## Environmental Management & Support

Rich Dailey Senior Director

March 9, 2009

Mr. Jim Dwyer  
U. S. Nuclear Regulatory Commission Region 1  
475 Allendale Rd  
King of Prussia, PA 19406

Re: Request for Additional Information  
General Licensee: Wal-Mart Stores, Inc.  
Docket Number: 999-90001  
Request Date: February 18, 2009

Dear Mr. Dwyer,

By email dated February 18, 2009, the U. S. Nuclear Regulatory Commission (NRC) submitted to Wal-Mart Stores, Inc. (Wal-Mart) several requests for additional information (RAIs) in connection with Wal-Mart's Tritium Exit Sign Inventory Project (TESIP) Final Report, dated January 29, 2009. The NRC also requested that Wal-Mart respond to the RAIs by formal letter. As such, this letter and attachments provide Wal-Mart's responses to the NRC's requests.

Wal-Mart understands that this response functions as a supplement to its TESIP Report. Please do not hesitate to contact me should you require additional information.

Sincerely,

Rich Dailey

Radiation Safety Officer  
Wal-Mart Stores, Inc.

cc: Angela Washington Esq., Wal-Mart Stores, Inc.  
Thomas Poindexter Esq., Morgan, Lewis & Bockius LLP

## ATTACHMENT 1: RAI RESPONSES

**NRC Question 1:** *In your TESIP Final Report, Section III (Inventory Program), you describe a critically damaged TES as "any sign in which the glass tubes were damaged, missing, did not glow, or the sign was crushed or punctured in a way that might cause the tubes to be broken, or the sign contents were in imminent danger of falling." Except for the case where the sign contents were in imminent danger of falling (and were not otherwise damaged) NRC would expect your critically damaged exit signs to be handled, decontamination be conducted and surveys be performed by someone specifically licensed by an Agreement State or NRC to do so. Please provide us with a list of your stores, by city and state, where critically damaged exit signs were identified and, for each store, provide: (1) the dates that the critically damaged signs were removed and packaged for shipment, decontamination was conducted or surveys were performed; and (2) the specific license under which this work was performed.*

**Response:** Attachment C of the TESIP Report provides a list of stores, by city and state, where Wal-Mart and its consultants identified critically damaged exit signs. Attachment C also indicates, for each store, the date that Dade Moeller visited the store to package the critically damaged signs for shipment, perform associated surveys, and decontaminate areas, as necessary. An initial visit to a location is either indicated by a "Visit 1" designation (where multiple visits occurred) or no indication (where it was the only visit). Attachment C also documents those circumstances that required a return visit by a health physicist indicated as Visit 2 or Visit 3, as appropriate. Because these were return visits for further decontamination, no TES would have been packaged and shipped during those visits.

Attachment 2 to this response includes the information from Attachment C of the TESIP Report, as well as visit-specific information about the applicable license and/or reciprocity to that license under which the health physicist worked. Attachment 2 also includes, for each store visit, the name of the primary contact from the state regulatory agency from which Dade Moeller obtained a reciprocity agreement.

All health physics activities conducted by Dade Moeller, including responses to potential imminent damage hazards, were conducted under the Dade Moeller Maryland radioactive materials license (#MD-31-244-01) or reciprocity of that license with the appropriate agreement state or with the NRC. In one case (Palmdale, California, Store #2950), the service of Thomas Gray & Associates, Inc. (TGA) was employed to decontaminate an outside area where damaged TES caused elevated tritium levels to be present in a parking lot area. TGA conducted the decontamination activities under its State of California license (#2105-30). Dade Moeller coordinated this activity with the State of California and the County of Los Angeles regulatory authorities.

**NRC Question 2:** *In your TESIP Final Report, Section III (Inventory Program, Footnote 6), you stated that Wal-Mart was able to gain access and inventory TES*

## ATTACHMENT 1: RAI RESPONSES

in all but nine facilities that were no longer owned or occupied by Wal-Mart. Of those nine, you stated that three were demolished, two were destroyed by Hurricane Katrina, and access to four could not be obtained. Did you enter serial numbers from those locations in your TES Management System and were those TES included in the total TES determined to be lost? Also, please provide the current or previous physical address for those locations and the number of TES purchased for each of those locations.

**Response:** Wal-Mart did enter serial numbers into its TES Management System for TES associated with the nine Wal-Mart facilities in question, and included lost TES from those facilities in its total number of lost TES. The requested information is provided for each of the nine facilities in Attachment 3.

**NRC Question 3:** In your TESIP Final Report, Section V (Response to Damaged TES), you indicated on page 30 that the total *leachate* to be released in a year was 2500 cubic meters or  $2.5E+9$  liters. According to our calculations, the value should be  $2.5E+6$  liters. This assumes one cubic meter equals 7000 liters. If you agree with our assessment of *leachate* volume in liters, your calculated dose of 0.15 millirem per year is underestimated by a factor of 1000 and would exceed the EPA drinking water standard. You may wish to revisit your assumptions and revise your projections.

**Response:** As Wal-Mart was developing its answer to this question, it confirmed that the unit conversion from cubic meters to liters shown in the TESIP Report was in error. Using the correct value of  $2.5 \times 10^6$  liters, as noted by the NRC, the resulting drinking water concentration would be 3,200,000 pCi/L, and the dose from ingestion for this hypothetical scenario would be 150 mrem/yr.

The corrected concentration value and estimated dose are inconsistent with the existing base of knowledge of the risk from TES, and as a result, are unreasonably high. In addition, the estimated landfill leachate concentration (64,000,000 pCi/L) is much higher than recent measurements of tritium concentration in landfill leachate. As a result, Wal-Mart and its consultant, Dade Moeller, have re-visited the bases of this hypothetical "maximum exposure" scenario.

Dade's scenario development process used a graded approach, which started with very conservative assumptions and progressively introduced more rigor into the calculation process to achieve more realistic results that provide a greater level of confidence. When the initial erroneous results showed the estimated drinking concentration to be very low and well below the drinking water standard, no additional calculations appeared to be necessary, thereby ending consideration of the next level of parameters. However, once the error was realized, it was apparent that additional analysis was required to develop more realistic estimates, for which there is confidence in the reasonableness of the approach and an appropriate level of conservatism in the calculations.

## ATTACHMENT 1: RAI RESPONSES

Application of this same graded approach, while retaining the basics of a generic "maximum exposure" scenario, resulted in a complete revision of Section V.D.6 (See Attachment 4). Each of the scenario parameters and assumptions is now indicated by a bulleted description. Bracketed text at the end of this bulleted description indicates if the parameter or assumption was changed or remains unchanged from the TESIP Report. Furthermore, intermediate and final calculation results are indicated by an arrow and text box, to allow the progression of the scenario calculation to be easily checked. Wal-Mart believes that the revised "maximum exposure" groundwater scenario is still conservative and continues to represent a level of public exposure that is very unlikely to occur.

**NRC Question 4:** *In your TESIP Final Report, Section V (Response to Damaged TES), you indicated that tritium removable and fixed contamination exceeded project action levels at two stores after follow-up activities were complete. Please provide the location of those stores and describe the removable and fixed contamination levels and circumstances leading to your conclusion that further remediation could not be justified by ALARA principles.*

**Response:** The first location, Store #1185 in Austin, Texas, had removable tritium contamination levels slightly above the project action level of 1000 dpm/100 cm<sup>2</sup> in two locations (plywood header and upper door jamb). The removable tritium contamination levels "as left" were 1184 and 1154 dpm/100 cm<sup>2</sup>. On behalf of Wal-Mart, Dade Moeller provided to Mr. Art Tucker of the Texas Radiation Control Program, Department of State Health Services (DSHS), Wal-Mart's and Dade Moeller's technical basis for not reducing the levels to below the project action level. The final correspondence to Texas related to this issue is provided as Attachment 5. The Texas DSHS has not requested any further action with respect to this location.

For the second location, Store #5210 in Wylie, Texas, the area of contamination spanned several square meters with the highest value at approximately 2,000,000 dpm/100 cm<sup>2</sup>. (The level of 3,700,000 dpm/100 cm<sup>2</sup>, which was noted on page 22 of the TESIP Report, was in fact associated with a component of a damaged TES itself, and is not considered contamination of a work or facility surface. This component was packaged and returned with the damaged TES to Isolite.) After an extensive decontamination effort at the Wiley, Texas store, removable contamination levels were reduced to below project action levels of 1000 dpm/100 cm<sup>2</sup>. Still, the fixed tritium contamination levels on the floor varied from below the project action level for fixed contamination (15,000 dpm/100 cm<sup>2</sup>), to as high as 74,000 dpm/100 cm<sup>2</sup>, with an average of 11,000 dpm/100 cm<sup>2</sup>.

Dade Moeller exhausted all reasonable non-destructive decontamination options. Dade Moeller advised Wal-Mart that, at that point, further reduction was not justified based on its conclusion that the as-left condition was As-Low-As-Reasonably-Achievable (ALARA). This conclusion was based on Dade Moeller's belief that the fixed contamination embedded in hard surface structures do not

## ATTACHMENT 1: RAI RESPONSES

present a significant risk to public health and safety because all of the realistic exposure scenarios evaluated for this case were determined to result in less than 1 mrem effective dose equivalent (most likely 0.0 mrem). Accordingly, additional personnel risks and costs that would be incurred by any destructive decontamination were not warranted. Wal-Mart documented these activities and as-left contamination levels in the site visit report for Wylie, Texas (Store #5210) submitted to the Texas Radiation Control Program, Department of State Health Services (DSHS) on May 23, 2008. The Texas DSHS has not requested any further action with respect to this location.

**NRC Question 5:** *In your TESIP Final Report, Section V (Response to Damaged TES), you indicated that 82 persons were offered bioassay analysis and 40 accepted. For those who did not accept, please indicate whether any were directly and immediately involved in TES damage. If so, what would be their expected reasonable maximum exposure? Also, did Dade Moeller's health physicists undergo bioassay analysis after handling damaged signs and conducting decontamination activities? If so, did their results differ from the exposures included in the report?*

**Response:** None of the Wal-Mart Associates who declined to provide bioassay samples were known or believed to have been directly or immediately (upon breakage) exposed to a damaged TES. Dade Moeller health physicists were monitored in accordance with Dade Moeller's State of Maryland radioactive materials license. Pursuant to the requirements of that license, two of Dade Moeller's health physicists were sampled and their results were negative (*i.e.*, not differentiable from background). These results are consistent with the exposures discussed in the January 29, 2009 TESIP Report.

**NRC Question 6:** *In your TESIP Final Report, Section V (Response to Damaged TES), you provide health and safety assessments for the following scenarios: a shopper or non-involved associate near a damaged TES; an associate involved with mechanical impact to TES and clean up; an associate directly and immediately involved in TES damage; TES placed in a store compactor; and inadvertent disposal of multiple TES in a municipal landfill. Please provide a health and safety assessment for the case where an individual is able to obtain and damage a TES, discarded or stolen from a Wal-Mart store or from a facility where the TES were transferred by your contractors, or tell us why this scenario or similar scenarios should not be considered.*

**Response:** Notwithstanding the event noted below, Wal-Mart does not believe that theft and intentional damage or abuse of a TES is a reasonable exposure scenario that should be included with the Wal-Mart-specific health and safety scenarios included in the TESIP report. Wal-Mart has no indication that such an exposure may have occurred.

## ATTACHMENT 1: RAI RESPONSES

The EPA has provided on its *www.trainex.org* website, a description of an event involving an adolescent youth who found a discarded sign, dismantled it, and broke the tubes while eating sunflower seeds. With intervention measures (additional consumption of water), the dose to the youth was 80 mrem. Without intervention, such a scenario could be expected to result in a dose of up to approximately 100 mrem. We believe this dose is representative of a TES theft and abuse scenario postulated by the NRC's question.

**NRC Question 7:** *In your TESIP Final Report, Section VI (TES Data Collection), you listed five likely reasons for missing TES. One involved the possibility of TES having been shipped back to Isolite or SRB. Did Wal-Mart request return shipment documentation from Isolite and SRB for data reconciliation? If not, does Wal-Mart intend to pursue this issue with both companies as part of its ongoing disposition and remediation plan?*

**Response:** Wal-Mart requested from both Isolite and SRB, all documentation that would assist Wal-Mart in identifying TES that were purchased and returned to the respective vendor, as part of its ongoing TES disposition efforts.

When Wal-Mart determined that Isolite was not providing requested information in a timely manner, Wal-Mart's representatives traveled to Isolite's headquarters in Berwyn, Pennsylvania, in order to understand Isolite's processes regarding the sale of TES to Wal-Mart and to review Isolite's records. During this visit, and numerous subsequent phone calls and e-mails, Wal-Mart's representatives obtained what Isolite purported to be a complete copy of all Isolite documentation pertaining to Isolite's contract with Wal-Mart. That documentation primarily included invoices, purchase orders, and email correspondence, but also included Credit or Return Merchandise Authorization documentation for TES returns in 29 states. Wal-Mart incorporated this information in its January 29, 2009 TESIP Report to the NRC.

Additionally, Wal-Mart and its representatives have made several attempts to retrieve relevant records from SRB. SRB was initially somewhat responsive, indicating that it would provide the requested information for a fee. When Wal-Mart indicated that it was willing to pay that fee, SRB ceased all communication with Wal-Mart for reasons unknown. As of this RAI response, SRB remains uncooperative and has not supplied any data or information to help Wal-Mart complete its inventory. Accordingly, it has not been possible for Wal-Mart to review any of SRB's return shipment documentation.

**NRC Question 8:** *In your TESIP Final Report, Section VI (TES Data Collection), you indicated that Kroll interviewed 22 general contractors among 36 identified in six Tier I states regarding their recollection of TES practices. Did Wal-Mart and Kroll consider identifying and interviewing contractors based upon number of TES lost versus number of TES purchased? Based upon NRC's review of lost TES reports for non-Agreement States, 39 of 189 stores had losses of 20 TES or*

## ATTACHMENT 1: RAI RESPONSES

more. This represents approximately 21% of stores and 61% of lost TES (1491 of 2439) in non-Agreement States. Also, did Wal-Mart investigate whether lost TES were shipped out of the country by Wal-Mart or contractors for use at other Wal-Mart locations or disposed of through companies other than Isolite?

**Response:** Wal-Mart determined that its sampling investigation would focus on the six states (Tier One States) that had among the highest percentage of unaccounted for TES. Wal-Mart did not specifically investigate whether TES may have been transferred from one of its stores to a location outside of the country. However, Kroll's review of available documentation did not reveal any information to suggest that TES were shipped from Wal-Mart's U.S. facilities to locations outside of the U.S. The only example that Wal-Mart could identify regarding its disposal of TES through a company other than Isolite involved two partially broken TES from Palmdale CA, which were disposed as radioactive waste by TGA.

Finally, Isolite assisted with Wal-Mart's formal TES removal program in connection with TESIP. Although Wal-Mart's contract with SRB included a provision that SRB would handle returns of TES for replacement or disposal, SRB has not participated in Wal-Mart's TESIP. While it is reasonable to conclude that SRB may have accepted returns of some TES prior to Wal-Mart's TESIP, we are unable to quantify the number of TES involved. Moreover, because Wal-Mart cannot confirm SRB's level of participation without records from the vendor, it did not report any shipments going to SRB. As of the date of this RAI response, SRB has not responded to any of requests for data from Wal-Mart or its representatives regarding any status of any TES it may have sold to Wal-Mart or received from Wal-Mart as a return.

**NRC Question 9:** Regarding the recently submitted lost TES reports for Agreement and non-Agreements States, the majority of entries listed device model number and curie content as "unknown." Considering that these lost TES have sequential serial numbers with known model numbers and curie content that may be included in purchase invoices or other documents, it appears feasible that Wal-Mart can establish model numbers and curie content for the majority of lost TES. Please explain why model numbers, curie content, and some serial numbers are listed as "unknown" for lost TES. Also, please provide the store number and estimated maximum curie content for TES lost at the store, where possible.

**Response:** Model numbers, curie content and serial numbers are listed as "unknown" for some lost TES because some of the vendor invoices obtained by Wal-Mart included only the total quantities of TES purchased or returned by Wal-Mart, and provided no other information. In other cases, documentation included the serial numbers of purchased or returned TES, but did not include information regarding model numbers or original curie content. Although Wal-Mart could extrapolate or make an educated guess of those entries based on existing

## **ATTACHMENT 1: RAI RESPONSES**

information, it could not verify or validate that information and thus did not provide it in its TESIP Report. Moreover, reporting initial TES curie content would not be appropriate because it would grossly overestimate the amount of curies actually lost due to a failure to consider the extent of isotope decay.

## ATTACHMENT 4: RESPONSE TO RAI #3/REVISED SECTION V.D.6

### 6. Inadvertent Disposal of Multiple TES in a Municipal Landfill

This exposure scenario examines the potential impact to a member of the public from inadvertent disposal of TES in a municipal landfill. The discussion evaluates the associated potential dose to a landfill worker, as is the unlikely scenario of tritium from damaged TES being released from a landfill and entering an aquifer, where the tritium could be consumed in drinking water. As for the earlier scenarios, project-specific knowledge is used wherever possible and applicable.

#### **Municipal Landfill Worker**

The potential dose to a disposal truck driver or municipal landfill worker would be very small. The subject work area would include both the landfill area and transfer stations. Dose to these workers is conservatively characterized by the TES in store compactor scenario discussed in Section V.D.5. Due to the nature of their jobs, landfill workers would not be in the immediate vicinity of TES (*i.e.*, they are expected to be much more than 1 meter away) when TES were broken, and they would be in an open air environment where the tritium gas would be dispersed and diluted. Similarly, a worker operating compacting equipment in a landfill cell would most likely receive zero dose from a broken TES.

- Estimated Dose:           Most likely:                   0 mrem  
                                  Reasonable maximum:       0.1 mrem

#### **Groundwater Exposure Scenario**

Modern municipal landfills are carefully located, scientifically-engineered facilities, built into or on the ground, that are designed to isolate waste from the environment. Such facilities typically include a series of disposal units, called "cells." Waste is isolated from the environment using engineered barriers, such as synthetic or clay liners, placed at the bottom of a landfill cell. The cell liner is designed to collect any water (from rainfall or snowfall) that might pass through the waste during and after landfill operations. Water in a landfill cell, known as "leachate," will contain soluble or suspended materials from the waste that could contaminate ground water resources. Modern landfills have leachate collection systems that are designed to collect and remove leachate water from a waste cell, further limiting the potential for ground water contamination. A closure cap is used to cover waste when a cell is full, and is designed to prevent infiltration of water after disposal operations cease. By minimizing the water entering a closed landfill cell, the potential for ground water contamination from leachate water is also limited.

Operation of municipal landfills is regulated by the U.S. Environmental Protection Agency (EPA) through its Resource Conservation and Recovery Act (RCRA) Subtitle D regulations (40 CFR Part 258). The operational and post-closure performance of landfills is monitored through a series of ground water monitoring wells located in a buffer zone between the landfill cells and the site boundary. Monitoring wells are sampled for indication of liner systems failure; if detected, corrective actions are required to prevent contamination of ground water beyond the site boundary.

#### *Most Likely Exposure Scenario.*

Modern municipal landfills are controlled and monitored. Any inadvertent disposal of TES likely would have occurred during a time when both operating and closed landfills are required to be

## ATTACHMENT 4: RESPONSE TO RAI #3/REVISED SECTION V.D.6

monitored. Closed landfills would have caps in place to prevent infiltration of water. All of the landfills to which TES could have been disposed would have been RCRA Subtitle D-compliant. Because of the control and monitoring for radioactivity in landfill content, exposure to members of the public through ground water consumption following disposal of TES is a remote possibility, regardless of the number of TES disposed and the extent of TES damage. The below analysis presents some results of landfill leachate monitoring, demonstrating the control and monitoring that is being done. Although tritium is detected in leachate, none is released from the confines of the disposal cell and the leachate monitoring system. The most likely dose to a member of the public is zero.

- Estimated dose from "most likely" exposure scenario: 0 mrem

### Reasonable Maximum Exposure Scenario.

Although unlikely, it is possible that older, smaller landfills, possibly those in rural areas, may not have the monitoring systems to provide effective control and monitoring of possible contaminants during operations and post-closure. These landfills are assumed to have a properly constructed liner but no cap. Tritium released from damaged TES could escape from the landfill disposal cell and enter a drinking water aquifer where it could be consumed by a member of the public. This scenario is a conservative representation of the reasonable maximum dose to a member of the public that might occur. No specific store or landfill is considered in this scenario and so no site-specific landfill characteristics are used. Simple, generic representations of the tritium source term, disposal cell release, aquifer transport, and public exposure are used in this drinking water scenario.<sup>1</sup> This approach conservatively represents the specific parameters that would be used in more sophisticated, site-specific modeling.

The bases of the scenario, including assumptions and parameter values, are presented in the following bullets. Intermediate and final calculation results are also shown, indicated by an arrow and text box outline. All values are limited to one or two significant figures, reflecting an appropriate level of uncertainty in this generic scenario. No additional significant figures are warranted.

- One hundred intact TES are inadvertently discarded from one store at the same time and disposed in a municipal landfill. One hundred discarded TES represents the 99.8<sup>th</sup> percentile of unaccounted for signs at one store. [parameter unchanged]
- The average activity per TES is 10 curies. The individual sign activity considers radioactive decay of the tritium while the signs were in stores and manufacturer differences in the initial sign activity. [parameter unchanged]

➤ Total disposed tritium activity: 1,000 curies

- All of the TES remain intact until the landfill daily soil cover is added and compaction occurs. During compaction of the waste and soil cover it is estimated that one-third (0.33) of the signs are damaged; in these damaged signs one-third (0.33) of the tritium-bearing tubes are broken and release tritium gas. These damaged fraction estimates of

---

<sup>1</sup> This basic scenario has been described and documented in a report prepared for the NRC, supporting license termination rulemaking (Kennedy and Strenge, 1992) and is consistent with the basis the EPA used to derive the tritium drinking water standard (EPA, 2000)

#### ATTACHMENT 4: RESPONSE TO RAI #3/REVISED SECTION V.D.6

signs and tubes are conservative based on project observations of damage to signs following compaction in stores;<sup>2</sup> discarded signs are assumed to have frames and faceplates intact. [both parameters changed from 0.4]

- When the tubes are broken, 50% (0.5) of the tritium gas is captured in the soil and waste and oxidized to HTO (tritiated water or tritiated water vapor). This fraction depends on how deep the soil cover is when the signs are broken. For signs broken on the surface, most of the tritium gas would escape. However, a deep layer of soil cover would prevent much potential sign damage. This combination of the sign and tube damage ratios and tritium capture fraction is considered reasonably conservative. [parameter changed from 1.0]

➤ Activity of tritium available for release: 54 curies

- The disposal cell is 100 meters (328 feet) long by 100 meters (328 feet) wide with a depth of 10 meters (33 feet). Although these dimensions could vary, a single cell of these dimensions would contain about 100,000 tons of waste, which is representative of a smaller landfill (NSMWA, 2005). The surface area of the cell is 10,000 m<sup>2</sup>. [parameter changed width from 50 m]
- One hundred percent of the precipitation incident on the disposal cell is assumed to be collected and remain in the cell. There is no leachate pumping or collection system, and there is no cap on a closed cell. Evaporation is not considered. [no change in this parameter, although not previously stated]
- The annual precipitation on the landfill is 0.5 meters (about 20 inches) per year. This value was selected since it is on the low side of average rainfall for most states. Additional precipitation would result in additional dilution with other assumptions remaining the same. [no parameter change]
- A total of five years of precipitation is accumulated in the landfill cell prior to closure. Under this generic scenario at least this much precipitation would be necessary to contact and transport the tritium from the sign location to a potential point of release in the failed liner system. This assumption provides adequate water to remove all the tritium yet avoid filling the disposal cell prior to liner failure. [parameter changed from 1 year, although not previously stated]

➤ Disposal cell leachate volume: 25,000 m<sup>3</sup>

- The liner system fails after one half-life of tritium (12.3 years) following disposal of the tritium exit signs; all of the available tritium is immediately released from the disposal cell. As discussed at the beginning of this section, failure of the cell liner or leachate collection systems would not be anticipated until long after closure, if at all. [parameter changed from no hold-up]

➤ Cell leachate tritium concentration (point of release): 1,700,000 pCi/L

➤ Activity of tritium released from cell: 27 curies

<sup>2</sup> TESIP observed a damage fraction of less than 0.1 for person-caused damage in dumpsters, and a damage fraction of zero for repeated compaction of signs in an hydraulic compactor. Intact signs in a flat position are reasonably robust; only direct impact to the face of the sign inside the frame is likely to cause damage. Considering activities and compaction likely to occur in a landfill, these damage estimates are reasonably conservative.

#### ATTACHMENT 4: RESPONSE TO RAI #3/REVISED SECTION V.D.6

- Leachate is released from the disposal cell directly to a shallow aquifer used for drinking water. [no parameter change]
- The transport time of tritium in the shallow aquifer from the cell to a drinking water well is one half-life of tritium (12.3 years). Although this value is low (non-conservative) compared with most ground water systems when a buffer zone is considered, it should provide a conservative basis for the maximum reasonable dose from drinking water pathway analysis. [no parameter change]
- Dilution in the shallow aquifer reduces the tritium concentration by a factor of 20, to 5% of the release concentration. A factor of 20 is the default value for EPA Soil Screening Guidance for Radionuclides(EPA 2000b). [parameter changed from 10]

➤ ***Tritium concentration in drinking water: 27,000 pCi/L***

The calculated maximum drinking water concentration under this conservative generic exposure scenario is 27,000 picocuries per liter (pCi/L). Notwithstanding this conclusion, Wal-Mart acknowledges that this scenario results in an estimated concentration is greater than the EPA drinking water standard for tritium, which is 20,000 pCi/L. This would be the limiting condition for any regulatory comparison. However, Wal-Mart does not believe that the NRC should use this unlikely scenario as a basis for any regulatory conclusions regarding the TESIP.

EPA originally established this drinking water concentration limit based on a dose of 4 mrem/year. However, as the technical basis changed for calculating the tritium dose, EPA chose not to change the drinking water concentration standard. The radiation dose associated with this exposure scenario is provided below. The dose to the individual ingesting tritium in water is calculated using the following equation:

$$H = Q * DF * C * I$$

Where

H is the committed dose equivalent in mrem/year,  
Q is the quality factor (set to 1.0 for beta radiation),  
DF is the dose conversion factor for ingestion, in mrem/pCi,  
C is the drinking water concentration (pCi/L), and  
I is the adult drinking water intake of 730 L/year.

The dose conversion factor for tritium ingestion by an adult is  $6.41 \times 10^{-8}$  mrem/pCi ingested, from EPA's Federal Guidance Report No. 11 (Eckerman, et al., 1988). The values in Federal Guidance Report No. 11 are based on the recommendations of the International Commission on Radiological Protection (ICRP) in their Publications No. 26 and 30 (ICRP 1977; 1979-1988). The drinking water rate for an adult is based on consumption of 2 liters per day (Lid), corresponding to 730 L/year (NRC, 1977; Kennedy and Strenge, 1992).

➤ ***Dose from ingesting tritium in drinking water: 1.3 mrem/year***

The estimated maximum dose to an adult from drinking tritium in the well water of this scenario is 1.3 mrem per year, about 30% of the EPA drinking water standard of 4 mrem per year. The tritium ingestion dose conversion factor for a 1-year-old child from ICRP Publication 67 (ICRP 1993) is higher at  $1.8 \times 10^{-7}$  mrem/pCi ingested. However, the water ingestion rate is lower at 330 L/year (0.9 L/d) for an infant (NRC 1977). This would result in a slightly higher dose of 1.6 mrem/year to an infant, if all drinking water were to be taken directly from such a well; this is somewhat higher than the estimated adult dose but still below the EPA drinking water dose limit.

## ATTACHMENT 4: RESPONSE TO RAI #3/REVISED SECTION V.D.6

- Estimated dose from "maximum" exposure scenario: 1.3 mrem

### ***Comparison of Modeling Results to Measured Tritium Leachate Data.***

The estimated leachate concentration from the maximum exposure scenario is compared to results of a project sponsored by the Pennsylvania Department of Environmental Protection, Bureau of Radiation Protection and the Bureau of Waste Management. The purpose of the Pennsylvania project was to investigate radioactive material potentially present in untreated landfill leachate (CEC, 2006). The project included all active and permitted landfills in the Commonwealth of Pennsylvania having a leachate collection system. A total of 54 of the 108 solid waste landfills in Pennsylvania (or half of the total) met this criterion in 2004. Samples of raw, untreated leachate were collected from these landfills, along with five quality control samples. The tritium data for the fall of 2004 indicated positive tritium results in 57 of the 59 leachate samples analyzed. The results ranged from 6.86 to 94,400 pCi/L, with a mean concentration of 25,200 pCi/L. There were 31 leachate samples (or 53% of the total number of samples) with tritium concentrations above the EPA drinking water standard of 20,000 pCi/L. The fall 2005 results showed positive tritium results in 55 of 59 leachate samples analyzed. The results ranged from -62 to 181,700 pCi/L, with a mean concentration of 20,900 pCi/L. There were 16 samples (or 27% of the total number of samples) with tritium concentrations above the EPA drinking water standard of 20,000 pCi/L (CEC, 2006). These results are summarized below and compared to the calculated result from the maximum exposure scenario.

Comparison to Pennsylvania Tritium Leachate Sampling Data

	Mean (pCi/L)	Maximum (pCi/L)
2004 Pennsylvania	25,200	94,400
2005 Pennsylvania	20,900	181,700
Maximum Exposure Scenario	n/a	1,100,000

The disposal cell leachate concentration estimated for this analysis is more than six times higher than the highest result measured in the Pennsylvania study, and more than 50 times the mean concentrations reported. Although there is uncertainty associated with the sources of tritium in the Pennsylvania landfills, this comparison would indicate that the modeling basis used in this study is conservative compared with actual data measured in the field.

The Commonwealth of Pennsylvania considers the EPA drinking water standard of 20,000 pCi/L as an applicable or relevant and appropriate requirement (ARAR) standard for leachates and any other waters at the point of intake to a drinking water supply. However, the Commonwealth concluded that, considering the treatment and discharge processes to which leachate is subject, and the dilution factors associated with human exposure scenarios involving drinking water, none of the fall 2004 or 2005 tritium sampling results would exceed the EPA criteria at the point of intake (CEC, 2006).

For the same reasons, it is also unlikely that the conservative assumptions used in Wal-Mart's generic "maximum exposure" scenario discussed in section 6.2 would result in the EPA drinking water concentration being exceeded for any member of the public.

Texas Department of State Health Services  
1100 W. 49<sup>th</sup> Street  
Austin, TX 78756

Dear Mr. Tucker;

Enclosed is our response to the questions you posed regarding potential residual tritium contamination from our broken tritium exit signs in Texas. The response was prepared by Dade Moeller, Inc., our health physics consultant on this project. I have reviewed Dade's summary and am in agreement with their conclusions. I have also enclosed an assessment of potential exposure and effective dose from tritium under two exposure scenarios that Dade provided to me.

**Please** let **me** know if you need any additional information or have any questions.

Sincerely,

Richard Dailey

Radiation Safety Officer

## ATTACHMENT 5: RESPONSE TO RAI #4

This summary was prepared by Dade Moeller, Inc in response to your questions provided to Mr. Rich Dailey of Wal-Mart on September 2, 2008 and the clarification in your October 17, 2008 email identifying the specific locations of concern to the State of Texas. All discussions pertain to tritium contamination levels that originated from generally-licensed Tritium Exit Signs (TES).

With respect to the tritium contamination levels that may remain in Wal-Mart Store locations 0772,3591 and 1185, we would like to address those individually.

### **WalMart Store (#0772) 3506 S. Hwy 6 South, Houston, Texas (Ref August 12,2008 letter)**

This location contained a contaminated plywood header where the damaged TES was mounted. Based on the high direct-reading instrument measurement (140,000 dpm/100 cm<sup>2</sup>), this header was removed, packaged, and shipped for disposal. It is no longer in that store or within the State of Texas.

With regard to the direct readings, Table 1 of Attachment A to the August 12,2008 letter lists the measurement locations and results. As indicated in the report, the results were provided in units of disintegrations per minute (dpm) per 100 cm<sup>2</sup> and include background. When background (ranging from 1300 to 2700 dpm/100 cm<sup>2</sup> depending on the surface) is subtracted from these measurements, the results (other than for the removed header) are not statistically distinguishable from zero. Additionally, swipe tests of the floor area (Table 2) indicated no detectable contamination. Therefore, it can be concluded that there is no detectable contamination remaining at the store.

### **WalMart Store (#3591) 18700 State Hwy. 105 West, Conroe, Texas (Ref. August 12, 2008 letter)**

This location contained two contaminated plywood headers (1,500,000 dpm/100 cm<sup>2</sup> and 430,000 dpm/100 cm<sup>2</sup>) where damaged TES were mounted. The contaminated portions of the headers were removed, packaged, and shipped for disposal. They are no longer in that store or within the State of Texas.

With respect to the direct readings, Tables 1 and 2 of Attachment A to the August 12, 2008 letter list the measurement locations and results. Similar to Store 0772, the reported results include background, and when background is subtracted (e.g., 3700 dpm/100 cm<sup>2</sup> for the plywood) there is no significant activity remaining and none that exceed the Texas standard [TAC 289.202(ggg)(6)] for either total or removable contamination. Additionally, swipe tests of the floor area (Tables 3 & 4) indicated no detectable contamination.

### **WalMart Store (#1185) 1030 Norwood Park Blvd, Austin, Texas (Ref. June 13,2008 letter)**

## ATTACHMENT 5: RESPONSE TO RAI #4

This location contained a contaminated plywood header (14,000 dpm/100 cm<sup>2</sup> removable) where the damaged TES was mounted. This header was removed, packaged, and shipped for disposal. It is no longer in that store or within the State of Texas.

Swipe test results reported in Table 1 of Attachment A to the June 13, 2008 letter indicated that two isolated locations were slightly above the Texas removable contamination standard of 1000 dpm/100 cm<sup>2</sup>. However, both results (1184 and 1154 dpm per 100 cm<sup>2</sup>) were within the analytical margin of error. In addition, when averaging over an area up to 1 m<sup>2</sup> (as allowed by footnote 'c' to TAC 289.202(ggg) 6), the average contamination levels are less than 500 dpm per 100 cm<sup>2</sup> in both cases, which is significantly below the release standard.

### General Discussion

Although none of the locations discussed above have fixed contamination levels exceeding the allowable levels in TAC 289.202(ggg)(6), if a situation were to exist at other Texas Wal-Mart locations where the remaining contamination were to approach or slightly exceed TAC 289.202(ggg)(6) maximum or average levels, we would propose that no further action be taken based upon the following justifications:

- A risk assessment bounding these levels has already been completed as part of the NRC General License process and the impacts were found to be acceptable.
- Low-levels of fixed tritium contamination pose no internal or external radiological hazard.
- The TAC 289.202(ggg)(6) values are based on NRC Regulatory Guide 1.86, which are in turn based on the "worst-case" beta-gamma emitter, and tritium is at the opposite end of the spectrum..

As a basis for the statement that low-levels of tritium contamination pose little or no hazard to humans, I have attached a technical paper assessing dose from two likely scenarios involving damaged TES. The first involves an airborne exposure to HTO in a limited air volume. The second determines the amount of tritium contamination that must be ingested/absorbed to cause an effective dose of 25 mrems. This value was determined to be 830,000,000 dpm. Our experience at recovering over 500 damaged TES across the nation to date indicates that contamination levels are several orders of magnitude below this figure and that any remaining tritium surface contamination cannot cause an effective dose that would approach or exceed 1 mrem.

As a commitment to its employees and to the regulators, Wal-Mart intends to leave no removable contamination levels above the regulatory standards at any of its locations. With respect to fixed contamination levels remaining, we anticipate addressing those on a case-by-case basis as the only alternative may be destructive decontamination methods.

## ATTACHMENT 5: RESPONSE TO RAI #4

**At** levels we have encountered (a few thousand dpm above the standard), destructive contamination methods that could be employed to remove the remaining fixed contamination would pose a greater risk than leaving the fixed contamination in place. These methods would also not be cost-effective and would not meet ALARA concept guidelines. Specifically, destructive decontamination would involve:

- Use of tools and equipment that pose increased occupational hazards to those performing decontamination activities
- Use of destructive decontamination methods that risk generating airborne contamination
- Greater costs to decontaminate these small areas that would not be cost-effective in avoiding the minimal potential doses, as noted above.

For these reasons, we state in each report the levels of any fixed tritium contamination remaining and our intention for no further action, if the levels warrant.

## ATTACHMENT 5: RESPONSE TO RAI #4

### **Estimate of Potential Dose from Immediate Exposure to Broken Tritium Exit Sign**

The dose from a broken exit sign depends on the amount of tritium released, the fraction of the released amount that is in the form of tritiated water (HTO) vs. tritium gas, the volume of air in the room, the air turnover rate in the room, and the exposure time.

The comprehensive document "Tritium Radioluminescent Devices Health and Safety Manual" (PNL-10620) indicates that the dose to a person in proximity to a sign when it is broken is primarily attributable to inhaled water vapor, but is also associated with skin absorption. The total dose is represented by the equation:

$$H = Q * 1.33 * C * T,$$

Where H is the committed dose equivalent in rem, Q is the quality factor (dimensionless, assumed to be 1 for tritium), C is the air concentration of MIO in microcuries/milliliter (uCi/mL), and T is the exposure time in minutes.

As an extreme example, assume a person is in a small room (10 ft X 10 ft X 8ft) when a sign is broken, remains in the room for 1 hour, and there is no air turnover. Assume further that the release involves the full inventory of tritium in a light (20 Ci) and that 12.2% of the material is in the form of HTO. Note that these two assumptions overestimate the release because the value of 12.2% is the maximum reported in PNL-10620 and is associated with a 14-year-old sign, and the 30 Ci assumption represents the activity in a new sign.

Under the above conditions, the average concentration of HTO in the room would be 0.1 uCi/ml, and the dose would be  $1.33 * 0.1 * 60 = 8$  rem. This should be considered an upper bound dose, because the actual amount of HTO released from a damaged sign is likely to be less than assumed, the room would likely be larger, the air turnover rate would likely not be zero, and the person would not be likely to remain in the room for a full hour if a catastrophic event occurred resulting in the complete breakage of a sign. A more realistic estimate would result in a dose less than 10% of the upper bound, i.e., less than 1 rem. For comparison purposes, PNL-10620 estimated (in Table 6.6) a dose of 1.3 rem from a release of 0.5 Ci of HTO in a 1000 cubic foot room with an air turnover rate of once per hour and a stay time of 1 hour. In practice, bioassay results from personnel involved in breakage incidents indicate doses substantially less than 1 rem.

### **Estimate of Potential Dose from Surface Contamination**

In some cases a light may be broken, but the light remains in place (e.g., on a wall or door) for an indefinite period of time because the breakage was not recognized immediately and/or the employee was not aware that action should be taken. In these cases, the area immediately surrounding the light can become contaminated, and this contamination may be present for months afterward. The potential doses from such residual contamination are substantially less than the potential doses associated with the initial air release. The question at hand is how much contamination would be needed to result in a dose of 25 mrem to an employee under bounding conditions, i.e., how much contamination warrants immediate action.

## ATTACHMENT 5: RESPONSE TO RAI #4

Contaminated surfaces near a damaged tritium exit light could result in doses to personnel via primarily the ingestion or skin absorption pathways. The ingestion dose coefficient for HTO is 66 rem per Ci (PNL-10620), which translates to  $3.0 \times 10^{-8}$  millirem per disintegration per minute (mrem/dpm). The dose coefficient is essentially the same for HTO absorbed through the skin.

In order to receive a dose 01-25 mrem, a person would need to ingest (or absorb)  $25/3.0 \times 10^{-8} = 830$  million dpm of tritium. In other words, a person coming in contact with a contaminated wall would need to ingest or absorb all of the contamination on a  $100 \text{ cm}^2$  surface contaminated to a level of 830 million dpm/ $100 \text{ cm}^2$ , or all of the contamination on a  $1 \text{ m}^2$  surface contaminated to a level of 83,000 dpm/ $100 \text{ cm}^2$ . Under realistic contamination transfer assumptions (i.e., 10% of the material is transferred to the hands, and 10% of the material on the hands is absorbed or ingested), the doses would be less than 1 mrem even at these contamination levels.

The above numbers compare favorably to the clearance (i.e., free release) levels of 600,000 dpm/ $100 \text{ cm}^2$  established for tritium in the ANSI/HPS standard "Surface and Volume Radioactivity Standards for Clearance" (ANSI/J-IPS N13.12-1999). This standard explains that the values in NRC Regulatory Guide 1.86 were not intended to apply to tritium. In fact, the NRC and most state regulatory agencies agree, which explains why tritium surface contamination levels exceeding the Regulatory Guide 1.86 values are typically allowed, on a case-by-case basis, by these agencies.

In conclusion, surface contamination may be detectable near exit signs broken four or more months in the past, but the associated contamination levels are not likely to result in doses of regulatory concern and would not warrant immediate action for health and safety reasons. Regulatory issues are the predominant concern, because the NRC and states do not formally recognize the ANSI/HPS N13.12 values except in case-by-case situations.
