INTRODUCTION

This Document is intended to provide users of Q3 Flood Data produced by the Federal Emergency Management Agency (FEMA) with an overview of the data files. Additional information in greater depth may be found in the *Q3 Flood Data Specifications*.

This document is presented in five main parts. They are:

1. **Background** - This section provides a history of the National Flood Insurance Program, the automation of its mapping program, and the Q3 Flood Data product history.
2. **Overview of Q3 Flood Data** - This section provides a summary of the contents of the Q3 Flood Data set, the data capture methods used, horizontal control, data sources, data quality, and a comparison of the Q3 Flood Data product to other FEMA digital data products.
3. **Use Policy** - This section presents FEMA's use policy regarding the Q3 Flood Data. It provides separate policy statements for standards of care, Community Rating System, and flood determination uses, and it explains the "Good Faith Standard."
4. **How to Obtain Q3 Flood Data** - This section discusses distribution issues including available file formats, conversion to other GIS formats, map projections for the various formats, file naming conventions, ordering instructions, organization of the Q3 Flood Data, user support, the Q3 Flood Data counties, and FEMA's revision/update plans for the Q3 Flood Data.
5. **Appendices** - These include a sample metadata file, FEMA's DFIRM and Q3 product sheets, a list of the Q3 Flood Data counties, and a glossary of terms and acronyms.

Part 1 BACKGROUND

This section summarizes the history of the National Flood Insurance Program, the automation of its mapping program, and the Q3 Flood Data product.

History of the National Flood Insurance Program

In response to increasing losses from flood hazards nationwide, the Congress of the United States passed the National Flood Insurance Act of 1968 which established the National Flood Insurance Program (NFIP). The 1968 Act provided for the availability of flood insurance within communities that were willing to adopt floodplain management programs to mitigate future flood losses. The act also required the identification of all floodplain areas within the United States and the establishment of flood-risk zones within those areas. As a result of the 1972 Hurricane Agnes flooding along the East coast, the 1968 Act was expanded by the Flood Disaster Protection Act of 1973. The 1973 Act added the mandatory purchase requirement and increased the awareness of floodplain mapping needs throughout the country. The responsibility for administration of the NFIP falls with the Federal Insurance Administration of the Federal Emergency Management Agency (FEMA).

The risk data to identify floodplain areas, as required by the Act, are acquired through Flood Insurance Studies (FISs). FISs are hydrologic and hydraulic studies of flood risks developed by FEMA. Using the results of a FIS, FEMA prepares a Flood Insurance Rate Map (FIRM) that depicts the spatial extent of Special Flood Hazard Areas (SFHAs) and other thematic features related to flood risk assessment. SFHAs are areas subject to inundation by a flood having a one-percent or greater probability of being equaled or exceeded during any given year. This flood, which is referred to as the 1% annual chance flood (or base flood), is the national standard on which the floodplain management and insurance requirements of the NFIP are based.

FEMA publishes the FIRM and distributes it to a wide range of users: private citizens, community officials, insurance agents and brokers, lending institutions, and other Federal agencies. The FIRM is the basis for floodplain management, mitigation, and insurance activities of the NFIP. Uses of the FIRM for insurance activities include enforcement of the mandatory purchase requirement of the 1973 Act, which "requires the purchase of flood insurance by property owners who are being assisted by Federal programs or by Federally supervised, regulated, or insured agencies or institutions in the acquisition or improvement of land or facilities located or to be located in identified areas having special flood hazards" (Section 2(b)(4) of the 1973 Act). In addition to the identification of SFHAs, the risk zones shown on the FIRMs are the basis for the establishment of premium rates for flood coverage offered through the NFIP.

At present, FISs have been completed and FIRMs published for virtually all communities in the

nation having flood risks. Flood risks have been assessed in approximately 20,400 communities nationwide. These studies, conducted at a cost of over \$900 million, have resulted in the publication of over 80,000 individual FIRM panels. Typically, 6 to 8 million FIRMs are distributed to users each year by FEMA. Over 2.5 million flood insurance policies have been written through the NFIP, providing coverage against flood loss for over \$200 billion in property nationwide.

In addition to initial FISs, FEMA is responsible for maintaining the FIRMs as communities grow, as new or better scientific and technical data concerning flood risks becomes available, and as some FISs become outdated by the construction of flood control projects or the urbanization of rural watersheds. Several thousand FIRMs need to be updated per year.

Automation of NFIP Mapping

Developments in the fields of automated cartography and Geographic Information Systems (GIS) technology led FEMA to study the potential of automating NFIP mapping and engineering. After a series of technology assessment and pilot projects, FEMA concluded that existing technology made the automation of NFIP mapping and engineering feasible. In Fiscal Year 1992, FEMA implemented a ten-year automation program, beginning with the conversion of FIRMs to a digital format.

Q3 Flood Data Product History

Starting with Hurricane Hugo in 1989, FEMA has attempted to support disaster relief operations with digital FIRMs. Disaster loan closings by the Small Business Administration (SBA), Temporary Housing Programs, and Individual Assistance and Family Grant Programs all require a flood hazard assessment. With automated flood map reading to support these assessments, significant time can be saved and map reading quality improved, thus resulting in faster disaster relief for victims.

More recently, increased funding for post-disaster mitigation activities has led to the extensive use of GIS and digital FIRMs for planning activities. Applications include selection of sites for relocation, prioritizing eligibility for home buyout programs, and identifying repeatedly damaged properties in SFHAs.

To support disaster recovery operations, FEMA has developed specifications for a digital product named the Q3 Flood Data. This product has the advantage of being far less costly in time and resources to produce than FEMA's other digital FIRM product, the Digital Flood Insurance Rate Map (DFIRM).

The Q3 Flood Data product is designed to serve FEMA's Response and Recovery activities as well as flood insurance policy marketing initiatives. This product is designed to allow rapid access to and distribution of digital FIRM data, and is compatible with all existing digital FIRM data already available and underway.

Part 2 OVERVIEW OF Q3 FLOOD DATA

This section summarizes the contents of the Q3 Flood Data set, the data capture methods, the horizontal control, the data sources, and the data quality. Finally, it compares the Q3 Flood Data product to other FEMA digital data products.

Contents

The Q3 Flood Data are developed by scanning the existing hardcopy FIRM to create a raster product suitable for viewing or printing and vectorizing a thematic overlay of flood risks. Q3 Raster FIRM files contain all FIRM data in raster format, but only certain features are contained in the vector Q3 Flood Data files.

Vector Files

The features contained in the vector Q3 Flood Data files include the following:

- 1% and 0.2% annual chance floodplain areas, including Zone V areas, certain floodway areas, and zone designations;
- Coastal Barrier Resources Act (COBRA) areas;
- political areas, including community identification number;
- FIRM panel areas, including panel number and suffix;
- 7.5-minute quadrangle areas; and
- mappable Letters of Map Change (LOMCs).

The vector Q3 Flood Data are contained in one single countywide file, including all incorporated and unincorporated areas of a county. The feature items and attributes are defined in detail in the *Q3 Flood Data Specifications* (Reference 1).

The means for linking other associated NFIP data to these files can be derived from the attributes contained within the files. For instance, the currently effective FIRM panel from FEMA's *Community Status Book* (Reference 2) or the Flood Map Status Information System (FMSIS) can be compared to the FIRM panel information in the Q3 Flood Data files to determine if the Q3 Flood Data files reflect the most current mapping.

The vector Q3 Flood Data files do NOT include the following:

- base map data (streets, etc.);
- base flood elevation lines and elevations;
- cross sections and letter identifiers;
- elevation reference marks and their elevations; and
- floodways if not shown on the FIRM.

Raster files

The Q3 Raster FIRMs are black and white scanned images collected at 400 dots per inch from mylar negatives. The raster files are not georeferenced. Letters of Map Change are not scanned.

Metadata

Each Q3 Flood Data file is accompanied by a metadata file that meets the Federal Geographic Data Committee's guidelines for metadata as contained in the *Content Standards for Digital Geospatial Metadata* (Reference 3). The metadata files are ASCII text files that describe the contents of and sources used for each Q3 Flood Data file. The metadata files may be accessed by users to determine if the vector or raster files meet their needs. In addition, the metadata file provides information specific to the county, including the FIRMs and LOMCs that were digitized.

A sample Q3 Flood Data metadata file is found in Appendix A.

Data Capture Methods

Data capture methods for the vector Q3 Flood Data vary, but include one or more of the following:

- scanning and heads-up (or on-screen) digitizing of the effective FIRMs;
- board (or table) digitizing of the effective FIRMs; and/or
- derivation from already existing digital files such as FIRM-DLGs or DFIRM-DLGs.

All of the above methods have as their end result a file meeting the *Q3 Flood Data Specifications*.

Horizontal Control

The hardcopy FIRMs from which the Q3 Flood Data vector data are extracted contain no horizontal control. The horizontal controlling of these data is typically performed by fitting the vectors to a georeferenced raster or vector 7.5-minute quadrangle file. The horizontal control of Q3 Flood Data vector data is consistent with that required for mapping at the scale of 1:24,000.

Data Sources

As stated above, the Q3 Flood Data are developed by scanning and vectorizing the existing hardcopy FIRM to create a raster product suitable for viewing or printing, as well as a thematic vector overlay of flood risks. Q3 Flood Data files contain all FIRM data in the raster file, but only certain features are vectorized.

Sources that reflect updates effected by Letters of Map Change (Letter of Map Revision or Letter of Map Amendment) are utilized in the preparation of Q3 Flood Data files. These revisions are included in the Q3 Flood Data if they are mappable at the published scale of the FIRM.

The Q3 Flood Data files may have been derived from DFIRM-DLGs, from FIRM-DLGs, or from FIRMs digitized previously for emergency applications, or they may be newly created files. Q3 Flood Data derived from previously created files may not contain certain items or may contain items that have been captured differently from the current Q3 Flood Data specifications. Items that may not be included in selected Q3 Flood Data files include the following:

- floodways
- COBRA boundaries
- gutters (or zone breaks)
- 0.2% annual chance floodplains
- FIRM panel neatlines for unprinted panels
- FIRM panel type attributes

In addition, the horizontal control of older data sets may have been consistent with that required for mapping at the scale of 1:100,000 instead of 1:24,000.

Data Quality

Edge-matching errors, overlaps and underlaps in coverage, and similar problems are not corrected during digitizing or scanning and vectorizing the Q3 Flood Data.

Although FEMA has established no independent quality control/quality assurance program for the Q3 Flood Data, the Q3 Flood Data files are distributed only after they have passed checking routines contained in FEMA's Q3QA Checking Software. The data are accompanied by documentation showing that the files have been evaluated and passed. FEMA has established a User Support mechanism through which any problems found with the data can be identified and channeled back to FEMA for resolution.

Attribute Accuracy

The attribute accuracy of the Q3 Flood Data vector files is tested by manual comparison of source FIRM with hardcopy plots and a symbolized display on an interactive computer graphic system. Selected attributes that cannot be visually verified are individually queried. In addition, FEMA's Q3QA Checking Software program is applied to the dataset to test the attributes against a master set of valid attributes and attribute combinations.

Topology

Polygon and line topology are present in Q3 Flood Data vector files. Certain node-area-line relationships are collected or generated to satisfy topological requirements, including the following:

- lines begin and end at nodes;
- lines connect to each other at nodes;
- lines do not extend through nodes;
- left and right areas are defined for each line segment and are consistent throughout the files; and
- the lines representing the limits of the file neatlines are free of gaps.

Logical Consistency

Tests of logical consistency are performed by ARC/INFO software modules. Check plots are made to test for closure of all internal polygons.

Completeness

Data completeness for Q3 Flood Data files reflect the content and completeness of the source FIRM. Features may have been eliminated or generalized on the FIRM due to scale and legibility constraints.

The flood risk data presented in the FIRM are developed only for communities participating in the NFIP for use in insurance rating and for floodplain management. Flood hazard areas are determined using the following sources:

- statistical analysis of records of river flow, storm tides, and rainfall;
- information obtained through consultation with the communities;
- floodplain topographic surveys; and
- hydrologic and hydraulic analyses.

Both detailed and approximate hydrologic and hydraulic analyses are employed. Generally, detailed analyses are used to generate flood risk data for developed or developing areas of communities. For undeveloped areas where little or no development is expected to occur, FEMA uses approximate analyses to generate flood risk data. Typically, only drainage areas that are greater than one square mile are studied.

Currentness

Flood Insurance Rate Maps continually undergo revisions and updates. Some of these revisions are effected by letter (Letter of Map Change). Q3 Flood Data may not reflect the most current information or information that is not mappable at the published scale of the FIRM. Users who need these updates should contact FEMA to obtain them in hardcopy format.

To determine if the Q3 Flood Data files contain the most current map information, users may compare the FIRM publication date contained in the source information section of the Q3 Flood Data metadata file to the date listed in FEMA's Community Status Book for that community. If the Community Status Book lists a more recent map date, users may contact FEMA's Map Service Center to obtain copies of the newer maps.

Comparison to Other FEMA Digital Data Products

FEMA distributes digital FIRM data in two basic product levels. These are the DFIRM (including the hardcopy DFIRM and the DFIRM-DLG) and the Q3 Flood Data. These two products differ in their contents, quality, and intended use.

Digital Flood Insurance Rate Map (DFIRM)

The DFIRM is comprised of all digital data required to create the hardcopy FIRM. This includes base map information, graphics, text, shading, and other geographic and graphic data required to create the final hardcopy FIRM product to FEMA standards and specifications (see the *Standards for Digital Flood Insurance Rate Maps*, Reference 4). This product serves the purpose of map design and provides the database from which the Digital Line Graph (DLG) thematic product of the flood risks is extracted to create the DFIRM-DLG. This product is generally produced in a countywide format. DFIRMs are subjected to community review and approval and are, therefore, the official basis for implementing the regulations and requirements of the NFIP within the community. Specifications for digitizing DFIRMs are consistent with those required for mapping at a scale of 1:24,000, or larger.

With increasing frequency, highly detailed large scale digital mapping is becoming available. DFIRMs may utilize this data as a source (new engineering data collected using photogrammetric techniques) or as a base map. Communities whose digital base mapping files were utilized as the base map for the DFIRM will find that they may use the DFIRM-DLG files for all determination and enforcement regulations.

Q3 Flood Data

The Q3 Flood Data do not replace the existing hardcopy FIRM or, if one exists, DFIRM product. The product has been designed to support planning activities, some Community Rating System (CRS) activities, insurance marketing, and mortgage portfolio review. It does not provide base flood elevation information; thus, it has limited application for engineering analysis, particularly for site design or rating of flood insurance policies for properties located within SFHAs.

Q3 Flood Data are developed by scanning the existing hardcopy FIRM to create a raster product suitable for viewing or printing and vectorizing a thematic overlay of flood risks. Vector Q3 Flood Data files contain only certain features from the existing hardcopy FIRM.

Q3 Flood Data are not tied to a base map, are not used to produce a new version of the hardcopy FIRM, and are not subjected to community review. Q3 Flood Data are intended to provide users with automated flood risk data suitable for determining whether features are within or outside the SFHA.

The Q3 Flood Data product can be a valuable tool to assist in screening property addresses within a GIS to determine flood risks. However, as the geographic processing performed to develop the Q3 Flood Data may introduce differences with the source hardcopy FIRMs, users must apply considerable care and judgment in the application of this product. For instance, the Q3 Flood Data may be overlaid on highly detailed large scale community base mapping data, but, if parcel level determinations are made, they must be prefaced with information about the accuracy of the data from which they are derived.

The following two tables (Figures 1 and 2) compare the contents of the DFIRM and Q3 Flood Data files. Additional information regarding these two data sets is contained in FEMA's product sheets, which may be found in Appendix B.

DFIRM and Q3 Flood Data Contents

	DFIRM	DFIRM-DLG	Vector Q3 Flood Data	Q3 Raster FIRM
1% Annual Chance Floodplain Boundary	√	√	√	√
0.2% Annual Chance Floodplain Boundary	√	√	√	√
Floodway	√	√	Some	Some
Gutters (Zone Breaks)	√	√	√	√

Community Review?	Yes	Yes	No	Yes

Figure 2

Part 3 USE POLICY

This section presents FEMA's use policy regarding the Q3 Flood Data. It provides separate policy statements for standards of care, Community Rating System, and flood determination uses and also explains the "Good Faith Standard."

Standards of Care

For the development of applications using the Q3 Flood Data, the user has the following responsibilities:

- to obtain and review the technical documentation of the Q3 Flood Data, with particular regard to the limitation of this product;
- to establish minimum mapping and accuracy standards required for the proposed application;
- to obtain digital base maps and ancillary data of appropriate scale, resolution, and accuracy to support the applications; and
- to determine whether Q3 Flood Data is based on the currently effective FIRM panel.

The quality, accuracy, and reasonableness of any applications developed using Q3 Flood Data are the sole responsibility of the end-user.

The Q3 Flood Data product is not suitable for engineering applications such as detailed site design and development plans, Letters of Map Change, or submittal of FIRM Map Revisions.

Community Rating System

For the purposes of the Community Rating System (CRS), Q3 Flood Data may be used in the following ways:

- for calculations of SFHA areas and similar applications that require geographic calculations and measures;
- for partial fulfillment of GIS provisions per the provisions of Section 440, "Flood Data Maintenance," as described in the *National Flood Insurance Program Community Rating System Coordinator's Manual* (Reference 5); and

- for development of "notification" lists of potentially flood-prone properties, per the provisions of Section 330; and
- for partial fulfillment of credits for the performance of flood determinations, when performed in conformance with guidelines for determination presented below.

Flood Determinations

The Q3 Flood Data can support flood determinations in a limited fashion, in conformance with the "Good Faith" standard, if used within the following guidelines:

- The end user has obtained a source of address or property location data and combined it with Q3 Flood Data in a manner that conforms to the Standards of Care outlined above.
- The end user has made no determinations as to the flood prone status of a property that is within 250 feet of an SFHA boundary. This requirement is due to the accuracy, resolution, and variations of the Q3 Flood Data relative to the source FIRMs.
- The end user has verified that the Q3 Flood Data FIRM panel and suffix conform to the panel and suffix of the currently effective FIRM.
- The end user has confirmed the availability of flood insurance in the community for which the determination is to be offered.
- The end user has confirmed the zone and BFE with the source FIRM or DFIRM for properties located within 250 feet of the SFHA boundary or within the SFHA.

The "Good Faith Standard"

The mandatory flood insurance purchase requirements of the 1973 National Flood Insurance Act apply only when a structure is located in an SFHA in a community that is participating in the NFIP. Such a structure must be insurable under the rules of the NFIP. Even though a portion of the land parcel upon which the structure is planned or built may be within an SFHA, the mandatory purchase requirement is triggered only if the structure itself is within an SFHA.

The compliance of lenders with the mandatory flood insurance purchase requirements of the 1973 Act is based on the "good faith standard." Determining whether a structure is located in an area of special flood hazard requires the examination of the location of the structure in relationship to the areas of special flood hazard as shown on the applicable FIRM. The good faith standard recognizes

that despite FEMA's best efforts to make the FIRMs as useful as possible, the descriptions of SFHA areas, as depicted by some maps, may, in some instances, not be clear enough to permit lenders to decide with certainty and precision whether or not property that is the security for a loan or that is the subject of financial assistance is located in such an area. It is for this reason that FEMA has recommended a "good faith standard."

The good faith standard requires lenders to exercise "due diligence and good faith" in determining the location of a property that is the subject of a loan relative to areas of special flood hazards as shown on a FIRM. This guidance is further explained, with additional information on the 1973 Act, in the publication *Mandatory Purchase of Flood Insurance Guidelines* (Reference 6).

When determinations are being made by lenders, or firms or individuals retained by lenders to assist in these endeavors, collateral data in addition to the FIRM is frequently required. FIRMs do not include all roads within communities, nor do they depict address, property boundary, or structure location information. As a result, determinations frequently can be made only by using an ancillary source of data, such as a land parcel map, to determine the location of a property on the FIRM.

Digital address range data, land parcel, and structure information is available for many communities across the nation. Using these digital data and GIS technology, it is possible to make determinations relative to the 1973 Act and meet the good faith standard. However, the lenders must assure that due diligence and good faith are exercised in application of digital mapping systems to make determinations. Because of both the increased complexity and analytical capabilities of GIS, assuring compliance with the good faith standard may require additional effort relative to use of paper maps.

A prime concern is to assure that the accuracy of the digital base map and structure location data are appropriate for use with the chosen digital FIRM data set (DFIRM or Q3 Flood Data) to make determinations relative to the 1973 Act. The concern for accuracy of the ancillary data used with DFIRMs should increase in direct proportion to the relative closeness of the property under analysis to the SFHA boundary. Thus, lenders might not find it prudent to use digital data at the 1:100,000 scale as the primary source of information upon which to make a determination regarding a property located within 250 feet of an SFHA. Such caveats should be carefully considered when U.S. Bureau of the Census TIGER data are used as the source from which property determinations will be made.

In some instances, GIS technology will enable the use of large-scale land parcel, topographic, structure, and other information, with digital FIRM data to make determinations. GIS technology allows maps to be created at any user-specified scale. Enlargement of scales does allow for precise determinations to be made. However, precise measurements are not inherently accurate. Accuracy can only be assessed from an appraisal of the quality of source data.

SFHA boundary information conveyed by Q3 Flood Data files was developed to overlay USGS 7.5-

minute topographic maps at a scale of 1:24,000. Thus, Q3 Flood Data cannot be assumed to have an accuracy of better than 40 feet. Due to other limitations, FIA recommends that determinations using GIS technology and Q3 Flood Data generally be made only when structures are located 250 or more feet outside an SFHA boundary. In cases where the structure is within 250 feet of the SFHA or inside the SFHA, data such as the BFE determined from a FIS flood profile and the surveyed lowest adjacent grade and/or lowest floor elevation should be used to make a determination.

Prudence may require that a more conservative margin than 250 feet be used to determine the need for ancillary data to support a GIS determination. Terrain variations, the nature of flood hazards in the area, and the quality of all digital data being used to make the determination should be considered when establishing the need for collecting survey and flood profile data.

Part 4 HOW TO OBTAIN Q3 FLOOD DATA

This section discusses distribution issues including available file formats, conversion to other GIS formats, map projections for the various formats, file naming conventions, ordering instructions, organization of the Q3 Flood Data, user support, the Q3 Flood Data counties, and FEMA's revision/update plans for the Q3 Flood Data.

Available Formats

Q3 Flood Data products are provided in a public domain data transfer format (DLG and Tagged Image File Format or TIFF) as well as proprietary formats (ARC/INFO and MapInfo).

Although the Federal government supports several digital geospatial data models, the DLG standard of the U.S. Geological Survey (USGS) offers one of the more efficient and widely recognized data formats for the distribution of vector data. DLG-3 supports basic topology (spatial relationships between data elements) in a vector data model, but is limited in the area of feature annotation, non-numeric data elements, and named features. FEMA is in the process of developing specifications for data sets in the Spatial Data Transfer Standard (SDTS), and when this effort is complete, it is expected that SDTS will replace DLG as FEMA's distributed public domain vector format.

ARC/INFO and MapInfo files are used by FEMA as internal working files; however, due to the popularity and utility of these two formats, they are distributed as well.

Figure 3 provides a comparison of the three vector file formats in which the Q3 Flood Data are available.

The Q3 Raster FIRMs are distributed in TIFF format compressed using CCITT, a universally-accepted digital data structure.

File Format Comparison

	DLG	ARC/INFO	MapInfo
# Attributes	28	21	21
Projection/coordinate system	UTM/meters	Geographic/decimal degrees	Geographic/decimal degrees
Horizontal datum	NAD27	NAD27	NAD27
Maximum # Points/polygon	4000	4000	4000
Precision	Single	Double	Single
Format	Digital Line Graph	ARC/INFO export file	MapInfo Native Table Format

Figure 3

Conversion to Other GIS Formats

The Q3 Flood Data files are distributed by FEMA in three formats: DLG, ARC/INFO, and MapInfo. These formats may be accessed directly by the following GIS software packages:

- ARC/INFO
- ArcView
- ArcCAD
- MapInfo
- GENAMAP

Some GIS software packages, such as MicroStation, provide utilities to convert DLG files into their own proprietary format. The MicroStation MGE GIS Translator module provides a utility for converting DLG files to MicroStation format (design files). Other CADD and GIS software packages, such as AutoCAD, may require the Q3 Flood Data to be translated using a third party utility.

Projections

FEMA utilizes the UTM projection and coordinate systems for its DLG vector data (both Q3-DLGs and DFIRM-DLGs). The geographic projection and coordinate system are used for the production of Q3 Flood Data in ARC/INFO and MapInfo formats. The Q3 Raster FIRMs are not georeferenced.

File Naming

In order to provide for efficient file retrieval and indexing, a standardized naming convention for Q3 Flood Data was established. The following convention is DOS compatible and allows for the unique identification of any county area of digital FIRM data. All file names are in lower case letters. The vector file names are:

cssccc

where:

c = the character 'c'
ss =State FIPS code (numeric code)
ccc =County FIPS code (numeric code)

and:

an extension specific to the file format follows.

Q3 Raster FIRM image files are stored within directories for each community, named by the State FIPS code and Community Identification Number of the community (e.g., 061234). Each image file is named using its four digit map panel number followed by the map panel suffix and the extension .tif (e.g., 0004b.tif). Panel number 0000 is used for the map index panels.

One metadata file will accompany each county file. The metadata files will be named using the same naming convention as the other files, with the exception of the letter "m" at the end (e.g., c06048.dlm, c06048m, c06048.tfm).

Ordering Instructions

The Q3 Flood Data will be distributed through FEMA's Internet server and on CD-ROM as the files become available.

Internet users may download data, along with associated data standards and metadata files by accessing FEMA's Map Service Center through FEMA's World Wide Web site. FEMA's address is <http://www.fema.gov>. Approximate download times based on file sizes will be included at this site. FEMA's *Community Status Book* is also available to Internet users through FEMA's Web site.

CD-ROMs containing the Q3 Flood Data files may be ordered from FEMA's Map Service Center at the following address:

**Map Service Center
6730 Santa Barbara Court
Baltimore, Maryland 21227-5832
Telephone: 1-800-358-9616**

FEMA's *Community Status Book* and hardcopy map products are also available from FEMA's Map Service Center at the above address. Requests for maps and map products should include the full name of the community or county and the FIRM panel number(s) covered by the request.

The following table (Figure 4) presents the available formats of the Q3 Flood Data products and their sources.

Q3 Flood Data Product Formats

	Vector Q3 Flood Data	Q3 Raster FIRM	DFIRM-DLG	Paper FIRM	LOMC
Internet	√ (future)		√ (future)		
CD-ROM	√	√ (future)	√ (future)		
Hardcopy				√	√

Figure 4

Data Organization

Q3 Flood Data are grouped by logical geographic areas by state for distribution on CD-ROM. An indexing scheme has been developed for each state, and the indexing scheme will be available on the Internet. Each CD-ROM contains all three file formats of each dataset and associated metadata. Small states may be grouped together on one CD-ROM. Large states will be split onto several CD-ROMs. In addition, an edition numbering scheme will be developed in order to track the currency of the Q3 Flood Data CD-ROMs.

The data documentation, including this document and the *Q3 Flood Data Specifications* will also be available.

User Support

User support for the Q3 Flood Data products is available through FEMA's Map Service Center's toll-free number at 1-800-358-9616. Any questions about the data or problems found with the data can be directed to that number. Any problems that require FEMA's attention will be channeled back to FEMA for resolution.

Q3 Flood Data Counties

Approximately 880 counties were chosen for the initial phase of Q3 Flood Data production to provide maximum digital FIRM coverage in areas having high population density or growth, significant risk (from hurricanes or other flood events), or a history of repetitive losses. A listing of the counties targeted for Q3 Flood Data production is provided in Appendix C.

All Q3 Flood Data production is scheduled to be completed by July 1996. FEMA has planned to release the data in increments as the data are completed. Each release will include all FEMA supported formats of the same geographic area (i.e. DLG, ARC/INFO, and MapInfo files for the same counties). All metadata for these files will be posted on the Internet as the data are released.

Revisions/Updates

Revisions to Q3 Flood Data sets will not begin until after all initial data capture is completed. The maintenance phase of Q3 Flood Data production provides for a review of all Q3 counties on the six month anniversary of their initial data capture to determine their update needs.

One exception to this procedure is when an effective DFIRM is issued prior to the six month anniversary date. When DFIRMs become effective, Q3 Flood Data will be generated from the DFIRM files as part of the DFIRM issuance procedures.

Description

Abstract: The Q3 Flood Data are derived from the Flood Insurance Rate Maps (FIRMs) published by the Federal Emergency Management Agency (FEMA). The file is georeferenced to the earth's surface using the geographic projection and the decimal degree coordinate system. Specifications for the horizontal control of Q3 Flood Data files are consistent with those required for mapping at a scale of 1:24000.

Purpose: The FIRM is the basis for floodplain management, mitigation, and insurance activities for the National Flood Insurance Program (NFIP). Insurance applications include enforcement of the mandatory purchase requirement of the Flood Disaster Protection Act, which "requires the purchase of flood insurance by property owners who are being assisted by Federal programs or by Federally supervised, regulated, or insured agencies or institutions in the acquisition or improvement of land facilities located or to be located in identified areas having special flood hazards" (Section 2 (b) (4) of the 1973 Flood Disaster Protection Act). In addition to the identification of Special Flood Hazard Areas (SFHAs), the risk zones shown on the FIRMs are the basis for the establishment of premium rates for flood insurance coverage offered through the NFIP.

Q3 Flood Data files convey certain key features from the existing hard copy FIRM. Edge-matching errors, overlaps and deficiencies in coverage, and similar problems are not corrected during digitizing or post-processing. The Q3 Flood Data files are intended to provide users with automated flood risk data that may be used to locate SFHAs. More detailed information may be obtained from the paper FIRM.

Data Quality Information

Attribute Accuracy

Attribute Accuracy Report: The Q3 Flood Data are countywide vector files derived from FEMA FIRMs. The attribute definitions may be found in the "Q3 Flood Data Specifications." Attribute accuracy was tested by manual comparison of source graphic with hardcopy plots and a symbolized display on an interactive computer system. Selected attributes that could not be visually verified were individually queried. In addition, an ARC/INFO Arc Macro Language (AML) software program was applied to the dataset to test the attributes against a master set of valid attributes for the specific data category and a complete set of valid attribute combinations. (See also Entity Attribute Information.)

Logical Consistency Report: Polygon and chain-node topology are present. Certain node-area-line relationships are collected or generated to satisfy topological requirements. Some of these requirements include the following: lines must begin and end at nodes, lines must connect to each other at nodes, lines do not extend through nodes, left and right areas are defined for each line segment and are consistent throughout the files, and the lines representing the limits of the file neatlines are free of gaps. Tests of logical consistency were performed by ARC/INFO software modules. Check plots were made to test for leaks in all internal polygons.

Completeness Report: Data completeness for Q3 Flood Data files reflects the content of the source graphic. Features may have been eliminated or generalized on the source graphic, due to scale and legibility constraints. Flood risk data are developed for communities participating in the NFIP for use in insurance rating and for floodplain management. Flood hazard areas are determined using statistical analysis of records of river flow, storm tides, and rainfall; information obtained through consultation with the communities; floodplain topographic surveys; and hydrologic and hydraulic analysis. Both detailed and approximate analyses are employed. Generally, detailed analyses are used to generate flood risk data only for developed or developing areas of communities. For undeveloped areas where little or no development is expected to occur, FEMA uses approximate analyses to generate flood risk data. Typically, only drainage areas that are greater than one square mile are studied.

Q3 Flood Data may be derived from DFIRM-DLGs, from FIRM-DLGs, or from FIRMs digitized previously for emergency applications, or they may be newly created files. In Q3 Flood Data derived from older data sets, certain items may not have been captured or may have been captured differently from the current Q3 Flood Data specifications. In some cases, preliminary FIRM data have been included in the Q3 Flood Data files. These data have been provided to the community for review and comment, and may be subject to change before their final publication date.

In addition, in some cases, areas designated as Flood Prone Areas on maps prepared by USGS and FIA have been included in the Q3 Flood Data files. These areas were delineated based on available information on past floods and are described by a unique attribute code that distinguishes them from areas of 1% annual chance flooding derived from FIRMs.

Flood Insurance Rate Maps continually undergo revisions and updates. Some of these revisions are effected by letter (Letter of Map Revision [LOMR], Letter of Map Amendment [LOMA]). Q3 Flood Data may not reflect the most current information or information that is not mappable at the publication scale of the FIRM. To obtain the latest information, contact the address listed under distributor.

Positional Accuracy

Horizontal Positional Accuracy

Horizontal Positional Accuracy Report: Specifications for the digitizing of FIRMs to create the Q3 Flood Data

Draft Q3 Flood Data Users Guide

are consistent with those requirements for mapping at a scale of 1:24000. Horizontal control of Q3 Flood Data was established using USGS quadrangle maps at 1:24000 or other standard scales. Users should assess the horizontal positional accuracy of the Q3 Flood Data with regard to the selected base map sources and the requirements of their application. With increased frequency, large-scale spatial data sets are becoming widely available for computer-based geographic information systems. Q3 Flood Data may be used in combination with other digital spatial data; however, users should be aware that scalar enlargements do not enhance the relative accuracy of the Q3 Flood Data.

Process Step

Process Description: Q3 Flood Data were produced by either scanning and vectorizing or manually digitizing a hardcopy version of the graphic materials. The scanning and vectorization process captured the digital data as raster data that were vectorized and attributed on an interactive editing station. The manual digitizing process used a digitizing table to capture the digital data; attribution was performed either as the data were digitized or on an interactive edit station after the digitizing was completed. The determination of the production methodology was based on various criteria, including availability of production systems. Four to nine control points per FIRM panel were used for registration during manual digitizing. A projective transformation was performed on the coordinates used in the data collection and editing systems to register the digital data to the Universal Transverse Mercator (UTM) grid coordinates. An ARC/INFO coverage of the Q3 Flood Data was generated and was used to create the Q3-DLG file. The Q3 Flood Data were checked for position and attribute accuracy by comparing plots of the digital data to the source graphic and by symbolized display on an interactive computer system. Selected attributes that could not be visually verified were individually queried. In addition, an ARC/INFO Arc Macro Language (AML) software program was applied to the dataset to test the attributes against a master set of valid attributes for the specific data category and a complete set of valid attribute combinations. Source graphics were revised to reflect updates effected by Letters of Map Change (Letter of Map Revision [LOMR], Letter of Map Amendment [LOMA]). These revisions were included in the Q3 Flood Data if they were mappable at the publication scale of the source graphic. Once final, the ARC/INFO coverage was projected into a geographic grid system, using decimal degree latitude and longitude coordinates and then converted into an ARC/INFO Export file and MapInfo native table files. In addition, the ARC/INFO coverage in UTM coordinates was converted into a Digital Line Graph file. All final files were checked for logical consistency and completeness.

Entity/Attribute Information

Overview Description

Entity and Attribute Overview: In addition to locational and topological information, Q3 Flood Data elements are explicitly encoded using attribute items. Each attribute item identifies characteristics about the Flood Hazard Area, COBRA, Floodway, Political Jurisdiction, Quadrangle, or FIRM panel. All polygon data elements may be encoded with one or more feature characteristics.

Entity and Attribute Detail Citation: The FEMA "Q3 Flood Data Specifications" contains a detailed description of each attribute code and a reference to other relevant information.

Address Type: mailing address

Address: 6730 Santa Barbara Court

City: Baltimore

State or Province: Maryland

Postal Code: 21227-5832

Contact Voice Telephone: 1-800-358-9616

Contact Instructions: Data requests should include the full name of the community or county and the Flood Insurance Rate Map panel number(s) or the 7.5-minute quadrangle sheet area(s) covered by the request.

Distribution Liability: No warranty expressed or implied is made by FEMA regarding the utility of the data on any other system nor shall the act of distribution constitute any such warranty. FEMA will warrant the delivery of this product in a computer-readable format and will offer appropriate adjustment of credit when the product is determined unreadable by correctly adjusted computer input peripherals or when the physical medium is delivered in damaged condition. Requests for adjustment of credit must be made within 90 days from the date of this shipment from the ordering site.

Standard Order Process

Non-digital Form: Printed Flood Insurance Rate Maps that match this data set are available from FEMA at the Map Service Center, cited above.

FEMA PRODUCT SHEETS

Digital Flood Insurance Rate Map-Digital Line Graph (DFIRM-DLG)

Hardcopy DFIRM

Graphic Image of a DFIRM-DLG

The Digital Flood Insurance Rate Map-Digital Line Graph (DFIRM-DLG) is a database created from the Digital Flood Insurance Rate Map (DFIRM). The DFIRM is comprised of all digital data required to create the hardcopy Flood Insurance Rate Map (FIRM). This includes base map information, graphics, text, shading, and other geographic and graphic data required to create the final hardcopy FIRM product to FEMA standards and specifications. DFIRMs are subject to community review and approval and are, therefore, the official basis for implementing the regulations and requirements of the National Flood Insurance

Program within the community.

The DFIRM is generally produced in a countywide format, where all flood hazards for the county and the incorporated communities are shown on one set of maps. The DFIRM-DLG is created by extracting the flood risk thematic data from the DFIRM. The format of this product is the U.S. Geological Survey (USGS) Digital Line Graph Level 3 Optional format, as described in the *Standards for Digital Flood Insurance Rate Maps*. The DFIRM-DLG does not include base map information, nor does it include graphic data required to create a hardcopy FIRM. This

product is intended to be the primary means of transferring flood-risk data depicted by FIRMs to Geographic Information Systems (GIS) through a public domain data exchange format. Communities whose digital base mapping files were utilized as the base map for the DFIRM will find that they may easily use the DFIRM-DLG files for all determination and enforcement regulations. The DFIRM-DLGs are tiled to the USGS 1:24,000 scale topographic map series. Specifications for the digitizing of DFIRMs are consistent with those required for mapping at the scale of 1:24,000, or better.

Specifications

The DFIRM-DLG has the following specifications:

- The source material for the DFIRM-DLG includes the hardcopy paper FIRM, new engineering data, and digital base mapping.
- The digital flood hazard information is georeferenced to the true ground coordinates of the digital base map used to produce the DFIRM. The DFIRM base map may have been obtained from the community, if available. If a digital base is not available from the community, the best available base map source is used. The digital information is provided in the Universal Transverse Mercator projection.
- The digital data captured from the hardcopy paper FIRM consist of FEMA hydrography, flood hazard zones, base (1% annual chance) flood elevations, cross-section locations, and elevation reference marks.
- All lines and area features in DLG files are encoded with one or more seven-digit attribute codes that provide the user with detailed information about the features. A copy of the *Standards for Digital Flood Insurance Rate Maps*, FIA-21, October 1993, which details these attribute codes, may be obtained from the address below.
- The DFIRM-DLG does not contain any base map information.
- The DFIRM-DLGs are

available on CD-ROMs compatible with ISO 9660 standards.

Attribute and Positional Accuracy

The DFIRM-DLG is intended to have a horizontal positional accuracy that is consistent with the National Map Accuracy Standards for mapping at a scale of 1:24,000. It should not be assumed that the DFIRM-DLG has a horizontal accuracy of better than 40 feet.

Uses of a DFIRM-DLG

Many commercially available GIS software packages allow the direct conversion of DLG data into vector data usable within the GIS environment. Third party conversion software is also available that will convert DLG data to other proprietary GIS formats not supported with their own conversion software.

The conversion of FIRMs to a digital format is expected to have many benefits. However, users must bear in mind that the simple conversion of FIRMs to a digital format does not inherently improve the engineering quality of the product. Many of the same difficulties with interpretation of flood risk data, and the requirement for users to apply sound judgement in methods selected for decision making and map interpretation remain unchanged. The DFIRM-DLG, when coupled with digital base map files such as TIGER data or USGS-DLGs, or the local community digital base, can be used in a GIS to determine

whether a structure is located within a Special Flood Hazard Area and would require the mandatory purchase of flood insurance. It should be noted that if a structure is determined to be within or near the Special Flood Hazard Area by using a GIS, and a different base map source was used to generate the hardcopy DFIRM, this determination should be confirmed by referencing the printed hardcopy DFIRM. The DFIRM-DLG may also be used for engineering and planning studies.

Information

Scanned Raster Image of FIRM

Graphic Image of Q3 Flood Data

Q3 Flood Data

(Q3)

The Q3 Flood Data product was developed to satisfy the need for a digital product that could be used to make in/out determinations and support the needs of a publish-on-demand system. This digital product is a suite of three products that includes raster Flood Insurance Rate Map (FIRM) files, vector FIRM files, and all accompanying metadata. These products are designed to allow rapid access to and distribution of

digital FIRM data and to be compatible with all existing digital Flood Insurance Rate Map data already available and underway at FEMA.

The USGS Digital Line Graph Level 3 Optional format was adopted by FEMA as the appropriate data model for the distribution and storage of vector Q3 Flood Data. In addition, FEMA utilizes the vector Q3

Flood Data in ARC/INFO and MapInfo formats as internal working files; due to the popularity and utility of these two proprietary formats, they are distributed as well.

The Q3 Flood Data are developed by scanning the existing hardcopy FIRM to create a raster product suitable for viewing or printing, as well as vectorizing a thematic overlay of flood risks. Q3 Flood

Data contain all FIRM data in the raster file, but only certain features are vectorized. The vectorized features include the floodplain boundaries for 1% and 0.2% annual chance floods; political boundaries; FIRM panel neatlines; 7.5-minute quadrangle neatlines; mappable Letters of Map Change; and may include floodways. Edge-matching errors, overlaps and underlaps in coverage, and similar problems are not corrected during digitizing or scanning and vectorizing. The hardcopy FIRMs from which the vector Q3 Flood Data are extracted contain no horizontal control. The specifications for the horizontal control of vector Q3 Flood Data are consistent with those required for mapping at the scale of 1:24,000. The horizontal controlling of these data is typically performed by fitting the vectors to a georeferenced 7.5-minute quadrangle file. The raster files generated by scanning the hardcopy FIRMs are not georeferenced. The Q3 Flood Data are not tied to a base map, are not used to produce a new version of the hardcopy FIRM, and are not subjected to community review. Q3 Flood Data are intended to provide users with digital flood-risk data suitable for in/out queries.

The vector Q3 Flood Data will be available through FEMA's Internet server and on CD-ROM as the files become available. Internet users may download these data, along with associated data standards and metadata files, by accessing FEMA's Map Service Center through their World Wide

Web site at

<http://www.fema.gov>. It is anticipated that Q3 Flood Data will be supplied on CD-ROM at a nominal cost. A listing of counties for which Q3 Flood Data will be developed can be obtained from the Internet address or the address listed below.

Comments on the specifications in this fact sheet are invited from the user community.

Specifications

The Q3 Flood Data have the following specifications:

- All FIRM data will be captured in a raster file.
- The floodplain boundaries for the 1% and 0.2% annual chance floods, political boundaries, FIRM panel neatlines, USGS 7.5-minute quadrangle neatlines, and mappable Letters of Map Change will be vectorized.
- The vector Q3 Flood Data are contained in one single countywide file that includes all incorporated and unincorporated areas of a county.
- Horizontal control of the vectorized features will typically be performed by fitting the vectors to a georeferenced USGS 7.5-minute quadrangle file.
- The raster files generated by scanning the hardcopy FIRMs are not georeferenced.
- The specifications for the Q3 Flood Data are consistent with the specifications outlined in the *Standards for Digital Flood Insurance Rate Maps*, FIA-21, dated October 1993.

Attribute and Positional Accuracy

The vector Q3 Flood Data are intended to have a horizontal positional accuracy that is consistent with the National Map Accuracy Standards for mapping at a scale of 1:24,000. It should not be assumed that the vector Q3 Flood Data have a horizontal accuracy of better

than 40 feet.

Uses of Q3 Flood Data

The Q3 Flood Data are designed to serve the needs of FEMA for both disaster response activities, as well as other National Flood Insurance Program flood insurance activities. The data are designed to answer basic in/out queries and questions about the location of the Special Flood Hazard Area, but do not provide Base Flood Elevations.

The Q3 Flood Data may be used in various GIS applications with the caveat that sound judgement must be used in interpreting the Q3 Flood Data. For instance, the Q3 Flood Data may be overlaid on highly detailed large scale community base mapping data, but, if parcel level determinations are made, they must be prefaced with information about the accuracy of the data from which they are derived.

The conversion of FIRMs to a digital format is expected to have many benefits. However, users must bear in mind that the simple conversion of FIRMs to a digital format does not inherently improve the engineering quality of the product. Many of the difficulties with interpretation of flood risk data, and the requirement for users to apply sound judgement in methods selected for decision making and map interpretation remain unchanged. **It should be noted**

that if a structure is determined to be within or near the Special Flood Hazard Area by using a GIS, this determination must be confirmed by referencing the printed hardcopy FIRM. Q3 Flood Data are not designed to be used for engineering studies.

APPENDIX D

GLOSSARY OF TERMS AND ACRONYMS

GLOSSARY OF TERMS

Accuracy - In mapping, the reduction of positional and attribute errors based on information sources and data input instruments. Data precision must reflect, not exceed its accuracy.

ARC Macro Language (AML) - A fourth generation programming language with facilities to use named variables, perform logical branching and loops, perform arithmetic and trigonometric operations, make calls and pass variables to other programs, and perform selected Geographic Information Systems operations. It also provides facilities to design and create custom menus. AML is also used to refer to a program written using the ARC macro language.

ASCII American Standard Code for Information Exchange - A popular standard for the exchange of alphanumeric data.

ARC/INFO - A software package that provides a menu and key-in operator interface with commands for generating, editing, and analyzing graphics and data. It is vector geo-relational software (Environmental Systems Research Institute, Redlands, CA).

Attribute - Descriptive characteristic or quality of a feature. Attributes may be represented by locational or non-locational descriptive information about a feature.

Base Flood Elevation (BFE) - The elevation associated with the flood having a one-percent annual chance of being equalled or exceeded in any given year. It is shown on the Flood Insurance Rate Map.

Base Map - Map of the community that depicts cultural features (roads, railroad, bridges, dams, culverts, etc.), drainage features, and the corporate limits.

Buffer Zone - An area of specified distance (radius) around a map item or items.

CCITT Group 4 Compression - An internationally accepted digital file compression scheme for black-and-white (1-bit) TIFF image data. TIFF data may also be stored as uncompressed files.

Compact Disk Read Only Memory (CD-ROM) - A digital medium for the storage of data in a standardized format (ISO 9660).

Coastal Barrier Resources Act (COBRA) - An act of Congress, signed into law in 1982 and amended in 1990 and later, that identifies units of land consisting of undeveloped coastal barriers

and other areas located on the coast of the U.S. Flood insurance is not available for structures built after the coastal barrier was identified.

Community Identification (CID) - A unique six-digit number assigned to each community by FEMA and used for identity in computer databases; it is shown on the FIS, FIRM, and in the Q3 Flood Data files. The first two digits of the number are always the State FIPS code.

Community Rating System (CRS) - A program created by FEMA to provide new incentive for activities that reduce flood losses and support the sale of flood insurance. Any community participating in the NFIP may apply for CRS classification by demonstrating that it is implementing floodplain management and public information activities that exceed the minimum requirements of the NFIP. Once qualified, the community benefits by obtaining flood insurance premium rate credits for its residents. The credits vary by the level of activities undertaken by the community.

Control Point - Any station in a horizontal or vertical control network that is identified in a data set or photograph and used for correlating the data shown in the data set or photograph.

Coordinate System - A particular kind of reference frame or system, such as plane rectangular coordinates or spherical coordinates, which uses linear or angular values to designate the position of points within that particular reference frame or system, e.g., State Plane, UTM.

Database - A collection of information related by a common fact or purpose.

Data Capture - Series of operations required to encode data in a computer-readable form (digitizing).

Data Layer - Refers to data having similar characteristics being contained in the same plane or overlay (e.g., roads, rivers). Usually information contained in a data layer is related and is designed to be used with other layers.

Data Set or Data File - A named collection of logically related data records arranged in a prescribed manner. The physical set of data of one data type being referred to or being used in the context of a data processing operation.

Digital Data - Data displayed, recorded, or stored in binary notation.

Digital Flood Insurance Rate Map - (DFIRM) - The Digital Flood Insurance Rate Map (DFIRM) is comprised of all digital data required to create the hardcopy FIRM. This includes base map information, graphics, text, shading, and other geographic and graphic data required to create the final hardcopy FIRM product to FEMA standards and specifications. These data serve the purpose of map design and provide the database from which the Digital Line Graph thematic product of the flood risks can be extracted to create the DFIRM-DLG. These products are generally produced in a countywide format. DFIRMs are subjected to community review and approval and are, therefore, the official basis for implementing the regulations and requirements of the NFIP within the community.

Digital Flood Insurance Rate Map -DLG (DFIRM - DLG) - This product is created by extracting the flood risk thematic data from the DFIRM. The format of this product is the U.S. Geological Survey Digital Line Graph Level 3 Optional format, as described in the FEMA specifications for digital FIRMs. The DFIRM-DLG does not include base map information, nor does it include graphic data required to create a hardcopy FIRM. This product is intended to be the primary means of transferring flood risk data depicted by FIRMs to GISs through a public domain data exchange format. The DFIRM-DLGs are tiled to the U.S. Geological Survey 1:24,000 scale topographic map series.

Digital Line Graph (DLG) - A computer file format for mapping data that provides a topological structure to describe points, lines, and polygons. A DLG may contain lists of point coordinates describing boundaries, drainage lines, and other linear or area features, which are organized by USGS quadrangle areas. These data are the digital equivalent of the linear hydrographic and cultural data on a topographic base map. The flood risk thematic layers developed by FEMA will fit the quadrangle as an overlay. The U.S. Geological Survey Digital Line Graph Level 3 Optional format has been adopted by FEMA for the purposes of the National Flood Insurance Program mapping and engineer requirements. Level 3 data files are fully topologically structured and are designed to be integrated into GISs.

Digitizing - A process of converting an analog image or map into a digital format usable by a computer.

Edge Matching - The comparison and graphic adjustment of features to obtain agreement along the edges of adjoining map sheets.

Elevation Reference Mark (ERM) - A point of vertical ground elevation reference shown on the FIRM for comparison to the BFE. ERMs are referenced to the National Geodetic Vertical Datum (NGVD) or the North American Vertical Datum (NAVD) or an alternative local datum if applicable.

Federal Emergency Management Agency (FEMA) - The agency reporting directly to the President and responsible for identifying and mitigating natural and man-made hazards.

Federal Geographic Data Committee (FGDC) - An interagency committee, established by the Office of Management and Budget, that promotes the coordinated development, use, sharing, and dissemination of geospatial data on a national basis. The FGDC is composed of representatives from 14 Cabinet level and independent Federal agencies.

Federal Information Processing Standards (FIPS) - The official source within the Federal government for information processing standards, which are developed and published by the Institute for Computer Sciences and Technology at the National Institute of Standards and Technology (NIST).

Federal Insurance Administration (FIA) - An administration within FEMA that provides flood and crime insurance.

Flood Insurance Rate Map (FIRM) - A map on which the 100- and 500-year floodplains, BFEs, and risk premium zones are delineated to enable insurance agents to issue accurate flood insurance policies to homeowners in communities participating in the NFIP.

Flood Insurance Study (FIS) - An examination, evaluation, and determination of the flood hazards, and if appropriate, the corresponding water-surface elevations.

FIRM-DLG - The FIRM-DLG is a product developed by digitizing and/or scanning the existing hardcopy FIRM to create a thematic overlay of flood risks. These products differ from the DFIRM as they are not tied to a base map, not used to produce a new version of the hardcopy FIRM, and not subjected to community review. FIRM-DLGs are intended to faithfully duplicate the existing hardcopy FIRM and provide users with automated flood risk data that is comparable to what they would derive from the hardcopy FIRM. To this end, edge-matching errors, overlaps and underlaps in coverage, and similar problems are not corrected during digitizing or scanning as they are during the DFIRM-DLG production.

Geographic Information System (GIS) - System of computer hardware, software, and procedures designed to support the capture, management, manipulation, analysis, modeling, and display of spatially referenced data for solving complex planning and management problems.

Geocoding - Associating either geographic coordinates or grid cell identifiers to data, points, lines, and shapes.

Geographic Coordinates - Coordinate system in which horizontal and vertical distances on a planimetric map are represented in units of latitude and longitude rather than feet or meters.

Georeference System - An X,Y or X,Y,Z coordinate system that locates points on the surface of the earth as a reference to points on a map.

Geo-relational - Geometry of the spatial data. Housed separately from its attributes.

Gutter (or Zone Break) - A line shown on the FIRM as a white line within the screened SFHA. This line separates different risk premium zones.

Horizontal Control - Network of stations of known geographic or grid positions referred to a common horizontal datum, which controls the horizontal positions of mapped features with respect to parallels and meridians or northing and easting grid lines shown on the map.

Layer - Refers to the various "overlays" of data, each of which normally deals with one thematic topic. These overlays are registered to each other by the common coordinate system of the database. In GIS, a layer or a theme represents a specific kind of data.

Letter of Map Amendment (LOMA) - An official determination that a specific structure or property is not within the 1% annual chance floodplain; a LOMA amends the effective FIRM.

Letter of Map Revision (LOMR) - A letter that revises BFEs, flood hazard zones, floodplain boundaries, or floodways that are shown on an effective FIRM or FBFM.

Letter of Map Change (LOMC) - A term used to refer to all letters that revise FIRMs, both LOMAs and LOMRs.

Line - A level of spatial measurement referring to a one-dimensional defined object having a length and direction, and connecting at least two points.

Macro - A series of instructions combined to be executed with a single command.

MapInfo - A desktop mapping system that combines map graphics and a relational database for cartographic display and spatial analysis (MapInfo Corporation, Troy, NY).

Menu- A list of options on a screen display or pallet allowing an operator to select the next operations by indicating one or more choices with a pointing device.

Merge - To combine items from two or more similarly ordered sets into one set that is arranged in the same order. In a GIS, to splice separate but adjacent mapped areas into a single data set.

Metadata - Literally, metadata are "data about data," or descriptive information about the contents of a digital geospatial data file. Metadata standards have been developed by the FGDC to govern the content and order of the information so that it may be readily queried by users to determine if the data meet their needs.

MicroStation - A software package that provides a menu and key-in operator interface with commands for generating and editing graphics and data (Bentley Systems, Inc., Exton, PA)..

National Flood Insurance Program (NFIP) - The Federal regulatory program under which flood-prone areas are identified and flood insurance is made available to residents of participating communities.

Node - A point at which two or more lines meet; called an edge or vertex in graph theory.

Operating System - The master control program that governs the operation of a computer system, running job entry, input/output services, data management, and supervision or housekeeping.

Planimetric Map - Map representing only horizontal positions from features represented; distinguished from a topographic map by the omission of relief in measurable form. A planimetrically accurate map shows accurate horizontal distances between features.

Pixel - Short for "picture element." The smallest discrete element that makes up an image.

Point - A level of spatial measurement referring to an object that has no dimension.

Point Data - In a vector structure, data consisting of a single, distinct X,Y coordinate pair. In a raster structure, point data are represented by single cells.

Polygon - A two-dimensional figure with three or more sides intersecting at a like number of points. In Geographic Information Systems, an area.

Projection - The mathematical transformation of three-dimensional space into a two-dimensional (flat) surface. Projection formulae are dependent on a variety of spherical models (spheroids) that distort the spatial characteristics of a location.

Quad (also USGS Quad) - A U.S. Geological Survey (USGS) topographic map; Quad stands for "Quadrangle."

Quality Assurance/Quality Control (QA/QC) - Intermediate and final review of the FIS and FIRM performed to ensure compliance with FEMA standards.

Q3 Flood Data - A digital FIRM product developed and distributed by FEMA. Q3 Flood Data are developed by scanning and vectorizing the existing hardcopy FIRM to create a raster product suitable for viewing or printing, as well as a thematic vector overlay of flood risks. Q3 Flood Data capture all FIRM data in the raster file, but vectorize only certain features.

Raster Data - The representation of spatial data as regular grid cells or tessellations. Cells may be subdivided or aggregated depending on the variety and density of features to be modeled.

Read Only Memory (ROM) - A microcircuit containing programs or data that cannot be erased. When new data or programs can replace old ones, the microcircuit is called an EROM, for erasable read only memory, or PROM, for programmable read only memory.

Record - A groups of items in a file treated as a unit. For example, all data items for a census tract can be grouped as a record and assigned to a single segment of a magnetic tape or other media file for convenient storage and retrieval.

Scale - A representative fraction of a paper map distance to ground distance. Example: 1:12,000 is the representative fraction in which one unit of measure on the map is equal to 12,000 of the same units of measure on the ground. FEMA map scales are expressed in a ratio of 1" of map distance equal to a given number of feet on the ground.

Scanner - Any device that systematically decomposes a sensed image or scene into pixels and then records some attribute of each pixel.

Scanning - Process of using an electronic input device to convert analog information such as maps, photographs, overlays, etc., into a digital format usable by a computer.

Spatial Data Transfer Standards (SDTS) - A FIPS standard (FIPS 173) developed as a mechanism for the transfer of digital spatial data between different computer systems. It specifies exchange constructs, addressing formats, structure, and content for spatially referenced vector and raster data.

Special Flood Hazard Area (SFHA) - Any area inundated by the base (1% annual chance) flood; these areas are identified on the FIRM as Zones A, AE, AH, AO, AR, A1-30, A99, V, VE, and V1-30.

Thematic Layer - A data layer containing selected information relating to a specific theme, such as soils, vegetation, land use, etc.

TIFF - Tagged Image File Format, a standard exchange format for raster or image files. Tags or identifiers are used to structure the raster data such that blocks of data may be interpreted based on tags that identify them. TIFF images may be black and white, gray scale, or color, and may be compressed using a variety of compression types.

TIGER --Topologically Integrated Geographic Encoding and Referencing File- The nationwide digital database of planimetric base map features developed by the U.S. Bureau of the Census for the 1990 Census.

Topology - A branch of non-euclidean geometry that analyzes the spatial relationships and connectivity of graphs and their components. In GIS, topology is a key element used in a number of data models, such as ARC/INFO.

U.S. Geological Survey (USGS) - The Federal agency responsible for nationwide civilian mapping projects and standards development.

UTM Grid - The Universal Transverse Mercator grid, a system of plane coordinates based upon 60 north-south trending zones, each 6 degrees of longitude wide, that circle the globe.

Vector Data - Coordinate-based data used to represent linear geographic features. Each linear feature is represented as an ordered list of vertices.
