localized fault to the south the mudstone bed dips gently to the south. From said fault to well MW 1298 the mudstone bed dips steeply to the south.

Exhibit D6-3 presents a Geologic Cross-Section B-B' in the east-west direction. The cross-section shows the mudstone bed being very deep. The sloping of mudstone bed from well MW 1292 to MW 1298 to MW 1299 is caused from well MW 1298 being further south of the other two wells.

Exhibit D6-1 presents structure contours on the top of the mudstone bed south of the localized fault. The structure contours do not continue north of well OW 1303 due to lack of adequate data, but would be spaced much further apart.

D6.2.2 WELL CONSTRUCTION

Five monitoring wells were drilled and completed with five-inch PVC casing, and six observation wells were drilled and completed with two-inch PVC casing. These wells were drilled and completed in late summer 1980. Table D6-1 presents the basic well information. Exhibit D6-4 shows the location of the wells. Well Jab #1 was drilled and completed in late summer 1978 with six-inch PVC casing. It is not known when well AX 34 was drilled, but it is cased with six-inch steel casing. This well is outside the project area located in section 21 and has been used to define water levels (see Exhibit D6-1 for location).

Wells OW 1300, OW 1303, and OW 1307 were drilled, and perforated casing was installed below the mudstone bed. Well 1307 was completed below the mudstone to define the hydrologic conditions below the mudstone in this area. Wells OW 1301, OW 1302, and OW 1303 are observation wells for monitoring well MW 1291 and have radii of 62 ft, 30.5 ft, and 50 ft, respectively, from the monitoring well. Well OW 1304, OW 1305, and OW 1307 are observation wells for monitoring well MW 1292 and have radii of 60.4 ft, 30.4 ft and 32.4 ft, respectively, from the monitoring well (see Exhibit D6-4 for location).

D6.2.3 AQUIFER PROPERTIES

D6.2.3.1 Pump Test Theory

The theories used to analyze these pump tests are presented in Addendum A. The Theis confined aquifer theory is mainly used to obtain the aquifer properties. The straight line or Jacob modification of Theis' equation and the Theis recovery equation are also used. The Neuman-Witherspoon method (see Addendum A for a discussion) was used to estimate the vertical permeability that exists below the ore sand.

D6.2.3.2 Pump Test Results

Two multi-well (1291 and 1292) pump tests and four single well (1298, 1299, 1300, and Jab No. 1) tests were used to define the aquifer properties at the Jab project area. Addendum B presents the results of the Jab pump tests.

D6.2.3.3 Summary of Aquifer Properties

Table D6-2 presents a summary of aquifer properties for this area. A multi- well pump test was conducted in the western portion of the Jab area at well MW1292. The average transmissivity in this area is thought to be 4400 gal/day/ft while a storage coefficient of 2 x 10^-4 is representative of the aquifer in this area. The horizontal permeability of the ore sand is roughly 8 ft/day.

A vertical permeability of 0.43 ft/day (1.6 x 10^-4 cm/sec) was calculated for the mudstone below the ore sand at well OW 1307. This value seems verh high and is probably not representative of the mudstone unless it is highly fractured.

The transmissivity of the ore sand is much less in the area of the other multi-well test at well 1291. The transmissivity seems to increase with distance from the local fault in this area from 210 gal/day/ft at well 1291 to 840 gal/day/ft at well OW 1301. The storage coefficient is roughly 8 x 10^-4 in this area of the aquifer. Permeabilities vary from less than one to 2.5 ft/day in this area of the ore sand.

The transmissivity of the aquifer varied considerable over the remainder of the Jab project area from a low of 45 gal/day/ft in the south central portion at well 1298 to a high at Jab Well No. 1 with a transmissivity of 3400 gal/day/ft. The transmitting ability of the sand at well 1299 is very good, with a value of 1500 gal/day/ft. A transmissivity of 660 gal/day/ft was

determined for the sand at well 1300.

D6.2.4 WATER-LEVEL AND GROUND-WATER MOVEMENT

D6.2.4.1 Water-Level Elevation

Figure D6-1 presents the water-level elevation plots for wells MW 1291, OW 1301, OW 1302, and OW 1303. Tables D6-3 through D6-6 present the static water level data for said wells, respectively. Wells OW 1302 and OW 1301 present an increase in the static water level, and stabilization by mid 1981. This change in the water level is due to the development of these wells by air lifting and bailing. Wells MW 1291 and OW 1303 have stayed close to the same water-level elevation since installation.

Figure D6-2 presents the water-level elevation plots for wells MW 1292, OW 1304, OW 1305 and OW 1307. Tables D6-7 through D6-10 present the static water level data for these wells, respectively. Wells MW 1292 and OW 1307 have been stable since installation, but wells OW 1304 and OW 1305 required development with air before their water levels stabilized.

Wells MW 1298, MW 1299, MW 1300, Jab No. 1 and AX 34 static water level measurements are presented in Tables D6-11 through D6-15, respectively. Figure D6-3B presents the plot of the static water elevation for these wells. All five wells show stability, with the exception of a measurement made in January, 1981 for well MW 1298 and June, 1981 for well AX 34. These two measurements were probably in error. Well Jab No. 1 had a

submersible pump installed and the water was being used in the drilling of the other monitoring and observation wells and drill holes.

Exhibit D6-4 presents the water-level elevation map in the Jab project area. Ground water flows in the more permeable sand channels to the southeast at an average rate of 50 ft/yr, based on a gradient of 0.0018 ft/ft, average permeability of 8 ft/day, and an effective porosity of 0.1. The movement is much less (~ one ft/yr) in the low permeability zones near well 1298.

D6.2.4.2 Water Level Changes

Water levels have been monitored since the Fall of 1980 in thirteen wells in the area of the proposed Jab mine and are presented in Tables D6-3 through D6-15. The water levels in all wells have been very stable without seasonal fluctuation or a long-term trend. The initial water levels in observation wells OW 1301, OW 1302, OW 1304, and OW 1305 were too low during the first few months of monitoring because the wells were not adequately developed. Water levels responded to air development of these observation wells and recovered to representative values after development.

Figure D6-1 presents the water levels for the east pump test cluster of wells, pumping well MW 1291 and observation wells OW 1301, OW 1302 and OW 1303. Water levels in the east cluster of wells have been very stable since the observation wells were developed. The head of the water level in observation well OW

1303 is two ft higher than the other wells in this cluster. Observation well OW 1303 is completed north of the fault below the mudstone. The higher head indicates that the fault retards flow across the fault. Potential flow is from the north to the south side of the fault.

Figure D6-2 presents the water levels for the west pump test cluster of wells OW 1304, OW 1305 and OW 1307. Well OW 1307 is completed below the mudstone in the next lower sand below the ore sand. The head in well OW 1307 is approximately one ft lower than that in the ore sand above the mudstone. Potential flow across the mudstone is from the ore sand downward through the mudstone.

Water levels for the other five wells monitored are presented in Figure D6-3. Water levels in well MW 1300, which is upgradient and to the north of the mine area have been very stable, as have all of the other wells. The three southern wells, MW 1298, MW 1299, and AX 34 have lower heads than wells north of them, but also demonstrate a gradient from the west to the east.

Water levels near the proposed Jab mine were very stable for the two and one-half years that they were monitored and therefore are not expected to vary much with time. These water levels indicate that recharge and discharge to this aquifer are very close to being in equilibrium.

D6.2.5 RECHARGE AREAS

Recharge to the ground-water system in the Jab permit area is from recharge in areas where the sands outcrop and from surface infiltration. Recharge from surface infiltration probably occurs mostly in the sandy stream channels.

D6.2.6 GROUND-WATER QUALITY

Ground water in the Jab project area is predominantly the calcium sulfate- bicarbonate type (see Table D6-16). However, sodium makes up a relatively high percentage of total cation content in some of the more diluted ground- water samples (see specifically analyses for wells MW 1292 and MW 1300).

In terms of total dissolved solids (TDS) and specific major ion concentrations, the Jab project area ground-water quality is quite variable and ranges from excellent to unsuitable for use as a domestic water supply. TDS ranges from 230 mg/l (well MW 1300, 3/30/82) to 1700 mg/l (well MW 1291, 3/30/82). Wyoming Department of Environmental Quality, Water Quality Division (DEQ, WQD) ground-water standards indicate that 500 mg/l is the TDS limit, although higher TDS water is commonly used for domestic purposes where a better quality water supply is not available.

Sulfate is the ion most often observed in excessive concentrations. Measured concentrations of sulfate have ranged as high as 1100 mg/l (well MW 1291, 3/30/82), which is more than four times greater than DEQ, WQD's domestic ground-water supply

standard of 250 mg/l for sulfate.

Currently, the most common use of ground water near the Jab project area is livestock watering. This use is also the most likely predominant use in the future. With respect to TDS and major ion concentrations, all Jab project area ground water is suitable for livestock consumption.

With some exceptions, trace element and heavy metal concentrations are acceptably low in the Jab project area ground water for use as a domestic or livestock watering supply. One arsenic concentration was observed in well MW 1291 water (0.06 mg/l, 3/30/82) which is slightly in excess of the DEQ, WQD domestic ground-water supply standard of 0.05 mg/l. No arsenic concentrations exceeded the livestock consumption ground-water standard of 0.2 mg/l.

Boron concentration exceeded the DEQ, WQD domestic ground-water supply standard of 0.75 mg/l on one occasion each in three Jab project monitoring wells (Jab No. 1, 9/17/80; MW 1291, 10/08/80; and MW 1299, 9/17/80). In each case, the measured value was 1 mg/l, which also corresponded to the lower limit of detection at that time. Because of the relatively large lower detection limit in 1980, and because no excessive boron values have been observed in Jab ground water since late 1980, the three reported excessive values are not considered to be significant.

Two values of cadmium have exceeded DEQ, WQD's domestic ground-water standard of 0.01 mg/l. One was measured in water collected

from well MW 1298 (0.026 mg/l) and the other in water collected from well MW 1299 (0.018 mg/l). Both water samples were taken on 3/30/82. No cadmium concentrations which exceed the DEQ, WQD livestock watering standard of 0.05 mg/l have been measured in Jab project area ground water.

Maximum allowable chromium concentration in ground water to be used as a domestic or livestock water supply is 0.05 mg/l, according to DEQ, WQD standards. Two measurements of chromium in Jab project area ground water exceeded this standard. The values, both measured in water samples collected on 12/09/81, are 0.15 mg/l and 0.083 mg/l for wells MW 1291 and MW 1299, respectively.

One excessive fluoride value of 11 mg/l was measured in water collected from well MW 1299 on 12/09/81. Because other fluoride concentrations measured in well MW 1299 water do not exceed 1 mg/l, and the highest concentration observed in ground water in other Jab area wells is 2 mg/l, the one excessive value is believed to be erroneous.

Only one iron concentration in Jab area ground water exceeds DEQ, WQD's domestic standard of 0.3 mg/l (0.575 mg/l in well MW 1300 on 3/30/82). Iron, in this concentration, does not pose a health hazard, but is undesireable for aesthetic reasons.

Several mercury concentrations in Jab area ground water exceed DEQ, WQD's livestock water-supply standard (0.00005 mg/l). None exceed the domestic water-supply standard of 0.002 mg/l.

A standard for manganese concentration in ground water to be used as a domestic water supply has been set by DEQ, WQD at 0.05 mg/l. Like iron, manganese is undesireable at these concentrations because of aesthetic, not health-hazard, reasons. Several manganese measurements in water collected from two Jab project area monitoring wells exceed the standard of 0.05 mg/l. Maximum observed manganese concentration is 0.401 mg/l.

DEQ, WQD's selenium standard for domestically used ground water is 0.01 mg/l, and is 0.05 mg/l in ground water to be used as a source for livestock consumption. One excessive value (0.07 mg/l on 11/30/79) has been measured in water collected from well Jab No. 1. Other selenium measurements in water collected from this well are less than the detection limit. Similarly, one excessive selenium value (0.41 mg/l on 10/08/80) is reported for well MW 1291, whereas all other measurements are less than the lower limit of detection.

Radium-226 has been observed in excessive concentrations in ground water collected from three Jab project area wells. Except for values measured in well MW 1291 water, excessive concentrations do not greatly exceed DEQ, WQD's standard of 5 pCi/l. However, radium-226 concentration in well MW 1291 water is greater than 200 pCi/l. Although these values are unusually large when compared to typical ground-water radionuclide activities, they are not rare when dealing with ground water in contact with a uranium ore body. Uranium has not been observed in concentrations which exceed the State of Wyoming's ground-water standards for

domestic or livestock water supplies.

D6.2.6.1 Correlation of Water-Quality Constituents

Correlation and regression analyses were performed on measurements of Jab project area ground water, whereby the relationships between individual major constituent ions (including TDS) and conductivity were tested.

TDS vs. Conductivity

Figure D6-4 presents a plot of conductivity vs. TDS concentration for Jab project area ground water. A least-squares line of best fit and correlation and regression parameters are also presented on Figure D6-4. An excellent relationship has been defined, for which the correlation coefficient is 0.99 and the standard error of estimate is 72 mg/l. Therefore, conductivity is useful as a predictor of TDS concentration for the Jab area ground water.

Sulfate vs. Conductivity

Sulfate vs. conductivity data, along with a regression line and associated parameter values, are presented on Figure D6-5. A good relationship exists between sulfate and conductivity (correlation coefficient equals 0.99 and standard error of estimate equals 45 mg/l), indicating that conductivity is a good predictor of sulfate concentration for the Jab area ground water.

Calcium vs. Conductivity

Calcium, like sulfate and TDS, relates well to conductivity in Jab project area ground water (see Figure D6-6). The correlation coefficient for this relationship is 0.98 and the standard error of estimate is 27 mg/l. Therefore, conductivity can be considered to be a useful indicator of calcium concentration.

Magnesium vs. Conductivity

Figure D6-7 presents magnesium concentration vs. conductivity and associated correlation and regression analysis information. The relationship between magnesium and conductivity for Jab project area ground water is not as strong as those previously discussed for TDS, sulfate, and calcium. However, conductivity can still be considered an adequate predictor of magnesium concentration.

Other Major Ions

Conductivity was determined to be an inadequate predictor of potassium, chloride, sodium, and bicarbonate. Potassium and chloride are relatively minor constituents in Jab area ground water. Although changes in potassium and chloride concentrations do affect conductivity, the percent change in conductivity remains small and therefore is not sensitive to the changes in potassium or chloride.

Sodium concentration appears to remain relatively constant in Jab area groundwater, regardless of the water's conductivity. Availability of sodium in host geologic formations is probably

limiting input of sodium to the ground water, but is relatively uniform areally.

Bicarbonate concentration in Jab area ground water varies over a relatively wide range (less than 75 mg/l to greater than 150 mg/l) but does not exhibit a definable trend or pattern. Reactions involving the CO2 - HCO3 - CO3 equilibria can cause volatilization and loss as CO2. Therefore, representative bicarbonate measurements are more difficult to achieve than for other major constituents, and a wider range of observations is expected.

D6.2.7 GROUND-WATER MONITORING

Before submittal of a permit to DEQ, wells 1291, 1292, 1298, 1299, 1300, 1307, Jab No. 1 and AX-34 should be sampled once for water level and for the complete Wyoming Department of Environmental Quality (WDEQ) water quality list. This information should be sufficient as long as there are no marked changes from previous data in the new results.

During mining, quarterly water levels should be measured with semi-annual water quality measurements of temperature, conductivity, pH, chloride, uranium, and radium-226. Complete water quality sampling per WDEQ list should be performed annually. The post mining monitor program would be similar to the monitoring program during mining.

D6.3.0 SURFACE WATER

D6.3.1 DRAINAGE BASIN DESCRIPTION

The channels and drainage areas of relevance to the Jab project area are shown on Exhibit D6-1. The project area is drained primarily by two westerly-flowing ephemeral tributaries to Arapahoe Creek, both unnamed. For convenience, the channel draining Antelope Reservoir and the southern portion of the project area is hereafter referred to as Antelope Reservoir Creek. The other, which drains the north portion of the project area, is referred to simply as Unnamed Creek in this appendix. A third channel drains a small drainage basin which includes a minor portion of the southern Jab project area. This third small channel joins Antelope Reservoir Creek very close to the southwestern corner of the project area. Surface water monitoring site SW-1 (see Exhibit D6-1) is located downstream from the confluence and should allow detection of potential impacts to either basin.

Antelope Reservoir Creek joins Arapahoe Creek approximately one and one- half miles west of the Jab project area, in T.26N., R.94W., Sec. 17, and Unnamed Creek joins Arapahoe Creek in the southeast corner of Sec. 10, T.26N., R.94W., less than one-fourth mile north of the project boundary.

Arapahoe Creek flows into Lost Creek less than 2 1/2 miles due

west of the Jab project area boundary. Lost Creek flows into Lost Creek Lake, from which there is no surface outflow.

Arapahoe Creek drainage area is several times the size of the drainage area to Angelope Reservoir Creek. Arapahoe Creek tributaries Antelope Reservoir Creek and Unnamed Creek have respective drainage areas of 8.64 mi^2 and 1.50 mi^2. Upstream from surface-water monitoring site SW-1, Antelope Reservoir Creek's drainage area is 8.16 mi^2, its drainage area upstream from site SW-3 (see Exhibit D6-1) is 6.12 mi^2, and its drainage area upstream from the eastern Jab project area boundary is 5.89 mi^2. Surface- water monitoring site SW-2 is located on Unnamed Creek close to where it crosses the Jab project area boundary. At this site its drainage area is 1.32 mi^2.

From its confluence with Arapahoe Creek to surface-water monitoring site SW-1, the length of Antelope Reservoir Creek's channel is approximately 1.2 mi. The total channel length upstream from this site is 9.1 mi, of which approximately 6.0 mi is upstream and 0.6 mi is downstream of the project area boundary. The total length of Unnamed Creek's channel is approximately 2.9 mi, 2.6 miles of which are upstream from surface-water monitoring site SW-2 and about 0.5 mi is upstream of the project area.

Average basin gradients of Antelope Reservoir Creek and Unnamed Creek are 0.035 ft/ft and 0.017 ft/ft, respectively. Channel gradients within the Jab Project area are considerably flatter, being 0.007 ft/ft at surface- water sites SW-2 and SW-3 and 0.004

ft/ft at site SW-1. Basin characteristics for the two Arapahoe Creek tributaries are summarized on Table D6-17.

D6.3.2 SURFACE WATER RUNOFF ESTIMATES

The Jab project area lies within the Great Divide Basin, from which no surface water flows. All precipitation in this closed basin is lost to evapotranspiration, direct evaporation, or ground-water recharge. Annual precipitation is generally low, and surface-water annual yield per square mile is small.

Flood-flow characteristics for Antelope Reservoir Creek and Unnamed Creek at sites SW-1, SW-2, and SW-3 (see Table D6-18) have been computed using Craig and Rankl's (1977) technique and Lowham's (1976) technique. Lowham's equations are generally applicable for basins larger than 5 mi^2, but graphical interpretations can be made for basins as small as 0.5 mi^2. Lowham divided the state into separate regions, but used only drainage area in his basin characteristics method. Craig and Rankl's method is applicable to drainage basins smaller than 11 mi^2, is applicable to all Wyoming prairie stream channels, and utilizes basin parameters in addition to drainage area. For small, prairie drainage basins, Craig and Rankl's technique is probably preferable, but flood flows calculated using Lowham's method are presented on Table D6-18 for comparison purposes. Flood peaks and volumes shown on Table D6-18 using Craig and Rankl's technique were calculated utilizing basin parameters of drainage area, maximum basin relief, and average basin gradient.

D6.3.3 CHANNEL GEOMETRY

Channel cross sections have been prepared for Antelope Reservoir Creek and Unnamed Creek at surface-water monitoring sites SW-1, SW-2, and SW-3. These cross sections are presented, respectively, on Figures D6-8, D6-9, and D6-10. Channel conveyance characteristics, including slope, cross- sectional area, hydraulic radius, velocity, discharge, and flood volumes for the five-year and one hundred-year floods are also presented on these figures. Only water in Unnamed Creek should exceed five feet per second during the one hundred year flood.

D6.3.4 SURFACE-WATER QUALITY

Crest-stage gages and self-sampling water collectors were installed at surface-water sites SW-1, SW-2, and SW-3 in fall of 1980. Since that time, no runoff events have occurred on Antelope Reservoir and Unnamed Creeks. As a result, no surface-water runoff samples have been collected for laboratory analysis.

Several springs in the region have been visited and sampled. These analyses are presented on Table D6-19, and locations are shown on Exhibit D6-1. Quality of water collected from these springs is more typical of ground-water quality than surface-runoff quality. The spring shown in section 11 of T26N R94W on Exhibit D6-1 was dry each time it was visited.

D6.3.5 SURFACE WATER MONITORING

The three surface water sites SW-1, SW-2, and SW-3 should be

checked each quarter. At anytime that it is known that a storm of significant rain occurrs, the surface water sites should be checked for both stage and a sample.

D6.4.0 WATER RIGHTS

D6.4.1 GROUND-WATER RIGHTS

The State Engineer's files were also searched for active ground-water rights in and within 4 miles of the project area. These rights and other pertinent information are listed in Table D6-20. Exhibit D6-1 shows the locations of the active ground-water rights.

D6.4.2 SURFACE-WATER RIGHTS

A list of active surface-water rights can be found in Table D6-21. The list covers surface-water rights within and within a 3/4 mile perimeter of the project area. The surface water rights are also shown on Exhibit D6-1.

ADDENDUM D6A:

AQUIFER-TEST THEORY

AQUIFER-TEST THEORY

Transmissivity is a definition of the ability of an aquifer to transmit water. Common units of transmissivity are gallons per day per foot (gal/day/ft). A transmissivity expressed in these units is the amount of water, in gallons per day, that can flow through a vertical strip of aquifer one-foot wide extending the full saturated height of the aquifer normal to the flow direction under a unit hydraulic gradient.

Transmissivity must be adjusted by the actual aquifer width and hydraulic gradient to determine actual aquifer flow rates.

THEIS EQUATION

Theis, in 1935, introduced his equation which describes a non-leaky, confined aquifer. The following is a general definition of the Theis equation:

$$T = 114.6\ Q\ W(u)/s$$
$$u = 2693\ r^2\ S/T\ t$$

where: s = drawdown, in feet
Q = discharge, in gallons per minute (gpm)
W(u) = well function
= the integral from u to infinity of $(e^{-u})/u\ du$
T = transmissivity, in gal/day/ft
u = well function variable
r = observation well radius from pumping well, in feet
S = storage coefficient,
and t = time since pumping started, in min.

NOTE: "^" denotes exponentiation.

Pump test data are analyzed by matching the log-log plot of drawdown versus time to Theis' type curve (W(u) vs. 1/u) and applying the above equations to the match. Pages 92-98 of Ferris and others (1962) present a more thorough discussion of the Theis equation.

The value of the integral expression for W(u) is given by the following series:

$$W(u) = -0.577216 - \ln u + u - u^2/2.2! + u^3/3.3! \ldots$$

where all terms are as previously defined.

STRAIGHT LINE EQUATION

Jacob developed a simplified form of Theis' drawdown equation by truncating the well function series after the first two terms.

Assuming the trunction, the following equations were developed to analyze drawdown versus time data on semi-log plots and is called the straight-line or Jacob equation:

$$T = 264\ Q\ [\log\ (t2/t1)]/(s2 - s1)$$
$$T = 264\ Q/DELTA\ s$$
$$S = T\ to/4800\ r^2$$

s1 = drawdown, in feet, at time since pumping started, t1, in min.
s2 = drawdown, in feet, at time since pumping started, t2, in min.
and t2 > t1
DELTA s = change in drawdown over one log cycle of time on a semi-log plot, in feet
S = storage coefficient
to = straight-line intercept of zero drawdown, in min.
r = radius of well, in ft

A straight line is fitted to the semi-log plot of drawdown versus time (log scale) to obtain transmissivity. Jacob suggested that u values less than 0.01 are needed before his straight-line method is useful. However, a plot of W(u) versus 1/u on semi-log paper indicates that this method should be applicable for values of u as large as 0.1. Pages 98-100 of Ferris and others (1962) should be consulted for additional information on Jacob's method.

THEIS RECOVERY EQUATION

Theis' equation can be modified to handle recharge of a well or multiple pumping periods by summation of the well functions. The following equation is the solution of Theis' equation for one pumping and recharge cycle (Recovery equation) using a log-log match format:

$$T = 114.6\ Q\ [w(u) - W(u')]\ /\ s'$$
$$u' = 2693\ r^2\ S\ /\ Tt'$$
$$T = 114.6\ Q\ [W(u) - W(u) + W(u')]\ /\ sr$$
$$= 114.6\ Q\ W(u')\ /\ sr$$
$$sr = s - s'$$

where: sr = recovery, in feet
s' = residual drawdown (static water level - water level @ t'), in feet
W(u') = recovery well function
u' = recovery well function variable
t' = time since pumping stopped, min.

The recovery data are analyzed by matching the log-log plot of the recovery versus time since pumping stopped to Theis' type curve. The type curve variables are W(u') and 1/u' for the recovery match. The recovery is computed by estimating the drawdown which would have occurred if pumping had continued, and subtracting this predicted drawdown from the residual drawdown. For example, the recovery at 100 minutes after pumping has stopped

is computed by estimating the drawdown at that time if the pumping had continued uninterrupted, and subtracting this drawdown from the residual drawdown. The straight-line fit of the drawdown is normally extended to obtain these estimates of drawdown.

The well functions of the residual-drawdown form of Theis' equation were approximated by using only the first two terms in the well function series. The following equations present the semi-log form of the Theis recovery equation:

$$T = 264\ Q\ [\log (t/t')]/s'$$

or $T = 264\ Q/\Delta s'$

where: t = time since pumping started, in min.
t' = time since pumping stopped, in min.
s' = residual drawdown, in feet

and

$\Delta s'$ = change in residual drawdown over one log cycle of t/t' on a semi-log plot, in feet

Therefore, when residual drawdown is plotted on an arithmetic scale versus t/t' on a logarithmic scale, the above equation can be used for the straight line fit. Pages 100-102 of Ferris and others (1962) should be consulted for a discussion of Theis' recovery method. Theis' recovery equation is for a non-leaky confined aquifer also.

NEUMAN-WITHERSPOON METHOD

A method for determining aquitard vertical permeability has been described by Neuman and Witherspoon (1971) and Neuman and Witherspoon (1972). In this technique, referred to as the Ratio Method, the ratio of drawdown in the aquitard to the drawdown in the pumped aquifer at the same time distance is related to a dimensionless time parameter, t'D:

$$t'D = K't / Ss' z^2$$

where K' = aquitard vertical permeability
t = time for which drawdown ratio was determined
Ss' = specific storage of the aquitard
$= K'/ALPHA'$
$ALPHA'$ = aquitard diffusivity,
and z = vertical distance from the center of the screened section of the well completed in the aquitard to the aquifer.

t'D is determined graphically. Therefore, aquitard diffusivity (ALPHA') can be calculated from $ALPHA' = K' / Ss' = t'D\ Z^2 / t$.

In order to determine aquitard vertical permeability, K', aquitard specific storage, Ss', must be ascertained.

$$Ss' = avWw / 1 + e$$

where av = coefficient of compressibility

Ww = weight of water,
and e = void ratio.

The values of av and e must be determined on samples of the aquitard in the laboratory or Ss' may be estimated based on published reports on similar sediments.

PUMP TEST RESULTS

TABLE OF CONTENTS

LIST OF FIGURES

LIST OF TABLES

D6B.1 PUMP TEST 1292

Well 1292 was pumped at 32 gpm for two days while wells 1304, 1305, and 1307 were observed for drawdown. Table D6B-1 presents the drawdown and field water quality data for pumping well MW 1292. The semi-log plot of the drawdown for pumping well 1292 is presented in Figure D6B-1. The straight line fit of this data yields a transmissivity of 2800 gal/day/ft for this aquifer. The specific capacity of well 1292 at the end of the pump test was one gpm per foot of drawdown. This data and the potential drawdown in this well indicates that the well should yield at least 100 gpm of water. The recovery of the water level in pumping well 1292 (see Fig. D6B-2) produced a similar transmissivity as the value from the drawdown data.

D6B.1.1 OBSERVATION WELL OW 1304

Drawdowns in observation well 1304, which is 60.4 feet from pumping well 1292 were greater than six feet after two days of pumping. Table D6B-2 presents the drawdown data for this observation well while Figure D6B-3 presents the semi-log plot of the drawdown data. The straight line fit to this drawdown produced a transmissivity of 4700 gal/day/ft and a storage coefficient of 2.4 x 10^-4. The log-log plot of the drawdown data in observation well 1304 yields the same aquifer properties from our match to the Theis type curve (see Fig. D6B-4).

D6B.1.2 OBSERVATION WELL OW 1305

Figure D6B-5 presents the drawdown data (see Table D6B-3) for observation well 1305, which is located 30.4 feet from pumping well 1292. The straight line fit of this data produced a transmissivity and storage coefficient of 4200 gal/day/ft and 1.4 x 10^-4, respectively. The log-log match of the drawdown (see Fig. D6B-6) to the Theis type curve produced similar aquifer properties on the straight line fit.

D6B.1.3 OBSERVATION WELL OW 1307

Observation well 1307 is completed in the sand below the mudstone which forms the base to the ore sand (see Figure D6B-7 and Table D6B-4 for drawdowns). This mudstone is 12 feet thick at well 1307. Neuman- Witherspoon's (1971) method (see Addendum D6A for a discussion of this technique) can be used to estimate the vertical permeability of the mudstone. Their method is designed to use drawdowns in the mudstone (aquitard) but use of an observation well just below the mudstone can be used to obtain an approximate permeability. A dimensionless time, tD, for the ore aquifer of 22 was computed from a transmissivity, storage coefficient and well radius, of 4400 gal/day/ft, 2 x 10^-4 and 30.4 feet, respectively. Drawdowns at ten minutes from wells 1307 and 1304 of 0.12 and 4.24 feet, respectively were used to calculate the drawdown ratio of 0.028. The dimensionless time for the aquitard, tD', was obtained from Figure IV-16 of Neuman and Witherspoon (1971). Specific storage of the aquitard was not

determined for this site, but a value determined for a similar mudstone in the Red Desert of 7.4 x 10^-5/ft was used to estimate the vertical permeability. These values produce a vertical permeability of 0.45 ft/day (1.6 x 10^-4 cm/sec). This value should be reduced some because observation well 1307 is also sampling the vertical movement through a few feet of sand. This adjustment was not made because the vertical permeability of the sand is unknown and the reduction would not be large. The drawdown in well 1307 indicates that the mudstone is very permeable, which would not be expected. Secondary permeability through fracturing would be needed for this mudstone to obtain a vertical permeability this large. It seems likely that the mudstone would have the ability to seal fractures and therefore not contain a high permeability. A poor bentonite seal in the annulus or pinching out of the mudstone near this area could cause the drawdowns observed in well 1307. This test indicates a ready connection between the sands above and below the mudstone.

D6.2 PUMP TEST 1291

Well 1291 was pumped at an average rate of 3.1 gpm for 405 minutes, while observation wells 1301, 1302, and 1303 were observed for drawdown. Table D6B-5 presents drawdown and recovery data and field water quality information for pumping well 1291. Figures D6B-8 and D6B-9 present the drawdown and recovery semi-log plots for pumping well 1291. The straight line fits to this data indicates the transmissivity near well 1291 is 200 gal/day/ft.

D6B.2.1 OBSERVATION WELL 1301

Observation well 1301 is located 62 feet south of pumping well 1291. The drawdown observed in this observation well is tabulated in Table D6B-6 and presented in Figures D6B-10 and D6B-11. The analysis of this drawdown data produced a transmissivity of roughly 800 gal/day/ft and a storage coefficient of 6 x 10^-4. These results indicate that the ore aquifer is more permeable at well 1301 than at the pumping well. The leveling off of drawdowns after 200 minutes of pumping is probably caused by the unconfined properties of the aquifer in this area. The length of the pump test needed to be several days long to develop an adequate drawdown curve to warrant using unconfined aquifer theory to analyze the test.

D6B.2.2 OBSERVATION WELL 1302

Observation well 1302 is spaced approximately one-half the distance between wells MW 1291 and OW 1301. Drawdown (see Table D6B-7) in this observation well produced a transmissivity between the values obtained from wells 1291 and 1301. Transmissivities of 580 gal/day/ft from the semi-log plot (see Fig. D6B-12) and 510 gal/day/ft from the Theis match (see Fig. D6B-13) were obtained from the well 1302 data. These results indicate that the transmissivity increases with distance away from the local fault.

D6B.2.3 OBSERVATION WELL 1303

Observation well 1303 is completed on the north side of the

localized fault and below the mudstone (see Exhibit D6-2) while all of the other wells in the 1291 test are south of the fault. Table D6B-8 presents the water level data collected from well 1303 during the 1291 test. Very little change in water level was observed in well 1303 during the test. Barometric pressure adjustments were made to the observed drawdown from well 1303 because these adjustments were significant for the small change in water level. The barometric pressure during this test gradually decreased from 29.66 to 29.57 inches of Hg at the end of the test. A barometric efficiency of 0.63 ft of water/inches of Hg was determined from static water level data. Drawdowns corrected for the barometric pressure changes indicates that a maximum drawdown of 0.08 ft was observed in well 1303. This data shows that the aquifer north of the fault below the mudstone is not readily connected to the ore sand aquifer in this area.

D6B.3 PUMP TEST 1298

Well 1298 was pumped at an average rate of 5.9 gpm for 55 minutes. Field water quality and drawdown data is presented in Table D6B-9. The plot of the drawdown and recovery data produced transmissivities of 50 and 40 gal/day/ft, respectively (see Figs. D6B-14 and 15). This shows that the sand just above the mudstone in the south central portion of the project area contains a much lower permeability.

D6B.4 PUMP TEST 1299

Well 1299, which is located in the southeast corner of the

project area, was pumped at an average rate of 23.7 gpm for 916 minutes (see Table D6B- 10). The drawdown and recovery plots for well 1299 indicate transmissivities of 1400 and 1700 gal/day/ft, respectively (see Figs. D6B- 16 and D6B-17). This data shows that the aquifer is very permeable in this area.

D6B.5 PUMP TEST 1300

Monitoring well 1300, which is in the northern portion of the Jab project area was pumped at an average rate of 6.9 gpm. Table D6B-11 presents the pumping and field water quality data for this test. The semi-log drawdown plot for well 1300 is presented in Figure D6B-18 and the straight line fit indicates a transmissivity of 670 gal/day/ft. The recovery plot of this test yields a similar transmissivity of 650 gal/day/ft.

D6B.6 PUMP TEST JAB WELL NO. 1

The Jab No. 1 well was used for a drilling water supply, and is completed in the ore sand below the mudstone. The recovery data for this well (see Fig. D6B-20 and Table D6B-12) produced a transmissivity of 3400 gal/day/ft. This test shows that the sands below the mudstone are very permeable in this area.

APPENDIX D-1

RESRAD Data Input Basis Parameters

RESRAD Data Input Basis

Parameters

This document summarizes the data input and modeling scenario that was used to determine the radium benchmark dose for the Antelope-JAB Project Project. The modeling was performed using RESRAD for Windows Version 6.3 developed by the Environmental Assessment Division at Argonne National Laboratory (ANL).

The resident farmer scenario was used since this is the most likely land use near the site. The following sections describe the data parameters that were used to model site-specific conditions.

The data input was based upon four principal sources:

1. The RESRAD Data Collection Handbook (ANL, 1993)

2. The RESRAD Users' Manual (ANL, 2003)

3. NUREG-1569

4. Site-specific information to be included in the Antelope-JAB Project license application

Soil Concentration

1. Lead 210: 5.0 pCi/g per the NUREG-1569.

2. Radium 226: 5.0 pCi/g regulatory limit as basis for determining benchmark.

Distribution Coefficient (K_d) (values based upon data in RESRAD Handbook)

1. Lead 210: Used a distribution coefficient of 270 cm^3/g for sandy soil based on the predominant soil type at the Antelope-JAB Project site. The RESRAD User's Manual specifies the following values:

    - Sand = 270
    - Loam = 16,000

A sensitivity analysis indicated (with a multiple of 100) no appreciable impact on maximum dose for the external dose pathway using a higher or lower K_d. For the Plant (water independent) pathway, the lower K_d resulted in a slightly lower maximum dose for this pathway. In this case, using the mid-range value of 270 would result in a conservative maximum dose estimate. Values of 2.7, 270 (mid range), and 27,000 were adopted, covering the range of potential values at the site based upon sandy and loamy soil types. See graph (attached).

2. Radium 226: Used a distribution coefficient of 500 cm^3/g for sandy soil based on the predominant soil type at the Antelope-JAB Project site. The RESRAD User's Manual specifies the following values:

    - Sand = 500
    - Loam = 36,000

A sensitivity analysis indicated (with a multiple of 100) no appreciable impact on maximum dose using the higher K_d. Values of 5, 500 (mid range) and 50,000 were adopted, covering the range of potential values at the site based on sandy and loamy soil types. See graph (attached).

Contaminated Zone

1. Area: Used default value of 10,000 square meters.

A sensitivity analysis was performed with a multiple of 2 (5,000, 10,000 and 20,000 square meters). There was no impact on maximum dose for the external dose component. See graph (attached).

2. Thickness: 15 cm (6 inches) based on regulatory requirement (minimum in RESRAD Handbook)

3. Length parallel to aquifer flow: Default of 100 meters was used and is based upon the square root of a 10,000 square meter contaminated zone.

No sensitivity analysis was performed since water dependent pathways were not significant contributors to dose.

Cover and Contaminated Zone

1. Cover depth: 0 inches (in accordance with NUREG-1569).

2. Density of contaminated zone: Used the value of 1.36 g/cm^3, which corresponds to the average of the value for sandy loam soil (1.44 g/cm^3) and clay loam soil (1.28 g/cm^3) in the RESRAD Handbook. This corresponds to the soil types at the Antelope-JAB Project and data in the Antelope-JAB Project license application.

   Because the RESRAD Data Collection Handbook considers this default value representative of the soil type, no sensitivity analysis was performed.

3. Contaminated zone erosion rate: Used the default value of 0.001 meters/year. NUREG-1569 states that the erosion rate should be lower at uranium recovery sites due to the semi-arid environment. The RESRAD Handbook states that this value should be adequate for screening purposes. It also states that, while water erosion is the primary factor, wind erosion can also be significant.

A sensitivity analysis was run using a multiple of 2 (0.0002, 0.001 and 0.005). The lower erosion rate resulted in the total dose remaining at a higher level over a longer period of time for both the external and vegetation (water independent) pathways. However, there was no impact on the maximum dose.

4. Contaminated zone total porosity: Default value of 0.4 is based on the soil types at Antelope-JAB Project.

No sensitivity analysis was performed since water dependent pathways were not significant contributors to dose.

5. Contaminated zone field capacity: Default value of 0.2 was used. This value was used because it is at the midpoint of the range for the soil types at Antelope-JAB Project.

No sensitivity analysis was performed since water dependent pathways were not significant contributors to dose.

6. Contaminated zone hydraulic conductivity: Used 199 m/yr based on site specific information on soil types.

No sensitivity analysis was performed since water dependent pathways were not significant contributors to dose and site specific information was used.

7. Contaminated zone b parameter: Default parameter is 5.3 for silty loam. The RESRAD Handbook and RESRAD Manual specify the range from sand to loam is 4.05 to 5.39. Used default value.

No sensitivity analysis was performed since water dependent pathways were not significant contributors to dose.

8. Evapotranspiration Coefficient: The RESRAD default value is 0.5. NUREG-1569 suggests that a value of 0.6 to 0.99 for uranium recovery sites is appropriate because they are located in a semiarid environment. For screening purposes, a mid-value (0.75) was used.

No sensitivity analysis was performed since water dependent pathways were not significant contributors to dose.

9. Wind Speed: The RESRAD default is 2 m/s. The average for the Antelope-JAB Project is 6.6 m/s based on meteorological data obtained at the site.

No sensitivity analysis was performed since this is actual site data.

10. Precipitation: The RESRAD default is 1 m/yr. The average for the Antelope-JAB site is 0.24 m/yr. Site data was used.

No sensitivity analysis was performed since this is actual site data as recommended in NUREG-1569.

11. Irrigation Rate: The RESRAD default is 0.2 m/yr. This default value is high for western states where irrigation may not be an option for some areas.

No sensitivity analysis was performed since water dependent pathways were not significant contributors to dose.

12. Runoff Coefficient: The RESRAD default value is 0.2. This is the value for open rolling land in the RESRAD Handbook and was used for the Antelope-JAB Project. The potential range in the RESRAD handbook for the site would be 0.1 to 0.4.

No sensitivity analysis was performed since water dependent pathways were not significant contributors to dose.

13. Watershed Area for nearby stream or pond: The RESRAD default value is 1×10^6 m^2. Used site-specific datum of 7×10^7 m^2.

No sensitivity analysis was performed since water dependent pathways were not significant contributors to dose and site specific data was used.

14. Accuracy: Used the default value of 0.001.

Saturated Zone

1. Density of saturated zone: Used the default value of 1.5 g/cm^3, which corresponds to sandy soil in the RESRAD Handbook. This compares with the first saturated zone at the Antelope-JAB Project.

No sensitivity analysis was performed since water dependent pathways were not significant contributors to dose.

2. Saturated zone total porosity: Used value of 0.25 is based upon site specific information.

No sensitivity analysis was performed since water dependent pathways were not significant contributors to dose and site specific information was used.

3. Saturated zone effective porosity: Used value of 0.1 based upon site specific information.

No sensitivity analysis was performed since water dependent pathways were not significant contributors to dose and site specific information was used.

4. Contaminated zone field capacity: Default value of 0.2 was used. This value was used because it is at the midpoint of the range for the soil types at Antelope-JAB Project.

   No sensitivity analysis was performed since water dependent pathways were not significant contributors to dose.

5. Saturated zone hydraulic conductivity: A value of 1090 m/y was used based upon site specific information.

   No sensitivity analysis was performed since water dependent pathways were not significant contributors to dose and site specific information was used.

6. Saturated zone hydraulic gradient: The default value of 0.02 was used for screening purposes.

   No sensitivity analysis was performed since water dependent pathways were not significant contributors to dose.

7. Saturated zone b parameter: This parameter was not used since the water table drop rate was zero.

   No sensitivity analysis was performed since water dependent pathways were not significant contributors to dose.

8. Water Table Drop Rate: The default value of 0.0 m/yr. was used for screening purposes. The site specific drop rate should be similar because there is little consumptive use of groundwater in the immediate area other than ranches that use local wells for domestic and livestock.

No sensitivity analysis was performed since water dependent pathways were not significant contributors to dose.

9. Well Pump Intake Depth: The RESRAD default is 10 m. Since the depth to saturated zone is approximately 150 meters, a value of 152 meters was chosen.

   No sensitivity analysis was performed since water dependent pathways were not significant contributors to dose.

10. Model for Water Transport Parameters: Used non-dispersion per NUREG-1569.

11. Well Pumping Rate: Used default of 250 m^3/yr. (66,000 gal/yr.).

    No sensitivity analysis was performed since water dependent pathways were not significant contributors to dose.

Unsaturated Zone

1. Unsaturated zone thickness: Used 108 meters based on site specific data to top of first saturated zone.

2. Density of unsaturated zone: Used site specific information of 1.44 g/cc.

3. Unsaturated zone total Porosity: Used value of 0.25 based on site specific information.

   No sensitivity analysis was performed since water dependent pathways were not significant contributors to dose and site specific data was used.

4. Unsaturated zone effective porosity: Used value of 0.1 based on site specific information.

No sensitivity analysis was performed since water dependent pathways were not significant contributors to dose.

5. Unsaturated zone field capacity: Default value of 0.2 was used. This value was used because it is at the midpoint of the range for the soil types at Antelope-JAB Project.

   No sensitivity analysis was performed since water dependent pathways were not significant contributors to dose.

6. Unsaturated zone hydraulic conductivity: A value of 1090 m/y was used based upon site specific information.

   No sensitivity analysis was performed since water dependent pathways were not significant contributors to dose.

7. Saturated zone b parameter: Used value of 4.9. The RESRAD Handbook and RESRAD Manual specify a value of 4.38 for loamy sand, which corresponds to the soil classification used for the hydraulic conductivity. The range from sand to loam is 4.05 to 5.39.

   No sensitivity analysis was performed since water dependent pathways were not significant contributors to dose.

Occupancy

1. Inhalation Rate: Used default value of 8,400 m^3/yr.

2. Mass Loading for Inhalation: Default is 0.0001 g/m^3. Handbook gives a value of 0.0003 g/ m^3 for agricultural generated dust loading. Used 0.0003 g/ m^3

No sensitivity analysis was performed since inhalation pathways were not significant contributors to dose.

3. Exposure Duration: Used default value of 30 years.

4. Indoor dust filtration factor: Used default value of 0.4.

5. External gamma shielding factor: The RESRAD default is 0.7, which assumes that the indoor gamma radiation level is 30% lower than the outdoor gamma radiation level. NUREG-1569 requires that a value between 0.33 and 0.55 be used. The screening level was set at 0.55. This is a value suitable for a 7-inch thick concrete slab on grade house (NUREG/CR-5512 Vol.3, p 6-25). This is representative of the thickness of the local slab or basement floor thicknesses.

   Sensitivity analysis using a 1.5 multiple (i.e., 0.367, 0.55 and 0.825 resulted in a change in the maximum dose. See graph. The low range (0.367) resulted in a maximum dose for the external exposure pathway of approximately 20 mrem/yr compared to a dose of 23 mrem/yr for a shielding factor of 0.55. Based upon the fact that most construction of rural homes in the local area includes a thick concrete basement floor or slab, a shielding factor of 0.55 for the Antelope-JAB Project area is justified.

6. Indoor/Outdoor Fractions: Used defaults of 0.5 indoors and 0.25 outdoors for farmer scenario. As discussed above, the resident farmer scenario was chosen as the most likely land use for the foreseeable future (i.e., 200 years).

7. Shape of contaminated zone: NUREG-1569 suggests use of actual shape. However, the shape is unknown at this time. Various shapes were assumed including a rectangle having a length of up to four times the width. The results were independent of these shapes as long as the receptor was centered. When the receptor

was at the edge of the area, the dose was reduced significantly as expected. A circular shape was adopted for the modeling.

Ingestion: Dietary

1. Consumption Rates:

A. Fruit, vegetable and grain: RESRAD default is 160 kg/yr. This value was used based upon EPA estimated consumption. NRC Reg. Guide 1.109 has an estimated consumption for an adult of 190 kg/yr. Screening level set at default of 160 kg/yr. This amount is the total consumption. RESRAD adjusts for contaminated and uncontaminated fractions based upon the size of the contaminated area.

B. Leafy Vegetable: Used default value of 14 kg/yr. NRC Reg. Guide 1.109 has an estimated consumption for an adult of 64 kg/yr, while NRC estimates for dose from nuclear power plants uses a consumption rate of 30 kg/yr. Screening level for total set at default of 190 kg/yr (see above entry). This amount is the total consumption. RESRAD adjusts for contaminated and uncontaminated fractions based upon the size of the contaminated area.

C. Milk: A value of 83 L/yr was used. Assumes resident farmer producing own milk locally.

D. Meat and Poultry: Used RESRAD default value of 63 kg/yr. According to NRC Regulatory Guide 1.109 (NRC, 1977), the recommended average value for consumption of meat and poultry is 37 kg/yr for children, 59 kg/yr for teenagers, and 95 kg/yr. for adults.

E. Fish/Seafood: No consumption of locally produced and consumed fish or seafood products was considered as recommended by NUREG-1569.

F. Soil ingestion: Used the RESRAD default value of 36.5 g/yr.

G. Drinking water intake: Used the RESRAD default of 510 l/yr. (1.4 L/d) as a screening level. This value is based upon EPA estimates of drinking water intake. The EPA (1990) has suggested that the average adult drinking water consumption rate is 1.4 L/d; the reasonable worst-case value is 2.0 L/d.

2. Contaminated Fractions:

NUREG-1569 states that for sites with over 25 acres (10,117 square meters) of contamination, the fraction of diet from contaminated area should be assumed to be 25% (0.25). A sensitivity analysis on these parameters was not performed based upon the guidance.

A. Water: Used the default value of 1 (i.e., 100% of consumption is from contaminated well water). All current water use in rural areas around the site is from private wells and will likely continue to be in the foreseeable future.

B. Livestock Water: Used default of 1 (i.e., 100% is from contaminated water). All current water use in rural areas around the site is from private wells and will likely continue to be in the foreseeable future.

C. Irrigation Water: Used the RESRAD default of 1 (i.e., 100% is from contaminated water). All current water use in rural areas around the site is from private wells and will likely continue to be in the foreseeable future.

D. Plant food: Used 0.25 as percentage of plant food that is contaminated.

E. Meat: Used 0.75 as percentage of meat that is contaminated.

F. Milk: Used o.75 as percentage of milk that is contaminated.

Ingestion: Nondietary

1. Consumption Rates:

A. Livestock fodder intake for meat: Used the RESRAD default of 68 kg/day.

B. Livestock water intake for meat: Used the RESRAD default of 50 L/day. According to NRC Regulatory Guide 1.109 (NRC 1977), the water ingestion rate for beef cattle is 50 L/d.

C. Livestock intake of soil for meat: Used the RESRAD default of 0.5 g/day.

D. Mass loading for foliar deposition: Used the same value of 0.0003 g/m^3 for agricultural generated dust loading as the inhalation parameter discussed above.

Sensitivity analysis was run with a multiple of 100 (i.e., 0.000003, 0.0003, and 0.03 g/m^3). There was no impact on dose.

E. Depth of soil mixing layer: Used the RESRAD default of 0.15 meters.

F. Depth of roots: Used 0.3 meters as a screening level based upon NUREG-1569 instead of the RESRAD default of 0.9. The root depth varies for different plants. For some plants, such as beets, carrots, lettuce, and so forth, it does not extend below about 0.3 m, which is the basis of the NRC guidance. For others, such as fruit trees, the roots may extend 2 or 3 m below the surface. Tap roots for some crops (e.g., alfalfa) can extend to 5 m. Most of the plant roots from which nutrients are obtained, however, usually extend to less than 1 m below the surface. Due to the common use of grazing crops such as alfalfa in the immediate area surrounding the Antelope-JAB Project site, a sensitivity

analysis was chosen that would determine the dose using the 0.3 m NRC guidance as the screening level as well as the 0.9 m RESRAD default.

Sensitivity analysis was run with a multiple of 2 (i.e., 0.15, 0.3, and 0.6 meters). There was a significant impact on the maximum dose. Assumption of a shallow root system increased the dose significantly. In a review of the exposure pathways, the plant pathway resulted in approximately 35% of the total maximum dose. The meat pathway, which would be the primary pathway affected by deeper roots such as alfalfa was insignificant. Therefore, the root depth recommended in the NRC NUREG-1569 was chosen for this parameter.

G. Groundwater fractional usage:

- Drinking water: Used the RESRAD default of 1 (i.e., 100% from well).
- Livestock water: Used the RESRAD default of 1 (i.e., 100% from well).
- Irrigation water: Used the RESRAD default of 1 (i.e., 100% from well).

***Storage** Times*

Used the RESRAD default values for all storage times (for vegetables, meats, fodder, etc.).
