APPENDIX A - AUXILIARY FEEDWATER SYSTEM (AFS)

APPENDIX A-1.1 INTRODUCTION

This chapter describes the work performed by Ebasco on the Indian Point No. 3 Nuclear Power Plant Auxiliary Feedwater System for systems interactions consistent with the criteria, methodology and guidelines presented in the Chapters 3 thru 6 of Volume I. Interconnected process coupled, and nonconnected spatially coupled systems interactions were investigated and the results presented in Sections A-2.1 and A-2.2 respectively.

APPENDIX A-1.2 SYSTEM BOUNDARY CONDITIONS

The Indian Point No. 3 Nuclear Power Plant Auxiliary Feedwater System was reviewed for systems interactions based on current unit installations with credit taken for specific commitments to the NRC regarding hardware and procedural modifications.

The boundary of the systems interaction study for the Indian Point No. 3 Nuclear Power Plant, Auxiliary Feedwater System is shown in Figure A-6. The turbine steam supply from the steam generators and all of the Auxiliary Feedwater System components (see Table A-1) are included in the study. The water supplies to the extent of the piping systems and valves that deliver water to the Auxiliary Feedwater System are included. Electrical power and control supplies are included to the extent presented in Figure A-1 for three electrical states, full power, loss of one bus, and no AC electric power (onsite or offsite).

This evaluation is conducted assuming the presence of an AFS actuation signal, therefore the AFS actuation signal is outside the boundary of this study. As discussed in Chapter 5, latent and dynamic operator (Human) induced failures are also outside the boundary of this study. Consistent with this, the effects of control system failures on operator actions, i.e., those failures which deprive the operator of required information for normally controlling plant conditions, or which provide confusing or incorrect information to the operator, have been specifically omitted from this study.

The effects of non-safety-grade control system failures on plant safety is excluded from this study. Justification for this exclusion is provided in the Authority's response to IE Information Notice 79-22, via IPN-79-74, dated October 9, 1979.

APPENDIX A-2.1 Results on AFS of Interconnected Systems Interactions (Cont'd)

Vent and drain lines and valves, and connected lines which are small in size were not evaluated since it was assessed that failure of these components would not significantly affect the system performance.

Other events that require operation of the Auxiliary Feedwater System are:

- Loss of main feedwater transient

- Loss of main feedwater with offsite power available
- Station blackout (loss of main feedwater without offsite power available)
- Rupture of a main steam line
- Loss of all AC Power
- Loss of coolant accident

APPENDIX A-2.1.1 SUMMARY AND CONCLUSIONS

For the case presented, the acceptance criteria for evaluating component failures of the Auxiliary Feedwater System were as follows:

1 - A flow rate of 400 gpm be delivered to at least two (2) steam generators (200 gpm to each)

2 - The flow is delivered within 30 minutes of the initial demand.

Random component failures are categorized as recoverable or nonrecoverable. A recoverable random failure is defined as a failure that does not cause a system failure since the operator is assumed to have sufficient time to take successful action to recover from the failure. Recoverable failures are those that can be corrected before a specified time criteria is exceeded. Nonrecoverable random failures are failures that cause a system failure due to the inability of the operator to recover from the failure because of a time criteria.

The results presented in this section as described in Table A-2.1 show that the Auxiliary Feedwater System emergency operating mode for the loss of normal feedwater event resulting from a feedline break outside containment coincident with a loss of all offsite power is reliable. Component redundancy and recoverability of component failures made the system sound. These results are consistent with the PRA findings of the Pickard, Lowe and Garrick, Inc. Study.

APPENDIX A-2.2 Results on the AFS of Nonconnected Systems Interactions

APPENDIX A-2.2.1 Systems Interactions Induced by the Effects of a Safe Shutdown Earthquake (SSE)

GENERAL DISCUSSION

General Design Criterior 2, "Design Bases for Protection Against Natural Phenomena", of Appendix A to 10CFR Part 50, "General Design Criteria for Nuclear Power Plants", require that structures, systems, and components important to safety be designed to withstand the effects of earthquakes without loss of capability to perform their intended safety functions.

NRC Regulatory Guide 1.29, "Seismic Design Classification", (formerly Safety Guide 29) describes an acceptable method of identifying and classifying those plant features that should be designed to withstand the effects of the SSE. Regulatory position C.1.g. of NRC 1.29 states that the Auxilary Feedwater System including components, supports and foundations shall be designated as Seismic Category I and should be designed to withstand the effects of the SSE and remain functional. In addition, regulatory position C.2 of NRC RG 1.29 states tnat those portions of structures, systems, or components whose continued function is not required but those failure could reduce the functioning of any plant feature designated Seismic Category I, to an unacceptable safety level should be designed and constructed so that the SSE would not cause such failure.

Based upon the above, a review of the seismic design classification of the structures, systems and components associated with the safe operation of the Auxiliary Feedwater System was conducted. In addition a plant walkdown of the auxiliary feed pump building and associated structures was conducted to review the effects of nonseismic structures, systems and components whose failure during an SSE could reduce the functionability of any plant features important to safety to an unacceptable level.

APPENDIX A-2.2 Results on the AFS of Nonconnected Systems Interactions (Cont'd)

APPENDIX A-2.2.1 Systems Interactions Induced by the Effects of a Safe Shutdown Earthquake (SSE) (Cont'd)

GENERAL DISCUSSION (Cont'd)

The plant walkdown activities were consistent with the methodology guidelines and evaluatioon criteria described in Chapters 5 and 6.

SUMMARY AND CONCLUSION

In general due to the lack of documentation, it was impossible to complete a comprehensive review of the seismic design classification. In those instances where documentation existed an appropriate reference was included.

Structures, systems and components that were not substantiated by seismic documentation consistent with the quality assurance requirements of Appendix B to 10CFR Part 50 were assumed to be nonseismic and were evaluated with respect to tneir effects on other Seismic Category I items.

Acceptable and unacceptable system interactions resulting from the failure of nonseismic structures, systems or components are presented in Appendix A-4.

From a review of the results of the seismic system interactions, the following items are considered to be the major contributors to the identification of adverse systems interactions,

1 - Crane/monorail structure located directly above the two (2) motor driven and the turbine driven auxiliary feedwater pumps.

2 - 4" nonseismic floor drain pipe directly above the electrical cable trays containing essential safety related equipment.

APPENDIX A-2.2 Results on the AFS of Nonconnected Systems Interactions (Cont'd)

APPENDIX A-2.2.1 Systems Interactions Induced by the Effects of a Safe Shutdown Earthquake (SSE) (Cont'd)

SUMMARY AND CONCLUSION (Cont'd)

3 - Space heaters and electrical lighting fixtures located directly above essential safety related equipment and structures.

4 - Nonseismic electrical cable trays and conduit routed directly above essential safety related equipmenmt and structures.

5 - Large nonseismic instrument rocks located within close proximity to essential safety related equipment and structures.

6 - Large roll-up door located in the shieldwall whose structural failure could affect the flow control stations of the turbine driven auxiliary feedwater pumps.

Modifications including the possible use of guard structures, protective covers, and restraining devices are expected to prevent impairment of function due to the above concerns.

SYSTEMS INTERACTION STUDY

APPENDIX A

AUXILIARY FEEDWATER SYSTEM

APPENDIX A-2.2 Results on the AFS of Nonconnected Systems Interactions (Cont'd)

APPENDIX A-2.2.2 Pipe Failure Induced Systems Interactions

The Auxiliary Feedwater System was reviewed for potential systems interactions resulting from high energy line breaks. The Indian Point No. 3, Nuclear Power Plant, Safety Evaluation Report, Docket No. 50-286, dated September 21, 1973, Chapter 6 entitled Engineered Safety Features was used as the base document for pipe failure induced systems interactions.

Several modifications have been made to this system in order to give it additional protection in the unlikely event of high energy line breaks outside the containment. The auxiliary feedwater lines are directly connected into the feedwater system and experience the same pressure as the feedwater system. The Staff had a concern that a break in an auxiliary feedwater line within the room that houses the motor-driven and the steam turbine-driven auxiliary feedwater pumps might result in back flow from the feedwater system and could possibly flood these three pumps. Because of this concern, check valves were installed in the piping that connects the discharge side of these pumps with the normal feedwater system. These check valves are located outside of the auxiliary feedwater pump room and prevent backflow from the feedwater system into the Auxiliary Feedwater System.

Another modification made was additional protection of the electric motor-driven auxiliary feedwater pumps from a high temperature-high humidity environment. A postulated high-energy pipe break in the steam supply to the steam turbine-driven auxiliary feedwater pump might result in temperature and humidity conditions in the pump room for which the electric motor-driven pumps

APPENDIX A-2.2.2 Pipe Failure Induced Systems Interactions (Cont'd)

were untested. These motor-driven pumps are "drip-proof," but their operability at elevated temperatures and in a steam environment was not demonstrated. Consequently, two redundant valves in the steam supply line to the auxiliary feedwater turbine-driven pump were installed. These valves are outside of the room that houses the auxiliary feedwater pumps. Each valve is signaled to close automatically on high temperature in the pump room. Each valve has its own separate temperature sensor. There is control room indication of each valve's position, and an alarm will sound upon closure. Operation of these valves would limit the temperature and humidity rise in th pump room due to a break in the steam supply to the steam turbine auxiliary feedwater pump.

The consequences of pipe ruptures in the vicinity of the auxiliary feedwater pumps which might cause flooding in the pump room were also examined. The drainage capabilities of the pump room were modified to prevent water levels from reaching a depth of 14 in. off the floor from such postulated break. At the 14 in. level, water would begin to touch the bottom of the electric motor-driven auxiliary feedwater pumps. Pipe restraints on feedwater lines in the room above the auxiliary feedwater room were also installed. This was done to eliminate any concrete from the pump room roof falling onto the pumps as a result of whipping of the pipes after a postulated pipe rupture.

The Staff reviewed these modifications and found them acceptable.

In view of the design modifications that have been made to limit the consequences of pipe whip, flooding, and temperature and pressure transients in the pump room, and in view of the design criteria that were in effect at the time of the construction permit, it was concluded that the design of the Auxiliary Feedwater System, as modified, does not lead to any unacceptable systems interactions.

APPENDIX A-2.2 Results on the AFS of Nonconnected Systems Interactions (Cont'd)

APPENDIX A-2.2.3 Systems Interactions Induced by the Effects of Internally and Externally Generated Missiles

General Design Criterion 4, "Environmental and Missile Design Bases", requires that all structures, systems and components that are necessary for attaining and maintaining a safe shutdown of the reactor facility and whose failure could result in a significant release of radioactivity, be designed to withstand the effects of internally and externally generated missiles.

Internally generated missiles are components of pressurized systems such as valve bonnets and hardware retaining bolts, relief valve parts, and instrument wells: high speed rotati g machinery, such as impellers and fan blades resulting from component overspeed or failure (resulting from seisure) which are within a structure protecting systems and components necessary for safe shutdown.

Externally generated missiles are missiles generated by natural phenomena such as tornado and those components of pressurized systems and high speed rotating machinery located outside structures protecting systems and components necessary for safe plant shutdown.

APPENDIX A-2.2 Results on the AFS of Nonconnected Systems Interactions (Cont'd)

APPENDIX A-2.2.3 Systems Interactions Induced by the Effects of Internally and Externally Generated Missiles (Cont'd)

A-2.2.3.1 Internally Generated Missile System Interactions

During the walkdown phase of the system interaction study, an observation was made relative to the potential for the generation of internal missiles from pressurized systems and high speed rotating machinery and the effects on safe shutdown capabilities. It was observed that adequate separation and system redundancy existed so as to preclude damaging effects from internally generated missiles such as valve bonnents and hardware retaining bolts, relief valve parts and instrument wells. In addition it was observed that high energy lines were provided with pipe whip restraints so as to prevent impact on safety related systems and components.

The auxiliary feedwater pumps located within the auxiliary feedpump building were evaluated for missiles assoicated with overspeed failure. The motor driven auxiliary feedwater pumps maximum no-load speed was assumed to be the synchronus speed of the motor which is no more than 2 percent above the rated operating speed. Consequently, no pipe break or single failure in the suction or discharge lines of the pump would increase the pump speed over that of the no-load condition. Therefore, the generation of missiles associated with the motor driven pumps is not a credible occurance. However, an evaluation of the turbine driven auxiliary feedwater pump showed that missiles could be generated due to turbine overspeed protection failure, and that several safety related systems and components in the auxiliary feed pump building were potential targets.

APPENDIX A-2.2 Results on the AFS of Nonconnected Systems Interactions (Cont'd)

APPENDIX A-2.2.3 Systems Interactions Induced by the Effects of Internally and Externally Generated Missiles (Cont'd)

A-2.2.3.1 Internally Generated Missile System Interactions (Cont'd)

In November 1971, the NRC informed the Power Authority of the State of New York (PASNY) of the NRC's requirements for the Auxiliary Feedwater system at the Indian Point No. 3 Nuclear Power Plant. Among the long-term recommendations was the requirment to evaluate the potential for the generation of internal missiles in the Auxiliary Feedwater Pump Room and its effect on vital equipment and systems. On July 15, 1980 the NRC issued Interim Safety Evaluations of the auxiliary feedwater system. One of the open items in these reports was the stipulation that the "Licensee provide a description of the results of the (missile generation) evaluation prior to August 11, 1980 and prior to implementation of any corrective measures."

PASNY contracted EDS Nuclear Inc to evaluate the capability of the auxiliary feedwater system to withstand internally generated missiles. The evaluation has determined that the auxiliary feedwater pump turbine could be a source of a destructive missile and therefore, an analysis of auxiliary feedwater pump turbine missiles was undertaken.

The evaluation showed that missiles could be generated and that several safety related systems at different locations in the auxiliary feed pump building were potential targets. Because of these results, it was decided that protection at the missile source was the best approach.

APPENDIX A-2.2 Results on the AFS of Nonconnected Systems Interactions (Cont'd)

APPENDIX A-2.2.3 Systems Interactions Induced by the Effects of Internally and Externally Generated Missiles (Cont'd)

A-2.2.3.1 Internally Generated Missile System Interactions (Cont'd)

From a systems interaction point of view, protection at the source designed for destructive overspeed missiles is an acceptable solution. This ensures that safe shutdown equipment will not interact with a missile source as a result of disk failure at any possible speed. Although the missile shield has not yet been installed it was assumed that near term modifications will be made. Therefore, based upon the commitment to install a missile shield system no credible interaction of a missile source with safety related target equipment located in the auxiliary feed pump building were found.

A-2.2.3.2 Externally Generated Missile System Interactions

A review of the Indian Point 3 Facility Safety Analysis Report, Chapter 3.5 and the NRC (then AEC) Safety Evaluation Report, dated September 21, 1973 was conducted to determine if the structures systems and components associated with the auxiliary feedwater system were protected against the effects of externally generated missiles. A review of this type was conducted in order to preclude the evaluation of systems interactions resulting from externally generated missiles.

Our review concluded that various structures at the Indian Point 3 site have been designed and constructed to withstand the effects of tornado generated missiles. Among these structures are the primary auxiliary building, the control room, the containment building, the diesel generator building, the cable tunnels, and the waste hold-up tank pit. The shield wall of the auxiliary feedwater pump building has been designed considering the effects of externally generated missiles.

APPENDIX A-2.2 Results on the AFS of Nonconnected Systems Interactions (Cont'd)

APPENDIX A-2.2.4 Systems Interactions Induced by the Effects of Flooding

Design Criterion 2, "Design Bases for Protection Against Natural Phenomena" require that all systems and components whose failure could prevent safe shutdown of the plant or result in uncontrolled release of significant radioactivity, be designed to withstand the effects of flooding due to natural phenomena.

A review of the Indian Point 3 Facility Safety Analysis Report, and the NRC (then AEC) Safety Evaluation Report, was conducted to determine to what extent the structures, systems and components associated with the Auxiliary Feedwater System were protected against the effects of flooding due to natural phenomena.

Our review concluded that it was established that the most severe flooding condition at the site, corresponds to a water elevation of 15 ft above mean sea level (MSL). As stated in the Facility SER, this elevation is lower by three inches than the critical elevation at which water would start seeping into the lowest of the plant buildings. The staff concluded in their report that under the most extreme conditions the flood level could reach a level of 15.0 ft MSL, exclusive of wind-generated wave action. Wind-generated wave action could raise the flooding level above plant grade in the vicinity of the service water pumps.

In the event of wind-generated wave action in conjunction with extreme flooding conditions, the plant will still be protected. In this unlikely event, the plant will be shutdown in accordance with the Techincal Specifications, and the service water pump areas will be protected. Other areas, such as the diesel generator area, will not require additional protection from the wind-generated waves in that these waves rapidly dissipate once they strike land.

Consequently, the combination of the elevation of the plant structures, and the Technical Specification requirements on plant operation and service water pump protection, result in accetable conditions to protect the plant against flooding.

Based upon our review and the findings above, we concluded that no credible flooding conditions caused by natural phenomena will exist and therefore, no adverse system interactions were identified for the structures, systems and components of the Auxiliary Feedwater System.

APPENDIX A-2.2 Results on the AFS of Nonconnected Systems Interactions (Cont'd)

APPENDIX A-2.2.5 System Interactions Induced by Severe Environment (Other Than Flooding) Resulting From Natural Phenomena.

General Design Criterion 2, "Design Bases for Protection Against Natural Phenomena", require that all systems, components and structures whose failure could prevent safe shutdown of the plant or result in uncontrolled release of significant radioactivity, be designed to withstand the resulting effects of severe environment due to natural phenomena.

A review of the Indian Point 3 Facility Safety Analysis Report, and the NRC (then AEC) Safety Evaluation Report, was conducted to determine to what extent the structures, systems and components associated with the Auxiliary Feedwater System were protected against the effects of severe environment due to natural phenomena.

Our review concluded that the effects of tornado wind loadings and depressurization was considered in the design of all Category I structures. The auxiliary feed pump building is designated as a Category I structure. Therefore, no adverse system interactions were identified for the structures, systems and components of the Auxiliary Feedwater System contained within the auxiliary feed pump building.

APPENDIX A-2.2 Results on the AFS of Nonconnected Systems Interactions (Cont'd)

APPENDIX A-2.2.6 Systems Interactions Induced by Fires

The Commission's basis criterion for fire protection is setforth in General Design Criterion 3, Appendix A to 10CRF Part 50, which states:

1 - "Structures, systems, and componets important to safety shall be designed and located to minimize, consistent with other safety requirements, the probability and effect of fires and explosions."

2 - "Noncombustible and heat resistant materials shall be used wherever pratical throughout the unit, particularly in locations such as the containment and the control room."

3 - "Fire detection and protection systems of appropriate capacity and capability shall be provided and designed to minimize the adverse effects of fires on structures, systems, and components important to safety."

4 - "Fire fighting systems shall be designed to assure that their rupture or inadvertent operation does not significantly impair the safety capability of these structures, systems, and components."

The Indian Point No. 3 Fire Protection Program Report, Revision 1, dated April 1977 was reviewed to determine to what extent the structures, systems and components associated with the Auxiliary Feedwater System were protected against the effects of fires.

It was concluded in the report that the results of the fire hazards evaluation had shown that there are no areas in the plant where a design basis fire would cause the loss of the primary as well as the redundant shutdown system. Therefore, no adverse system interactions were identified due to fire induced failures of systems, components and structures of the Auxiliary Feedwater System.

APPENDIX A-3.0 Auxiliary Feedwater System Description

APPENDIX A-3.1 System Functional Description [1]

The Auxiliary Feedwater System serves as a backup system for supplying feedwater to the secondary side of the steam generators at times when the feedwater system is not available, thereby maintaining the heat sink capabilities of the steam generator. The Auxiliary Feedwater System is an Engineered Safeguards System, and is directly relied upon to prevent core damage and primary system overpressurization in the event of transients such as a loss of normal feedwater or a secondary system pipe rupture, and to provide a means for plant cooldown following any plant transient.

Following a reactor trip, decay heat is dissipated by evaporating water in the steam generators and venting the generated steam either to the condensers through the steam dump or to the atmosphere through the steam generator safety valves or the power-operated relief valves. Steam generator water inventory must be maintained at a level sufficient to ensure adequate heat transfer and continuation of the decay heat removal process. The water level is maintained under these circumstances by the Auxiliary Feedwater System which delivers an emergency water supply to the steam generators. The Auxiliary Feedwater System is capable of functioning for extended periods, allowing time either to restore normal feedwater flow or to proceed with an orderly cooldown of the plant to the reactor coolant temperature where the Residual Heat Removal System can assume the burden of decay heat removal. The Auxiliary Feedwater System flow and the emergency water supply capacity must be sufficient to remove core decay heat, reactor coolant pump heat, and sensible heat during the plant cooldown.

APPENDIX A-3.0 AUXILIARY FEEDWATER SYSTEM DESCRIPTION (Cont'd)

APPENDIX A-3.1 System Functional Description (Cont'd)

DESIGN CONDITIONS

The reactor plant conditions which impose safety-r l ted performance requirements on the design of the Auxiliary Feedwater System are as follows for Indian Point Unit No. 3 Nuclear Power Plant.

- Loss of main feedwater transient
- Station blackout (i.e., loss of main feedwater without offsite power available)
- Rupture of a Main Steam Line
- Loss of all AC Power
- Loss of Coolant Accident (LOCA)
- Cooldown

Loss of Main Feedwater Transients

The design loss of main feedwater transients are those caused by:

- Interruptions of the Main Feedwater System flow due to malfunction in the feedwater or condensate system
- Loss of offsite power or blackout with the consequential shutdown of the main feedwater system pumps, auxiliaries, and controls

Loss of main feedwater transients are characterized by a rapid reduction in steam generator water levels which results in a reactor trip, a turbine trip, and auxiliary feedwater actuation by the protection system logic. Following reactor trip from high power, the power quickly falls to decay heat levels.

DESIGN CONDITIONS (Cont'd)

Loss of Main Feedwater Transients (Cont'd)

The water levels continue to decrease, progressively uncovering the steam generator tubes as decay heat is transferred and discharged in the form of steam either through the steam dump valves to the condenser or through the steam generator safety or power-o era ed relief valves to the atmosphere. The reactor coolant temperature increases as the residual heat in excess of that dissipated tnrough the steam generators is absorbed. With increased temperature, the volume of reactor coolant expands and begins filling the pressurizer. Without the addition of sufficient auxiliary feedwater, further expansion will result in water being discharged through the pressurizer safety and relief valves. If the temperature rise and the resulting volumetric expansion of the primary coolant are permitted to continue, then (1) pressurizer safety valve capacities may be exceeded causing over-pressurization of the Reactor Coolant System and/or (2) the continuing loss of fluid from the primary coolant system may result in bulk boiling in the Reactor Coolant System and eventually in core uncovering, loss of natural circulation, and core damage. If such a situation were ever to occur, the Emergency Core Cooling System would be ineffectual because the primary coolant system pressure exceeds the shutoff head of the safety injection pumps, the nitrogen over-pressure in the accumulator tanks, and the design pressure of the Residual Heat Removal Loop. Hence, the timely introduction of sufficient auxiliary feedwater is necessary to arrest the decrease in the steam generator water levels, to reverse the rise in reactor coolant temperature, to prevent the pressurizer from filling to a water solid condition, and eventually to establish stable hot standby conditions. Subsequently, a decision may be made

to proceed with plant cooldown if the problem cannot be satisfactorily corrected. The blackout transient differs from a simple loss of main feedwater in that emergency power sources must be relied upon to operate vital equipment. The loss of power to the electric driven condenser circulating water pumps results in a loss of condenser vacuum and condenser dump valves. Hence, steam formed by decay heat is relieved through the steam generator safety valves or the power-operated relief valves. The calculated transient is similar for both the loss of main feedwater and the blackout, except that reactor coolant pump heat input is not a consideration in the blackout transient following loss of power to the reactor coolant pump bus.

The station blackout transient serves as the basis for the minimum flow (400 gpm) required for Indian Point No. 3 Nuclear Power Plant. The system is designed so that a minimum of 400 gpm is provided against the steam generator safety valve set pressure (with 3% accumulation) to prevent water relief from the pressurizer. This is accomplished, even considering the effect of the turbine driven pump throttling with an assumed single failure.

APPENDIX A-3.0 AUXILIARY FEEDWATER SYSTEM DESCRIPTION (Cont'd)

APPENDIX A-3.2 System Operating Description [2]

Auxiliary Feedwater Flow Path

The Auxiliary Feedwater System consists of two subsystems. One system utilizes a steam turbine-driven pump, with the steam capable of being supplied from No. 32 and No. 33 steam generators upstream of the isolation valves. A pressure reducing control valve reduces the pressure to the 600 psi design value of the turbine. This system is capable of supplying a total of 800 gpm to all four steam generators. The other system utilizes two motor-driven pumps each with a capacity of 400 gpm. The discharge piping is arranged so that each pump supplies two steam generators (see Figure A-2).

Water Supplies

Water supplies to the Auxiliary Feedwater System is redundant. The normal source is by gravity feed from the condensate storage tank which is sized to meet the normal operating and maintenance needs of the turbine cycle. Each auxiliary feedwater pump takes suction on the header through a check and normally open stop valve. Individual flow elements are provided on the suction to each of the two motor driven pum s (No. 31 and No. 33). Pump suction pressure is indicated in the control room by PI-1263-R, PI-1264-R and PI-1265-R for each pump. Availability of water from this source is guaranteed by LCV-1158 which closes when the quantity of water in the condensate storage tank drops to 360,000 gallons. When LCV-1158 closes, make-up to the main condensers is prevented and a sufficient quantity of water is assured to be available to remove the residual heat generated by the reactor for 24 hours at hot shutdown condition.

APPENDIX A-3.2 System Operating Description (Cont'd)

Water Supplies (Cont'd)

An alternate supply of water for the pumps is provided for emergency backup and long-term cooling from the city water system. Each pump is supplied from a header through a check and control valve which is normally closed. This valve is controlled by a switch located in the control room which will operate the solenoid, applying or removing air from the valve. Valve position is indicated in the control room.

Discharge Routing

Discharge from the pumps is routed to the steam generators. Steam generators No. 31 and No. 32 are supplied by No. 31 and No. 32 auxiliary boiler feed pumps. Steam generators No. 33 and No. 34 are supplied by No. 32 and No. 33 feed pumps. Each feedwater line is provided with a flow control valve for feedwater regulation. A common flow transmitter for each steam generator is used to indicate flow in the control room from the motor driven or turbine driven flow paths. Pump discharge pressure is provided both locally and in the control room. Recirculation lines, which are provided for pump protection are routed back to the condensate storage tank.

Motor Driven Auxiliary Feedwater Pumps

The motor driven pumps are Ingersoll-Rand Company No. 3HMTA, nine stage, horizontal split case centrifugal units, each of which supplies 400 gpm of water at a head of 1350 psi. The motor drives are furnished by Westinghouse Electric Corporation.

APPENDIX A-3.0 AUXILIARY FEEDWATER SYSTEM DESCRIPTION (Cont'd)

APPENDIX A-3.2 System Operating Description (Cont'd)

Motor Driven Auxiliary Feedwater Pumps (Cont'd)

a. Motor Driven Pump Control

Auxiliary feed pumps No. 31 and No. 33 are driven by motors supplied from 480V buses 3A and 6A respectively. Control switches exist both locally and in the control room on the Condensate and Feedwater Supervisory Panel. The local switches allow "Start and Stop" pushbutton operation of the pumps. The switches in the control room have three positions "On-Auto-Trip". The following conditions will automatically start the pumps as described.

- Automatic loss of either main boiler feed pump will start both No. 31 and No. 33.

- Low-Low steam generator level in any steam generator will start both No. 31 and No. 33.

- In the event of a unit trip which is initiated by a safety injection signal the following Auxiliary Feedwater System events will occur:

    1) Actuates the turbine driven AFW pump.
    2) The pumps will be provided with a start signal as the safeguards buses are reloaded.

APPENDIX A-3.2 System Operating Description (Cont'd)

Motor Driven Auxiliary Feedwater Pumps (Cont'd)

a. Motor Driven Pump Control (Cont'd)

- Loss of outside power without safety injection will provide both pumps with a start signal after the diesels have tied into the 480V buses. A time delay is associated with starting the pumps to allow for loading of the diesels.

Undervoltage on either bus 3A or 6A will trip the pump fed by the bus. The following indication and alarms are provided in the CCR to monitor the pumps.

- Pump on-off-auto trip lights.
- Pump lock off alarm
- Pump auto trip alarm
- Pump on local control alarm

Each motor driven pump is provided with a pressure sustaining control system to prevent the pump from "running out" on its curve. As the discharge pressure of the pump decreases below the set point of 1355, PT-406A for No. 31 pump and PT-406B f No. 33 pump will generate a signal that will override the signal from the flow controllers on the Condensate and Feedwater Supervisory Panel. The signal will operate to close the valves until the pressure is restored in the discharge line having low pressure.

APPENDIX A-3.0 AUXILIARY FEEDWATER SYSTEM DESCRIPTION (Cont'd)

APPENDIX A-3.2 System Operating Description (Cont'd)

Motor Driven Auxiliary Feedwater Pumps (Cont'd)

b. Turbine Driven Auxiliary Feedwater Pump

The full size turbine driven pump is a Worthington Corporation No. 4-WT-127, horizontal, multi-stage, centrifugal pump with a capacity of 800 gpm at 1350 psi.

Auxiliary Feedwater Turbine

a. Turbine Description

The turbine drive is a Worthington Corporation horizontal axial flow, non-condensing unit rated at 970 HP at 3570 RPM.

b. Auxiliary Turbine Steam Supply

Steam to drive the turbine is supplied from the main steam

shut ff

will close whenever the temperature in th- Pump Room reaches 120°F preset valve. These valves have been added to protect motor driven pumps from being rendered inoperable in the unlikely event of the steam line rupturing within the building.

Auxiliary Feedwater Turbine (Cont'd)

b. Auxiliary Turbine Steam Supply (Cont'd)

During turbine operation the steam supply pressure is regulated by PCV-1139. This pressure control valve maintains a 600 psig steam pressure to the turbine. Pressure controller 1176-S senses the downstream pressure and generates a signal for use by the positioner. The control signal generated by the positioner is then applied to the diaphragm of PCV-1139 through the start solenoids (3 and 4). Pressure controller 1176-S will also alarm low pressure at 550 psig in the control room. Once the pressure has been reduced the steam enters the turbine steam chest which contains the governor and turbine trip valves.

To remove moisture in the main steam supply, traps have been provided where necessary. The discharge from the traps have been routed to the main steam trap system which is directed to the drains provided on the turbine casing, steam chest and exhaust piping. The exhaust from the turbine is directed to the atmosphere.

c. Auxiliary Turbine Cooling System

The thrust bearing and turbine inboard and outboard bearings are cooled by water from the discharge of the pump.

Auxiliary Feedwater Turbine (Cont'd)

c. Auxiliary Turbine Cooling System (Cont'd)

A pressure control valve PCV-1213 maintains the water supply to the bearing at 65 psig. The pressure control valve receives its signal from PC-1213 downstream of the control valve. The return water from each bearing is tied together and returned to the condensate storage tank. Flow through each bearing and the combined return temperature are indicated locally.

d. Turbine Driven Pump Control

The turbine driven pump is a variable speed device, and the two motor driven pumps are constant speed devices. The speed of the turbine driven pump is governed by a remote pneumatic speed changer (HC-1118) that is located on the Condensate and Feedwater Supervisory Panel in the control room. The speed changeris designed to operate over an entire speed range of 0 to 100%.

Pressure Reducing Valve PCV-1113 is used as the steam shutoff and start valve for the Auxiliary Feed Pump Turbine. The mode of operation of this valve is controlled by "Trip-Auto-On" switches; one located in the control room, and one in the Auxiliary Boiler Feed Pump Building. These switches control the position of four solenoid valves mounted on the air inlet

Auxiliary Feedwater Turbine (Cont'd)

d. Turbine Driven Pump Control (Cont'd)

to the valve actuator. These solenoid valves are in their de-energized state, which allows the positioner output to open the valve. Normally the valve is maintained in stand-by with the control switches in "Auto". In this position SOV's 1 and 3 are energized, this will cut off the positioner output (SOV-3 closed) and apply full instrument air pressure to the valve actuator (SOV-1 open) holding the valve closed. The SOV's will be de-energized and the pump started by any of the following:

- Low-Low water level in any two of the four steam generators (15% of span).
- Loss of outside power (provided a S.I. signal DOES NOT exist).
- Positioning the control switch to "START".

The turbine governor valve is controlled by a governor and speed changer. The speed changer can be operated locally or from the control room by HC-1118 as shown. A trip valve has been provided to immediately shutdown the turbine on an overspeed of approximately 4516 R.P.M. Turbine speed is indicated in the control room.

APPENDIX A-3.2 System Operating Description (Cont'd)

Recirculation Flow Path and Control

An automatic pump recirculation control system is provided on each motor driven pump to recirculate the pump discharge back to the condensate storage tank at low flow. A maintained contact "Close-Auto-Open" control switch and valve position indicating lights are located in the control room on the Condensate and Feedwater Supervisory Panel for each recirculation valve. A manual operator is provided on each valve for local operation. Suction flow is measured by flow switchs FC-1135-S, FC-1135SA-S and FC-1136-S, FC-1135SB-S for pumps No. 31 and No. 32 respectively. These swtiches are provided with contacts which are interlocked as follows:

- A decrease in flow to 100 gpm actuates a low flow annunciato- in the CCR.

- A further decrease in flow to 50 gpm will de-energize solenoid valve SOV 1321 SOV1323 on control valves FCV 1121 and FCV 1123 in the recirculation lines to initiate recirculation flow back to the condensate storage tank and also energize a time-delay relay.

- The time delay interlock functions to trip the pump in the event that the flow does not increase to 100 gpm in a preset amount of time. If the flow returns to above 100 gpm in less than the preset time, the recirculation valve will close, and the trip timer is reset.

If the pump is tripped by the low flow timer, the timer circuit must be reset by selecting the pump to the trip position prior to restarting. This will

Recirculation Flow Path and Control (Cont'd)

clear the trip circuit of the auxiliary feed pump circuit breaker and reset the common pump low flow alarm so that a low flow condition on the second pump, if operating, will still be alarmed. Pump control switch manual trip action, or automatic electrical stripping action will automatically perform the above trip timer and low flow alarm reset function. Selecting the recirculation valve control switch to the "Open" or "Close" position will defeat all automatic features (except the low flow alarm) and hold the valve in that position regardless of flow through the pump.

If during the winter a prolonged shutdown of the turbine generator is experienced a means has been provided to heat the condensate storage tank. The recirculation lines back to the condensate storage tank from the two motor driven pumps provides a source of both heat and flow in sufficient quantities to protect the tank from freezing. When using the pumps in this manner the recirculation flow must be adjusted to provide a flow of 125 gpm for each pump, using the special high pressure drop valves BFD-77 and 78. The flow to the tank is extremely important in order to provide the maximum BTU input to the tank with the minimum hazard to the pumps. Only one pump is required to protect the tank from temperatures above $15^{o}F$.

The turbine driven pump is provided with a continuous recirculation system back to the condensate storage tank. An additional feature provided on the turbine driven pump is that part of recirculated water is used to cool the thrust bearing and turbine bearings.

APPENDIX A-3.2 System Operating Description (Cont'd)

Auxiliary Feedpump Flow Control

As previously described, two auxiliary feed systems exist which are independent of each other. Flow control to the steam generators is provided by eight controllers located on the Condensate and Feedwater Supervisory Panel in the control room. There are two controllers associated with each steam generator, one each for the feedwater supplies from the motor and turbine driven pumps. Which controller is used will be dependent on the operating conditions of the unit.

Flow indication is provided for each auxiliary feedwater line to each steam generator. The flow nozzle is located in the common terminal line from the steam driven and the motor driven pumps. The output from each of these transmitters is connected to flow indicators located on the Condensate and Feedwater Supervisory Panel and in the auxiliary feedwater pump building. The steam generator wide range level recorders have also been located on this panel.

Level in the steam generator is maintained by positioning the flow controller. All pneumatic instruments associated with the auxiliary pump flow controls are provided with nitrogen back-up. Three nitrogen bottles are located inside the auxiliary feed pump room which connect into the instrument air supply down stream of a check valve. A pressure regulator set at 50 psig will feed nitrogen into the instrument air supply system whenever the normal air supply pressure decreases below this setting. A pressure switch (PC-1355-S) located at the bottles will annunciate in the control room to warn the operator whenever the bottles require changing.

SYSTEMS INTERACTION STUDY
APPENDIX A
NOTES TO TABLE A-2.1

NOTE:

(1) Failure mode(s) for each type of component listed on Table 6-1 are summarized as follows:

A - Complete loss of function due to instantaneous loss of electrical power
  1) Loss of one redundant electrical division comcident with loss of all offsite power
  2) Loss of all AC power (onsite and offsite)
  3) Loss of DC power
  4) Other

B - Complete loss of function due to instantaneous loss of power (other than electrical)
  1) Loss of pneumatic power (plant air, compressed gas, etc)
  2) Loss of hydraulic power
  3) Other (explain where necessary)

C - Partial loss of function due to instantaneous loss of electrical power
  1) Loss of one redundant electrical division comcident with loss of all offsite power
  2) Loss of all AC power (onsite and offsite)
  3)
  4) Other

D - Partial loss of function due to instantaneous loss of power (other than electrical)
  1) Partial loss of pneumatic power (eg crimped air supply line)
  2) Partial loss of hydraulic power
  3) Other (explain where necessary)

E - Complete loss of function due to instantaneous mechanical failure(s)
  1) plugged component
  2) component normally open and does not close
  3) component normally closed and does not open
  4) component does not start due to mechancial interference
  5) other (explain where necessary)

NOTE:

(1) Failure mode(s) for eacn type of component listed on Table 6-1 are summarized as follows: (Cont'd)

F - Partial loss of function due to instantaneous mechanical failure(s)
1) plugged component, partial
2) component normally open and does not close completely
3) component normally closed and does not open completely
4) component does not reach full speed due to mechanical interference
5) other (explain were necessary)

G - Other failures not covered by A thru F. (describe where necessary)

(2) It has been assumed that the loss of function, either completely or partially of pressure transmitters, pressure controllers, pneumatic/electrical converters, etc associated with the instrumentation and control components of the auxiliary feedwater system is less limiting than complete or partial loss of controlled component, eg pressure or flow control valves.

M-55	LCV-1158		(1)		(1)				full or partial loss of function in the open position will jeopardize suction flow to auxiliary feedwater pump 31, 32 & 33 from the condensate storage tank	1) Valve indication in control room for open/closed position only. Partially open/close position not monitored. Local position indicator only.	redundant level switches on the condensate storage tank provide reliability to the system in regard to alarming low water level in tank. Mechanical failure of valve however will be independent of actuation signal and as such, isolation of non-essential users is not assured Operator can take corrective action - close valve manually only after he/she determines extent of damage - may not be possible	Unacceptable 1. recommend the addition of second similar valve in series with presently installed valve
M-56	SOV-1258		(1)		(1)							
M-57	Air Operated FCV-406A		(1)		(1)	(1)	(1)		loss of auxiliary feedwater flow to corresponding steam generator from pump number 31 or 33. -or- partial loss of auxiliary feedwater flow to corresponding steam generator from pump number 31 or 33	1) position indication in control room, for open/close only.	turbine driven auxiliary feedwater pump and associated control valves and appurtenances provide redundant auxiliary feedwater flow to unaffected steam generators. Operator must isolate affected steam generator by closing FCV 405A, B, C or D and opening FCV-1139 to admit steam to turbine. Turbine speed is controlled by	Acceptable
M-58	Air Operated FCV-406B		(1)		(1)	(1)	(1)					
M-59	Air Operated FCV 406C		(1)		(1)	(1)	(1)					
M-60	Air Operated FCV 406D		(1)		(1)	(1)	(1)

FAILURE MODES & EFFECTS ANALYSIS
SHEET 9 OF 9
FIGURE A-2.1

SYSTEMS INTERACTION STUDY
APPENDIX A
NOTES TO TABLE A-2.1

NOTE:

(1) Failure mode(s) for each type of component listed on Table 6-1 are summarized as follows:

A - Complete loss of function due to instantaneous loss of electrical power
  1) Loss of one redundant electrical division comcident with loss of all offsite power
  2) Loss of all AC power (onsite and offsite)
  3) Loss of DC power
  4) Other

B - Complete loss of function due to instantaneous loss of power (other than electrical)
  1) Loss of pneumatic power (plant air, compressed gas, etc)
  2) Loss of hydraulic power
  3) Other (explain where necessary)

C - Partial loss of function due to instantaneous loss of electrical power
  1) Loss of one redundant electrical division comcident with loss of all offsite power
  2) Loss of all AC power (onsite and offsite)
  3) Loss of DC power
  4) Other

D - Partial loss of function due to instantaneous loss of power (other than electrical)
  1) Partial loss of pneumatic power (eg crimped air supply line)
  2) Partial loss of hydraulic power
  3) Other (explain where necessary)

E - Complete loss of function due to instantaneous mechanical failure(s)
  1) plugged component
  2) component normally open and does not close
  3) component normally closed and does not open
  4) component does not start due to mechancial interference
  5) other (explain where necessary)

SYSTEMS INTERACTION STUDY
APPENDIX A
NOTES TO TABLE A-2.1 (Cont'd)

NOTE:

(1) Failure mode(s) for each type of component listed on Table 6-1 are summarized as follows: (Cont'd)

F - Partial loss of function due to instantaneous mechanical failure(s)
1) plugged component, partial
2) component normally open and does not close completely
3) component normally closed and does not open completely
4) component does not reach full speed due to mechanical interference
5) other (explain were necessary)

G - Other failures not covered by A thru F. (describe where necessary)

(2) It has been assumed that the loss of function, either completely or partially of pressure transmitters, pressure controllers, pneumatic/electrical converters, etc associated with the instrumentation and control components of the auxiliary feedwater system is less limiting than complete or partial loss of controlled component, eg pressure or flow control valves.

DESCRIPTION OF POSTULATED INTERACTION:

Monorail fails from support and hits 2"BFD-1010 causing rupture of the line,

Monorail also hits 2"BFD 1009 causing rupture of the line (see L-2 sheet 9)

EVALUATION & DISPOSITION OF INTERACTION: Unacceptable

Monorail failure and subsequent rupture of lines 2BFD-1010 and 1009 results in loss of function of motor driven pumps No 31 and 33. Coincident with a single failure of the turbine driven pump, results in complete loss of auxiliary feedwater supply to all steam generators.

IDENTIFICATION OF INTERACTION COMPONENTS:

(Source) Exide Emerg Light Fixture

(Target) 8" AFW Pump Supply Header From Condensate Storage Tank, Line # CT-1071

DESCRIPTION OF POSTULATED INTERACTION:

Exide emergency lighting fixture fails from it's wall support and hits 8" AFW Pump Supply header #CT-1071

EVALUATION & DISPOSITION OF INTERACTION:

Acceptable interaction, Exide emergency lighting fixture does not have sufficient mass to damage the line. CT-1071

INTERACTION DOCUMENTATION SHEET

BUILDING: AFW Pump Building

FIRE ZONE: 23

LOCATION WITHIN FIRE ZONE: N.A.

INTERACTION NO.: 01-09-11-12, 02-09-11-12, Matrix No I-1

INTERACTION SKETCH NO.: 5-3, Photo 46 for sources, Photo 8 & 9 for targets

IDENTIFICATION OF INTERACTION COMPONENTS:
Targets: PT-1264 sensing line & PI-1264
Sources: Mono Rail, 4" & 1/2" Conduits, Light # 2

DESCRIPTION OF POSTULATED INTERACTION:
Seismically induced failures of the sources can cause damages to PT-1264 and its instrument tubing thereby resulting in water spillage and a loss of AFW Pump 32 suction pressure indication in the control room (for NPSH protection)

EVALUATION & DISPOSITION OF INTERACTION:
Interaction is unacceptable.
Review seismic documentation. If the sources are not seismically supported, provide seismic supports.

INTERACTION NO.: 04-02-03-08, 05-02-03-08, Matrix No I-1

INTERACTION SKETCH NO.: 5-3, Photo No. 32, 34

IDENTIFICATION OF INTERACTION COMPONENTS:

Targets: FC-1136-S & FC-1136A-S (Flow switches to monitor AFW Pump 33 inlet flow)
Sources: 2" conduit, 2" station air pipe, switch boxes and conduits

DESCRIPTION OF POSTULATED INTERACTION:

Seismically induced failures of the sources can cause damages to the targets and their sensing lines thereby resulting in water spillage and a loss of Pump 33 suction flow alarm in the control room.

EVALUATION & DISPOSITION OF INTERACTION:

The loss of suction flow alarm is not critical, However, the water spillage can cause damages to other components in the area. Therefore, the sources should be seismically supported.

INTERACTION NO.: 09-04-05-06-07, 10-07 Matrix No I-1

INTERACTION SKETCH NO.: 5-3, photo No. 24, 25, 26, 27

IDENTIFICATION OF INTERACTION COMPONENTS:

Targets: FC-1135-S, FC-1135A-S (Flow switches to monitor AFW Pump 31 suction flow)

Sources: Elec. box 232 and conduit, Light #3, space heater #9, 4" drain line

DESCRIPTION OF POSTULATED INTERACTION:

Seismically induced failures of the sources can cause damages to the targets and their sensing lines thereby resulting in water spillage and a loss of Pump 31 suction flow alarm in the control room.

EVALUATION & DISPOSITION OF INTERACTION:

The loss of suction flow alarm is not critical, However, the water spillage can cause damages to other components in the area. Therefore, seismic documentation review should be conducted. If the sources are not seismically supported, provide seismic supports.

INTERACTION DOCUMENTATION SHEET

BUILDING: AFW Pump Building

FIRE ZONE: 23

LOCATION WITHIN FIRE ZONE: N.A.

INTERACTION NO.: 15-01-02-03-04-05-07-08, 16-01-02-03-04-05-06-07
Matrix No. I-2

INTERACTION SKETCH NO.: 5-3, Photo No. 17, 18, 19, 22

IDENTIFICATION OF INTERACTION COMPONENTS:

Targets: PCV-1187 Valve Station (including valve, solenoid, instrument air lines, electrical wires and terminal box)

Sources: Electrical box SX-1, space heater #3, Light #3, space heater #4, 2" conduit, 2" station air pipe.

DESCRIPTION OF POSTULATED INTERACTION:

Seismically induced failures of the sources can cause: 1) a loss of function of city water supply valve PCV-1187 of AFW Pump 31 and 2) instrument air piping rupture.

EVALUATION & DISPOSITION OF INTERACTION:

The rupture of instrument air piping is a common mode failure in the entire instrument air piping in the pump room. Such failure will cause pneumatically operated valves in the room to be inoperable.
The loss of function of PCV-1187 will require manual operation to open the valve. However, PCV-1187 does not have a hand operator.
Interaction is unacceptable. Review seismic documentation and provide seismic supports for the sources if they are not seismically supported.

INTERACTION SKETCH NO.: 5-3, Photo No. 12 & 23

IDENTIFICATION OF INTERACTION COMPONENTS:

Targets: PCV-1188 Valve Station (including valve, solenoid, instrument air lines, electrical wires and terminal box)

Sources: 2" conduit, 2" station air pipe, Light # 2.

DESCRIPTION OF POSTULATED INTERACTION:

Seismically induced failures of the sources can cause: 1) a loss of function of the city supply valve PCV-1188 of AFW Pump 32 and 2) instrument air piping rupture.

EVALUATION & DISPOSITION OF INTERACTION:

The rupture of instrument air piping is a common mode failure in the entire instrument air piping in the pump room. Such failure will cause pneumatically operated valves in the room to be inoperable. The loss of function of PCV-1188 will require manual operation to open the valve. However, PCV-1188 does not have a hand operator. Interaction is unacceptable. Review seismic documentation and provide seismic supports for the sources if they are not so supported.

BUILDING: AFW Pump Building

FIRE ZONE: 23

LOCATION WITHIN FIRE ZONE: N.A.

INTERACTION NO.: 19-09-10-11-12, 20-09-10-11-12, 21-09-10-11-12, 22-09-10-11-12, Matrix No. I-2

INTERACTION SKETCH NO.: 5-3, Photo No. 44, 47

IDENTIFICATION OF INTERACTION COMPONENTS:

Targets: PT-406B, PI-1262, PT-1262, PT-1262R

Sources: Light # 7, 3" conduit, Monorail, instrument tubings between Rack #28 & Rack #5

DESCRIPTION OF POSTULATED INTERACTION:

Seismically induced failures of the sources can cause damages to the targets thereby resulting in water spillage and loss of functions the pressure transmitters which sense outlet pressure of AFW Pump 31.

Seismically induced failure of instrument lines between Rack #28 and Rack #5 is aggravated by the fact that Rack #28 is not anchored

EVALUATION & DISPOSITION OF INTERACTION:

Interaction is unacceptable.

Review seismic documentation and provide seismic supports for the sources if they are not so supported.

SYSTEMS INTERACTION STUDY
EXTERNALLY INDUCED SYSTEMS INTERACTION
INTERACTION DOCUMENTATION SHEET

BUILDING: AFW Pump Building

FIRE ZONE: 23

LOCATION WITHIN FIRE ZONE: N.A.

INTERACTION NO.: generic.

INTERACTION SKETCH NO.: 5-3, Photo No. 53
Event Analysis Figure No. EA-1

IDENTIFICATION OF INTERACTION COMPONENTS:
Instrument Rack #28 contains flow transmitters which share the same sensing tubings as those of flow transmitters that generate signals for the control room indication of main feedwater flow and for the steam-feedwater flow mismatch plant protection function.

DESCRIPTION OF POSTULATED INTERACTION:
Rack #28 is not secured. It is not supported from the floor or wall. Therefore, a seismically induced movement of this rack will cause sensing line ruptures, damages to FCV-1121 and FCV-406D resulting in the losses of valve functions, steam-feedwater flow mismatch protection and important information to the control room operator.

EVALUATION & DISPOSITION OF INTERACTION:
Interactions are unacceptable.
Corrective actions:
- Review seismic qualification of Rack #28. If not qualified, modify the rack.
- Provide anchor bolts for the rack
- Perform seismic review for the sensing tubings and supports. Seismically support the tubings if required.

POWER AUTHORITY OF THE STATE OF NEW YORK
INDIAN POINT 3 NUCLEAR POWER PLANT
SYSTEMS INTERACTION STUDY
EXTERNALLY INDUCED SYSTEMS INTERACTION
INTERACTION DOCUMENTATION SHEET

BUILDING: AFW Pump Building

FIRE ZONE: 23

LOCATION WITHIN FIRE ZONE: N.A.

INTERACTION NO.: generic

INTERACTION SKETCH NO.: Composite Piping and Instrument Air Tubing Flow Diagram No. (later), Event Analysis Diagram No EA-2

IDENTIFICATION OF INTERACTION COMPONENTS:
Instrument tubings and N_2 Backup cylinders.

DESCRIPTION OF POSTULATED INTERACTION:
A rupture in instrument air tubing circuit can cause the AFW flow control/shutoff valves, steam pressure control valve and turbine control valve to be inoperable because of a loss of instrument air or N_2 backup pressure in the tubing circuit.

EVALUATION & DISPOSITION OF INTERACTION:
Interaction can prevent a timely termination of AFW to a faulted steam generator. It can cause all three trains of the AFW system to be inoperable from the control room. Independence of the tubing circuit contradicts the separation criteria of the electrical circuits that operate instrument air solenoids etc.
Instrument air piping should be modified to three train circuits, each of which is provided with a N_2 backup cylinder

INTERACTION SKETCH NO. 795-4, photo 101, 102

IDENTIFICATION OF INTERACTION COMPONENTS:

(Source): Overhead Mono Rail

(Target): Motor #31
Motor #33
Feeder Conduits #755 & 7551 for motor #33

DESCRIPTION OF POSTULATED INTERACTION:

Mono rail - falls from supports and hits motor #33, its feeder conduits 755 & 7551 and motor #31.

Both motors are 400 HP, 440 Volt with open drippproof enclosure.

EVALUATION & DISPOSITION OF INTERACTION:

Unacceptable Interaction - Targets may be damaged by the failure of the Mono rail support. Motor terminal boxes, which are made of fabricated steel plates, are deemed to be the most susceptible.

INTERACTION SKETCH NO.: Fig 5-4, photo 103

IDENTIFICATION OF INTERACTION COMPONENTS:

(Sources); paging speaker
Instrument Air Tubing
Space heater Unit no. 6

Target : Conduit to CT-64

DESCRIPTION OF POSTULATED INTERACTION:

Speaker, Instrument Tubing and space heater Unit fall from their suppot and hit the conduit.

EVALUATION & DISPOSITION OF INTERACTION:

Acceptable Interaction - a. Speaker and Tubing do not have sufficent mass to cause unacceptable damage to the target.
b. Space heater is located approx 4'-0" from the wall and is unlikely to damage the conduit which is supported 1" off the wall.

INTERACTION SKETCH NO.: Fig 5-4, photo 104, 105, 106

IDENTIFICATION OF INTERACTION COMPONENTS:

Source: 4" Drain Line

Targets: Box # SX-3, Box # X282,
Conduits for FC-1135, FC-1135A, FC-1136 & FC-1136A

DESCRIPTION OF POSTULATED INTERACTION:

Drain line fail from its supports and hit target identified.

EVALUATION & DISPOSITION OF INTERACTION:

Interaction is deemed "not credible" due to the locations of the targets which are all mounted against the wall. The Source, however, may cause unacceptable damage to the Instrument which are identified separately.

EXTERNALLY INDUCED SYSTEMS INTERACTION
INTERACTION DOCUMENTATION SHEET

BUILDING: AFW Pump Building

FIRE ZONE: 23

LOCATION WITHIN FIRE ZONE: NA

INTERACTION NO.: 34-02-18-107, 34-02-19-108, 34-03-18-107, 34-03-19-108
34-04-18-107, 34-05-18-107

INTERACTION SKETCH NO.: Fig 5-4, photo 107, 108

IDENTIFICATION OF INTERACTION COMPONENTS:

Sources: 1" Instrument Air, 2" Conduit, 1" Conduit, Space Heater DS and Heater Disconnect Switch

Targets: Box SX-1 and conduit to PCV-1187
Box SX-2 and Conduit to PCV-1188

DESCRIPTION OF POSTULATED INTERACTION:

Instrument Air piping, electrical conduits fail from their support and hit the targets identified.

EVALUATION & DISPOSITION OF INTERACTION:

Unacceptable Interaction - a. Boxes SX-1 and SX-2 are unlikely to be damaged. Boxes are wall mounted.
b. Flexible conduits for PCV-1187 & PCV-1188 are very suseptible to any falling objects.

INTERACTION NO.: 34-06-19-108

INTERACTION SKETCH NO.: Fig 5-4, Photo 108

IDENTIFICATION OF INTERACTION COMPONENTS:

Source: Conduit box FM-279

Target: Box SX-2 and associated conduits including 1-1½" rigid and 3-¾" flexible conduits

DESCRIPTION OF POSTULATED INTERACTION:

Conduit box FM-279 fails from its support and hits SX-2 and its associated conduits

EVALUATION & DISPOSITION OF INTERACTION:

Unacceptable Interaction - a. Wall mounted rigid conduit and box is unlikely to be damaged

b. Flexible conduit may be damaged when struck by box FM-279

INTERACTION NO.: 34-07-19-108

INTERACTION SKETCH NO.: Fig 5-4, photo 108

IDENTIFICATION OF INTERACTION COMPONENTS:

Source : Electrical Unit Space Heater # 2

Target : Box SX-2 and its associated conduits

DESCRIPTION OF POSTULATED INTERACTION:

Space Heater # 2 fails from its support and hit the target

EVALUATION & DISPOSITION OF INTERACTION:

Unacceptable Interaction: Unit heater with a motor driven fan has sufficient mass to cause an unacceptable damage.

INTERACTION SKETCH NO.: Fig 5-4, Photo 111

IDENTIFICATION OF INTERACTION COMPONENTS:

Source: 4" Drain Line

Target: Ventilation Fan

DESCRIPTION OF POSTULATED INTERACTION:

4" Drain line falls from its support and hit Ventilation fan directly below.

EVALUATION & DISPOSITION OF INTERACTION:

Unacceptable Interaction

INTERACTION NO.: 34-09-20-111

INTERACTION SKETCH NO.: Fig 5-4, photo 111

IDENTIFICATION OF INTERACTION COMPONENTS:

Source : Roll-up Door

Target : Ventilation Fans

DESCRIPTION OF POSTULATED INTERACTION:

Roller-up door damaged due to external missile and hit ventilation fans

EVALUATION & DISPOSITION OF INTERACTION:

Acceptable Interaction - The location of the ventilation fan units makes the damage very unlikely. However, the failure of the Roller-up door will cause excessive damage to other indoor equipment which shall be evaluated separately.

INTERACTION SKETCH NO.: Fig 5-4, photo 203

IDENTIFICATION OF INTERACTION COMPONENTS:

Sources: Roll-up door, Hanging INCANDECENT LTG, TRAY I, TRAY III, N_2 Bottles

Target: AFW pump Local control panel

DESCRIPTION OF POSTULATED INTERACTION:

Failure of the support or restraint for the sources will enable one or more of the soupres to hit the target.

EVALUATION & DISPOSITION OF INTERACTION:

Unacceptable Interaction - Control panel can not withstand the force caused by any flying or falling objects. Unacceptable Control wiring short circuit, instrument false indication are very possible when struck by the sources identified.
