## Shearon Harris Nuclear Power Plant Units 2 and 3 (HAR) Future Wetlands Impact Analysis

### Introduction

The proposed expansion of the Progress Energy Carolinas, Inc. (PEC) nuclear facility will include the construction of two new nuclear units: Shearon Harris Nuclear Power Plant Units 2 and 3 (HAR). The HAR will be collocated with the existing Shearon Harris Nuclear Power Plant Unit 1 (HNP). The HAR site is located in southwest Wake County and southeast Chatham County, North Carolina. The water level of Harris Lake will be raised to provide the water needed to meet HAR operation objectives and to allow for flexibility in meeting water requirements during drought conditions when withdrawal from the Cape Fear River may be curtailed. The current normal pool elevation for Harris Reservoir is 67.1 meters (m) (220 feet [ft.]) National Geodetic Vertical Datum of 1929 (NGVD29) and the proposed pool elevation for Harris Reservoir is 73.1 m (240 ft.) NGVD29.

The U.S. Nuclear Regulatory Commission (NRC) conducted an audit from July 14 through July 18, 2008, on the HAR Environmental Report (ER). At the audit, there were questions regarding wetland impacts and the formation of new wetlands associated with an increased water level of Harris Lake. During the audit, two activities were discussed: (1) a jurisdictional wetland determination to quantify the amount of existing wetlands that would be impacted by the proposed project; and (2) an estimate of the area for potential formation of emergent and forested or mixed forested wetlands.

With regard to the first activity, a jurisdictional wetland delineation for the project area, including the identification of emergent areas associated with Harris Lake, is currently being completed. This work covers the area to be inundated between the 220-ft. and 240-ft. contour lines, as well as additional areas where ground disturbing activities are planned (for example, laydown areas and proposed transportation projects). This delineation is expected to be finalized by April 2009.

To accomplish the second activity, a geographic information system (GIS) analysis based on topography and slope of existing wetlands was suggested during discussions with the NRC and U.S. Army Corps of Engineers (USACE) staff (NRC Information Needs LU-1 and TE-7 from the NRC July 2008 ER audit).

The purpose of this technical memorandum (TM) is to describe the GIS analysis discussed with the NRC and the USACE at the July 2008 ER audit. This analysis is intended to provide the NRC with a general description of the areas where wetlands could form due to an increased lake level. This approach was discussed during the audit and is based on the fact that the hydrology of the wetlands associated with the area to be inundated is driven by the water level of Harris Lake. Additionally, the NRC has specifically requested graphics showing areas of potential formation of wetlands depending on slope and soil classification.

This analysis uses existing National Wetlands Inventory<sup>1</sup> (NWI) data, soils, topography, and slope of existing wetlands. These data were selected since they are publicly available and exist for the entire area to be examined. Due to the age and known limitations of the NWI data, this analysis should not be strictly interpreted in terms of changes in acreage. The current wetland jurisdictional delineation has not been finalized and was not available for this effort. The USACE-verified wetland delineation will describe existing wetlands and will be used to develop the final wetlands mitigation plan.

### **Basis for Technical Approach**

Harris Reservoir was created by impounding Buckhorn Creek, a tributary of the Cape Fear River. Buckhorn Creek has five primary tributaries above the Harris Reservoir Dam: Tom Jack Creek, Thomas Creek, Little White Oak Creek, White Oak Creek, and Cary Branch (PEC 2006). The dam was completed in late 1980, and the reservoir reached its full pool elevation of 67.1 m (220 ft.) in February 1983. Harris Lake (main body) has a surface area of approximately 3610 acres (ac.) (5.6 square miles [mi.<sup>2</sup>]), a maximum depth of 18 m (59 ft.), and a mean depth of approximately 5.3 m (17.4 ft.). In 2006, preliminary field-reconnaissance-level observations found numerous wetlands within the 67.1-m to 73.2-m (220-ft. to 240-ft.) NGVD29 elevations. At that time, approximately 117 ac. of wetlands were estimated to exist within the 67.1 m to 73.2 m (220 ft. to 240 ft.) NGVD29 contours, as determined by field observation and described in HAR ER Subsection 2.4.2.1 (CH2M HILL 2007). It is assumed that between 1983, when Harris Lake reached its full pool elevation, and 2006, the majority of these wetlands were formed. As discussed at the ER audit, in theory increasing the water level will have the potential to create new wetland areas similar to those that currently exist in the immediate vicinity of Harris Lake (associated with the 240-ft. contour).

Raising the lake by 20 ft. will nearly double the perimeter from 457,281 linear ft. to 784,327 linear ft. Relatively level areas exist near the 240-ft. contour where wetlands will form when the water level rises. Because the areas will become inundated or saturated for much of the biologically active portion of the year, wetlands will form. Where the areas are below the 240-ft. mark, emergent or willow/alder shrub wetlands would be expected to form. Where the elevation is slightly above 240 ft., the saturated ground conditions would lead to development of forested or mixed forested wetlands. These types of wetlands developed around Harris Reservoir after it was filled. Once the hydrology is set, hydrophytic vegetation propagules will establish in suitable areas around the reservoir (very gentle to gentle slopes around the water line). Hydric soils will eventually form as a result of the accumulation of organic matter and development of anaerobic conditions. This is the same process by which the current Harris Reservoir fringe wetlands formed; they did not exist prior to construction of the reservoir (as described in the NRC Information Need TE-7).

The audit included discussions on the fact that hydrology of the area adjacent to lands to be inundated will be driven by the water level of Harris Lake. This change in hydrology will provide the potential for wetland creation, much like the creation of wetlands that resulted from the construction of Harris Lake. It was discussed that a GIS analysis could use existing

---

<sup>1</sup>NWI data is based on the analysis of high altitude imagery. Wetlands are identified based on vegetation, visible hydrology and geography. A margin of error is inherent in the use of imagery; thus, detailed on-the-ground inspection of any particular site may result in revision of the wetland boundaries or classification established through image analysis.

Federal, state, and local regulatory agencies with jurisdiction over wetlands may define and describe wetlands in a different manner than that used in this inventory. There is no attempt, in either the design or products of this inventory, to define the limits of proprietary jurisdiction of any Federal, state, or local government or to establish the geographical scope of the regulatory programs of government agencies.

digital data on soils, slope (or topography), and NWI to support the statements in the ER that new wetlands could be created by the new level of the lake. These data could be used to determine the slope of existing wetlands (as defined by NWI or the presence of hydric soils based on soil data) and then used to identify potential areas where wetlands could be created. This approach was agreed upon to provide a relative measure of effects of the increased lake level since detailed information was not known at that time of the audit. This analysis is based on desktop review and manipulation of existing data that were not developed for detailed predictive modeling. The final determination of wetland loss and any new wetland creation will be based on field surveys and a final mitigation plan that will need to be approved by the USACE.

## **Methodology**

First, two impact areas were identified for the analysis: (1) the area of wetlands plus hydric soils associated with the existing lake level, and (2) the area associated with an increased lake level. The existing impact area is defined as the land that extends from the shoreline of Harris Lake (220-ft. contour) to the 240-ft. contour boundary (see Figure 1). The future impact area is defined as the land that extends from the 240-ft. to the 260-ft. contour boundary (see Figure 1). The existing impact area was selected to establish an area of similar topographic change as the area to be impacted. The areas in the existing impact area classified either as NWI wetlands, hydric soils, or as both NWI wetlands and hydric soils were selected. The two data sets were merged so that an area mapped as both NWI wetland and as hydric soils would not be included as separate units in the analysis. This defined an area within the 220-ft. to 240-ft. contour lines of NWI wetlands and hydric soils. These slope and soils classifications were then used as selection criteria to identify areas within the 240-ft. to 260-ft. contour lines where physical conditions indicated the potential for future wetland formation. To minimize the area considered suitable for future wetland formation, any areas within the 240-ft. to 260-ft. contour lines that were identified as either NWI wetlands or hydric soils at present were considered to already be wetland areas and were removed from consideration for potential future wetland formation.

## **Data Collection**

GIS data were collected from a variety of sources to provide localized information on soil types and components, vegetation, and topography. Datasets used in this analysis and their source agencies are presented in Table 1.

TABLE 1. SOURCE DATA

Dataset	Format	Source
Soils	Polygon	Natural Resources Conservation Service (NRCS) Soils Data Mart (NRCS 2007)
2-foot Contours	Polyline	North Carolina Department of Transportation GIS Unit website (NCDOT 2007)
20-foot Digital Elevation Models	Raster Grid	NCDOT GIS Unit website (NCDOT 2007)
Wetlands	Polygon	U.S. Fish and Wildlife Service (USFWS 1983)

## Data Processing

Data processing began by downloading the datasets listed in Table 1. The datasets were then reduced to focus on only the areas related to the HAR project. Intermediary files were created from county specific datasets for soils, wetlands, and slope. These files were then used to follow the methodology described above. Listed below are the general steps used to prepare the series of final datasets containing soil-type slopes classified by wetlands, major hydric soils, and non-wetland non-hydric soils.

1. The two impact areas—existing and future—were defined. The existing impact area is defined as all areas between the 220-ft. and 240-ft. contour lines associated with Harris Lake. The future impact area is defined as all areas between the 240-ft. and 260-ft. contour lines. This defined two non-overlapping geographical areas.
2. The county wide soils dataset was “clipped” to the existing and future impact areas to provide reduced datasets showing soil types for all areas within the existing and future impact areas. These two “clipped” datasets were then merged into one dataset with areas uniquely identified as occurring either in the existing or future impact area. In this way, analyses could be performed on one dataset with unique non-overlapping areas.
3. The subunits in the dataset are based on soil polygons as defined by the NRCS (2007) data. The attributes of these subunits were then defined on tabular data from the NRCS data to include soil-type name, major component classification, and hydric rating.
4. The NWI dataset was “clipped” to the existing and future impact areas to provide a reduced dataset to show NWI areas within the existing and future impact areas. These two “clipped” datasets were then merged into one dataset with areas uniquely identified as NWI areas occurring in either the existing or future impact area. In this way, analyses could be performed on one dataset with unique non-overlapping areas.
5. The two datasets (NWI dataset and soil dataset) were merged to create a single dataset that uniquely identified a geographic area based on the polygons from the NRCS data. These polygons included information on the soil classification, including the presence or absence of hydric soils, and if the polygon were classified as NWI wetlands, included the type of wetland.

6. The digital elevation models (NCDOT 2007) for Wake and Chatham counties were downloaded from the NCDOT website. The data for each county were then processed using ARCGIS to create slope grid data polygons. These polygons were square-shaped grid cells with 20-ft. sides. These uniquely identified polygons contained data on the slope of each polygon. The two county datasets were then merged into a single dataset.
7. The dataset containing information on soils and wetlands for the two impact areas was intersected with the dataset containing information on slope to create a dataset containing information on unique geographical areas within each impact area. Each unique geographical area was defined by the original shape of the soil area and the 20-ft. grid cell. This resulted in irregularly shaped cells that had an area of less than or equal to the original 20-ft. grid cell. This process allowed data to be analyzed for unique non-overlapping cells that contained data on the slope of the cell, the soil classification (including the presence of hydric soils), and classification as a NWI wetland (and type).

The output for the existing impact area wetlands and major hydric soils was then used to calculate a weighted average of slope (weighted by area) of 2.75 percent. The average of the slope is heavily influenced by very small polygons in the GIS analysis. To eliminate the bias towards these very small areas, a weighted average was calculated. This weighted average served as the slope criteria for identifying soil types in the future impact area that will have the potential for becoming wetlands.

## Analysis Results

Total acreage by impact area and soil category is presented in Table 2. The raw data for each of these categories are provided in Attachment A. Since all soil types may not have the ability to become wetland soils even in the presence of the appropriate hydrology, the list of areas of future wetlands was further refined to include only the same soil types as the soil types in the existing wetland category; these wetlands are called Adjusted Potential wetland areas in Table 2. Figures 2 through 4 show graphically the areas identified as having the potential for future wetland formation relative to the new lake level.

**TABLE 2. ANALYSIS RESULTS**

Impact Area	Soil Category	Total Acres
Existing	NWI Wetlands plus Hydric Soils <sup>1</sup>	802
Future	Potential wetland areas <sup>2, 3</sup>	1338
Future	Adjusted Potential wetland areas <sup>2, 3</sup>	1081

Notes:

<sup>1</sup>The weighted average of the slope for this soil category is 2.75 percent.

<sup>2</sup>The total acreage for this soil category has been filtered for slopes less of 2.75 percent.

<sup>3</sup>Areas identified as either NWI wetlands or hydric soils based on existing data were removed from consideration for potential future wetland formation.

The area of the existing impact area is approximately 3570 ac. (area to be inundated) and the area of the future impact area is approximately 4828 ac. (area between 240-ft. and 260-ft. contour lines). This increase in area is due to the increase in the length of shoreline from an

existing 457,281 linear ft. to 784,327 linear ft. (PEC 2008). This analysis is not designed to predict exactly how many acres would be transformed to wetlands with a larger lake. However, the results of this analysis support the theory that a larger lake could support the formation of wetlands associated with the hydrology of the lake and that there could be no net loss of wetland acreage as a result of the elevation change.
