## **Exhibit SNC 000001**

# Environmental Report for Southern Nuclear Operating Company's Vogtle Early Site Permit Application

#### **PUBLIC DISCLOSURE VERSION**

## **SOUTHERN NUCLEAR OPERATING COMPANY**

## **Vogtle Early Site Permit Application**

Part 3
Environmental Report

**Revision 2** 

## **Chapter 1 Introduction**

### 1.0 Introduction

In accordance with the provisions of 10 CFR 52, Early Site Permits; Standard Design Certifications; and combined Licenses for Nuclear Power Plants, and supporting guidance, Southern Nuclear Operating Company (SNC or Southern Nuclear) has developed an application to the U.S. Nuclear Regulatory Commission (NRC) for an early site permit. An Early Site Permit (ESP) represents NRC approval of a site or sites for one or more nuclear power facilities, separate from the filing of an application for a construction permit or combined license for such a facility. The SNC ESP application is for the Vogtle Electric Generating Plant (VEGP) site in Burke County, Georgia. In accordance with NRC regulations, SNC has included in its application this environmental report (ER) that analyzes impact to the environment from construction, operation, and decommissioning of two additional nuclear reactors at this site. NRC will use the environmental report to develop an Environmental Impact Statement meeting the National Environmental Policy Act (NEPA) requirement that federal agencies consider the impacts that their actions (e.g., permit issuance) might have on the environment.

## 1.1 Proposed Action

The proposed Federal action is issuance, under the provisions of 10 CFR Part 52, of an Early Site Permit (ESP) to SNC for the VEGP site for two additional nuclear units, both of which will be Westinghouse Electric Company, LLC (Westinghouse), AP1000, advanced light water reactors. In addition, SNC proposes a plan for redressing the environmental effects of certain sitepreparation and preliminary construction activities, i.e., those activities allowed by 10 CFR 50.10(e)(1), performed by an ESP holder under 10 CFR 52.25. In accordance with the plan, the site would be redressed if the NRC issues the requested ESP (containing the site redress plan), the ESP holder performs these site-preparation and preliminary construction activities, the ESP is not referenced in an application for a construction permit or COL, and no alternative use is found for the site. While the ESP would not authorize construction and operation of any new nuclear units (other than those site-preparation and preliminary construction activities addressed herein), this ER analyzes the environmental impacts that could result from the construction and operation of one or two new nuclear units at the VEGP site or at one of the alternative sites. These impacts are analyzed to determine if the proposed ESP site is suitable for the addition of the new nuclear units and whether there is an alternative site that is obviously superior to the proposed site.

#### 1.1.1 Purpose and Need

Georgia Power Company (GPC), through the Georgia Public Service Commission's Integrated Resource Planning process, has identified a need for additional base load generation by no later than 2015. This need was identified through a detailed economic analysis associated with the IRP process. SNC is submitting the ESP application to preserve the option for new nuclear generation to meet GPC needs as well as the needs projected by the co-owners.

Underlying this need for baseload generation is the role that the State of Georgia and the NRC play in GPC business decision to pursue new nuclear generation. States retain approval authority over the types of electric generation that will be constructed and operated within their borders. However, states (and facility owners) cannot include nuclear power in their generation mix without NRC approval of the construction and operation of a nuclear generation facility. Conversely, NRC approval gives the state a generation option that the state may or may not exercise, at its discretion.

The NRC established the licensing process used by SNC in 10 CFR Part 52. NRC regulation 10 CFR 52 Subpart C, *Combined Licenses*, allows generating entities to apply for a combined license, that is, a combined construction permit and operating license for a nuclear facility. A COL authorizes construction and operation of the facility. Part 52 includes the ability to seek an ESP that allows an applicant to bank a reactor site for up to 20 years prior to obtaining a COL. A COL can reference an ESP for environmental issues.

The ESP process addresses and resolves site safety, environmental protection, and emergency preparedness issues. As part of an ESP application, the applicant must prepare an environmental report that addresses the safety and environmental characteristics of the site.

An application for a COL can reference an ESP issued under 10 CFR 52 Subpart A, *Early Site Permits*. In general, if the combined license application references an ESP, the application need not contain certain information or analyses submitted to NRC in connection with the early site permit. Instead, the combined license application must contain the following:

- Information and analyses otherwise required
- Information sufficient to demonstrate that the facility falls within the parameters specified in the ESP
- Information to resolve any other significant environmental issue
- Information not considered in any previous proceeding on the site or design

In accordance with NRC regulations, SNC is submitting this ESP application in order to obtain the option of including new nuclear capability in the future generation mix for the owners and the state of Georgia. The ESP also allows for a Limited Work Authorization (LWA) to perform certain activities such as backfill and initial concrete pours subject to redress, in advance of issuance of a COL.

Page intentionally left blank.

## 1.2 The Proposed Project

Section 1.2 provides a brief summary of project information that subsequent chapters and sections, particularly Chapter 3, *Plant Description*, describe in detail.

#### 1.2.1 The Applicant and Owners

Georgia Power Company, Oglethorpe Power Corporation, the Municipal Electric Authority of Georgia, and the City of Dalton, Georgia an incorporated municipality in the State of Georgia acting through its Board of Water, Light, and Sinking Fund Commissioners (Dalton Utilities) are the owners of the VEGP site and existing facilities. SNC has been authorized by GPC, acting as agent for the other owners (also known as co-owners) of the existing VEGP, to apply for an ESP for the VEGP site.

SNC is the plant licensee and operates VEGP Unit 1 and Unit 2 under contract with the owners. GPC and SNC are subsidiaries of Southern Company, and SNC is the licensed operator for all existing Southern Company nuclear generating facilities. SNC's business purpose is management and operation of nuclear generating facilities owned or co-owned by Southern Company subsidiaries. The SNC ESP application, Part 1, *Administrative Information*, Section 1.3 provides additional information about Southern Company, GPC, the VEGP co-owners and SNC.

#### 1.2.2 Site Location

The VEGP site is located on the west bank of the Savannah River in eastern Burke County, in east-central Georgia. The site is approximately 100 miles northwest of Savannah, Georgia, and approximately 26 miles southeast of Augusta, Georgia, and across the river from the U.S. Department of Energy's Savannah River Site (Barnwell County, South Carolina). The proposed VEGP Units 3 and 4 footprint will be adjacent to and west of the existing VEGP Units 1 and 2. The original VEGP design was for a four unit plant. The new VEGP Units 3 and 4 will occupy generally the same area that was developed for the original VEGP Units 3 and 4 when the plant was first proposed for construction.

#### 1.2.3 Reactor Information

SNC has selected the Westinghouse Electric Company, LLC (Westinghouse), AP1000 advanced light water reactor for construction and operation of two new units at the VEGP site. The NRC has approved the Design Control Document (DCD) for the AP1000. Previous ESP applications included the AP1000 technology, in addition to others, in their plant parameters envelopes. Unlike previous ESP applicants, SNC is not relying on a plant parameters envelope methodology to bound environmental impacts. The SNC application analyzes the environmental impacts of two AP1000 reactors at the VEGP site to be referred to as VEGP Units 3 and 4 in this application.

ER Section 3.2, *Reactor Power Conversion System*, provides additional information on the AP1000.

#### 1.2.4 Cooling System Information

Each new unit will use a recirculating cooling water system that includes a natural draft cooling tower similar to the towers for Units 1 and 2. A new recessed shoreline intake structure will supply makeup water from the Savannah River to Units 3 and 4. A common line for Units 3 and 4 will be constructed to discharge cooling tower blowdown and other miscellaneous wastewater to the river. ER Section 3.4, *Cooling System*, provides additional detail.

## 1.2.5 Transmission System Information

The existing VEGP site is interconnected with the regional power grid via two 500 kV transmission lines and four 230 kV transmission lines. SNC has determined one new 500 kV transmission line will be added initially to handle the additional new generation capacity to the electric grid. SNC has performed a Macro-Corridor assessment for this proposed new 500 kV line to evaluate the NEPA aspects of line construction and operation. ER Section 3.7, *Power Transmission System*, provides additional detail.

## 1.2.6 Pre-application Public Involvement

The NRC held public outreach meetings in Waynesboro, Georgia, on May 10 and 11, 2006, to provide information to the public on the ESP review process, and to provide information on opportunities for public involvement in that process for the VEGP site. The meetings included a discussion of perspectives, roles, and responsibilities of the NRC with regard to VEGP. The May 10 meeting was held at the Burke County library. It utilized an informal open house format that allowed the public the opportunity to speak directly with NRC staff. On May 11, the NRC staff held a second public meeting at the Augusta Technical College Waynesboro Branch. The meeting began with another open house, followed by staff presentations on the regulatory framework for the ESP review process and a question-and-answer session. The staff also discussed opportunities for public involvement during the application review process.

#### 1.2.7 Construction Start Date

The ESP does not constitute a decision or approval to build new units. SNC is pursuing the necessary steps to preserve the nuclear generation option. SNC has notified the NRC that they plan to submit a COL application in March of 2008 that could support a projected construction start date sometime in 2010. NRC regulations (10 CFR 50.10, *License Required*) provide for ESP holders to perform limited site preparation activities. SNC estimates that such site preparation activities will take 18 months to complete. SNC estimates that construction of two

AP1000 units will occur over about a 5-year period, beginning after NRC approval of an SNC COL application. ER Section 3.9, *Construction Activities*, provides additional detail.

Page intentionally left blank.

## 1.3 Status of Reviews, Approvals and Consultations

SNC has divided its discussion of the status of Federal, state, and local environmental protection licenses, permits, reviews, approvals, and consultations, collectively called authorizations, by activity. Tables 1.3-1 through 1.3-5 identify, for each activity, the following information:

- Jurisdictional agency
- Authority, law, or regulation that dictates the requirement
- Name of the required authorization
- License or permit number as applicable
- Expiration date of any existing licenses or permits
- Description of the requirements to be fulfilled by SNC prior to issuance of the authorization

The tables are structured on the assumption that authorizations for previously-initiated and ongoing activities were captured in the table representing the initiation of the work and, therefore, not repeated in subsequent tables. Except for ESP issuance, discussed below, SNC has not completed work to secure any other necessary authorizations and, therefore, the columns for permit numbers and expiration dates have been left blank. SNC will apply for and receive any required authorizations prior to initiating the activity. The following sections describe the activities to be authorized.

#### 1.3.1 ESP Issuance

Table 1.3-1 lists ESP authorizations required prior to NRC issuance of an ESP. As shown, four authorizations are consultations that NRC must undertake in accordance with following statutes:

<u>Endangered Species Act</u> - The Endangered Species Act requires Federal agencies to ensure that agency action is not likely to jeopardize any species that is listed or proposed for listing as endangered or threatened. Depending on the action involved, the Act requires consultation with the U.S. Fish and Wildlife Service (USFWS) regarding effects on non-marine species, the National Marine Fisheries Service (NMFS) for marine species, or both. Due to the presence of diadromous fish categorized as marine species in the Savannah River near the Vogtle site, the NRC must consult with both USFWS and NMFS. In addition, as a matter of policy, the NRC consults with states regarding state-protected species.

<u>National Historic Preservation Act</u> - The National Historic Preservation Act requires federal agencies having the authority to license any major federal action, prior to issuing the license, to take into account the effect of the undertaking on historic properties and to afford the Advisory Committee on Historic Preservation an opportunity to comment on the undertaking. Committee regulations provide for establishing an agreement with any State Historic Preservation Officer (SHPO) to substitute state review for Committee review (35 CFR 800.7). The NRC will consult with both the Georgia SHPO and the South Carolina SHPO due to the site's location.

Federal Clean Water Act Section 401 requires for any activity that may result in a discharge into navigable waters, a certification from the state that the discharge will comply with applicable Clean Water Act requirements, including state Water Quality Standards. Certain construction-related activities conducted under the authority of the ESP will likely require a Construction Stormwater Permit issued by the Georgia Department of Natural Resources – Environmental Protection Division. This is a general permit and coverage is obtained by submitting a Notice of Intent (NOI) requesting coverage under the general permit. The State of Georgia provides a generic 401 certification for the general permit.

The Federal Coastal Zone Management Act imposes requirements on applicants for a federal license to conduct an activity that could affect a state's coastal zone. The Act requires the applicant to certify to the licensing agency that the proposed activity will be consistent with the state's federally approved coastal zone management program. The VEGP site is approximately 100 air miles and 150 river miles from the ocean. An existing VEGP transmission line traverses Georgia coastal counties. Construction of new reactors at the VEGP site will not result in any changes to this line. Due to the site's distance from the coast, small environmental effects, and lack of transmission line changes, SNC has concluded that the proposed action will not affect Georgia's coastal resources and that consistency certification requirements are not applicable.

#### 1.3.2 Pre-Construction Activities

Pre-construction activities are those that NRC can authorize for undertaking prior to NRC issuance of a construction permit. A subset of these activities is limited to site preparation and construction of structures, systems, and components that are not nuclear-safety related. NRC approval of such activities can be obtained in either of two ways. First, if an ESP application includes a site redress plan, ESP issuance constitutes NRC authorization to conduct the activities. Second, rather than waiting for permit issuance, the ESP applicant can apply for authorization to perform these activities, commonly referred to as Limited Work Authorization 1, or LWA-1, early. The NRC would grant such authorization only after the presiding officer for the mandatory ESP hearing determines that NRC has satisfied NEPA requirements and that there is reasonable assurance that the proposed site and reactor are suitable from an environmental and radiological standpoint. This enables the applicant to start pre-construction before resolution of all safety issues and exhaustion of all appeals to construction permit issuance. SNC has included a site redress plan in this ESP application and is also preserving its option to seek a separate LWA-1 authorization. Table 1.3-2 lists authorization required for pre-construction activities.

The other subset of pre-construction activities is nuclear-safety-related and is commonly referred to as Limited Work Authorization 2, or LWA-2. The NRC would grant such authorization only after, in addition to making the same determinations as for LWA-1, making a determination that there are no unresolved safety issues relating to the LWA-2 activities. SNC is preserving its

option to seek an LWA-2 but has identified no required non-NRC authorizations not already included for LWA-1 or actual construction.

#### 1.3.3 Site Redress Activities

Table 1.3-3 lists authorizations required prior to conducting site redress activities. "Redress activities" are activities that the licensee must perform to return the site to an environmentally stable and aesthetically acceptable state if LWA activities were undertaken but construction abandoned.

### 1.3.4 Construction Activities

Table 1.3-4 lists authorizations required prior to start of construction activities.

### 1.3.5 Operation

Table 1.3-5 lists authorizations required prior to start of operation.

Table 1.3-1 Authorizations Required for Early Site Permit

Agency	Authority	Requirement	License/ Permit No. (1)	Expiration Date (1)	Activity Covered
USFWS	Endangered Species Act	Consultation regarding potential to adversely impact protected species (non-marine species)	NA	NA	Concurrence with no adverse impact or consultation on appropriate mitigation measures.
NMFS	Endangered Species Act	Consultation regarding potential to adversely impact protected species (marine species)	NA	NA	Concurrence with no adverse impact or consultation on appropriate mitigation measures.
GDNR	National Historic Preservation Act, (36 CFR 800)	Consultation regarding potential to adversely affect historic resources	NA	NA	Confirm site construction or operation would not affect protected historic resources.
South Carolina Department of Archives and History	National Historic Preservation Act, (36 CFR 800)	Consultation regarding potential to adversely affect historic resources	NA	NA	Confirm site construction or operation would not affect protected historic resources.
GDNR	Federal Clean Water Act (FCWA) (33 U.S.C. 1251 et seq.)	Section 401 Certification			Compliance with water quality standards.

USFWS - U.S. Fish and Wildlife Service

NMFS - National Marine Fisheries Service

Agency	Authority	Requirement	License/ Permit No.	Expiration Date	Activity Covered
State of Tennessee Department of Environment and Conservation Division of Radiological Health	Tennessee Department of Environment and Conservation Rule 1200-2-10.32	Revision of existing Tennessee Radioactive Waste License-for-Delivery			Transportation of radioactive waste into the State of Tennessee.
State of Utah Department of Environmental Quality Division of Radiation Control	R313-26 of the Utah Radiation Control Rules	Revision of existing General Site Access Permit			Transportation of radioactive materials into the State of Utah.
GPSC	GA Radiation Control Act (O.C.G.A. 31-13-1 et seq.), GA Rules and Regulations 391-3-1706	Revision of existing General Permit – Transportation of Radioactive Materials			Transportation of radioactive materials in the State of Georgia.

Assumes that SNC obtained the authorizations that Tables 1.3-2 and 1.3-4 identify.

## 1.4 Methodology

NRC regulation 10 CFR 52.17(a)(2) specifies the contents of an Environmental Report (ER) for an ESP application and Regulatory Guide 4.2, *Preparation of Environmental Reports for Nuclear Power Stations, Revision 2,* July 1976 (RG 4.2) provides guidance to applicants preparing environmental reports for nuclear power stations. The NRC's *Standard Review Plans for Environmental Reviews for Nuclear Power Plants, Revision 0,* 1999 (NUREG-1555), provides guidance for NRC staff to use when conducting environmental reviews of applications related to nuclear power plants. Because RG 4.2 is an earlier NRC document (1976) and NUREG-1555 is relatively new (1999), SNC chose to look to the latter for guidance in establishing the format and content of its environmental report. SNC has provided additional information and organization in the material presented as seemed appropriate when applying lessons learned from the first three ESP applicants. SNC prepared Table 1.4-1 to verify conformance with regulatory requirements. The table identifies each requirement and indicates where in the ER SNC has responded to the requirement.

SNC also evaluated the conclusions of NRC's *Generic Environmental Impact Statement for License Renewal of Nuclear Plants*, Revision 0, 1996 (NUREG-1437), for input in assessing the impacts of the new nuclear units on the VEGP site. SNC concluded that if characteristics of the proposed reactors are similar to those of the existing fleet, then NUREG-1437 significance determination criteria could be applied in the ESP environmental review. SNC has indicated in its ER where it has used NUREG-1437 in assessing VEGP environmental impacts.

## **Chapter 2 Environmental Description**

Chapter 2 describes the existing environmental conditions at the Vogtle Electric Generating Plant (VEGP) site, the site vicinity and the region. The environmental descriptions provide sufficient detail to identify those environmental resources that have the potential to be affected by the construction, operation, or decommissioning of the new units. The chapter is divided into nine sections:

- Site Location (Section 2.1)
- Land (Section 2.2)
- Water (Section 2.3)
- Ecology (Section 2.4)
- Socioeconomics (Section 2.5)
- Geology (Section 2.6)
- Meteorology, Air Quality, and Noise (Section 2.7)
- Related Federal and Other Project Activities (Section 2.8)
- Existing Plant Site Characteristics, Design Parameters, and Site Interface Values (Section 2.9)

The following descriptions should help the reader understand the scope of the discussion:

- VEGP site the 3,169 acre site as described in the Unit 1 and Unit 2 licenses
- New plant (VEGP Units 3 and 4) footprint the approximately 500 acres within the VEGP site
  that will encompass the construction and operation of the new nuclear units
- Vicinity the area within approximately the 6- or 10-mile (depending on the issue) radius around the VEGP site
- Region the area within approximately the 50-mile radius around the VEGP site

Page intentionally left blank.

### 2.1 Site Location

SNC proposes to construct and operate two Westinghouse AP1000 reactors at VEGP in Burke County, Georgia. The two AP1000 reactors will be referred to as VEGP Units 3 and 4.

The proposed early site permit (ESP) is for the existing 3,169-acre VEGP site. VEGP Units 3 and 4 and supporting infrastructure will be sited in the area delineated in Figure 2.1-1. The centerline of VEGP Units 3 and 4 will be approximately 2,100 feet west and 400 feet south of the center of the existing Unit 2 containment building. Unit 4 containment will be approximately 800 feet west of Unit 3 containment.

The coordinates of the center of the containment buildings for VEGP Units 3 and 4 are given below in State Plane and Universal Transverse Mercator (UTM) coordinates:

Unit		Georgia East Coordinates (NAD27)	UTM (NAD83)
3	N	1,142,600	3,667,166.728
	E	621,800	428,315.413
4	N	1,142,600	3,667,169.439
	E	621,000	428,071.651

The 3,169-acre VEGP site is located on a Coastal Plain bluff on the southwest side of the Savannah River in eastern Burke County. The site and its exclusion area boundary (EAB) are generally bounded by River Road, Hancock Landing Road, and approximately 1.7 miles of the Savannah River (River Miles 150.0 to 151.7). The site is approximately 30 river miles above the U.S. 301 highway bridge and directly across the river from the Department of Energy's Savannah River Site (Barnwell County, South Carolina). The site is approximately 15 miles east north east of Waynesboro, Georgia and 26 miles southeast of Augusta, Georgia, the nearest population center (i.e., having more than 25,000 residents) (Figure 2.1-2). It is also about 136 miles from Savannah, Georgia and 150 river miles from the mouth of the Savannah River.

Access to the site is from River Road via U.S. Route 25, and Georgia Routes 56, 80, 24 or 23 (Figure 2.1-3). Barge access is available from the Savannah River which is navigable to a point upstream of VEGP. A railroad spur runs to the site from the Norfolk Southern Savannah-to-Augusta track.

Figure 2.1-1 VEGP Site and Proposed New Plant Footprint

Figure 2.1-2 50-Mile Region

Figure 2.1-3 6-Mile Vicinity

#### 2.3 Water

This section describes the physical and hydrological characteristics of the VEGP site and surrounding region that could affect or be affected by the construction and operation of two new AP1000 units at the VEGP site. The new units will be referred to as VEGP Units 3 and 4. The potential construction and operational impacts of the project on near- and far-field water resources are discussed in Chapters 4 and 5, respectively.

The 3,169-acre VEGP site is located high on a coastal plain bluff on the west bank of the Savannah River in eastern Burke County Georgia. The new AP1000 units will be located approximately 220 feet above mean sea level (msl). This site is located at River Mile 151; approximately 30 river miles upstream of the U.S. Highway 301 Bridge and directly across the river from the Department of Energy's Savannah River Site (Barnwell, South Carolina). It is approximately 26 miles southeast of Augusta, Georgia.

### 2.3.1 Hydrology

This section describes surface water bodies and groundwater resources that could be affected by the construction and operation of VEGP Units 3 and 4. The site-specific and regional data on the physical and hydrologic characteristics of these water resources are summarized in the following sections.

#### 2.3.1.1 Surface Water Resources

The watershed of the Savannah River extends into the mountains of North Carolina, South Carolina, and Georgia near Ellicott Rock, the point where the borders of those three states meet. The river system drains a basin of 10,577 sq mi, divided between the three states as follows (SR 2006):

- 4,581 sq mi in South Carolina
- 5,821 sq mi in Georgia
- 175 sq mi in North Carolina

Within the three states, the Savannah River basin includes portions of 44 counties and two major metropolitan centers, Augusta and Savannah. The lower 50-mi reach of the river is tidally influenced (USACE 1996).

The Savannah River watershed and sub-basins, as delineated by the National Weather Service (NWS 2005) and further subdivided by USGS Hydrologic Unit Code (HUC-12) sub-basins (USGS 2006f), are shown in Figure 2.3.1-1. The drainage areas of the NWS sub-basins are given in Table 2.3.1-1.

The watershed crosses through three distinct physiographic provinces: the Mountain, Piedmont, and Coastal Plain. The Mountain and Piedmont provinces are within the Appalachian Mountain range, with the border between them extending from northeast to southwest, crossing the

Tallulah River at Tallulah Falls. The Fall Line, or division between the Piedmont province and the Coastal Plain province, also crosses the basin in a generally northeast to southwest direction, near Augusta, Georgia (USACE 1996).

Watershed elevations range from 5,030 ft msl at Little Bald Peak in North Carolina, to sea level at Savannah. The approximate range of elevations for each physiographic region is **(USACE 1996)**:

- 5,030 to 1,800 ft msl within the Mountain province
- 1,800 to 500 ft msl within the Piedmont province
- 500 to 0 ft msl within the Coastal Plain province

The Savannah River, together with certain of its tributaries, forms the border between the states of Georgia and South Carolina. The confluence of the Seneca and Tugaloo rivers, formerly known as "The Forks" but now inundated by Hartwell Lake, marks the upstream end of the Savannah River. The length of the Savannah River from The Forks to its mouth on the Atlantic Ocean is about 312 mi (USACE 1996).

The following principal streams make up the Savannah River stream system (USACE 1996):

- The Tallulah and Chatooga Rivers combine to form the Tugaloo River at River Mile 358.1
- Twelve Mile Creek and the Keowee River join to form the Seneca River at River Mile 338.5.
- The Tugaloo and Seneca rivers join to form the Savannah River proper at River Mile 312.1, at the point known as The Forks.

The entire 312-mi length of the Savannah River is regulated by a series of three U.S. Army Corps of Engineers (USACE) multipurpose projects, forming a chain along the Georgia–South Carolina border 120 mi long. The three lakes, from upstream to downstream, are:

- Hartwell Lake and Dam, with 2,550,000 acre-feet of gross storage
- Richard B. Russell Lake and Dam, with 1,026,000 acre-feet of gross storage
- J. Strom Thurmond (also known as Clarks Hill) Lake and Dam, with 2,510,000 acre-feet of gross storage

Of the 6,144 sq mi drainage basin above Thurmond Dam, 3,244 sq mi (53 percent) are between Thurmond and Russell Dams, 812 sq mi (13 percent) are between Russell and Hartwell Dams, and 2,088 sq mi (34 percent) are above the Hartwell Dam (USACE 1996). Table 2.3.1-2 is a list of key natural and man-made landmarks along the Savannah River with the distance in river miles upstream of the mouth of Savannah Harbor noted.

The climate in the upper Savannah River watershed is classified as temperate, with generally mild winters and long summers. The basin is protected by the Blue Ridge Mountains from the extremes of winter continental weather experienced in the adjacent Tennessee Valley. The annual mean temperature for the basin is 60°F. January, which is usually the coldest month of the year, frequently has night temperatures of 20°F or lower. July and August, the hottest months of

the year, have many days with temperatures over 90°F. In the lower section of the basin, the winters are milder and the summer temperatures higher (USACE 1996).

There are generally two periods of maximum rainfall in the upper basin: February–March and July–August, although heavy rainfall has occurred in practically every month. The mean annual precipitation decreases from 83.5 in. at the upper end of the watershed, near Highlands, North Carolina, down to 49.2 in. at Savannah, Georgia (USACE 1996).

### 2.3.1.1.1 USGS Topographic Maps

USGS seven-and-one-half-minute topographic maps are available for the entire Savannah River watershed. The river miles upstream of the mouth of the Savannah River are marked off along the stream centerline on each of the quadrangles photo-revised in 1989.

Figure 2.3.1-2 provides an index map showing an identification number and the outline of each USGS quadrangle superimposed on a line map of the Savannah River watershed. The name and map identification number of each quadrangle is listed with its reference coordinates (latitude and longitude of the lower right hand corner of the quadrangle) in Table 2.3.1-3, ordered from upper left to lower right throughout the coverage area.

### 2.3.1.1.2 Local Site Drainage

The VEGP site is bordered on the east by the Savannah River and by Beaverdam Creek to the south. The Savannah River Plant Site (SRS) is located directly across the river to the east.

Local drainage is shown in Figure 2.3.1-3, which was developed from the Shell Bluff Landing, Girard NW, Alexander, and Girard USGS quadrangle sheets (see Figure 2.3.1-2 and Table 2.3.1-3). The site is on a high, steep bluff on the west bank of the Savannah River. State Road 23 (River Road) runs roughly parallel to the river, about 4 miles from the VEGP site. It runs along the ridge line that separates local drainage running northeast to the river from runoff draining generally to the southwest.

An unnamed, highly incised creek drains the area of the site north of River Road into the Savannah River just upstream of the site, at the point denominated Hancock Landing on the USGS quadrangle Shell Bluff Landing.

To the west, the site is drained by the Red Branch and Daniels Branch, which join with Beaverdam Creek just upstream of Telfair Pond, south of the site. Beaverdam Creek intercepts three streams draining runoff from north of State Road 23 before it reaches the site. The names, estimated channel lengths, and slopes of the natural channels draining the VEGP site area are provided in Table 2.3.1-4.

#### 2.3.1.1.3 Savannah River Flow Series Data

The USGS maintains stream flow records for nine stream gages on the Savannah River between River Miles 288.9 and 60.9, upstream and downstream of the VEGP site. A tenth gage was recently installed at the VEGP intake at Waynesboro, Georgia (Gage 21973269), but the period of record is too short to support statistical analysis. The location, datum elevation, upstream drainage area, start and stop date, and number of flow records for each of the ten gages are presented in Table 2.3.1-5.

As indicated in Table 2.3.1-5, the nearest USGS gage upstream of the VEGP site with a significant period of record is Gage 2197320, near Jackson, South Carolina (5.9 River Miles upstream); the nearest gage downstream of the VEGP site is Gage 2197500 at Burtons Ferry near Millhaven, Georgia (about 39 River Miles downstream of the site). While the Jackson gage is less than 6 mi upstream of the site, the record length for Gage 2197000, at Augusta, Georgia (48.7 River Miles upstream) is much longer, making it desirable to evaluate all three sets of records.

A number of statistics are presented in this section for flow data on these three gages to facilitate the evaluation of the water supply and flood hazard characteristics of the site, including:

- Average daily and monthly flow series
- Low flow series
- Historic flooding and analytical annual peak flood frequencies

After 1952, flows on the Savannah River at the three gage sites, were impacted by regulation from upstream reservoirs: J. Strom Thurmond (a.k.a. Clarks Hill) Lake and Dam in 1952, Hartwell Lake and Dam in 1961, and Richard B. Russell Lake and Dam in 1984 (USACE 1996). The records for the Augusta, Georgia and Burtons Ferry gages include regulated and unregulated periods. The entire length of record for the Jackson, South Carolina, gage occurs after closure of upstream dams and is, in that sense, homogenous. In this subsection, stream flow statistics for each of the gages is presented as necessary for both the regulated and the unregulated period, as detailed in the text.

## 2.3.1.1.3.1 Annual Average Daily and Mean Daily Flow Series

Table 2.3.1-6 **(USGS 2006c)** presents the mean daily flow for each day of the year for the Savannah River at Augusta, Georgia, based on the entire 98-year gage record, without respect to upstream regulation after 1952.

Table 2.3.1-7 **(USGS 2006d)** presents the mean daily flow for each day of the year for the Savannah River near Jackson, South Carolina, based on the entire 31-year (regulated) gage record.

Table 2.3.1-8 **(USGS 2006g)** presents the mean daily flow for each day of the year for the Savannah River at Burtons Ferry, near Millhaven, Georgia, based on the entire 52-year gage record, without respect to upstream regulation after 1952.

The mean daily flow series for each of these gages are plotted together in Figure 2.3.1-4. For all sites, the mean daily flow exhibits a strong seasonality, with higher mean flows in the winter season and lower mean flows in the summer.

Additionally, the figure gives a qualitative indication of the impact of upstream regulation on flow: daily mean values at Jackson, South Carolina, are based on a fully regulated period of record, while the daily mean values for the Augusta and Burtons Ferry gages are based on periods of record that include substantial periods prior to the completion of the upstream dams; as a consequence, these gages show a substantially higher mean daily flow in the winter season compared with the Jackson mean flows based on records during the regulated period only. Taking mean daily flows for only the unregulated period of record exacerbates this difference.

In addition to the mean daily flows for each day of the year, the USGS publishes statistics on the annual mean flow, which provide a lumped annual statistic masking all seasonality.

Table 2.3.1-9 **(USGS 2006c; USGS 2006g)** presents the annual mean stream flow for the periods of record at Augusta, Georgia, and Burtons Ferry. Data are not presented for the Jackson, South Carolina and Waynesboro, Georgia (VEGP intake) gages because of insufficient record length.

#### 2.3.1.1.3.2 Monthly Flow Series

Table 2.3.1-10 **(USGS 2006d)** presents mean daily discharges by month for the Savannah River at Jackson, South Carolina, for the period of record between 1971 and 2002. A number of "holes" in the USGS series occur where a sufficient number of daily readings were not available to make meaningful monthly averages.

Table 2.3.1-11 (**USGS 2006c**) presents mean daily discharges by month for the Savannah River at Augusta, Georgia, upstream of the VEGP site, for the period of record between 1883 and 2003.

Table 2.3.1-12 **(USGS 2006g)** presents mean daily discharges by month for the Savannah River at Burtons Ferry, near Millhaven, Georgia, downstream of the VEGP site, for the period of record between 1939 and 2003.

Mean daily flows for the Jackson, Augusta, and Burtons Ferry gage sites for each month are provided in Table 2.3.1-13.

Figure 2.3.1-5 provides a plot of the seasonal variation in mean daily flows for each month on the Savannah River between Augusta, Georgia, for the full-period and regulated periods, and Jackson, South Carolina, for the full, regulated period. It can be inferred from the plot that the

operation of the upstream dams has had a significant impact on the mean daily flow for each month in the period from January to May, inclusively.

#### 2.3.1.1.3.3 Low Flow Series

Flow duration curves are developed by ranking the recorded mean daily flows for the period of record to estimate the percentage of days that a flow of a given value is equaled or exceeded. Flow duration curves for the Savannah River at Augusta, Georgia, for the entire period of record (1883 to 2003) and the period after closure of the three upstream dams (1984 to 2003) are presented in Figure 2.3.1-6. As would be expected, the curves indicate that regulation has increased minimum daily flows and has reduced maximum daily flow on the Savannah River downstream.

The n-day low flow for a stream is the mean flow measured during the n consecutive days of lowest flow during any given year. It is customary to group the mean daily flow data into low-flow years (defined from April 1 to March 31 in North America) to prevent splitting the low-flow season into two parts for each year. The 7-day, 10-year low flow statistic, 7Q10, is an estimate of the lowest mean flow that would be experienced during a consecutive 7-day period with an average recurrence interval of 10 years, and is used as an indicator of low flow conditions during drought periods (McMahon and Mein 1986).

Table 2.3.1-14 shows the 3-, 7-, 10-, 30-, 60-, 90-, 183-, and 365-day mean low flows for each year of record for the Savannah River gage at Augusta (Gage 2197000) as determined from the daily flow data for the low-flow years between 1986 and 2003, the available period of continuous upstream regulation, using the USGS program SWSTAT (USGS 1994).

The 7-day low flow data for each complete low-flow year in the regulated period was used to estimate 7-day low flow frequency based on a Log-Pearson Type III (LP3) distribution, from which the 7Q10 low flow parameter is estimated as 3,828 cfs (see Table 2.3.1-15). The assumption of an LP3 distribution provides a good fit of the calculated 7-day low flows, as indicated in Figure 2.3.1-7.

#### 2.3.1.1.3.4 Historic Flooding and Annual Peak Flood Frequencies

Table 2.3.1-16 **(USGS 2006c)** provides the date, stage elevation, and annual peak discharge for the entire period of record for USGS Gage 02197000 on the Savannah River at Augusta, Georgia, approximately 48.7 River Miles upstream of the VEGP site. The annual peak floods include estimated values from historic floods reported in 1796, 1840, 1852, 1864, and 1865.

The maximum annual peak flood discharge for the period of record is 350,000 cfs, from the storm of October 2, 1929. The storm of January 17, 1796, estimated from reported stages using slope-conveyance methods, is the oldest event used to extend the record length. The estimated value of the peak flow for this storm ranges between 280,000 cfs for a reported stage of 38 ft (USGS 2006c) and 360,000 cfs for a reported maximum flood stage of 40 ft (USGS 1990a). This puts

the maximum flood elevation of the Savannah River at Augusta, Georgia, for the historic period between 134.6 and 136.6 ft msl, based on an El. 96.58 ft msl for the Augusta, Georgia, stream gage datum (see Table 2.3.1-5).

After 1952, annual peaks on the Savannah River at Augusta, Georgia, are attenuated by regulation from upstream reservoirs: J. Strom Thurmond (a.k.a. Clarks Hill) Lake and Dam in 1952, Hartwell Lake and Dam in 1961, and Richard B. Russell Lake and Dam in 1984 (USACE 1996). This attenuation of floods is shown in Figure 2.3.1-8 (USGS 1990a), which is based on the historic record from 1796 to 1985.

Annual peak flood frequency curves for regulated and unregulated conditions for the Savannah River at Augusta, Georgia, were developed for the period between 1796 and 1985 and are presented in Figure 2.3.1-9 (USGS 1990a). Unregulated annual peak discharge values for the period after 1952 and regulated annual peak discharge values for the years previous to 1952 were generated by modeling reservoir operation based on the stage-storage-discharge characteristics reported for the three projects, using the 1990 operating rule set for the entire period (USGS 1990a).

Figure 2.3.1-9 clearly shows the convergence of the regulated and unregulated annual flood frequency plots as discharge increases. On the left-hand side of the graph, for the 80 percent chance-of-exceedence event (a return period of 1.25 years), the unregulated peak discharge exceeds the regulated peak by a factor of about 2.14; on the left-hand side, for the 0.2 percent chance-of-exceedence event (a return period of 500 years), the unregulated peak discharge exceeds the regulated peak by a factor of about 1.29. On this basis, regulation would not be expected to significantly affect the probable maximum flood on the Savannah River downstream of Augusta, provided that the upstream dams do not fail.

## 2.3.1.1.4 Dams and Reservoirs

There are a number of water control structures on the Savannah River and its major tributaries, as identified in **USGS** (1990a) and **USACE** (1996). Table 2.3.1-17 presents a list of these structures with hydraulic design information for each project and identification of its location with respect to the VEGP site.

Three projects operated by the Corps of Engineers upstream of the VEGP site have a significant influence on the discharge of the Savannah River:

- Hartwell Lake and Dam, with 2,550,000 acre-feet of gross storage
- Richard Russell Lake and Dam, with 1,026,000 acre-feet of gross storage
- J. Strom Thurmond Lake and Dam, with 2,510,000 acre-feet of gross storage

The authorized water management goals of the three-dam, multiuse project are specified for normal operation, flood operation, and drought condition operation in the Corps Water Control Plan as follows:

- For normal conditions, the operation policy is designed to maximize the public benefits of hydroelectric power, flood damage reduction, recreation, fish and wildlife, water supply, and water quality (USACE 1996).
- Under flood conditions, the water management objective is to operate the reservoir system to minimize flooding downstream by timing turbine discharge, gate openings, and spillway discharge as required.
- For drought conditions, the water management objectives of the project are:
  - o To prevent draw-down of lake levels below the bottom of the conservation pool
  - o To make use of most of the available storage in the lake during the drought-of-record
  - o To maintain hydroelectric plant capacity throughout the drought
  - o To minimize adverse impacts to recreation during the recreation season (generally considered from May 1 through Labor Day)

The Corps also operates the New Savannah Bluff Lock and Dam, 36.8 River Miles upstream of the VEGP site. This project has very little impact on flows at the site, due to its run-of-river status and negligible storage volume (**USACE 1996**).

The four projects are described briefly in the following paragraphs (USACE 1996).

**The Hartwell Lake and Dam** is located at River Mile 288.9, 7 mi east of Hartwell, Georgia, and 138 River Miles upstream of the VEGP site. The top of the conservation pool is set at El. 660 ft msl. At this level, the reservoir extends 49 mi up the Tugaloo River in Georgia and 45 mi up the Seneca and Keowee rivers in South Carolina. The shoreline at El. 660 ft msl is about 962 mi long, excluding island areas. The project became operational in 1965.

The reservoir has a total storage capacity of 2,550,000 acre-feet below El. 660 ft msl, and 293,000 acre-feet of flood control storage between El. 660 ft msl and El. 665 ft msl. The dam consists of a concrete gravity section, which is 1,900 ft long and rises about 204 ft above the streambed, and two earth embankment sections extending to high ground on the Georgia and South Carolina shores of the river, for a total length of 17,880 ft.

**The Richard B. Russell Lake and Dam** is located at River Mile 259.1 in Elbert County, Georgia, and Abbeville County, South Carolina, 108.2 River Miles upstream of the VEGP site. The dam is 18 mi southwest of Elberton, Georgia; 4 mi southwest of Calhoun Falls, South Carolina; and 40 mi northeast of Athens, Georgia. Operation of the project began in 1985.

The top of the conservation pool is set at El. 475 ft msl, at which elevation the reservoir has a total storage volume of about 1,026,000 acre-feet and a useable storage capacity of 126,800 acre-feet. The flood control pool provides about 140,000 acre-feet of additional storage between elevations 475 and 480 ft msl.

The dam consists of a concrete gravity section, which is 1,883.5 ft long, and two earth embankment sections, 2,180 ft long in Georgia and 460 ft long in South Carolina. A concrete

overflow spillway section is located in what was formerly the stream channel. It has an ogee-shaped crest controlled by 10 tainter gates.

**The J. Strom Thurmond Lake and Dam** (also known as the Clarks Hill Lake and Dam) is at River Mile 221.6 on the Savannah River, 22 mi upstream of Augusta, Georgia, and 70.7 River Miles upstream of the VEGP site. The project became operational in 1952. The reservoir at the top of the flood control pool, El. 335 ft msl, has an area of 78,500 acres. At El. 330 ft msl, the top of the conservation pool, the reservoir extends about 40 mi up the Savannah River and about 30 mi up the Little River in Georgia and has about 1,050 mi of shoreline, excluding island areas.

The reservoir has a total storage capacity of 2,510,000 acre-feet below EI. 330 ft msl, with an additional 390,000 acre-feet of flood control storage between EI. 330 ft msl and EI. 335 ft msl. The dam consists of a concrete gravity section, which is 2282 feet long, and two earth embankment sections extending to high ground on the Georgia and South Carolina shores, with at total length of 5680 feet,

The New Savannah Bluff Lock and Dam is at River Mile 187.7, 36.8 river miles upstream of the VEGP site. The structure is located on the Savannah River about 13 mi below Augusta. It is a concrete dam 360 ft long containing five vertical-lift crest control gates. The lock chamber, located on the Georgia side of the river, is 56 ft by 360 ft and is closed by miter gates. The lift is 15 ft. The normal pool elevation is about 115.0 ft msl. The dam was originally constructed to provide a lock to support navigation to Augusta, Georgia. Currently it is used primarily to reregulate upstream releases for downstream water supply withdrawals.

In 2000, the Savannah District Corps of Engineers issued a Disposition Study under Section 216 of the Flood Control Act of 1970 to examine the current uses of the New Savannah Bluff Lock and Dam and recommend disposition for the future. The study concluded that the only feasible option was to remove the dam. This result was met with vehement opposition by property owners, water supply, recreational interests and in 2005 a decision was made to repair the lock chamber and keep the dam in service. This decision has no significant impact on existing or proposed units at VEGP.

#### 2.3.1.1.5 Estimated Erosion Characteristics

Bank erosion caused by wave action has been measured in the reservoirs upstream of the VEGP site (Hoke 2000), but no references to measurements of river cross-sections to assess bank erosion along the middle reaches of the Savannah River or at the site were found in the literature.

A number of meanders are a feature of the plan-form of the middle reaches of the Savannah River, but the river near the site has a relatively straight and stable reach extending approximately from River Mile 143 to River Mile 152. A comparison of river bank-lines along this reach between 1965 and 1989, obtained from USGS topographic maps (USGS 1989a; USGS

**1989b; USGS 1989d)** and topographic maps used for VEGP Units 1 and 2 shows a nearly unchanged river plan-form.

Hale and Jackson (2003) describe how dredging for navigation has altered the hydrology and geomorphology of the Savannah River over the past century. They present a table of 40 cut-offs constructed on the lower Savannah River between 1889 and 1962 that had the cumulative effect of reducing stream length by a total of 26.5 miles. Each of these cut-offs will have had some impact on local channel conditions and sediment transport due to change in bed slope.

According to their table, the 4,350-foot Cox Point cut-off at River Mile 153.2 (about 2.3 miles upstream of the Vogtle site) was completed in 1959. The cutoff is visible on the Shell Bluff Landing 1:24,000-scale USGS topographic map.

It can be inferred from the alignment of the channel shown on the map, which is based on aerial photography from 1965 with photorevisons from 1989, that the stability of the Savannah River channel section at the VEGP site does not appear to have been adversely affected by the cut-off, as would be expected for the relatively short length of the cut-off and the mild gradient of the reach.

In general, channel straightening of the type affected by the Cox Point cutoff will cause a local reduction in water level and an increase in velocity, so that the small creeks that are tributary to the reach may experience increased gradients causing scour and head cutting (USDOT, 1977). No evidence of such impacts is noticeable at the scale of the available mapping, however.

#### 2.3.1.1.6 Sediment Transport Rates

A search of the literature shows that there have been a number of studies of sediment transport on the Savannah River within the piedmont physiographic region, resulting from requirements to establish Total Maximum Daily Loads for the E.P.A. (i.e. **EPA 1999, Keyes and Radcliffe, 2002, Freshley, 2003**). There have also been a number of studies of sedimentation in Savannah Harbor (Goodrich, Way, and Liu 2003; Semmes et al 2003; Phillips and Slattery 2006). Sedimentation rates resulting from these studies, where available, are not directly applicable at the study site within the coastal plain physiographic region because of the different bed slopes and stream power typical of each physiographic region.

There have been very few studies of sedimentation on the Savannah River near the site because sedimentation has not been considered a critical environmental issue in the coastal plain below the Corps's three-dam reservoir project, where the Vogtle site is located. According to the Savannah District of the U.S. Army Corps of Engineers (USACE 1996):

The problem of sediment in the Savannah River Basin has been greatly reduced since the early 1900's by the conversion of much former cropland to silviculture and pasture. Cotton farming, considered a highly erosive land use, has greatly declined during this century in central Georgia and western South Carolina. The combination of agricultural decline, transition of cropland to timber and pasture, and widespread implementation of soil conservation practices have resulted in lessened stream sediment loads. Deposits of silt in the reservoirs and channel retrogression below the dams are not major problems.

Duncan and EuDaly (2003) discuss the possibility that the reduced variation in discharge downstream of the dams since closure has lead to accumulations of silt with an adverse impact on fish habitats in the shoals, but they present no measurements or quantitative estimates of sedimentation rates.

# 2.3.1.1.6.1 Suspended Load Transport Rates

Table 2.3.1-24 summarizes the availability of water quality data for the USGS gages on the Savannah River. There is no bed-load measurement information, and, of the 23 gage stations listed as having water quality data, only 2 have data on suspended load transport rates and only the gage at Clyo is in the coastal plain reach (USGS 2006h).

While water quality data for the Savannah River at Clyo, Georgia (2198500) includes entries from 1938 to the present, only 97 records of suspended sediment load measurement between 1974 and 1983 are reported (as time-weighted daily mean values).

These data points are listed in Table 2.3.1-25 and are plotted in Figure 2.3.1-28 against the average daily discharge recorded for those days. There is only a slight correlation between average daily discharge in cubic feet per second and suspended sediment load in tons per day, so the suspended load data time series cannot be extended with much reliability.

There are gages on the Savannah River nearer to the site than Clyo for which turbidity measurements are available, offering the possibility of estimating suspended sediment loads from a correlation with turbidity measurements, but no statistically significant relation was discerned between turbidity measurements and average daily suspended sediment discharge for these data sets.

The 97 reported measurements of daily suspended sediment loads were sorted to permit the calculation of monthly statistics, as summarized in Table 2.3.1-26 and plotted in Figure 2.3.1-28. The data shows some seasonality, but because the relationship between discharge and suspended load is not strong, the seasonality is not pronounced.

Based on the assumption that the suspended sediment load at Clyo is not significantly different from the load at the Vogtle site, 90 miles upstream, the monthly average suspended load at the site will range between 200 and 1,600 tons per day with a 95 percent probability.

### 2.3.1.1.6.2 Bed Load Sediment Transport Rates

No bed-load sediment transport measurements have been reported for any reach of the Savannah River and cannot be easily estimated as a fraction of the suspended load because the portion of sediment that moves as bed load varies widely between rivers and on the same river over time (**Keyes & Radcliffe 2002**). However, to obtain an order-of-magnitude estimate, the globally averaged ratio of suspended load to bed load sediment flux for rivers of 9:1 reported by Syvitski et al. (2003) can be used. For the suspended load range of 320 to 880 tons per year calculated from the data at Clyo, Georgia, this would indicate a range for bed load transport of between about 35 and 100 tons per day.

### 2.3.1.2 Groundwater Resources

The VEGP site lies within the Coastal Plain Physiographic Province. The site is underlain by approximately 1,000 ft of Coastal Plain sediments. The hydrogeologic conditions within the Coastal Plain sediments can be summarized as permeable coarse-grained materials separated by less-permeable fine-grained materials, resulting in a multiple aquifer system.

#### 2.3.1.2.1 Regional Hydrogeology

The region within a 200-mi radius around the VEGP site encompasses parts of four physiographic provinces. These include, from northwest to southeast, the Valley and Ridge, Blue Ridge, Piedmont, and Coastal Plain Physiographic Provinces. Several major aquifers or aquifer systems are present within these physiographic provinces. Figure 2.3.1-10 illustrates the extent of these major aquifers or aquifer systems at the land surface. The VEGP site and associated groundwater are located within the Coastal Plain Physiographic Province. However, groundwater within the other provinces is discussed below to provide a complete picture of regional hydrogeologic conditions.

The Valley and Ridge Physiographic Province lies about 180 mi northwest of the VEGP site. Aquifers underlying the Valley and Ridge province occur within Paleozoic-age folded and faulted sedimentary rock. The sedimentary strata consist predominantly of sandstone, shale, and limestone, with minor amounts of dolomite, conglomerate, chert, and coal. The carbonate and sandstone layers form the principal aquifers in the province. Typical well yields are from 10 gpm in sandstone formations to 10 to 50 gpm within the limestone units. Locally high yields, equal to 100 gpm or greater, are possible within highly fractured strata or solution cavities. Localized weathered rock and alluvium can provide lesser, but adequate, groundwater yields for domestic use. (Miller 1990)

The Piedmont and Blue Ridge Physiographic Provinces are hydrologically similar in nature. Both provinces are composed primarily of metamorphic and igneous rocks. Surface materials in the Blue Ridge Province consist mainly of thin residual soils, alluvium, and colluvium. Surface materials in the Piedmont Province consist generally of more deeply weathered residual soils

(saprolite) and alluvium. Groundwater occurs both in the fractured portions of bedrock and within the saprolite and alluvium material. Well yields generally depend on the local fracture density and fracture connectivity of the bedrock and range from a few to 30 gpm. Localized groundwater well yields of 100 gpm or greater are possible. (Miller 1990)

The majority of Georgia's groundwater use occurs in the Coastal Plain Physiographic Province. The Coastal Plain sediments are thin, less than 200 ft thick, along the western boundary of the province (where they terminate at the contact with the Piedmont province, the Fall Line) and thicken to over 4,000 ft in an eastern-to-southeastern direction. The sediments range in age from Holocene to Cretaceous and overlie crystalline igneous and metamorphic bedrock, which is an eastward extension of the Piedmont province (Miller 1990).

Groundwater in the Coastal Plain is withdrawn from both unconfined, shallow aquifer systems and deeper, confined aquifer systems. These aquifers are recharged principally from their outcrop area along the western boundary of the province near the Fall Line and from localized infiltration of precipitation within the province. Precipitation migrates downward and laterally through the unconsolidated surficial materials and discharges to nearby streams and low areas or percolates downward into the deeper unconsolidated and consolidated material. The thickness and areal extent of the Coastal Plain sediments result in a storage capacity for groundwater that exceeds that of any other physiographic provinces in Georgia (Miller 1990).

#### 2.3.1.2.1.1 Conceptual Model Description

The conceptual hydrogeological model for the VEGP site was developed using site-specific data acquired to support the ESP application, information and data included in the VEGP Updated Final Safety Analysis Report (UFSAR), U.S Geological Survey studies, and Georgia Geologic Survey studies.

As discussed above, the VEGP site is located in the Coastal Plain physiographic province. Coastal Plain sediments comprise three aquifer systems consisting of seven aquifers that are separated hydraulically by confining units. As presented by Clarke and West (1997), the aquifer systems are, in descending order: (1) the Floridan aquifer system, which consists of the Upper Three Runs and Gordon aquifers in sediments of Eocene age; (2) the Dublin aquifer system, consisting of the Millers Pond, upper Dublin, and lower Dublin of Paleocene-Late Cretaceous age; and (3) the Midville aquifer system, consisting of the upper Midville and lower Midville aquifers in sediments of Late Cretaceous age. Note that nomenclature used by the U.S. Geological Survey (Clarke and West 1997) for geologic and hydrogeologic units differs from that used in this ESP application. In this ESP application, the Water Table aquifer comprises the Upper Three Runs aquifer, the Tertiary sand aquifer comprises the Gordon aquifer, and the Cretaceous aquifer comprises the Dublin and Midville aquifers. Figure 2.3.1-11 and Figure 4 of Clarke and West (1997) provide additional details.

The Upper Three Runs aquifer is the shallowest aquifer and is unconfined-to-semi-confined throughout most of the area. Groundwater levels in the Upper Three Runs aquifer respond to a local flow system and are affected mostly by topography and climate. Groundwater flow in the deeper, Gordon aquifer and Dublin and Midville aquifer systems is characterized by local flow near outcrop areas to the northwest, changing to intermediate flow and then regional flow downdip (southeastward) as the aquifers become more deeply buried. Water levels in these deeper aquifers show a pronounced response to topography and climate in the vicinity of outcrops that diminishes southeastward where the aquifer is more deeply buried. Stream stage and pumpage affect groundwater levels in these deeper aquifers to varying degrees throughout the area. (Clarke and West 1997)

The geologic characteristics of the Savannah River alluvial valley substantially control the configuration of potentiometric surfaces, groundwater flow directions, and stream-aquifer relations. Data from 18 shallow borings (Leeth and Nagle 1996) indicate incision into each aguifer by the paleo Savannah River and subsequent infill by permeable alluvium have resulted in direct hydraulic connection between the aquifers and the Savannah River along various parts of its reach. This hydraulic connection may be the cause of large groundwater discharge to the river near Jackson, South Carolina, as evidenced by stream baseflow and potentiometric measurements, where the Gordon aquifer is in contact with Savannah River alluvium, and also the cause of lows or depressions in potentiometric surfaces of confined aquifers that are in contact with the alluvium. Groundwater in these aguifers flows toward the depressions. The influence of the river diminishes downstream where the aquifers become deeply buried beneath the river channel, and where upstream and downstream groundwater flow is possibly separated by a water divide or "saddle." Water-level data indicate that saddle features probably exist in the Gordon aguifer and Dublin aguifer system, with the groundwater divide occurring just downstream of the VEGP site, and also might be present in the Midville aguifer system. (Clarke and West 1997).

Basin-wide potentiometric-surface maps for the unconfined Upper Three Runs aquifer and confined Gordon, Dublin, and Midville aquifer systems have been prepared using historical data (Clarke and West 1997) and numerical simulation (Cherry 2006). Detailed discussions of these maps are provided in the cited references. Data from observation wells installed and monitored for an 18-month period at the VEGP site have also been used to develop potentiometric-surface maps on a more highly resolved, site-specific basis. These maps are discussed in detail in Section 2.3.1.2.3. The groundwater flow directions inferred from these maps are generally consistent with the larger-scale maps produced by Clarke and West (1997) and Cherry (2006), i.e., groundwater flow in the Upper Three Runs (Water Table) aquifer generally conforms with surface topography, while that in the confined Gordon (Tertiary) aquifer is toward the Savannah River.

Recharge to the Upper Three Runs (Water Table) aquifer is almost exclusively by precipitation, while discharge is primarily to local drainages. Recharge to the confined Gordon, Dublin, and

Midville (Tertiary and Cretaceous) aquifers occurs primarily by direct infiltration of rainfall in their outcrop areas northwest of the VEGP site that are generally parallel to the Fall Line (the boundary between the Coastal Plain and Piedmont physiographic provinces). Because the permeable alluvium of the Savannah River valley allows for direct hydraulic connection between aquifers and the Savannah River, the river serves as the major discharge area for the confined aquifers in hydraulic connection with the river valley alluvium. Potentiometric maps presented by Clarke and West (1997) indicate groundwater discharge from the confined Gordon, Dublin, and Midville aquifers to the Savannah River. For the shallower Gordon confined aquifer, groundwater flow directions are generally perpendicular to the river reach. In the case of the deeper Dublin and Midville aquifers, there are upriver components to the groundwater flow directions that depend on where the paleo river channel has breached confining units. Clarke and West (1997) provide a detailed discussion of this phenomenon.

Although a water budget for the VEGP site has not been quantified, recharge and discharge rates have been estimated on a basin-wide basis by other investigators. Clarke and West (1997) estimated groundwater discharge to the Savannah River based on the net gain in stream discharge for local, intermediate, and regional groundwater flow systems and for different hydrologic conditions. Groundwater discharge ranged from 910 ft<sup>3</sup>/s during a drought year (1941) to 1,670 ft<sup>3</sup>/s during a wet year (1949), and averaged 1,220 ft<sup>3</sup>/s. Of the average discharge, the local flow system contributed an estimated 560 ft<sup>3</sup>/s and the intermediate and regional flow systems contributed an estimated 660 ft<sup>3</sup>/s. Clarke and West (1997) approximated the long-term average recharge by weighting these values according to drainage area, and estimated the average groundwater recharge in the Savannah River basin to be 14.5 in., of which 6.8 in. is to the local flow system, 5.8 in. is to the intermediate flow system, and 1.9 in. is to the regional flow system. Mean-annual precipitation in the basin ranges from 44 to 48 in. Cherry (2006) presents simulated water budgets for different hydrologic conditions using a numerical model for groundwater flow near the Savannah River Site, Georgia, and South Carolina. Estimates of inflow or outflow across lateral boundaries, recharge, discharge, groundwater pumpage, and vertical flow upward and downward across confining units are obtained from the numerical model.

#### 2.3.1.2.1.2 Tritium in Unconfined and Confined Aquifers

Several investigators have documented the presence of tritium in groundwater in eastern Burke County, Georgia. These investigations include those of Summerour et al. (1994), Summerour et al. (1998), and Georgia Department of Natural Resources (DNR) (2004). Descriptions of the data resulting from these investigations and associated conclusions are summarized below.

Summerour et al. (1994) reports the results of seven sub-investigations conducted to determine any possible threat to public health due to tritium in eastern Burke County. These sub-investigations included: (1) sampling and analyzing 109 domestic and public water wells; (2) performing baseflow studies to measure tritium abundance in local springs and creeks; (3)

installing and sampling 15 new groundwater monitoring wells at six cluster sites in eastern Burke County; (4) defining the local lithostratigraphic and hydrostratigraphic framework using core sample analyses, field mapping, and literature; (5) characterizing the hydrologic characteristics of the unconfined Upper Three Runs aquifer, the Gordon aquitard, and the confined Gordon aquifer using data from aquifer tests; (6) characterizing the geochemical characteristics of the Upper Three Runs and Gordon aquifers using analyses of water samples from public, private, and monitoring wells; and (7) conducting a seismic refraction survey of the Savannah River channel to evaluate the extension of the Pen Branch fault into the channel of the Savannah River and investigate the thickness of the river alluvium, the possible breaching of aquitards, and the correlation of seismic stratigraphic sequences with the local stratigraphy. The main conclusions resulting from this study are as follows:

- There is no evidence of a public health threat due to tritium pollution of aquifers in Burke County.
- There is widespread evidence of tritium in the water table aquifer in eastern Burke County, at levels well below the maximum concentration level (MCL) standard for drinking water set by the United States Environmental Protection Agency.
- There is no evidence of regional tritium pollution of the Gordon aquifer in eastern Burke County.
- Existing data do not fully resolve the issue of the tritium occurrence in water table aquifer. However, the investigation shows that some pathways are more likely than others and suggests specific pathway models for future investigations.

Follow-on, Phase II sub-investigations were conducted by the Georgia Geological Survey, results of which are reported by Summerour et al. (1998). The Phase II sub-investigations, conducted in eastern Burke County, recommended the following: (1) continued monitoring of tritium in the unconfined aquifer; (2) conducting high-resolution tritium analyses of groundwater in confined aquifers; (3) investigating the vertical distribution of tritium in the vadose zone; (4) investigating the vertical distribution of tritium in the unconfined aquifer; (5) completing a seismic survey across the projected location of the Pen Branch fault into Georgia; (6) investigating well construction in the public water supply well in which tritium was first discovered in Burke County groundwater; and (7) revising the lithostratigraphy and hydrostratigraphy of Burke County. Conclusions resulting from these sub-investigations, pertinent to the VEGP site, are summarized below.

- Tritium concentrations in the unconfined aquifer are declining. This decline in tritium concentration is probably due to a combination of radioactive decay, dilution by untritiated groundwater, and recharge by untritiated (or low tritium) rainwater.
- Very low, but measurable, levels of tritium are present in all of the confined aquifers. Because the water in these aquifers is very old (11,000 to 32,000 years) compared with the half-life of tritium (12.35 years), there should be no tritium present within the confined aquifers. The

tritium in these deep aquifers is believed to be due to cross contamination during drilling and well installation or to cross-contamination sampling. There is insufficient evidence to distinguish between these alternatives.

- Tritium is not uniformly distributed with depth in either the unsaturated (vadose) zone or in the unconfined aquifer. Within the vadose zone, tritium concentrations generally increase with increasing depth. Within the unconfined aquifer, tritium concentrations increase with increasing depth but then rapidly drop to below the detection limit in the basal units of the unconfined aquifer. Vertical tritium variations observed in the unsaturated zone and the upper part of the unconfined aquifer may represent a historical record of tritium influx into the water table aquifer.
- A seismic reflection survey across the projected location of the Pen Branch fault identified a series of 13 high-angle faults along approximately 4,550 ft of a 7,620-ft seismic line. The entire series of faults is considered to represent an extension of the Pen Branch fault zone into Georgia from South Carolina. Figure 23 of Summerour et al. (1998) shows the locations of the seismic survey line and the projected location of the Pen Branch fault. All 13 faults affect the basement rock and project upwards into the overlying Cretaceous-age sediments. None of these faults appear to have disturbed the Gordon aquitard, which isolates the unconfined aquifer from underlying confined aquifers. The seismic profile also shows other numerous minor fractures or faults within the Cretaceous and Tertiary Coastal Plain sediments. Summerour et al. (1998) indicate that while these minor fractures may cut the lower Midville, upper Midville, lower Dublin, upper Dublin, and Millers Pond aquitards, it is unclear whether the fractures also cut the Gordon aquitard (Lisbon Formation). The effect of the Pen Branch fault zone and other minor faults on groundwater flow patterns and pathways was not resolved in this investigation.
- The preponderance of evidence indicates that the primary pathway for tritium into the Upper
  Three Runs aquifer is through recharge of the aquifer by tritiated rainfall related to
  atmospheric tritium releases at the Savannah River Site. A possible secondary pathway for
  tritium is suggested by the presence of very low levels of tritium in all confined aquifers in
  Burke County.

More recently, the Georgia DNR (2004) reported tritium sampling results for the 2000–2002 period from monitoring wells and public water-supply wells located in the Savannah River Site/Vogtle Electric Generating Plant area. Georgia DNR (2004) concludes that no significant tritium contamination has been positively identified in any confined aquifers in Georgia, based on monitoring well data. On the other hand, it notes that extensive tritium contamination was present in groundwater in the relatively shallow (up to 200 ft deep) Upper Three Runs aquifer during the 2000–2002 period, with tritium concentrations averaging less than 1,000 pCi/l, which is well below the drinking water MCL of 20,000 pCi/l established by EPA. Georgia DNR (2004) indicates that contamination appears to be concentrated primarily within the Savannah River Site's

downwind footprint, suggesting a possible connection with airborne (or rain-borne) tritium from the Savannah River Site.

Based on the results of the investigations described above, it is likely that tritium is present in the Upper Three Runs (Water Table) aquifer at the VEGP site, given that tritium has been detected in adjacent monitoring wells and springs and creeks. The source of the tritium is most likely associated with atmospheric releases of tritium from the Savannah River Site because the VEGP site falls within the downwind footprint of the Savannah River Site and is in an area where elevated levels of tritium have been detected in the rainfall. The same investigations suggest the possibility of very low, but measurable, levels of tritium in the deeper, confined aquifers underlying the VEGP site. Possible sources of tritium in the confined aquifers of Burke County, Georgia, include cross contamination from well drilling, installation and during sampling.

#### 2.3.1.2.1.3 Trans-River Flow

The potential for trans-river flow in the vicinity of the Savannah River Site and VEGP site has been discussed by Clarke and West (1997). Trans-river flow is a term that describes a condition under which groundwater originating on one side of a river migrates beneath the river floodplain to the other side of the river. Although some groundwater could discharge into the river floodplain on the opposite side of the river from its point of origin, such flow would likely be discharged to the river because flow in the alluvium is toward the river. Potentiometric-surface maps developed by Clarke and West (1997) for the Upper Three Runs aguifer and Gordon aguifers do not indicate the possible occurrence of trans-river flow. However, flow lines on potentiometric-surface maps of the confined Dublin and Midville aguifer systems do suggest the possible occurrence of transriver flow for a short distance into the Savannah River alluvial valley. The possible occurrence of trans-river flow in the Dublin aguifer system also is suggested by the chemical and isotopic composition of water from the Brighams Landing well-cluster site in Georgia. Clarke and West (1997) suggest that the potential for trans-river flow may be facilitated by groundwater withdrawal, particularly at pumping centers located near the Savannah River. Pumped wells on one side of the river could intercept groundwater that originates on the other side. For this to occur, pumping would need to be sufficient to reverse the hydraulic gradient away from the river and towards the pumping center.

Numerical simulation techniques have been used to further evaluate areas of previously documented trans-river flow on the Georgia side of the Savannah River (Clarke and West 1998; Cherry 2006). At such areas, local head gradients might allow the migration of contaminants from the Savannah River Site into the underlying aquifers and beneath the Savannah River into Georgia. Cherry (2006) identified the area near Flowery Gap Landing (covering about 1 mi<sup>2</sup>) as an area of potential trans-river discharge. Backward particle tracking analysis was conducted to better quantify trans-river flow. Between 29 and 37 percent of the particles released in this area backtracked to recharge areas on the Savannah River Site (trans-river flow), depending on the scenario being evaluated. Of the particles exhibiting trans-river flow, the median time-of-travel

ranged from 366 to 507 years. For the worst-case scenario evaluated (deactivation of Savannah River Site production wells), the median time-of-travel decreased to about 370 years, with a shortest time-of-travel period of about 80 years.

While the potential for trans-river flow exists, it is likely that such flow would be quickly discharged to the river because flow in the river alluvium is toward the river. Also, any tritiated water originating from the Savannah River Site and participating in trans-river flow would undergo significant radioactive decay, considering its 12.35-year half-life, relative to even the worst-case 80-year time-of-travel. Furthermore, pumping of the current makeup water wells for VEGP Units 1 and 2 does not appear to have intercepted groundwater originating from the other side of the river, based on the particle tracking results presented **by Cherry (2006). It** is also unlikely that pumping the additional water needed to supply VEGP Units 3 and 4 would be sufficient to reverse that hydraulic gradient and cause groundwater originating from South Carolina to be drawn any further into Georgia, given the high transmissivities of the confined Tertiary and Cretaceous aquifers. Therefore, trans-river flow does not appear to be a mechanism that would contribute to the contamination of aquifers underlying the VEGP site.

#### 2.3.1.2.1.4 The Location and Role of the Pen Branch Fault

There is no evidence to suggest that the potential for groundwater leakage between the Upper Three runs (Water Table) aquifer and Gordon (Tertiary sand) aquifer in the vicinity of the Pen Branch fault exists at the VEGP site. SSAR Section 2.5.1.2.4 describes previous investigations of the Pen Branch fault and the site subsurface investigation of the fault that was conducted for the ESP application. Results of this investigation, which included seismic reflection and refraction surveys, clearly document that the Pen Branch fault strikes northeast and dips southeast beneath the VEGP site. SSAR Figure 2.5.1-42 shows the vertical projection of the Pen Branch fault from the top of basement rock in relation to VEGP Units 3 and 4. The plan projection of the intersection of the Pen Branch fault with the top of basement rock is located beneath or slightly southeast of the antiformal hinge at the top of the monocline in the Blue Bluff Marl (SSAR Figure 2.5.1-39). Because of its spatial association with the Pen Branch fault, it is likely that this monocline feature is the result of reverse or reverse-oblique slip on the Pen Branch fault. The seismic survey data further indicate that the fault terminates in the Cretaceous Coastal Plain deposits and overlying Tertiary deposits, including those comprising the Gordon (Tertiary sand) aquifer, Gordon aquitard (Blue Bluff Marl), and Upper Three Runs (Water Table) aquifer, are not considered to be affected by the Pen Branch fault. This result is consistent with that of Summerour et al. (1998), who reported that none of the faults identified in their seismic surveys appear to have disturbed the Gordon aquitard (Blue Bluff Marl), which isolates the unconfined aguifer from underlying confined aguifers.

Based on the results and discussion presented above, the Pen Branch fault has not affected the Tertiary age deposits at the VEGP site and would be neither a barrier nor a conduit for groundwater transport in these deposits. Insufficient data is available to determine if the fault

would be a barrier or conduit in the deeper, Cretaceous deposits that have been affected by the fault.

#### 2.3.1.2.2 Local Hydrogeology

The VEGP site lies within the Coastal Plain Physiographic Province. The site is located approximately 40 mi southeast of the Fall Line, the northwestern boundary of the Coastal Plain province, and is adjacent to the Savannah River. Geologic conditions beneath the VEGP site generally consist of about 1000 ft of Coastal Plain sediments with underlying Triassic Basin rock southeast of the Pen Branch fault and Paleozoic crystalline rock northwest of this fault.

The Savannah River lies along the northeast border of the VEGP site and influences the local hydrogeologic conditions within the site area. This local hydrogeology discussion is restricted to the VEGP site vicinity (approximate radius of 5 mi) south of the Savannah River.

Geotechnical and hydrogeological investigations performed for this ESP application provide information on the VEGP site from the Triassic Basin rock to the ground surface. Results from these investigations indicate that there are three aquifers underlying the VEGP site, the Cretaceous, Tertiary, and Water Table (or Upper Three Runs), all of which belong to the Southeastern Coastal Plain aquifer system. Although present regionally, the Surficial aquifer system, consisting of Miocene (Hawthorne Formation) through Quaternary deposits, is not continuous over Burke County or the VEGP site (Miller 1990).

The lower aguifer at the VEGP site overlies the bedrock and is comprised of Cretaceous-age sediments. Locally, this aguifer system is known as the Cretaceous aguifer. The sediments include sands, gravels, and clays of the Cape Fear Formation, Pio-Nono Formation and associated unnamed sands, Gaillard Formation, Black Creek Formation, and Steel Creek The middle aguifer is made up of Tertiary-age sediments occurring over the Cretaceous-age sediments described above. The middle aguifer system is locally known as the Tertiary aguifer. It consists primarily of the permeable sands of the Still Branch and Congaree The relatively impermeable clays and silts of the Snapp and Black Mingo Formations overlie and confine the Cretaceous aquifer, while the clays and clayey sands of the Lisbon Formation overlie and confine the Tertiary aquifer. The upper aquifer is unconfined and is comprised of Tertiary-age sands, clays, and silts of the Barnwell Formation, which overlie the relatively impermeable Lisbon Formation. This aquifer is known locally as the Water Table aquifer or Upper Three Runs aquifer. A hydrostratigraphic section showing geologic units, confining units, and aquifers for the VEGP site and surrounding areas is shown in Figure 2.3.1-11. Further discussion of the aquifers underlying the VEGP site and surrounding area is provided below.

#### Cretaceous Aquifer

The Cretaceous aquifer locally comprises the Cape Fear Formation, Pio-Nono Formation/ unnamed sands, Gaillard Formation/Black Creek Formation, and Steel Creek Formation. These

formations generally consist of fluvial and estuarine deposits of cross-bedded quartzitic sand and gravel interbedded with silt and clay. The coarse-grained sediments are mostly unconsolidated and are generally permeable, while the fine-grained sediments are partially consolidated and are generally impermeable. In addition to the varying lithology, the formation also exhibits lateral facies changes, on-lap and off-lap relationships, and discontinuous lenses (Huddlestun and Summerour 1996). The elevations, thicknesses, and descriptions of these geologic formations, as determined from VEGP geotechnical boring B-1003, are summarized below:

- The basal Cape Fear Formation overlies the Triassic Dunbarton Basin bedrock, which is of Paleozoic age and consists of alternating mudstone, sandstone, and breccia. Boring B-1003 encountered top of bedrock at an elevation of approximately -826 ft msl and was advanced an additional 289 ft to elevation of -1,115 ft msl. The Cape Fear Formation consists of interbedded sands, silts, clays, and gravels. The formation is approximately 191 ft thick, with the top of the formation being at El. -635 ft msl.
- The Pio-Nono Formation and other unnamed sands overlie the Cape Fear Formation. This formation consists of sand, silt, and clay. The formation is approximately 60 ft thick, while the top of the formation is at approximately El. -575 ft msl.
- The undifferentiated Gaillard Formation and Black Creek Formation overlie the Pio-Nono Formation and unnamed sands. Most of the formation consists of sand with silt and clay, and layers of gravel. The deposit is approximately 211 ft thick, with the top of the formation being at approximately El. -364 ft msl.
- The Steel Creek Formation overlies the undifferentiated Gaillard Formation and Black Creek Formation. It consists mainly of sand with clay and silt. The formation is approximately 110 ft thick; the top of the formation is at approximately El. -254 ft msl.

The Cretaceous aquifer system has not been extensively developed, primarily because the shallower Tertiary system is adequate for most groundwater needs and is available for use throughout the region. Quantitative data from the limited number of test and production wells in the Cretaceous strata, and inferred data from geologic and stratigraphic studies, indicate clearly that the Cretaceous aquifer system is highly capable of yielding large quantities of good quality groundwater.

Recharge to the Cretaceous aquifer system is primarily by direct infiltration of rainfall in its outcrop area, located north of the VEGP site in a 10- to 30-mile-wide belt extending from Augusta, Georgia, northeastward across South Carolina to near the state line separating North and South Carolina. In the outcrop areas, precipitation penetrates the Cretaceous sediments. Groundwater in the outcrop areas is under water table conditions, but as it moves progressively downdip, it becomes confined beneath the overlying Snapp and Black Mingo Formations in the vicinity of the VEGP site. Hence, the Cretaceous aquifer system is under confined conditions for most of its areal extent. Discharge of the Cretaceous aquifer system is primarily from

subaqueous exposures of the aquifer that are presumed to occur along the Continental Shelf. Other discharge sources are to the Savannah River and by pumping.

## **Tertiary Aquifer**

The most productive aquifer at the VEGP site consists of the Congaree and Still Branch Formations, which are hydraulically connected and are referred to as the Tertiary sand aquifer. The overlying Lisbon Formation, containing the Blue Bluff Marl, acts as a confining layer. The elevations, thicknesses, and descriptions of geologic formations comprising the Tertiary aquifer, as encountered in boring B-1003, are described below.

- The Black Mingo and Snapp Formations constitute a semi-confining hydrogeologic unit under the VEGP site that separates the underlying Cretaceous aquifer from the overlying Tertiary sand aquifer as they dip to the southeast. The Paleocene-age Black Mingo Formation is approximately 39 ft thick and consists of sand, clay, and silt. The top of the formation is at approximately El. -215 ft msl. The Snapp Formation overlies the Black Mingo Formation and consists of sand, clay and silt, and includes a basal gravel layer. The stratum is also Paleocene in age. The formation is approximately 107 ft thick. The top of the formation is at approximately El. -108 ft msl.
- Above the Snapp is the Eocene-age Congaree Formation. The Congaree Formation has a thickness of about 115 ft and consists primarily of sand with clay and silt, and a basal gravel layer. The top of the formation is at an elevation of approximately 7.3 ft msl. The overlying Still Branch and Bennock Millpond Sands Formation consist of sand, clay, and silt and has a weak carbonate component. The formation thickness is approximately 67 ft, with the top of the formation being approximately El. 74 ft msl.
- The Lisbon Formation overlies the Tertiary sediments is the Lisbon Formation. The Lisbon Formation is Eocene in age and is comprised of sand, clay, and silt with interbedded layers of fossiliferous limestone. The Lisbon Formation contains a marl known as the Blue Bluff Member (Blue Bluff Marl). The Lisbon Formation also contains the McBean Limestone Member, a fossiliferous limestone layer. The formation has a thickness of approximately 63 ft, and the top of the formation is at approximately El. 137 feet msl. This formation separates the confined and unconfined aguifer systems beneath the VEGP site.

VEGP Units 1 and 2 UFSAR Section 2.5.1.2.2.2.1.1 states that the Blue Bluff marl is a distinct unit that is relatively constant in thickness over many square miles, although variable in lithology. Contours of the upper and lower surfaces, as well as an isopach map of the marl in the vicinity of the plant, are shown on drawings AX6DD352, AX6DD371, and AX6DD372 of the UFSAR. These drawings indicate the Blue Bluff Marl to be continuous over the entire VEGP site. On the VEGP site, the ESP subsurface investigation (SSAR Appendix 2.5A) determined that the Blue Bluff Marl ranges in thickness from 63 to 95 ft at three locations

where the stratum was fully penetrated, with an average thickness of 76 ft and a median thickness of 69 ft.

Recharge to the Tertiary aquifer is primarily by infiltration of rainfall in its outcrop area, which is a belt 20 to 60 miles wide extending northeastward across central Georgia and into portions of Alabama to the west and South Carolina to the east. Discharge from the Tertiary aquifer occurs from pumping, from natural springs in areas where topography is lower than the piezometric level of the aquifer, and from subaqueous outcrops that are presumed to occur offshore. Discharge also occurs to the Savannah River where the river has completely eroded the Blue Bluff Marl confining layer allowing discharge from the aquifer to the river.

#### Water Table Aquifer

The uppermost aquifer at the VEGP site is unconfined and consists of the Barnwell Group, including the discontinuous deposits of the Utley limestone, as well as Quaternary deposits along adjacent stream channels. The saturated interval within the Barnwell Group is commonly referred to as the Water Table aquifer (also known as the Upper Three Runs aquifer) and is the first water-bearing zone encountered beneath the VEGP site. The descriptions of the Barnwell Group were determined from VEGP ESP geotechnical and hydrogeological borings and are described below.

• The basal Utley Limestone Member of the Barnwell Group consists of sand, clay, and silt with carbonate-rich layers. The stratum is discontinuous across the VEGP site and was not encountered in several of the borings. To assess its degree of discontinuity, borings logged for the hydrogeological and geotechnical investigations have been examined for the presence/ absence of the Utley limestone. Logs for these borings are included in SSAR Appendices 2.4A and 2.5A. In completing this assessment, effort was made to eliminate spatial bias. Therefore, only one boring log was considered when there were adjacent borings from OW-series well pairs, or adjacent B- and OW-series borings. The results are summarized in Table 2.3.1-27.

The data presented in Table 2.3.1-27 indicates that the Utley limestone is absent in 8 out of 18 borings, or 44 percent of the borings. Spatial trends in the presence/absence of the Utley limestone indicate that the unit tends to be present in the power block area for VEGP Units 3 and 4 and the area to the north toward Mallard Pond. The Utley limestone tends to be absent in the cooling tower area for VEGP Units 3 and 4 and the area to the south. These results are consistent with the Utley limestone isopachs presented in the UFSAR for VEGP Units 1 and 2 (Drawing No. AX6DD376). These isopachs indicate that the limestone increases in thickness to a maximum of about 80 ft and then decreases in thickness to 10 ft or less along a profile extending from the power block to Mallard Pond, with the long axis of this unit trending in a northeast-southwest direction.

 Overlying the Utley limestone are undifferentiated sands, clays, and silts. The thickness of the group is variable with a range of approximately 14 to 119 ft. The top of the group ranges from approximately El. 205 to 264 ft msl. At boring B-1003, the formation is approximately 48 ft thick with the top of the formation being at an elevation of approximately 223 ft msl.

Recharge to the Water Table aquifer is almost exclusively by infiltration of rainfall. The presence of porous surface sands and the moderate topographic relief in the VEGP site area suggest that a significant fraction of the precipitation either infiltrates the ground or is lost to the atmosphere by evapotranspiration. Discharge is to localized drainages and wells.

#### 2.3.1.2.3 Observation Well Data

Data from a combination of new wells installed for the ESP application and existing VEGP site wells were used to develop the groundwater elevation contour maps. The new wells, designated OW-1001 through OW-1015, were installed in May and June 2005. (One of the wells, OW-1001, had very little change in groundwater levels and is not included in the analysis. A replacement well, OW-1001A, was installed in October 2005.) Ten of the new wells are screened in the Water Table aquifer and five are screened in the confined Tertiary aquifer system below the Blue Bluff Marl. No wells were installed into the deeper Cretaceous aquifer. Existing wells 142 and 179, remaining from the pre-construction monitoring network for VEGP Units 1 and 2, are screened in the Water Table aquifer. Existing wells with identifications beginning with the number 8 were installed between 1979 and 1985 to monitor construction dewatering of VEGP Units 1 and 2. These wells are screened in either the Water Table or Tertiary aquifers. Existing wells with an LT designation were installed in 1985 as part of post-construction monitoring activities and screened in the Water Table aquifer.

Observation well OW-1001A was installed at the site in October 2005 to replace OW-1001. Observation well OW-1001 was replaced because, following a period of groundwater level monitoring from June to September 2005, the groundwater level data from this well was considered invalid. This is discussed in more detail in the following section. Observation well OW-1001A was the only new "A" well installed at the site for the ESP application. Observation well OW-1001A should not be confused with the borings or drill logs contained in SSAR Appendix 2.4A that also use the suffix "A." The confusion arises because the boring or drill logs contained in SSAR Appendix 2.4A are labeled "OW" (for Observation Well) as opposed to "B" (for Boring log) or "D" (for Drill log). A summary of borings or holes drilled at the site to accommodate installation of the new observation wells is provided in Table 2.3.1-28.

Groundwater level elevations in OW-1001 measured between the period June 2005 and November 2006 (groundwater level data continues to be collected in wells OW-1001 and OW-1001A for observation purposes) range from about 114 to 118 ft msl, with a seasonal fluctuation of about 4.4 ft. These groundwater levels and seasonal fluctuations are not consistent with the groundwater levels and seasonal fluctuations of groundwater levels in the Water Table

aquifer and suggest that the screened portion of the well is not in good hydraulic communication with the Water Table aquifer. Review of the boring log, daily field log, well development log, and in situ hydraulic conductivity test results for the well indicate that either the formation material adjacent to the well was adversely affected by well construction or that the well was inadvertently installed in the confining unit underlying the formation material. Observation well OW-1001A was installed to replace well OW-1001, as discussed above. The construction log for OW-1001A contained in SSAR Appendix 2.5A (report Appendix D) indicates that the screened portion of the well ranges in elevation from 146.13 to 136.13 ft msl, while groundwater level elevations for the 17-month monitoring period range from 135.91 to 135.99 ft msl. These groundwater level data reveal that groundwater levels in the well are close to or below the bottom of the screened interval of the well, indicating no hydraulic communication with the Water Table aquifer. Groundwater data obtained from OW-1001 and OW-1001A are considered invalid and are not used in the following groundwater evaluations.

Monthly water levels in the observation wells were measured to characterize seasonal trends in groundwater levels and flow directions for the VEGP site. Monthly monitoring of these wells began in June 2005 and is continuing. An 18-month data set representing June 2005 through November 2006 is used for this ESP application. In addition, longer-term data is available for some of the existing wells completed in the Water Table and Tertiary aquifers, which are used to characterize historic trends.

The locations of VEGP site observation wells that are being monitored are shown in Figure 2.3.1-12. Table 2.3.1-18 lists the observation wells currently being used to monitor the Water Table aquifer, while Table 2.3.1-19 lists the observation wells currently being used to monitor the Tertiary aquifer.

The following groundwater piezometric surface trend discussion is based on the information presented in Figures 2.3.1-30 through 2.3.1-35, Figures 2.4.12-16 through 2.4.12-21, Figures 2.3.1-23 through 2.3.1-27, and Tables 2.3.1-18 and 2.3.1-19.

## Water Table Aquifer

Groundwater level data for the Water Table aquifer available for 1979 through 2006 is provided in Figure 2.3.1-30. Also shown on this figure is annual precipitation measured at three climate stations close to the VEGP site, which includes the Augusta WSO Airport, Waynesboro 2 NE, and Milen 4N climate stations. Precipitation data was obtained from the South Carolina Department of Natural Resources website (SC DNR 2007). In addition, the Palmer Drought Severity Index (PDSI) and Palmer Hydrological Drought Index (PHDI) are plotted on Figure 2.3.1-31 for the same period. The PDSI attempts to measure the duration and intensity of the long-term cumulative meteorological drought and wet conditions. The PDHI is another long-term drought index intended to measure the hydrological impacts of drought (e.g., reservoir levels, groundwater levels, etc.). PDSI and PHDI data were obtained from the National Climatic Data Center website (NCDC 2007). These indices provide an indication of the severity of a wet or dry

spell. The indices generally range from +6 to -6, with negative values denoting dry spells and positive values denoting wet spells. Values of +0.5 to -0.5 indicate normal conditions.

Figure 2.3.1-30 shows that for the period 1979 to 1984, groundwater level elevations in the Water Table aguifer were affected (lowered) by construction dewatering of the power block excavation for VEGP Units 1 and 2 that was in effect from June 1976 to March 1983. Groundwater levels for subsequent years exhibit variability in response to meteorological conditions. The magnitude of the variability can be estimated using data from the wells having the longest period of record, which include wells 802A, 805A, 808, LT-7A, LT-12, and LT-13. Table 2.3.1-29 summarizes the minimum and maximum water levels recorded at each of these wells. These results indicate a 5to-8-ft range in water levels over the 17-year period of record for these wells. Inspection of the long-term hydrographs for wells 802A, 805A, 808, LT-7A, LT-12, and LT-13 in conjunction with the drought severity indices for the same period indicates that groundwater levels in the Water Table aguifer generally correlate with the PDSI and PDHI. Water levels tend to remain unchanged when the drought severity indices remain near normal (±1). During drought periods when the PDSI or PDHI index falls to -2 or below, groundwater levels tend to decline. Conversely, during wet periods when the PDSI or PDHI increases to +2 or more, groundwater levels tend to rise. Increases or decreases in the drought indices would be associated with the increases or decreases in the rate of recharge of the Water Table aquifer. Because of the relatively large depth to the water table (at least 60 ft), prolonged wet or dry periods on the order of a year in duration are apparently required to affect the recharge to the water table at these depths.

Groundwater data from June 2005 to November 2006 for the Water Table aquifer is summarized in Table 2.1.1-18 and shown in Figure 2.3.1-32. Groundwater elevations for this 18-month monitoring period range from about 133 to 165 ft msl, with seasonal fluctuations averaging about 1 ft. This data exhibits very little variability because the recharge during this period was evidently relatively constant. Comparison of historical groundwater level elevations with precipitation events and other meteorological indices over a longer period of time suggest that persistent and significant wet weather is required to elicit significant water table response, as discussed above. The annual precipitation, the PDSI, and the PDHI for 2004 to 2006 have been relatively stable and near normal values. Due to the absence of any upward or downward trends in these indices, it is expected that groundwater elevations in the Water Table aquifer would be relatively steady over this period.

The groundwater elevation data summarized in Table 2.3.1-18 were used to develop quarterly groundwater surface elevation contour maps for the Water Table aquifer. These maps are presented in Figures 2.3.1-16 through 2.3.1-20 and Figure 2.3.1-33 for June 2005 through November 2006. Note that a contour map for November 2006 was developed because no groundwater level data was available for September and October 2006. Note that October 2005 data, as opposed to September 2005 data, were used to develop the contour map for the second quarter so that data from replacement well OW-1001A, installed in October 2005, could be

incorporated. For each quarter, the spatial trend in the piezometric surface is similar, with elevations ranging from a high of approximately El. 165 ft msl in the vicinity of well OW-1013 to a low of less than El. 135 ft msl at well OW-1005. The groundwater surface contour maps indicate that horizontal groundwater flow across the VEGP site is in a north-northwest direction toward Mallard Pond (also known as Mathes Pond). This surface water feature is a local discharge point for the shallow groundwater flowing beneath the VEGP site. The horizontal hydraulic gradient across the site for the Water Table aquifer is relatively consistent between the five figures and is approximately 0.014 ft/ft.

## Tertiary Aquifer

Historical groundwater elevations from 1971 through 1985 for Tertiary aquifer wells 27 and 29 are provided in Figure 2.3.1-21.

Recent groundwater elevation data from June 2005 to November 2006 for the Tertiary aquifer is summarized in Table 2.3.1-19 and shown in Figure 2.3.1-34. Groundwater elevations for this 18-month monitoring period range from about 82 to 128 ft msl. Elevations are relatively constant from June to August 2005. In most cases, the piezometric head of the aquifer declines from August 2005 through November 2005. The elevations begin to rebound in December 2006, continuing through February 2006. The lowering of the piezometric surface is likely in response to a decrease in precipitation. October and November are the months with the lowest precipitation during the year for this area. Well 27 shows a higher degree of variability than the others and is likely influenced by its proximity to the river.

The groundwater elevation data summarized in Table 2.3.1-19 were used to develop piezometric surface maps for the Tertiary aquifer. The Tertiary aquifer piezometric surface is presented in Figures 2.3.1-23 through 2.3.1-27 and Figure 2.3.1-35 for June 2005 through November 2006. The piezometric surfaces for the Tertiary aquifer show a relatively consistent flow pattern. In general, the groundwater in this aquifer unit shows an east-to-northeast flow pattern, toward the Savannah River. Head elevations range from approximately El. 125 ft msl in the western portion of the VEGP site to less than El. 100 ft msl in the vicinity of the bluff next to the Savannah River flood plain. The elevation of the piezometric head at the bluff and that of the Savannah River flood plain suggest groundwater is discharging to the Savannah River. The piezometric elevations in the Tertiary aquifer decreased at least 1.5 ft across the VEGP site in December 2005, reflecting the seasonal decrease in precipitation.

The horizontal hydraulic gradient across the site for the Tertiary aquifer is relatively consistent among the five figures and is approximately 0.006 ft/ft. In the center of the VEGP site, there is a downward head difference of approximately 50 ft between the Water Table aquifer and the Tertiary aquifer, suggesting hydraulic separation of the two aquifers. The Blue Bluff Marl confining unit that separates the aquifer systems has an average thickness of about 70 ft at the VEGP site.

Cretaceous Aquifer

At the VEGP site, both the Cretaceous and the Tertiary aquifers are considered confined beneath the Blue Bluff Marl but are in apparent hydraulic connection with each other. At some distance downdip of the VEGP site, the Cretaceous aquifer becomes hydraulically separated from the Tertiary aquifer. This separation is believed to be due to facies changes in the intervening clays and silts of the Snapp and Black Mingo formations becoming relatively impermeable. The point at which this occurs is not well defined but it is believed to be a few miles downdip (south) of the site.

The regional direction of the groundwater flow in the Cretaceous (and the Tertiary) aquifer system is south-by-southeast at a hydraulic gradient of approximately 6 to 20 ft/mi (0.001 to 0.004 ft/ft) (Siple 1967). From the vicinity of the Fall Line to a point expected to be a few miles south of the site, the Savannah River has downcut through the Blue Bluff Marl confining layer and into the underlying strata. The Savannah River channel cut allows both the Cretaceous and the Tertiary aquifers to discharge to the riverbed, resulting in a localized hydraulic (groundwater) sink. The aquifer flow directions in the vicinity of the river cut are affected by the hydraulic sink and do not follow regional trends.

### 2.3.1.2.4 Hydrogeologic Properties and Groundwater Travel Time

Slug tests were performed in the new groundwater observation wells installed in connection with the ESP application to determine in situ hydraulic conductivity values for the Water Table and Tertiary aquifers. Table 2.3.1-20 summarizes the test results. Soil samples collected from selected geotechnical and hydrogeological borings were submitted for laboratory tests to determine grain size, moisture content, and specific gravity, results from which are included in Tables 2.3.1-21 through 2.3.1-23. Similar data are available for the adjacent VEGP Units 1 and 2 site. The hydrogeological properties of the Water Table aquifer, Lisbon Formation (Blue Bluff Marl) confining unit, Tertiary aquifer, and Cretaceous aquifer at the VEGP site are discussed below.

## Water Table Aquifer

In the vicinity of the VEGP site, the basal unit of the Barnwell Group, the Utley limestone member, is capable of transmitting groundwater but is of limited areal and vertical extent. In addition, the horizontal and vertical hydraulic conductivity of the saturated clays, silts, and sands within the Barnwell Group varies considerably, due to variable clay content.

The hydraulic conductivity of the Water Table aquifer within the vicinity of the VEGP site was measured previously by both in situ and laboratory testing methods during site characterization investigations for VEGP Units 1 and 2. In situ hydraulic conductivity values for the Barnwell Group sands, silts, and clays were found to range between 200 and 267 ft/yr (0.5 to 0.7 ft/day). Laboratory values varied considerably beyond the range of the in situ tests from 9.8 to 302 fy/yr (0.03 to 0.8 ft/day). Well pumping tests conducted in the Utley limestone resulted in hydraulic conductivities ranging from 3,250 to 125,400 ft/yr (9 to 343 ft/day), while falling and constant

head tests suggested lower values, ranging from 96 to 5,800 ft/yr (0.3 to 16 ft/day). These results indicate the possibility of localized, highly permeable zones in the Utley limestone. Laboratory porosity values for the Barnwell Group sands, silts, and clays were found to range from 34 to 61 percent, with a mean value of 44 percent.

Hydraulic conductivities were determined for the VEGP Units 3 and 4 site as part of the ESP investigation. Slug test results for the Water Table aquifer range from 0.12 to 2.65 ft/day, with a geometric mean of 0.41 ft/day (Table 2.3.1-20). Table 2.3.1-21 summarizes the laboratory test results for geotechnical samples of the Barnwell Formation, which were at depths ranging from EI. 108 to 248 ft msl. Sand and clay make up the majority of samples, with some gravel present. Measured moisture contents, by weight, range from 4 to 93 percent and have a median value of about 25 percent. Specific gravity analysis was performed only for the samples collected from the observation well borings. Values range between 2.59 to 2.75 and have a median value of 2.66. Using the median moisture content of 25 percent and a value of 2.66 for the specific gravity, the void ratio is estimated to be about 0.67. A total porosity of 40 percent is calculated from this void ratio (Craig 1994), and an effective porosity of about 32 percent is estimated based on 80 percent of the total porosity (de Marsily 1986). The specific yield for the Water Table aquifer was not determined; however, an estimate of this value taken from published literature for similar aquifer materials indicates that it may be in the range of 0.20 to 0.33 (McWhorter and Sunada 1977).

The groundwater travel time in the Water Table aquifer was calculated from the ESP site to the projected discharge point (Mallard Pond). A horizontal hydraulic gradient of 0.014 ft/ft was estimated using the maximum water level observed at OW-1009 (163.03 ft msl), the minimum water level observed at OW-1005 (132.53 ft msl), and the distance between the two observation wells of about 2,200 ft. A hydraulic conductivity value of 0.5 ft/day was used, which is considered to be a representative hydraulic conductivity value for the Barnwell Formation, which includes the Utley limestone. Using this hydraulic conductivity of 0.5 ft and an effective porosity of 32 percent, an average horizontal groundwater velocity of 0.02 ft/day was calculated (Heath 1998). Using a distance of approximately 2,450 ft from center of the power block area for the new AP1000 units to the closest point of Mallard Pond, the groundwater travel time from the power block area to Mallard Pond is estimated to be about 336 years.

The geotechnical boring logs contained in SSAR Appendix 2.5A, which report some occurrences of water loss during drilling through the Utley limestone, and high hydraulic conductivity test results for the Utley limestone obtained during site investigations for VEGP Units 1 and 2 indicate the possibility of localized highly permeable zones in the Utley limestone. These zones could act as preferential pathways for groundwater flow if there was an accidental liquid release of effluents to the groundwater at the VEGP site.

As described in SSAR Section 2.5.4.5, construction of the new Units 3 and 4 will require a substantial amount of excavation and backfill. The excavation will be necessary to completely

remove the sands, silt, clays, and Utley limestone of the Barnwell Group. Total excavation depth to the Blue Bluff Marl bearing stratum is expected to range from approximately 80 to 90 ft below existing grade. Backfilling will be performed from the top of the Blue Bluff Marl to the bottom of the containment and auxiliary buildings at a depth of about 40 ft below final grade. Filling will continue up around these structures to final grade. The fill will primarily consist of granular materials, selected from portions of the excavated sands and from other available borrow sources. Following the guidelines used during construction of VEGP Units 1 and 2, structural fill will be a sandy or silty sand material with no more than 25 percent of the particle sizes smaller than the No. 200 sieve. This structural fill will be compacted to a minimum of 97 percent of the maximum dry density.

Excavating existing soils and replacing these soils with structural fill will alter the hydrogeologic characteristics of the subsurface materials within the footprint of VEGP Units 3 and 4. In situ hydraulic testing of fill material for VEGP Units 1 and 2 indicates a hydraulic conductivity range of 480 ft/yr (1.3 ft/day) to 1,220 ft/yr (3.3 ft/day), based on data included in UFSAR Table 2.4.12-15. Values for Units 3 and 4 are expected to be similar because the borrow sources and compaction criteria for the fill will be the same. Compared with the hydraulic conductivities for the Water Table aquifer, as described above, it can be seen that the hydraulic conductivity of the fill is generally higher than that of the in situ soils.

Development of VEGP Units 3 and 4 will also increase the impervious area across the VEGP site where power generation and associated facilities are constructed. Storm water management facilities (e.g., catch basins, storm sewers) will be used to convey runoff from precipitation offsite. The increased impervious area and use of storm water management facilities will tend to reduce the recharge to the Water Table aquifer in areas affected by Unit 3 and 4 construction.

Construction of VEGP Units 3 and 4 will entail the placement of relatively large and impermeable structures below grade. The base elevations of the major structures (containment and auxiliary buildings) will be at about El. 180.5 ft msl. This elevation is at least 20 ft above the water table. Because these structures will not extend below the water table, they will not affect the hydrogeologic characteristics of the underlying saturated zone.

Lisbon Formation (Blue Bluff Marl) Confining Unit

The hydraulic conductivity of the marl layer is very low, and it effectively confines the aquifer underlying it. It is considered a barrier to vertical groundwater movement. In situ permeability tests (packer tests) were performed in the marl during site characterization investigations for VEGP Units 1 and 2. In 90 percent of the intervals tested, no measurable water inflow occurred. Laboratory permeability tests were also conducted on core samples collected from the marl. Laboratory measurements ranged from 0.0052 to 8.8 ft/yr (1.4×10<sup>-5</sup> to 2.4×10<sup>-2</sup> ft/day) with a geometric mean of 1.3×10<sup>-3</sup> ft/day, indicating the marl is nearly impermeable. Porosity values ranged from 24 to 62 percent, with a mean value of 48 percent.

Geotechnical laboratory results for the Lisbon Formation (Blue Bluff Marl) confining unit are summarized in Table 2.3.1-22 for the VEGP site. Soil samples were collected between El. 51 and 135 ft msl. The samples consist of gravel, sand, and clay. Moisture contents range from 13.5 to 67 percent, with porosities of 25 to 59 percent. Using the median moisture content of 29 percent from geotechnical laboratory results and an assumed specific gravity of 2.65, the void ratio of the confining unit is estimated to be 77 percent. Based on the void ratio value, total porosity is calculated to be 44 percent. The effective porosity of the Lisbon Formation was estimated using Figure 2.17 of de Marsily (1986). This figure plots total and effective porosity as a function of grain size. To estimate the effective porosity for the Lisbon Formation (Blue Bluff Marl), the ratio of effective to total porosity determined from Figure 2.17 was applied to the site-specific total porosity value for the VEGP site. Using the median D50 value of 0.24 mm as a representative grain size (Table 2.3.1-22), a ratio of effective to total porosity of about 0.8 was determined. Multiplying the median total porosity of 0.44 by this ratio yields an effective porosity of 0.35.

The effective porosity was also estimated as the difference between the total porosity and the residual water content, as given by Equation 4.4 of Yu et al. (1993). Grain size distribution data indicate that most of the Lisbon Formation samples can be classified as a silty sand (SM) or clayey sand (SC). The residual water content for SM or SC soils obtained from Carsel and Parrish (1988) using equivalent USDA-SCS soil textural classifications, ranges from 0.07 to 0.10. The effective porosity would then range from 0.34 to 0.37. This result indicates that the 0.35 value for effective porosity is representative of the Lisbon Formation.

# **Tertiary Aquifer**

Hydraulic conductivities determined from Tertiary aquifer slug tests range from 0.35 to 2.1 ft/day, with a geometric mean of 0.83 ft/day (Table 2.3.1-20). These results are consistent with those for the VEGP Units 1 and 2 site for which the geometric mean was determined to be 0.51 ft/day. The laboratory results from the selected geotechnical samples collected in the Tertiary aquifer are presented in Table 2.3.1-23. Sample elevations range from El. -273 ft msl to 69 ft msl, with the samples consisting mainly of sand and fine particles, with some gravel. Moisture content ranges from 19 to 41 percent, with specific gravity values varying from 2.62 to 2.69. Using the median moisture content of 24 percent and a value of 2.67 for the specific gravity, the void ratio of the Tertiary aquifer is estimated to be about 0.64. A total porosity of 39 percent is calculated from this void ratio (Craig 1994), and an effective porosity of about 31 percent is estimated based on 80 percent of the total porosity (de Marsily 1986). The storage coefficient for the Tertiary aquifer alone was not determined; however, previous tests of wells completed in the combined Cretaceous/Tertiary aquifers suggest that a value on the order of 10<sup>-4</sup> would be a reasonable estimate (see below).

The horizontal hydraulic gradient of the Tertiary aquifer is approximately 0.005 ft/ft, based on the maximum water level observed at well OW-1008 (127.99 ft msl), the minimum water level

observed at well 27 (81.5 ft msl), and the distance between the two observation wells of about 8,700 ft. The average horizontal groundwater velocity was calculated at 0.013 ft/day using a hydraulic conductivity of 0.83 ft/day, a hydraulic gradient of 0.005 ft/ft, and an effective porosity of 31 percent (Heath 1998). Using a distance of 5,600 ft from center of the power block area for the new AP1000 units to the closest point of the Savannah River, the groundwater travel time from the power block area to the Savannah River in the Tertiary aquifer is estimated to be about 1,180 years.

#### Cretaceous Aquifer

Two makeup water wells (designated as MU-1 and MU-2A) for VEGP Units 1 and 2 were reported to be capable of supplying water at 2,000 gal./min and 1,000 gal./min, respectively. The water is withdrawn from the combined Cretaceous/Tertiary aquifers. Pumping tests were conducted at these wells in 1977. Transmissivity values ranged between 110,400 to 130,900 gallons per day per foot (gpd/ft). A storage coefficient was calculated at  $1.07 \times 10^{-4}$ .

A pumping test was also conducted in a Cretaceous aquifer test well identified as TW-1 during site characterization activities for VEGP Units 1 and 2. A transmissivity value of 158,000 gpd/ft was calculated as an average value for the aquifer. The storage coefficient ranged between 3.3 x  $10^{-4}$  and  $2.1 \times 10^{-4}$ , indicating the aquifer is effectively under confined conditions.

Vertical hydraulic conductivities were estimated assuming that the anisotropy ratio between the vertical and horizontal directions is 1:3, based on measured horizontal and vertical hydraulic conductivities for sandstone deposits (Freeze and Cherry 1979). The vertical hydraulic conductivities for the Water Table aquifer, Lisbon Formation confining unit, and Tertiary aquifer are estimated to be 0.14, 0.00045, and 0.28 ft/day, respectively.

#### 2.3.1.2.5 Summary

The VEGP site lies within the Coastal Plain Physiographic Province. Geologic conditions beneath the VEGP site generally consist of about 1000 ft of Coastal Plain sediments with underlying Paleozoic sedimentary Triassic sediments and Paleozoic crystalline rock Groundwater at the site occurs in three aquifers that are part of the Southeastern Coastal Plain aquifer system. The lower (Cretaceous) aquifer is comprised of Cretaceous-age sediments, while the middle (Tertiary) aquifer is comprised of Tertiary-age sediments. Both are under confined conditions. The upper (Water Table) aquifer, comprised of Tertiary-age sediments, is unconfined. Recharge to the Cretaceous and Tertiary aquifers occurs in their outcrop areas north of the VEGP site. These aquifers discharge to the Savannah River and to subaqueous outcrops along the Continental Shelf. Recharge to the Water Table aquifer occurs by infiltration of precipitation. Discharge is to localized drainage and stream incisions.

Observation wells completed in the Water Table and Tertiary aquifers were used to develop piezometric contour maps and hydraulic gradients. Hydrogeologic properties of these aquifers were determined by laboratory testing of soil samples and by in situ testing. Piezometric contour

maps for the Water Table aquifer indicate that groundwater flow across the VEGP site is northward towards Mallard Pond, which serves as a discharge area. The groundwater travel time from the center of the VEGP site to Mallard Pond is estimated to be about,336 years. Piezometric contour maps for the Tertiary aquifer show groundwater flow across the VEGP site to be in the east-to-northeast direction toward the Savannah River, which serves as a discharge area. The groundwater travel time in the Tertiary aquifer, from the center of the VEGP site to the Savannah River, is estimated to be about 1,180 years. The Water Table and Tertiary aquifers are separated by a very low permeability stratum known as the Lisbon formation. Observation well data suggest that there is little to no hydraulic connectivity between the Water Table and Tertiary aquifers. No sole-source aquifers have been designated within the VEGP site region.

Table 2.3.1-20 Hydraulic Conductivity Values

Observation	<b>Depth Test</b>			Hydraulic C	onductivity
Well No.	Interval	Aquifer	Material		
	(ft)			(cm/sec)	(ft/day)
OW-1003	72 - 91	Water Table	Reddish brown silty SAND (SM) with Light tan silty SAND with Tan and grey clayey COQUINA.	4.4E-05	0.12
OW-1005	143 - 169	Water Table	Pale yellow, silty SAND, calcareous (SM), fine-coarse-grained with shell pieces.	1.1E-04	0.32
OW-1006	113 - 136	Water Table	Very light tan silty SAND (SM) with light gray COQUINA, unconsolidated (OW-1006A). Tan sandy and shelly CLAY (CH), saturated with light tan, fine-coarse grained SAND with shell (SW) (OW-1006).	4.8E-04	1.4
OW-1007	99 - 120	Water Table	Tan fine-grained silty SAND (SM), saturated with very light tan silty SAND (SM) becoming shelly with light olive grey CLAY (CH).	9.3E-04	2.65
OW-1009	81 - 98	Water Table	Very light tan silty SAND (SM) with Tan limestone shell hash, very light tan silty SAND (SM) WITH "Brown silty CLAY.	4.0E-04	1.1
OW-1010	70 - 92	Water Table	Tan poorly graded SAND with silt (SP-SM) with brownish yellow clayey silty SAND (SC-SM), soft with white SHELL HASH.	6.4E-05	0.18
OW-1012	71 - 94	Water Table	Brown SAND, fine-to-medium-grained with pale yellow silt (SM) with Pale olive silt (ML) with pale yellow SILT, micaceous (ML).	1.4E-04	0.39
OW-1013	81 - 104	Water Table	Tan fine-to-medium-grained SAND (SP-SM) with tan or clay tubes or bioturbation with light olive tan calcareous silty fine grained-grained SAND (SP-SM) with light olive tan calcareous CLAY (CL), wet but not saturated.	1.3E-04	0.38
OW-1015	90 - 120	Water Table	Grayish white, fine-to-medium-grained SAND (SP) saturated with very light tan poorly graded SAND with silt (SP-SM) with tan shelly (coarse) fine to medium grained clayey SAND (SC).	1.5E-04	0.44

Table 2.3.1-20 (cont.) Hydraulic Conductivity Values

Observation	Depth Test			Hydraulic C	onductivity
Well No.	Interval	Aquifer	Material		
	(ft)			(cm/sec)	(ft/day)
OW-1002	216 - 237	Tertiary	Light greenish gray fine- to medium- grained silty, glauconitic SAND with gray clay layer (SM).	3.2E-04	0.9
OW-1004	150 - 187	Tertiary	Fine- to medium- grained dark gray SAND with organics, wet, poorly graded with silt (SP-SM).	1.3E-04	0.35
OW-1008	226 - 247	Tertiary	Gray, fine SAND (SW) with light gray fine sand (SM).	7.5E-04	2.1
OW-1011	197 - 218	Tertiary	Dark bluish-gray silty fine- to medium- grained SAND, very moist with gray, poorly graded sand with silt (SP-SM) with silty gravelly sand with fossils, shark teeth with gray medium-to coarse-grained SAND.	3.8E-04	1.1
OW-1014	179 - 197	Tertiary	Dark gray silty SAND (SM-SP), high organic content, saturated with light gray fine quartz SAND (SP), silty SAND (SM) and dark gray Sandy SILT (ML).	1.9E-04	0.54
	<u>'</u>		Geometric Mean Water Table Aquifer	1.75E-04	0.5
			Geometric Mean Tertiary Aquifer	2.95E-04	0.83

Note.

Hydraulic conductivity values provided in SSAR Appendix 2.5A (report Appendix D)

Material descriptions from the borings logs provided in SSAR Appendix 2.4A (report Appendix E)
