EXECUTIVE SUMMARY

Section 316(b) of the Clean Water Act (CWA) requires that cooling water intake structures reflect the best technology available to protect aquatic organisms from being killed or injured by impingement (being pinned against screens or outer part of a cooling water intake structure) or entrainment (being drawn into cooling water systems and subjected to thermal, physical and/or chemical stresses). Phase II of the 316(b) rule for existing electric generating plants is designed to reduce impingement mortality by 80-95% and entrainment by 60-90%.

In March 2007, the Second U.S. Circuit Court of Appeals remanded several provisions of the Phase II rule on various grounds. The provisions remanded included:

- EPA's determination of the Best Technology Available under Section 316(b);
- The rule's performance standard ranges;
- The cost-cost and cost-benefit compliance alternatives;
- The Technology Installation and Operation Plan provision;
- The restoration provisions; and
- The "independent supplier" provision.

Shortly thereafter, USEPA issued a memorandum to provide guidance on the status of the Cooling Water Intake Structures Phase II regulation under 316(b) of the Clean Water Act. With so many provisions of the Phase II rule affected by the decision, the rule should be considered suspended. In the meantime, all permits for Phase II facilities should include conditions under Section 316(b) of the Clean Water Act developed on a Best Professional Judgment basis.

This report provides of a summary of the baseline assessment fish and invertebrates impinged at Crystal River Power Plant located in Citrus County, Florida over the December, 2006 to November, 2007 time period.

Results for the impingement sampling program can be summarized as follows:

Fish Impingement:

- Approximately 4% of all fish impinged at Crystal River were impinged at Unit 1. It is estimated that a total of 40,930 fish (1,102 kg) were impinged at Unit 1. The most abundant species were silver perch (17.9%), spotfin mojarra (16.9%) and polka-dot batfish (15.5%).
- Approximately 9% of all fish impinged at Crystal River were impinged at Unit 2. It is estimated that a total of 83,556 fish (3,251 kg) were impinged at Unit 2. The most abundant species were polka-dot batfish (24.9%), pigfish (13.9%) and silver perch (11.5%).
- Approximately 87% of all fish impinged at Crystal River were impinged at Unit 3. It is estimated that a total of 821,144 fish (14,896 kg) were impinged at Unit 3. The most abundant species were Atlantic thread herring (23.6%), bay anchovy (15.7%) and scaled sardine (12.7%).
- It is estimated that a total of 945,631 fish (19,249 kg) were impinged at Crystal River (all units combined). The most abundant species were Atlantic thread herring (21.6%), bay anchovy (14.7%) and scaled sardine (11.4%).
- Peak levels of impingement were observed in February-March, 2007. Approximately 69% of all fish impinged (649,503 out of a total of 945,631 fish) at Crystal River Power Plant were impinged during these two months. In terms of biomass, approximately 46% of the total annual biomass impinged during these months.
- The initial condition of the fish was recorded as part of the impingement abundance study. The majority of fish (79.5% to 92.6%) were categorized as recently dead. The percentages of live fish varied between the three units. Approximately 7.3% of fish collected at Unit 3 were live while 17.3% to 19.9% of fish collected at Units 1 and 2, respectively, were live. This difference in survivability may be related to the increased flows observed at Unit 3 compared to Units 1 and 2. With an increase in flow, fish may be subjected more to abrasions.
- Differences were observed in survivability among species. For instance, approximately 78% of the polka-dot batfish collected at Crystal River were alive. Survival levels for Units 1, 2 and 3 were comparable at 79%, 70% and 80%, respectively. This is typically a hardier species compared to some of the pelagic types such as bay anchovy or blue-back herring.

Invertebrate Impingement:

- Approximately 10% of all invertebrates impinged at Crystal River were impinged at Unit 1. It is estimated that a total of 35,165 invertebrates (529 kg) were impinged at Unit 1. The most abundant species were pink shrimp (44.9%), Atlantic brief squid (11.9%) and iridescent swimming crab (11.2%).
- Approximately 15% of all invertebrates impinged at Crystal River were impinged at Unit 2. It is estimated that a total of 50,178 invertebrates (663 kg) were impinged at Unit 2. The most abundant species were pink shrimp (46.3%), iridescent swimming crab (14.2%) and Atlantic brief squid (11.3%).

- Approximately 75% of all invertebrates impinged at Crystal River were impinged at Unit 3. It is estimated that a total of 256,437 invertebrates (2,633 kg) were impinged at Unit 3. The most abundant species were pink shrimp (44.6%), Atlantic brief squid (17.3%) and false arrow crab (10.8%).
- It is estimated that a total of 341,780 invertebrates (3,826 kg) were impinged at Crystal River (all units combined). The most abundant species were pink shrimp (43.8%), Atlantic brief squid (15.9%) and false arrow crab (10.5%).
- The initial condition of the invertebrates was recorded as part of the impingement abundance study. The majority of invertebrates (57.4% to 66.1%) were categorized as alive. The percentage of live invertebrates was comparable for the three units. This is different from that observed from fish, which indicates the hardiness of most invertebrate species. Very few long dead invertebrates were recorded.

Trawl Collections:

- A total of 141 trawls were conducted at central, south and north locations.
- A total of 581 specimens (137 invertebrates, 444 fish) were collected at the central location in the vicinity of the intake channel with a mean density of 4.1 specimens per 1,000 m³.
- A total of 961 specimens (130 invertebrates, 831 fish) were collected at the south trawl location, with a mean density of 6.8 specimens per 1,000 m³.
- A total of 1,137 specimens (275 invertebrates, 862 fish) were collected at the north trawl location, with a mean density of 8.0 specimens per 1,000 m³.
- The mean densities of invertebrates collected at the central and south trawl locations were comparable (0.9 – 1.0 invertebrates per 1,000 m³). The mean density of invertebrates collected at the north location (1.9 invertebrates per 1,000 m³) was approximately twice that observed at the central and south trawl locations.
- The mean fish density at the central trawl location (3.1 fish per 1,000 m³) was approximately half of that observed for the south and north (5.9 - 6.1 per 1,000 m³) trawl locations. The reduced fish density observed for the central trawl location may be due to avoidance of the intake channel partly because of the configuration, or alternatively may be related to barge traffic.

Historical Levels of Impingement:

- The most recent impingement study at Crystal River Power Plant was conducted over 20 years ago. As part of this study, it was estimated that a total of 2,628,484 fish and invertebrates (33,953 kg) were impinged at Crystal River in 1985. Over the duration of the 1985 impingement study, a total of 61,195 fish were collected. The most commonly impinged fish were bay anchovy (18.3%), polka-dot batfish (14.6%) and bighead searobin (13.0%). A total of 171,907 invertebrates were also collected over the duration of the impingement study. The most commonly impinged invertebrates were pink shrimp (44.7%), blue crab (24.2%) and false arrow crab (9.6%).
- The number of fish and invertebrates impinged at Crystal River in 2006-2007 (1,287,720) was approximately one-half of that estimated to be impinged in 1985. The number of blue crab impinged at Crystal River in 2006-2007 (32,567) was an order of magnitude lower than that observed in 1985 (383,560). Similarly, the number of pink shrimp impinged at Crystal River in 2006-2007 (149,710) was substantially lower than that observed in 1985 (640,887).
- Spot represented the third most abundant fish species impinged at Crystal River Power Plant in 1985 (28,094 fish, 62.7 kg). While spot was collected during central (2 fish), north (7 fish) and south (2 fish) trawls, this species was not impinged during the 2006-2007 sampling program. In 2005, statewide landings of spot in Florida were 65% lower than the average landings in the previous five years (2000-2004) and were 96% lower than the 1982-2005 historical average landings.

CRYSTAL RIVER POWER PLANT FISH IMPINGEMENT STUDY REPORT

1.0 INTRODUCTION

Section 316(b) of the Clean Water Act (CWA) requires that cooling water intake structures reflect the best technology available to protect aquatic organisms from being killed or injured by impingement (being pinned against screens or outer part of a cooling water intake structure) or entrainment (being drawn into cooling water systems and subjected to thermal, physical and/or chemical stresses). Phase II of the 316(b) rule for existing electric generating plants is designed to reduce impingement mortality by 80-95% and entrainment by 60-90%.

In March 2007, the Second U.S. Circuit Court of Appeals remanded several provisions of the Phase II rule on various grounds. The provisions remanded included:

- EPA's determination of the Best Technology Available under Section 316(b);
- The rule's performance standard ranges;
- The cost-cost and cost-benefit compliance alternatives;
- The Technology Installation and Operation Plan provision;
- The restoration provisions; and
- The "independent supplier" provision.

Shortly thereafter, USEPA issued a memorandum to provide guidance on the status of the Cooling Water Intake Structures Phase II regulation under 316(b) of the Clean Water Act. With so many provisions of the Phase II rule affected by the decision, the rule should be considered suspended. In the meantime, all permits for Phase II facilities should include conditions under Section 316(b) of the Clean Water Act developed on a Best Professional Judgment basis.

This report provides of a summary of the baseline assessment fish impinged at Crystal River Power Plant located in Citrus County, Florida over the December, 2006 to November, 2007 time period.

1.1 Facility Description

The Crystal River Power Plant (Figure 1) is located in Citrus County, Florida, about 13.7 km north of the town of Crystal River. Two coal-fired units (CR1 and CR2) and one nuclear unit (CR3) utilize once through condenser cooling with water drawn through a common canal located south of the units and extending generally westward into the Gulf of Mexico.

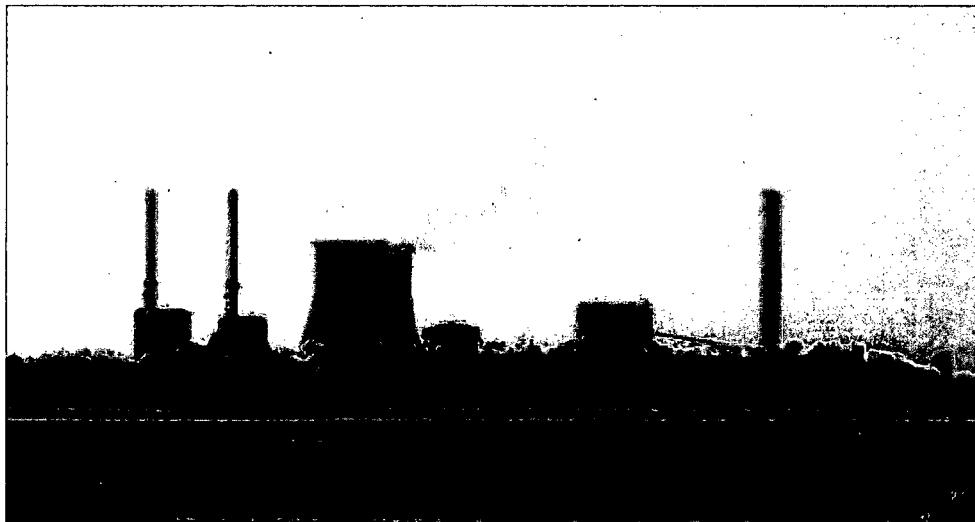

Figure 1. Crystal River Power Plant

1.1.1 Units 1 and 2 (Fossil Side)

The intakes for Units 1 and 2 are very similar in construction and are immediately adjacent on the northern bank of the canal. They are located at the head of a slight embayment with the Unit 2 screenwell to the west. A floating barrier and a coarse mesh wire fence extend across the embayment to keep floating or partially submerged debris away from the intakes. The combined intakes are about 43 meters across with external bar racks. The racks have 10 cm (5 in) spacing between bars and are continuous from the slab of the screenwell to above the surface of the water. Each intake has four bays with a circulating water pump and traveling water screens in each bay.

The traveling water screens are the same in Units 1 and 2. Screen trays are 3 meters wide and are equipped with standard 9.5 mm (3/8 inch), square opening, wire mesh. The screens are generally operated once every 8 hours to keep the screens clean but this depends on debris loading. When operating, the screens are cleaned by an internal spray was directed at the front surface of the screens. Debris and any impinged organisms are washed. From all screens of each unit into a common trough and directed to sumps located adjacent to the intakes (Stone & Webster Engineering Corporation, 1985).

1.1.2 Unit 3 (Nuclear Side)

The intake structure for Unit 3 is separate from the intakes of Units 1 and 2. A chain link fence extends across the entire width of the intake canal upstream of the intakes for Units 1 and 2. The fence both restricts access to the Unit 3 intake and collects floating debris.

This intake is about 36 meters across and has external bar racks. The racks have 10 cm (5 in) spacing between bars and are continuous from above the surface of the water to the slab. There are 4 pump bays and seven traveling screen bays separated from the pump bays by a common plenum. An eighth traveling screen bay provides service water.

The traveling water screens are similar to those in Units 1 and 2. The screen trays are 3 meters wide and have 9.5 mm mesh. They are generally operated once every 8 hours, and they are cleaned by a front wash system. The screenwash trough slopes to the west where material is collected in a sump. The trough receives combined wash water from all screens. (Stone & Webster Engineering Corporation, 1985).

Operating data for Crystal River Units 1, 2 and 3 are summarized in Table 1.

Table 1. Crystal River Units 1, 2, and 3 Operating Data

Unit	MWe	Cooling Water Flow (gpm)	Condenser ΔT	Startup
1	440	310,000	8.3°C	1966
2	524	328,000	9.4°C	1969
3	855	680,000	9.7°C	1977

2.0 METHODS

2.1 Impingement Sampling Protocol

2.1.1 Frequency and Duration

Impingement sampling was conducted on a bi-weekly basis at Crystal River Energy Complex Units 1, 2 and 3 from December 2006 to November 2006. The 24-hour monitoring period was broken into daytime and nighttime intervals. From December 2006 to February 2007 two day and two night samples were collected at each sample location (4 samples per event). However, it was physically challenging to collect samples from all locations prior to each event so the sampling was modified. Gantry cranes were used to lift the sample which on occasion exceeded 1500 lbs (mostly consisting of debris). From March 2007 to November 2007 one day and one night sample were collected at each sample location (2 samples per event). Using this revised methodology, no loss of information occurred. On occasion, impingement samples could not be collected due to plant operation (e.g. Unit outage) or unsafe working conditions. An impingement sampling schedule is presented in Table 2. Over the sampling period, there were 20-24 events (dependent on Unit), and a total of 164 samples collected. Forty-five (45) samples were collected from Unit 1, fifty-four (54) from Unit 2 and sixty-three (63) from Unit 3.

2.1.2 Location

Impingement samples were collected from the traveling screen wash debris collection sumps for Units 1, 2 and 3 (total of 3 locations). The design of the baskets had to be modified since the mesh size exceeded 3/8 inch which would have resulted in loss of sample especially some invertebrate species. The baskets for each sump were therefore modified with a 3/8 in lining which was similar in mesh size to the traveling screens. All Impinged organisms and debris off the screens were therefore collected. The screens were rotated and washed prior to the beginning of the 24-hour sampling event. During the 24-hour sampling event the screens were fixed for the sampling period unless operational circumstances (such as debris load) required otherwise. Once the sampling period time interval was complete, the screens were rotated with debris and aquatic organisms being washed into the sluiceway and hence into the sampling basket. The basket was removed from the sumps and the content of the basket was emptied on the deck. All fish and other organisms were separated from debris for processing.

2.1.3 Taxonomy

Organisms were identified to the lowest practicable taxonomic level, sorted (typically by species), and enumerated. The batch weight was obtained for each species. Up to 25 organisms per species were individually measured for length (total length, mm) and weight. For sample sizes greater than 25, 25 organisms were randomly selected for measurements. Organisms were counted, identified, measured and weighed, and surviving organisms that could be identified in the field were released. Immediate mortality was noted and recorded.

2.1.4 Fish and Invertebrate Condition

Condition of impinged organisms (live, recently dead, long dead) was assessed using a modification of the criteria developed by White (1986).

Live or Recently Dead: Live organism. Recently dead- Fish with the eyes clear, gills red, and body mucus layer fresh and intact. The flesh is firm. All fish that look like they may have been alive just prior to sampling are included in this category.

Long Dead: This category includes all dead fishes or invertebrates that have been dead for more than several hours. For fish, the eyes are cloudy, body mucus spotty or nonexistent, gills very light pink or white. The body is in rigor mortis and coloration had paled. For some fish the body texture is softer than in living or recently dead specimens. In some cases, individuals had been obviously dead for more than twenty-four hours, often days. The body is extremely soft and partially decomposed. The body colour is completely gone and often the specimen will be covered with decomposer fungi and bacteria.

2.1.5 Data Analysis

Data was collected during both the day and night so that an assessment of diel variation could be made. These time periods were approximately 12-h each although some adjustment was required over the course of the study. Day and night abundance estimates were summed to obtain 24-hour impingement estimates.

To calculate the base density of impinged organisms ($\rho_{i\text{-base}}$), the number impinged during each sampling period (day versus night) was divided by the corresponding volume through each screenhouse.¹ This is expressed as:

$$\rho_{i\text{-base}} = N_i / V_i$$

where:

$\rho_{i\text{-base}}$ = Base impingement density (#/m³)

N_i = Number of organisms impinged

V_i = Volume of impingement sample (m³).

Day and night abundance estimates were summed to obtain 24-hour impingement estimates. Monthly impingement estimates were calculated using the following formula:

$$\text{Estimated Number Impinged per Month} = \frac{\text{Monthly Number of Organisms}}{\text{Monthly Sample Volume}} \times \text{Total Monthly Flow}^1$$

2.2 Nearfield Trawling

Trawl catch data were collected to describe the spatial and temporal trends in abundance (general community characterization) nearfield, and to identify the fish and invertebrates that potentially may enter the intake channel and become impinged.

2.2.1 Frequency and Duration

Nearfield sampling was scheduled to be conducted monthly. However, inclement weather prevented sampling on certain dates. Each of three stations was sampled during the day and the night. A summary of trawl samples collected is presented in Table 3. Over the 10 sampling events, there was a total of 141 samples collected, 66 during the day and 75 during the night. Replicate trawls (typically 3 trawls per station) were run for approximately 5 minutes. This time period was considered adequate based on earlier trawl work conducted by FIT.

2.2.2 Location

Nearfield trawling was conducted at three stations (Figure 2) in the vicinity of the intake canal. Two of these locations were positioned south and north of the intake channel whereas the central location was near the intake entrance:

¹ Daily cooling water flow volumes in million gallons per day (MGD) are summarized in Appendix 1. Cooling water flow volumes corresponding to sample collection periods are summarized in Appendix 2.

- North: 28° 56.802' N, 082° 48.160' W
- Central: 28° 56.272' N, 082° 48.046' W
- South: 28° 55.909' N, 082° 48.077' W

Trawl sampling was conducted using a 4.3 x 1.2 meter trawl net constructed of 2.5 cm mesh in the body and 2.0 cm mesh at the cod end. The length of the net was 4.9 meters.

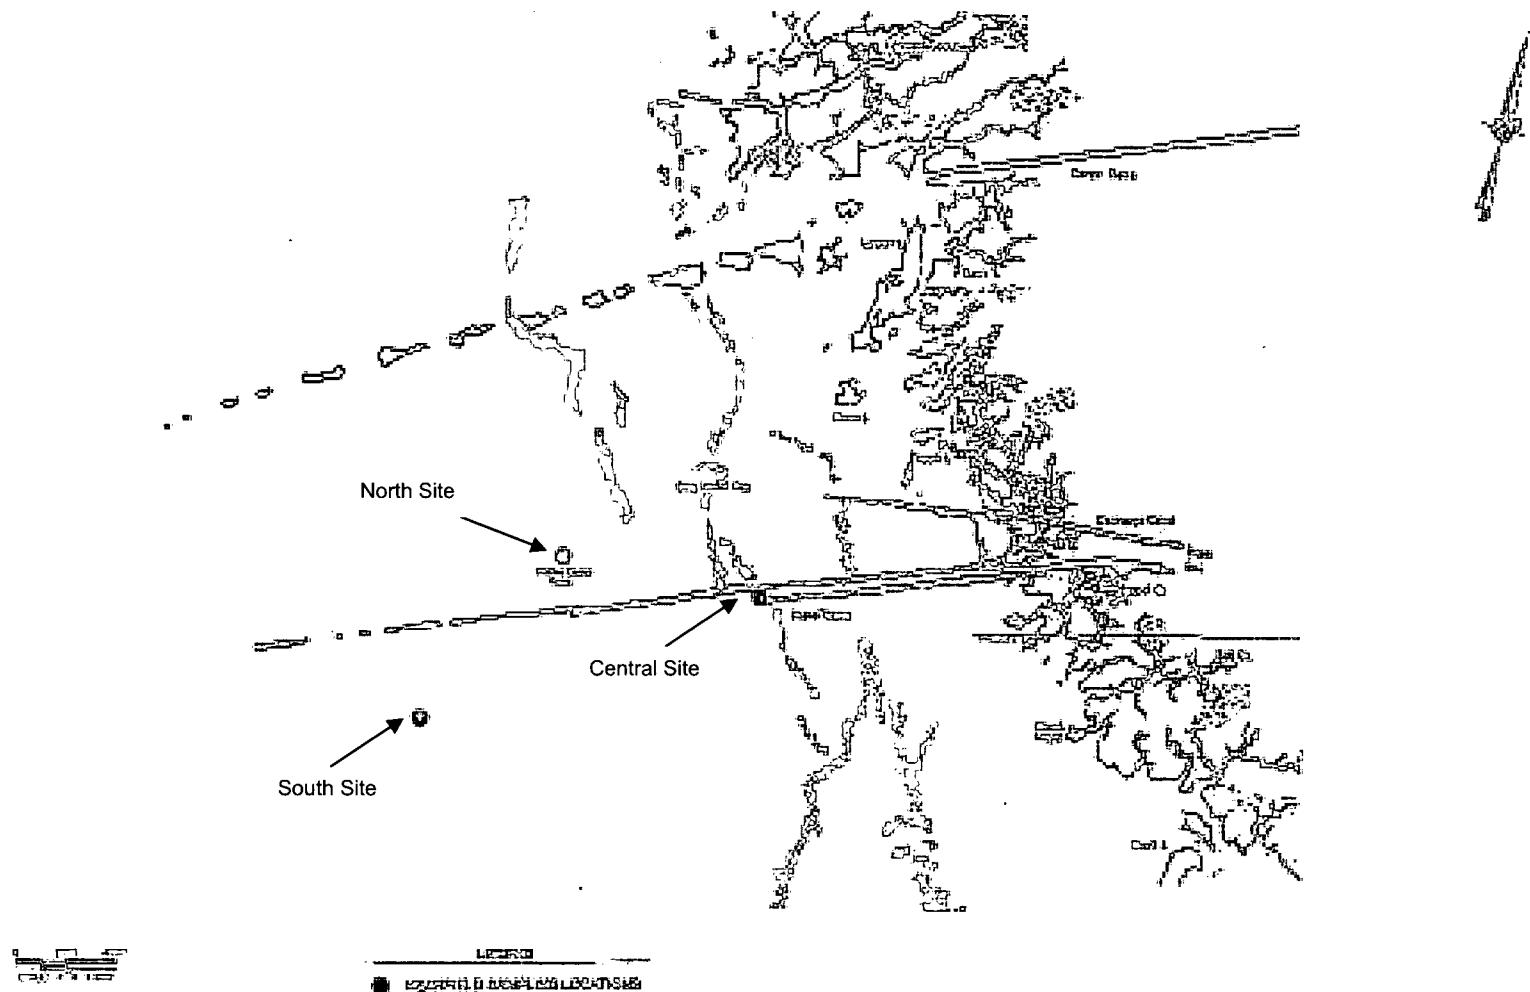

2.3 Water Quality and Meteorological Parameters

Water quality was assessed at the intake of Unit 3, and was considered representative for all Units because of their close proximity to each other. Intake water temperature, conductivity, dissolved oxygen (DO) and salinity was determined. Water quality measurements were obtained using a YSI Multiparameter meter. Measurements and weekly calibrations as per ISO 9001 requirements were carried out as described in the manufacturer's instruction manual.

3.0 RESULTS AND DISCUSSION

3.1 Fish Impingement

A total of 26 impingement events were carried out between December 7, 2006 and November 30, 2007.² A summary of fish collected is presented in Appendix 3 (Unit 1), Appendix 4 (Unit 2) and Appendix 5 (Unit 3).

The total extrapolated number and weight of fish estimated to be impinged at Crystal River Unit 1 is presented in Tables 4-5. Approximately 4% of all fish impinged at Crystal River were impinged at Unit 1. It is estimated that a total of 40,930 fish (1,102 kg) were impinged at Unit 1. The most abundant species were silver perch (17.9%), spotfin mojarra (16.9%) and polka-dot batfish (15.5%).

The total extrapolated number and weight of fish estimated to be impinged at Crystal River Unit 2 is presented in Tables 6-7. Approximately 9% of all fish impinged at Crystal River were impinged at Unit 2. It is estimated that a total of 83,556 fish (3,251 kg) were impinged at Unit 2. The most abundant species were polka-dot batfish (24.9%), pigfish (13.9%) and silver perch (11.5%).

The total extrapolated number and weight of fish estimated to be impinged at Crystal River Unit 3 is presented in Tables 8-9. Approximately 87% of all fish impinged at Crystal River were impinged at Unit 3. It is estimated that a total of 821,144 fish (14,896 kg) were impinged at Unit 3. The most abundant species were Atlantic thread herring (23.6%), bay anchovy (15.7%) and scaled sardine (12.7%).

The total extrapolated number and weight of fish estimated to be impinged at Crystal River (All Units Combined) is presented in Tables 10-11 and Figures 3-4. It is estimated that a total of 945,631 fish (19,249 kg) were impinged. The most abundant species were Atlantic thread herring (21.6%), bay anchovy (14.7%) and scaled sardine (11.4%).

Peak levels of impingement were observed in February-March, 2007. Approximately 69% of all fish impinged (649,503 out of a total of 945,631 fish) at Crystal River Power Plant were impinged during these two months (Figure 3). In terms of biomass, approximately 46% of the total annual biomass impinged during these months (Figure 4).

² Due to plant operation or unsafe working conditions, it was not possible to sample all units for each of the 26 impingement events. A summary of units sampled is provided in Table 2.

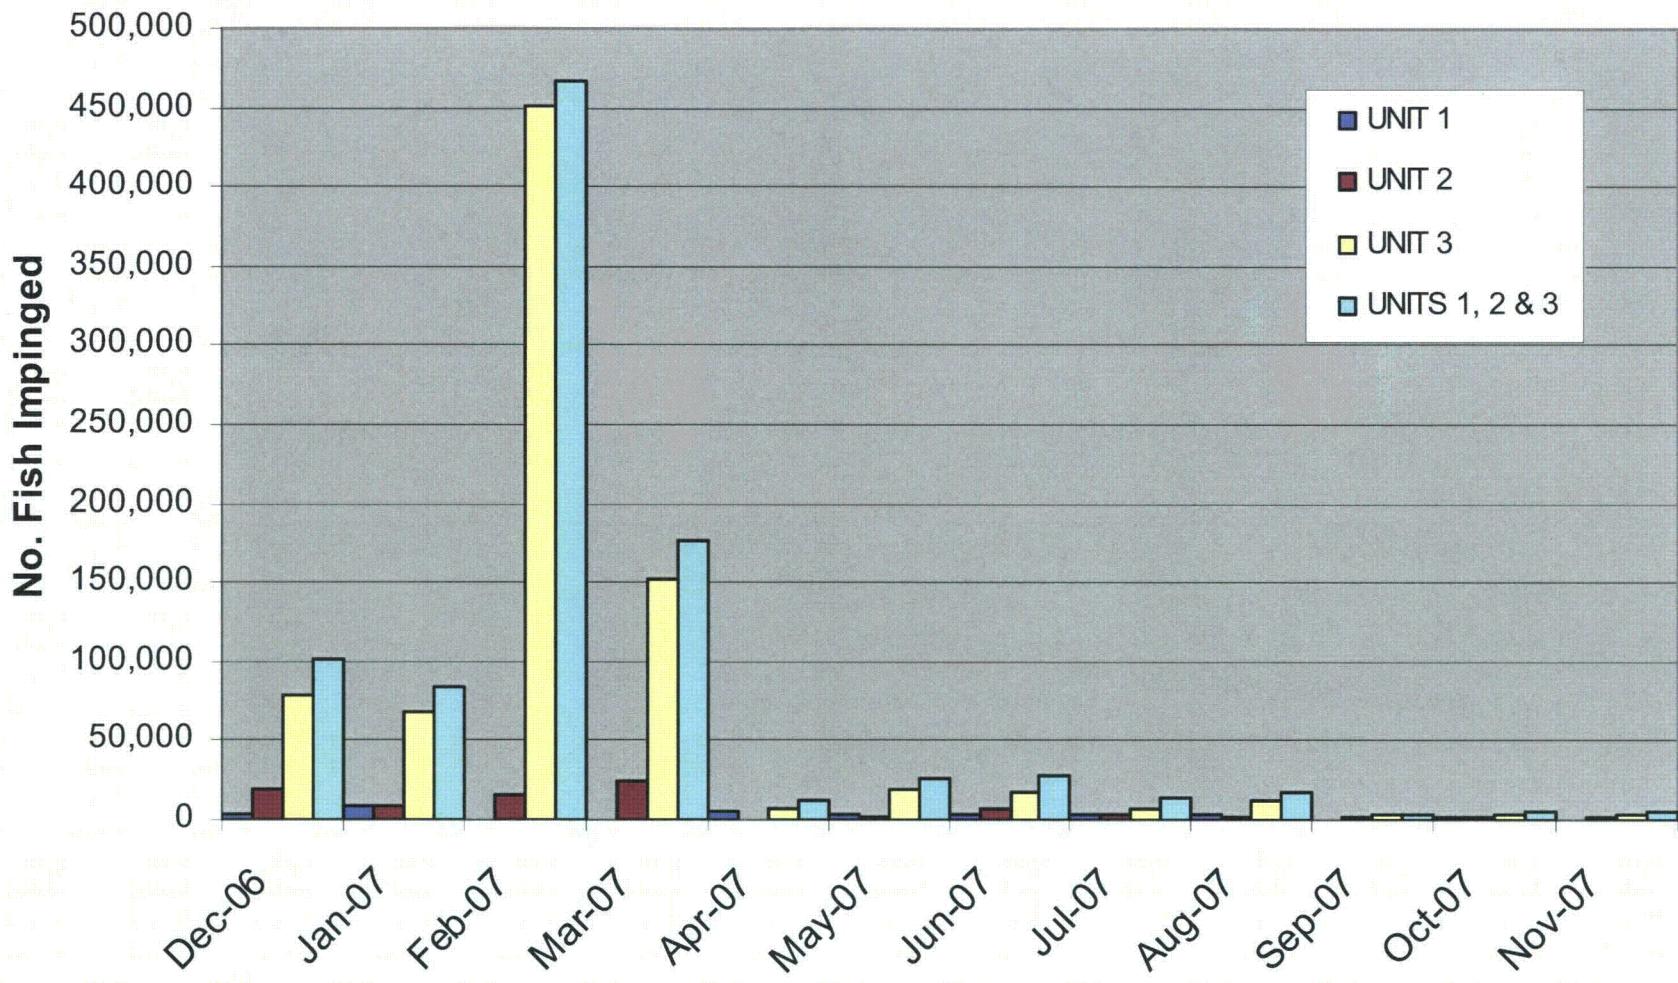

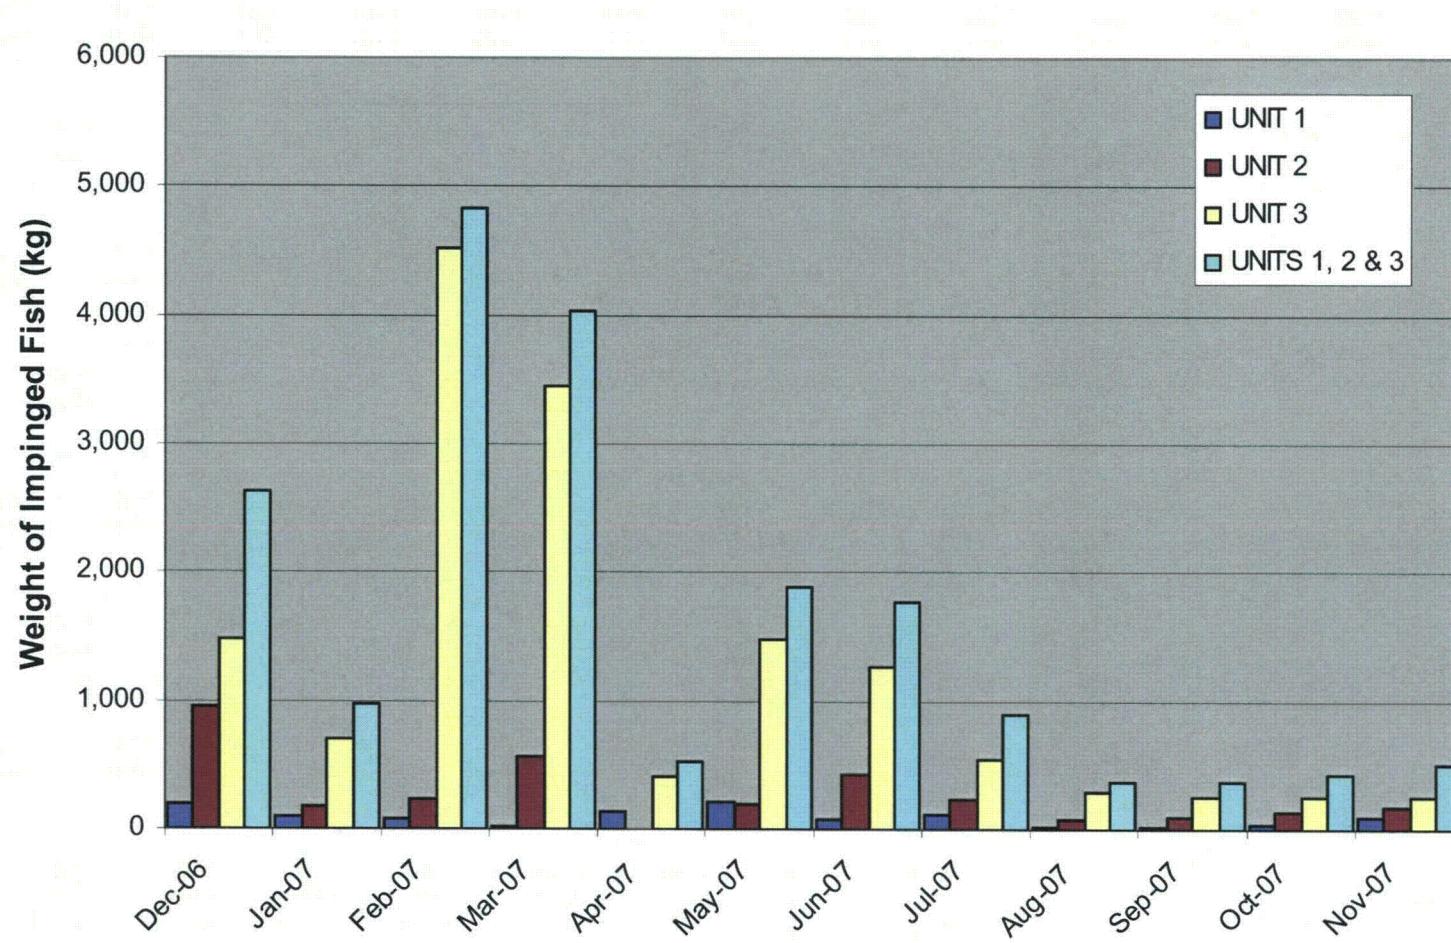

Figure 4
Estimated Weight of Fish Impinged each Month at Crystal River Power Plant – All Units (December 2006 - November 2007)

3.1.1 Condition of Impinged Fish

The initial condition of the fish was recorded as part of the impingement abundance study. The total extrapolated numbers of live, recently dead and long dead fish impinged at Crystal River on a daily and monthly basis are presented in Appendices 3-8. An annual summary of fish condition is presented in Table 12. The majority of fish (79.5% to 92.6%) were categorized as recently dead. The percentages of live fish varied between the three units. Approximately 7.3% of fish collected at Unit 3 were live while 17.3% to 19.9% of fish collected at Units 1 and 2, respectively, were live. This difference in survivability may be related to the increased flows observed at Unit 3 compared to Units 1 and 2 (Appendix 1). With an increase in flow, fish may be subjected more to abrasions.

Table 12. Condition of Fish Impinged at Crystal River Power Plant

Unit	Fish Condition		
	Live	Recently Dead	Long Dead
1	17.3%	82.5%	0.2%
2	19.9%	79.5%	0.6%
3	7.3%	92.6%	0.2%
Mean	14.8%	84.9%	0.3%

Differences were observed in survivability among species. For instance, approximately 78% of the polka-dot batfish collected at Crystal River were alive. Survival levels for Units 1, 2 and 3 were comparable at 79%, 70% and 80%, respectively. This is typically a hardier species compared to some of the pelagic types such as bay anchovy or blue-back herring. Extrapolated numbers of live versus dead polka-dot batfish impinged at Crystal River on a monthly basis are presented in Figure 5.

3.1.2 Length Distribution of Impinged Fish

The lengths of impinged fish were recorded as part of the impingement abundance study. Summaries of length distributions for commonly impinged species are presented in Appendix 9.

3.1.3 Diel Distribution of Impinged Fish

The diel distributions of fish impinged at Crystal River Power Plant Units 1, 2 and 3 are presented in Appendices 10-12 and Figures 6-8. Considerable variability in impingement between day and night occurred among the Units. For example, at Unit 1, a peak density of 0.62 fish per 1,000 m³ was observed during the day sampling event of January 5, 2007. At Unit 2, a peak density of 2.5 fish per 1,000 m³ was observed during the night sampling event of March 2, 2007. At Unit 3, a peak density of 15.7 fish per 1,000 m³ was observed during the night sampling event of February 2, 2007.

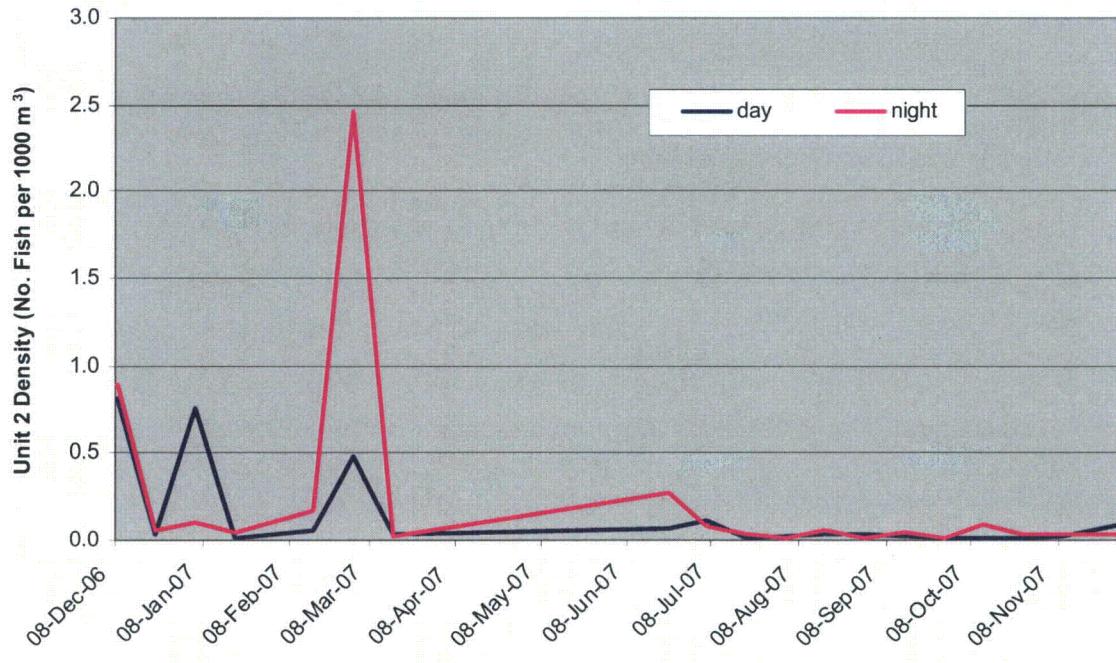

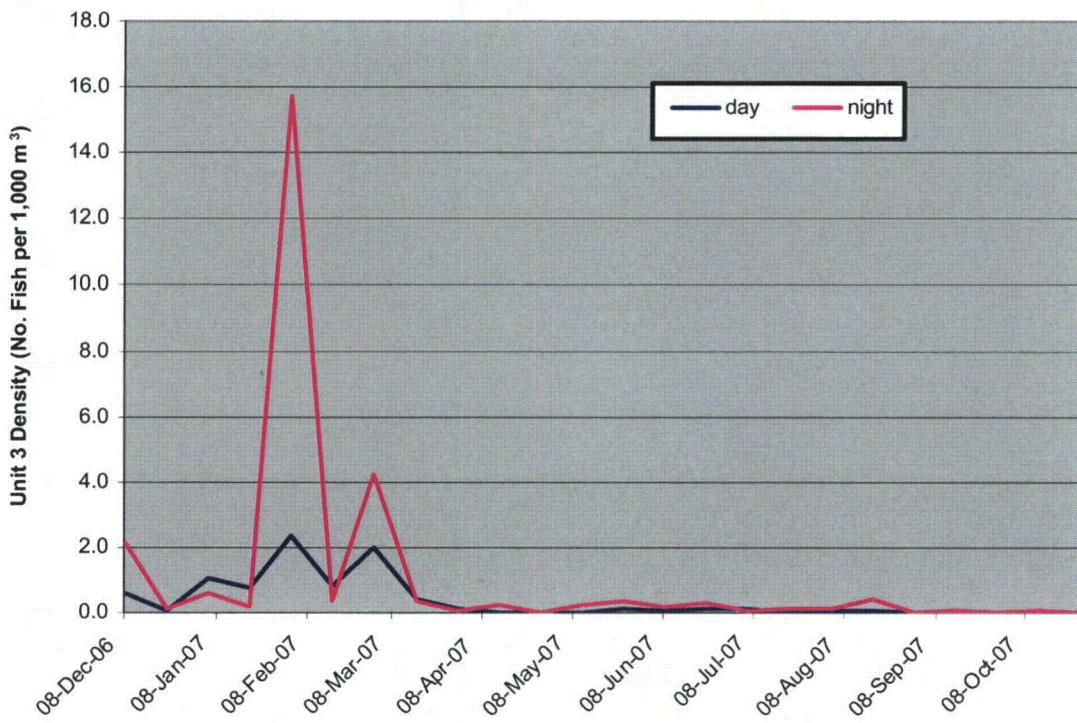

Figure 8. Diel Distribution of Fish Impinged at Crystal River Power Plant – Unit 3

3.2 Invertebrate Impingement

A total of 26 impingement events were carried out between December 7, 2006 and November 30, 2007. A summary of invertebrates collected is presented in Appendix 13 (Unit 1), Appendix 14 (Unit 2) and Appendix 15 (Unit 3).

The total extrapolated number and weight of invertebrates estimated to be impinged at Crystal River Unit 1 is presented in Tables 13-14. Approximately 10% of all invertebrates impinged at Crystal River were impinged at Unit 1. It is estimated that a total of 35,165 invertebrates (529 kg) were impinged at Unit 1. The most abundant species were pink shrimp (44.9%), Atlantic brief squid (11.9%) and iridescent swimming crab (11.2%).

The total extrapolated number and weight of invertebrates estimated to be impinged at Crystal River Unit 2 is presented in Tables 15-16. Approximately 15% of all invertebrates impinged at Crystal River were impinged at Unit 2. It is estimated that a total of 50,178 invertebrates (663 kg) were impinged at Unit 2. The most abundant species were pink shrimp (46.3%), iridescent swimming crab (14.2%) and Atlantic brief squid (11.3%).

The total extrapolated number and weight of invertebrates estimated to be impinged at Crystal River Unit 3 is presented in Tables 17-18. Approximately 75% of all invertebrates impinged at Crystal River were impinged at Unit 3. It is estimated that a total of 256,437 invertebrates (2,633 kg) were impinged at Unit 3. The most abundant species were pink shrimp (44.6%), Atlantic brief squid (17.3%) and false arrow crab (10.8%).

The total extrapolated number and weight of invertebrates estimated to be impinged at Crystal River (All Units Combined) is presented in Tables 19-20 and Figures 9-10. It is estimated that a total of 341,780 invertebrates (3,826 kg) were impinged. The most abundant species were pink shrimp (43.8%), Atlantic brief squid (15.9%) and false arrow crab (10.5%).

Figure 9
Estimated Number of Invertebrates Impinged each Month at Crystal River Power Plant – All Units
(December 2006 - November 2007)

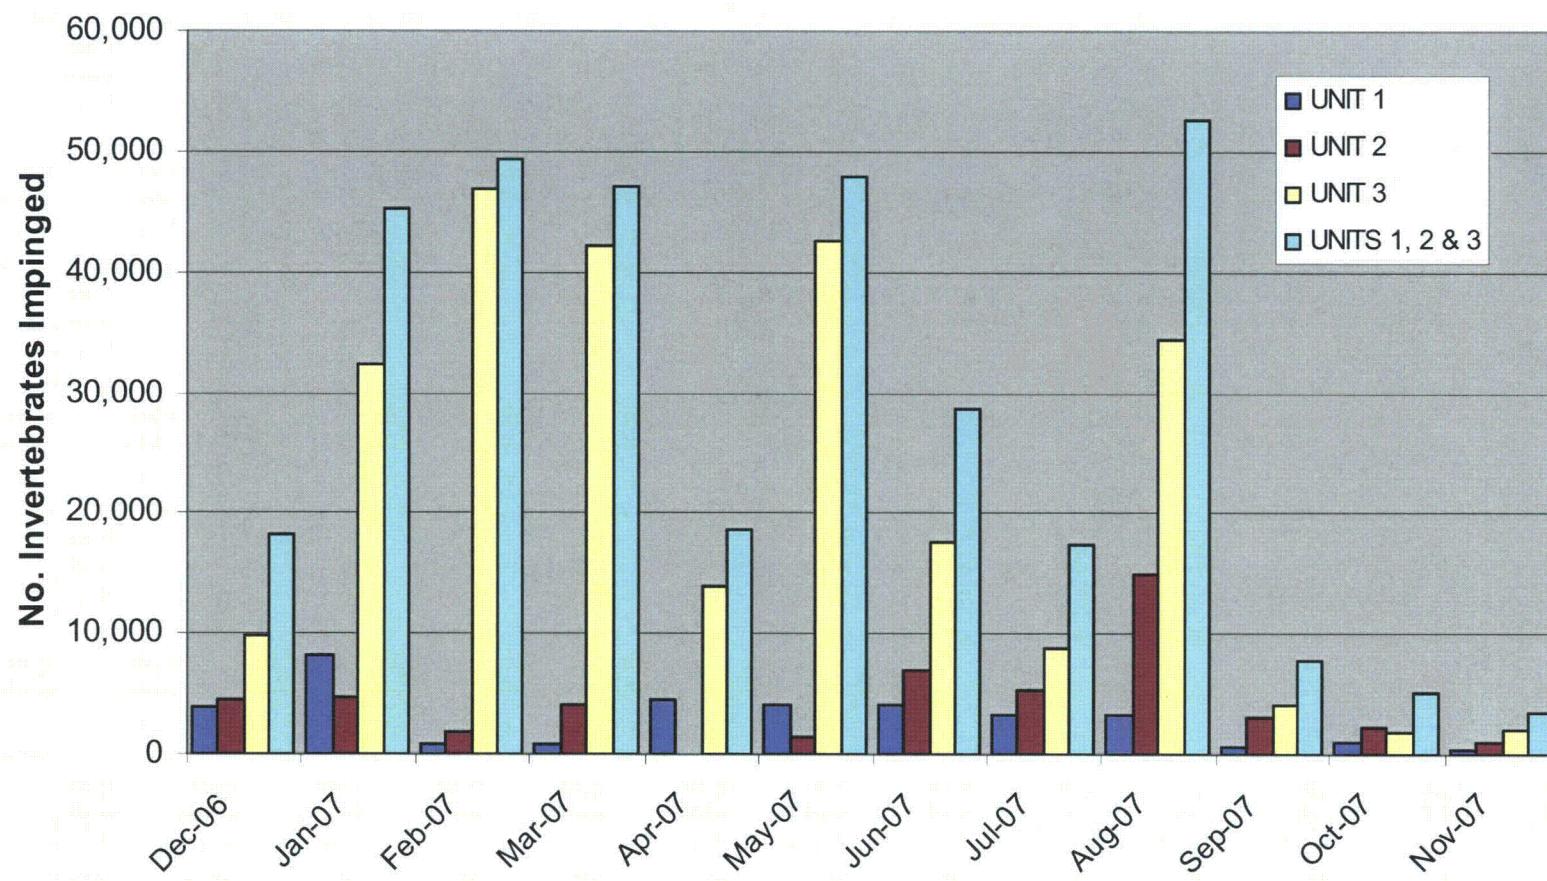

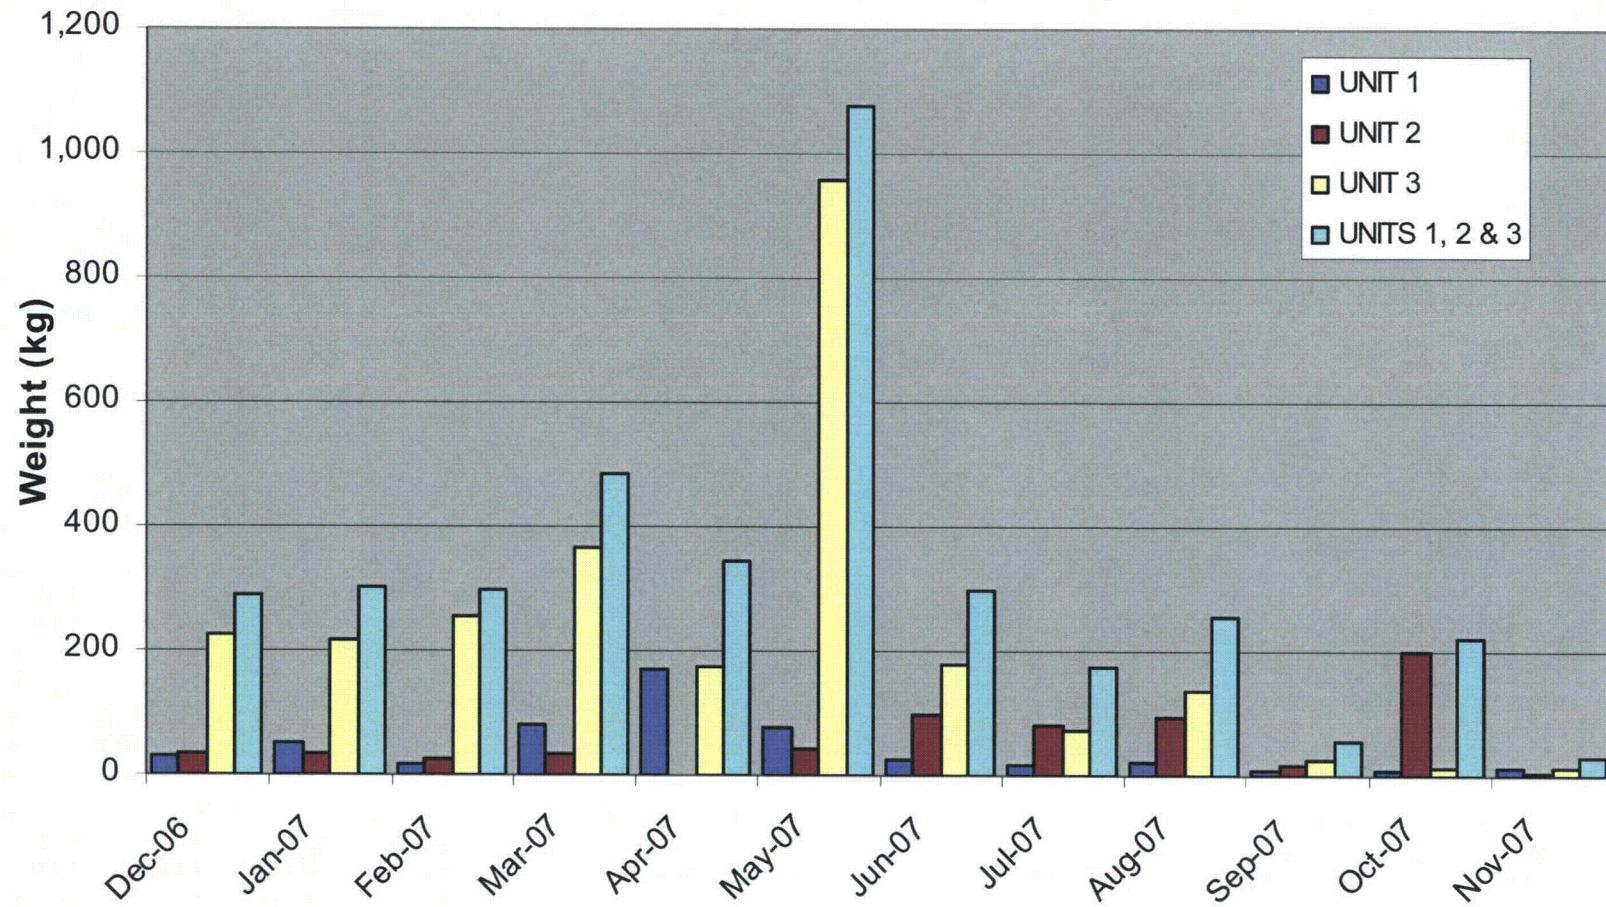

Figure 10
Estimated Weight of Invertebrates Impinged each Month at Crystal River Power Plant – All Units
(December 2006 - November 2007)

3.2.1 Condition of Impinged Invertebrates

The initial condition of the invertebrates was recorded as part of the impingement abundance study. The total extrapolated numbers of live, recently dead and long dead invertebrates impinged at Crystal River on a daily and monthly basis are presented in Appendices 13-18. An annual summary of invertebrate condition is presented in Table 21. The majority of invertebrates (57.4% to 66.1%) were categorized as alive. The percentage of live invertebrates was comparable for the three units. This is different from that observed from fish (Table 12) which indicates the hardiness of most invertebrate species. Very few long dead invertebrates were recorded (Table 21).

Table 21
Condition of Invertebrates Impinged at Crystal River Power Plant

Unit	Invertebrate Condition		
	Live	Recently Dead	Long Dead
1	65.9%	34.0%	0.05%
2	66.1%	33.9%	0.00%
3	57.4%	42.5%	0.02%
Mean	63.1%	36.8%	0.02%

3.2.2 Length Distribution of Impinged Invertebrates

The lengths of impinged invertebrates were recorded as part of the impingement abundance study. Summaries of length distributions for commonly impinged species are presented in Appendix 19.

3.2.3 Diel Distribution of Impinged Invertebrates

The diel distributions of invertebrates impinged at Crystal River Power Plant Units 1, 2 and 3 are presented in Appendices 20-22 and Figures 11-13. Similar to fish impingement, considerable variability in diel distribution occurred for each Unit. At Unit 1, a peak density of 0.81 invertebrates per 1,000 m³ was observed during the day sampling event of January 5, 2007. At Unit 2, a peak density of 0.76 invertebrates per 1,000 m³ was observed during the day sampling event of August 17, 2007. At Unit 3, a peak density of 1.6 invertebrates per 1,000 m³ was observed during the night sampling event of February 2, 2007. At Unit 3, there appeared to be higher numbers impinged at night compared to the day (Figure 13), but was less obvious at Units 2 and 1. This preference for higher collections during the night at Unit 3 is likely related to the higher flows.

Figure 11. Diel Distribution of Invertebrates Impinged at Crystal River Power Plant – Unit 1

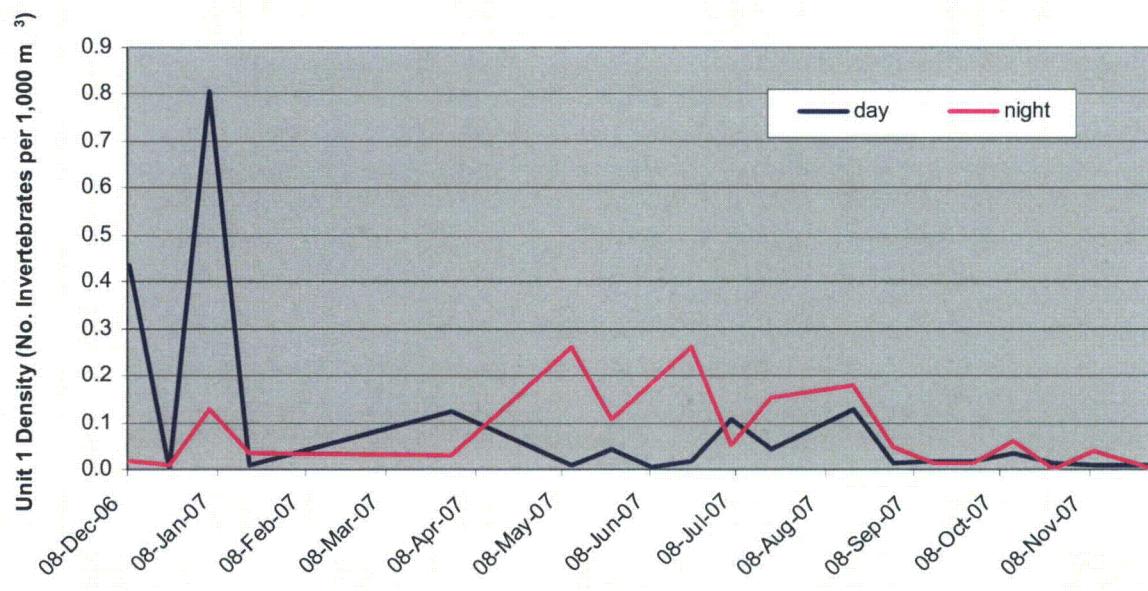

Figure 12. Diel Distribution of Invertebrates Impinged at Crystal River Power Plant – Unit 2

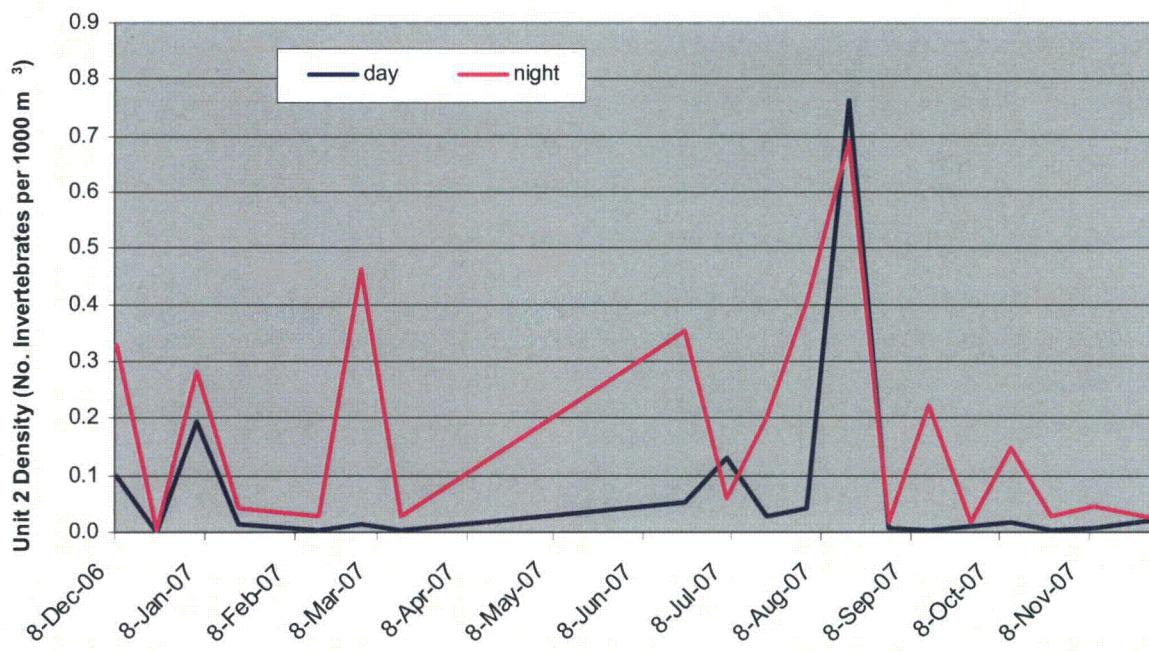

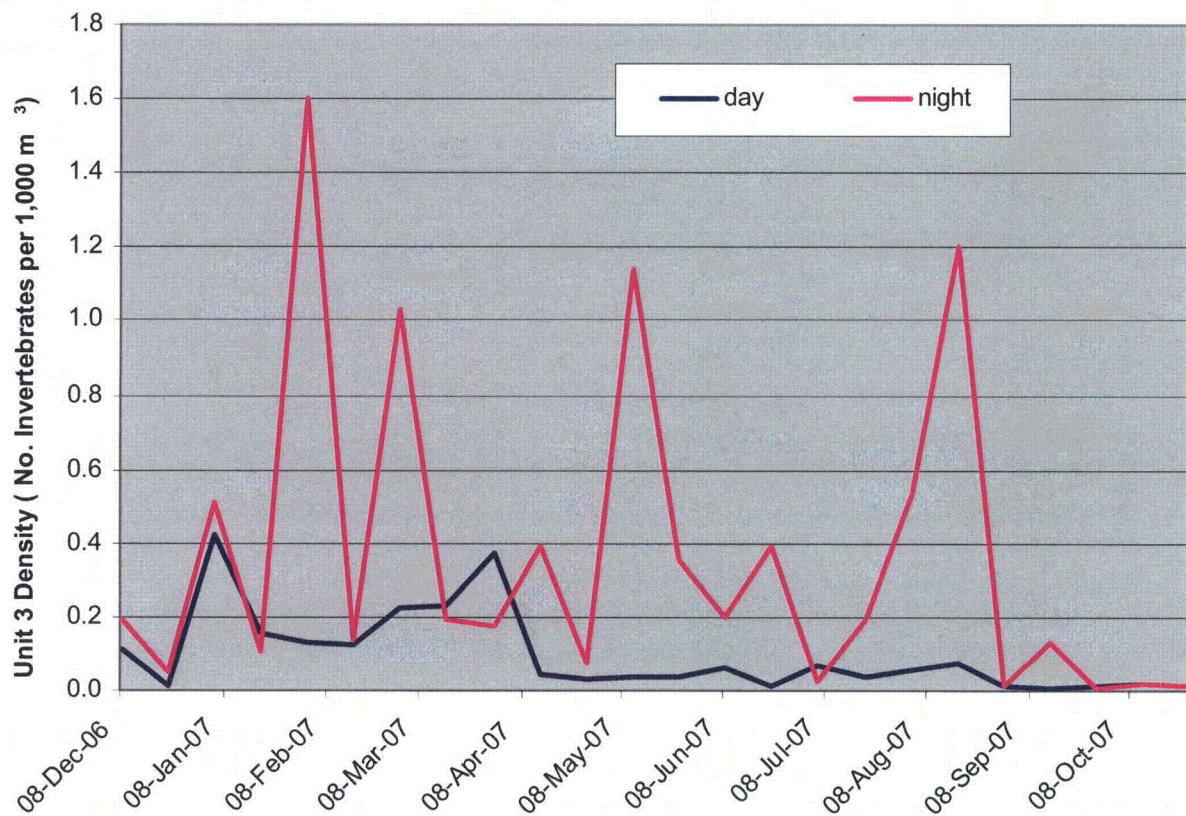

Figure 13. Diel Distribution of Invertebrates Impinged at Crystal River Power Plant – Unit 3

3.3 Nearfield Trawl Studies

Trawl catch data were collected to describe the spatial and temporal trends in abundance (general community characterization) and to identify the fish and invertebrates that may enter the plant and become impinged. Summaries of fish and invertebrates collected for each sampling event and time-period (day versus night) are summarized in Appendices 23-28.

3.3.1 North Trawl

The North trawls captured a total of 37 species (27.5 kg) of fish and 14 species (1.9 kg) of invertebrates. The most abundant fish species included pinfish (29.7%), pigfish (27.3%) and spotfin mojarra (9.3%). The most abundant invertebrate species included iridescent swimming crab (60.0%), pink shrimp (16.0%) and mantis shrimp (8.7%). Summaries of fish and invertebrates collected during the North trawl surveys are summarized in Tables 22-25. In comparison to species actually impinged, there was a reduction in the number of pelagic species collected by trawl. This is likely related to the sampling technique which is less efficient in sampling pelagic species than benthic ones.

The diel distributions of fish and invertebrates collected during the North trawl surveys are presented in Appendix 29 and Figures 14-15. Peak densities of 13 invertebrates per 1,000 m³ and 25 fish per 1,000 m³ were observed during the night sampling event of January 19, 2007. Overall, the preference for higher catch at night is very consistent over the sampling period.

3.3.2 South Trawl

The South trawls captured a total of 43 species (29 kg) of fish and 14 species (0.9 kg) of invertebrates. The most abundant fish species included pinfish (37.1%), pigfish (17.4%) and silver perch (15.4%). The most abundant invertebrate species included pink shrimp (24.6%), yellowline arrow crab (24.6%) and iridescent swimming crab (21.5%). Summaries of fish and invertebrates collected during the South trawl surveys are summarized in Tables 26-29.

The diel distributions of fish and invertebrates collected during the South trawl surveys are presented in Appendix 30 and Figures 16-17. Peak densities of 5.4 invertebrates per 1,000 m³ and 22.1 fish per 1,000 m³ were observed during the night sampling event of January 19, 2007. An elevated fish density (21 fish per 1,000 m³) was also during the day sampling event of October 26, 2007. Overall, the preference for higher catch at night is very consistent over the sampling period.

3.3.2 Central Trawl (Intake Location)

The Central Trawl location is directly in front of the intake and somewhat more comparable to impingement results than the other two trawl locations. The Central trawls captured a total of 30 species (20.3 kg) of fish and 16 species (1.7 kg) of invertebrates. The most abundant fish species included pinfish (35.1%), pigfish (16.0%) and silver perch (15.3%). The most abundant invertebrate species included iridescent swimming crab (38.0%), false arrow crab (21.2%) and pink shrimp (15.3%). Summaries of fish and invertebrates collected during the Central trawl surveys are summarized in Tables 30-33.

The diel distributions of fish and invertebrates collected during the Central trawl surveys are presented in Appendix 31 and Figures 18-19. A peak density of 5.4 invertebrates per 1,000 m³ was observed during the night sampling event of December 22, 2006. A peak density of 10.7 fish per 1,000 m³ was observed during the day sampling event of November 9, 2007. Overall, the preference for higher catch at night is very consistent over the sampling period.

3.3.4 Comparison of Trawl Locations

A total of 141 trawls were conducted at central, south and north locations. A summary of specimens collected over the course of the study is provided in Table 34. A total of 581 specimens (137 invertebrates, 444 fish) were collected at the central location in the vicinity of the intake channel with a mean density of 4.1 specimens per 1,000 m³. A total of 961 specimens (130 invertebrates, 831 fish) were collected at the south trawl location, with a mean density of 6.8 specimens per 1,000 m³. A total of 1,137 specimens (275 invertebrates, 862 fish) were collected at the north trawl location, with a mean density of 8.0 specimens per 1,000 m³.

The mean densities of invertebrates collected at the central and south trawl locations were comparable (0.9 – 1.0 invertebrates per 1,000 m³). The mean density of invertebrates collected at the north location (1.9 invertebrates per 1,000 m³) was approximately twice that observed at the central and south trawl locations.

The mean fish density at the central trawl location (3.1 fish per 1,000 m³) was approximately half of that observed for the south and north (5.9 - 6.1 per 1,000 m³) trawl locations. The reduced fish density observed for the central trawl location may be due to avoidance of the intake channel partly because of the configuration, or alternatively may be related to barge traffic.

Table 34. Comparison of Trawl Collections at North, South and Central Locations

Location	No. Specimens Collected			Mean Density (No. per 1,000 m ³)		
	Invertebrates	Fish	Total	Invertebrates	Fish	Total
Central	137	444	581	1.0	3.1	4.1
South	130	831	961	0.9	5.9	6.8
North	275	862	1137	1.9	6.1	8.0

The number of fish species collected at the south, north and central trawl locations were 42, 36 and 30, respectively. Fish species collected at the south trawl location, but not observed at north or central trawl locations, or as part of the impingement collections, included:

- Bigeye scad
- Emerald parrotfish
- Hogfish
- Pygmy filefish
- Summer flounder
- Whitebone porgy
- Yellowfin menhaden

The number of invertebrate species collected at the south, north and central locations were comparable (13-14).

3.4 Historical Levels of Impingement

The most recent impingement study at Crystal River Power Plant was conducted over 20 years ago (Stone & Webster Engineering Corporation, 1985). Impingement sampling was conducted for one, randomly chosen, 24-hr period once a week for 12 months at Units 1, 2 and 3. During each 24-hr sampling period, samples were taken at each unit at 6-hr intervals for a total of four samples per unit.

Over the duration of the 1985 impingement study, a total of 61,195 fish were collected. The most commonly impinged fish were bay anchovy (18.3%), polka-dot batfish (14.6%) and bighead searobin (13.0%). A total of 171,907 invertebrates were also collected over the duration of the impingement study. The most commonly impinged invertebrates were pink shrimp (44.7%), blue crab (24.2%) and false arrow crab (9.6%).

It was estimated that a total of 2,628,484 fish and invertebrates (33,953 kg) were impinged at Crystal River in 1985. Total impingement by unit for Selected Important Organisms (SIO) is presented in Table 35. The number of SIO invertebrates impinged was much greater than the number of fish. SIO invertebrates represented 83.2% of the total number of SIO impinged annually and 42.3% of the total number of organisms impinged.

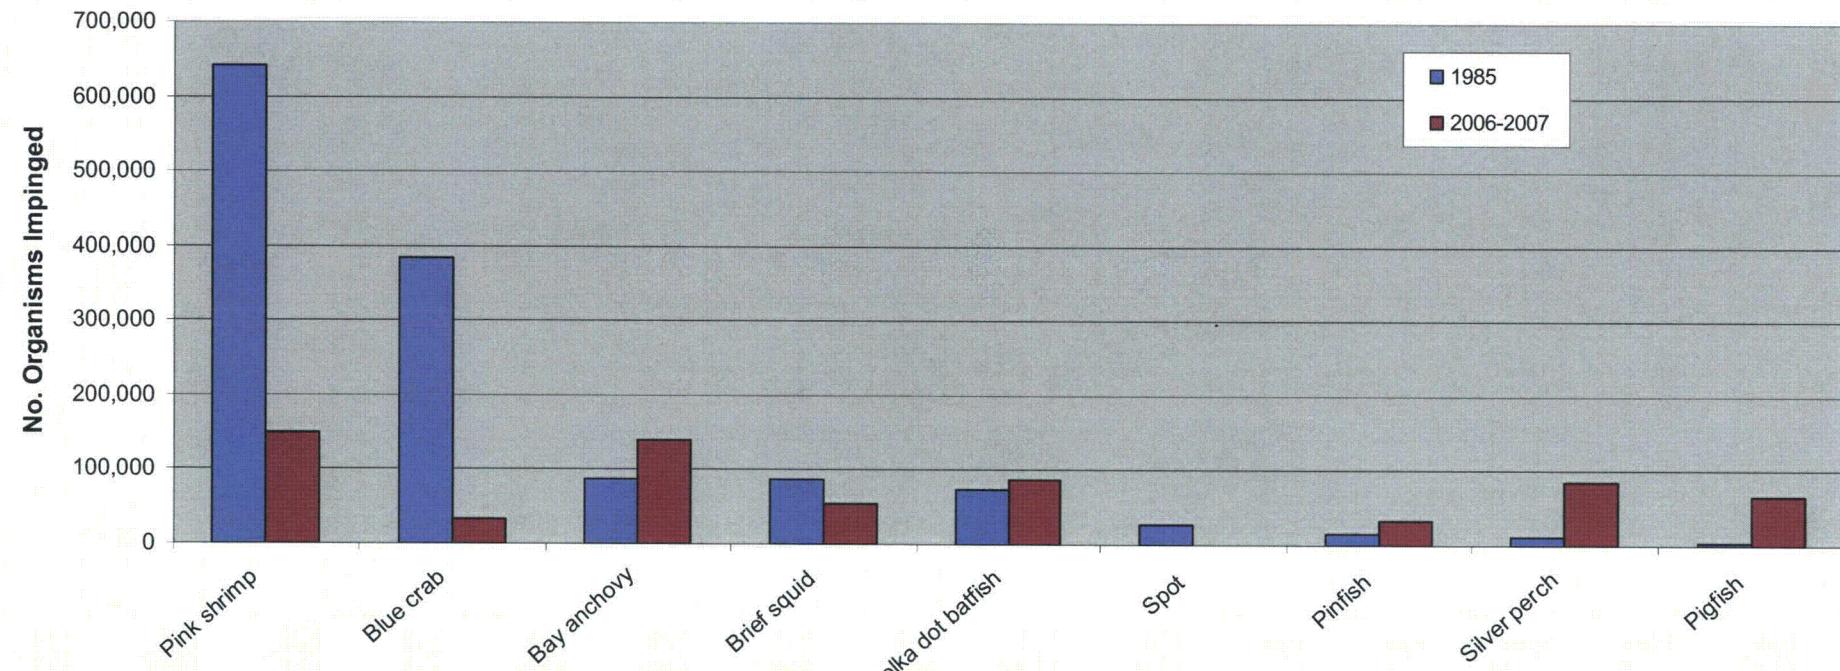

Table 35. Annual Impingement by Unit for Selected Important Organisms (SIO) – 1985*

Species	Unit 1		Unit 2		Unit 3		All Units	
	Number	Weight (kg)	Number	Weight (kg)	Number	Weight (kg)	Number	Weight (kg)

Red drum	0	0.0	0	0.0	8	0.0	8	0.0
Total	278,854	2,256.3	747,830	10,191.9	1,601,800	21,505.6	2,628,484	33,953.8

* Stone & Webster Engineering Corporation (1985).

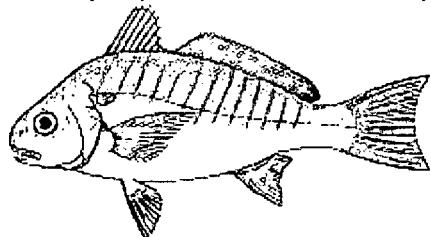

The number of fish and invertebrates impinged at Crystal River in 2006-2007 (1,287,720) was approximately one-half of that estimated to be impinged in 1985. A comparison of selected important organisms impinged in 1985 versus 2006-2007 is presented in Figure 20. The number of blue crab impinged at Crystal River in 2006-2007 (32,567) was an order of magnitude lower than that observed in 1985 (383,560). Similarly, the number of pink shrimp impinged at Crystal River in 2006-2007 (149,710) was substantially lower than that observed in 1985 (640,887).

Figure 20. Comparison of Organisms Impinged at Crystal River Power Plant. 1985 versus 2006-2007

Spot (Figure 21) represented the third most abundant fish species impinged at Crystal River Power Plant in 1985 (28,094 fish, 62.7 kg). In 2005, statewide landings of spot in Florida were 65% lower than the average landings in the previous five years (2000-2004) and were 96% lower than the 1982-2005 historical average landings (Figure 21) (FWRI, 2006). While spot was collected during central (2 fish), north (7 fish) and south (2 fish) trawls, this species was not impinged during the 2006-2007 sampling program.

Figure 21. Spot (*Leiostomus xanthurus*)

3.5 Water Quality and Meteorological Parameters

Water quality was assessed at the intake of Crystal River Power Plant Unit 3. Daily water quality is summarized in Appendix 32.

3.6 Species List

Over the course of this study 120 fish and invertebrate species were impinged at Crystal River Power Plant (Tables 36-37). By comparison, the number of fish and invertebrate species collected during Central, North and South trawl surveys were 45, 51, and 57 respectively. ***None of the species collected over the duration of this study are listed as endangered, threatened or of special concern.³***

Eighteen species collected as part of the trawl surveys, but not collected as part of the impingement collections included:

1. Bank cusk-eel
2. Bigeye scad
3. Emerald parrotfish
4. Flatclaw hermit crab
5. Fringed filefish
6. Grass porgy
7. Hermit crab
8. Hogfish
9. Keyhole sand dollar
10. Long-wristed hermit crab
11. Pygmy file fish
12. Sand snapping shrimp
13. Spot
14. Spottail tonguefish
15. Summer flounder

3.7 Calculation Baseline

The calculation baseline is defined as an estimate of impingement mortality that would occur at a facility assuming:

- a once-through cooling system
- a CWIS opening located at the shoreline near the surface of the source water body, with the face of a standard 3/8-inch mesh traveling screen oriented parallel to the shoreline and
- baseline practices, procedures, and structural configurations that would be maintained in the absence of any structural or operational controls, including flow or velocity reductions, implemented in whole or in part for purposes of reducing impingement mortality and entrainment.

In concept, the calculation baseline is an attempt to give credit to facilities that may already have installed fish protection technologies or have adopted procedures or intake modifications such as an extended intake canal. The impingement reduction resulting from the existing CWIS can be evaluated by comparing impingement levels at Crystal River Units 1, 2 and 3 versus trawl catch data at the entrance to the intake canal. The central trawl location is likely the most appropriate for comparison since it is located directly in front of the intake channel. This location also provides the most conservative estimate since the mean fish density at the central trawl location (3.1 fish per 1,000 m³) was approximately half of that observed for the south and north (5.9 - 6.1 per 1,000 m³) trawl locations. As noted earlier (Section 3.3.4), the reduced fish density observed for the central trawl location may be due to avoidance of the intake channel partly because of the configuration, or alternatively may be related to barge traffic.

Summaries of fish and invertebrate densities at the entrance to the intake canal compared to the immediate vicinity of Crystal River Units 1, 2 and 3 are presented in Tables 38-39. On average, fish densities at the entrance to the intake canal were, 7 to 62-times greater than that observed in the immediate vicinity of Units 1, 2 and 3. Similarly, invertebrate densities at the entrance to the intake canal were, on average, 2 to 19-times greater than that observed in the immediate vicinity of Units 1, 2 and 3. Overall, the extended intake canal appears to offer an impingement reduction of approximately 95% (Table 40).

Appendix 33

**General Biology of the Ten Most Abundant Fishes Impinged at Crystal River Power Plant
(December 2006 – November 2007)**

General Biology of the Ten Most Abundant Fishes Impinged at Crystal River Power Plant (November 2006 – December 2007)

R.G. Turingan, Ph.D., Florida Institute of Technology

This report is largely drawn from information in www.fishbase.org, Nelson, J.S. 2006. Fishes of the World. Fourth Edition. Wiley, NY. and the citations referred to in the text and listed at the end of each species account.

***Opisthonema oglinum*, Atlantic threadfin herring
(Order Clupeiformes, Family Clupeidae)**

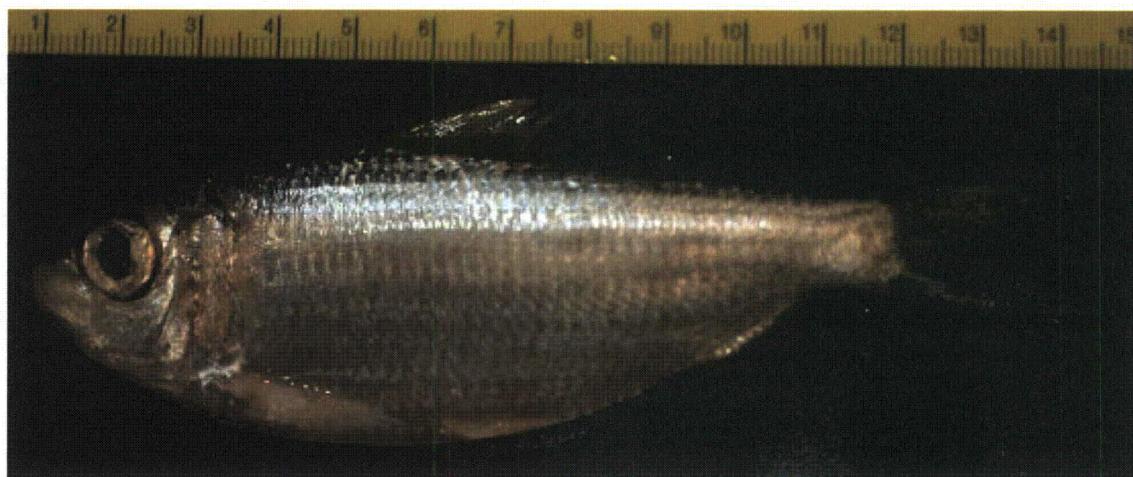

Figure 1. A photograph of the Atlantic threadfin herring, *Opisthonema oglinum*, caught in the collecting screens of the Progress Energy Nuclear and Coal Power Plant in Crystal River, Florida.

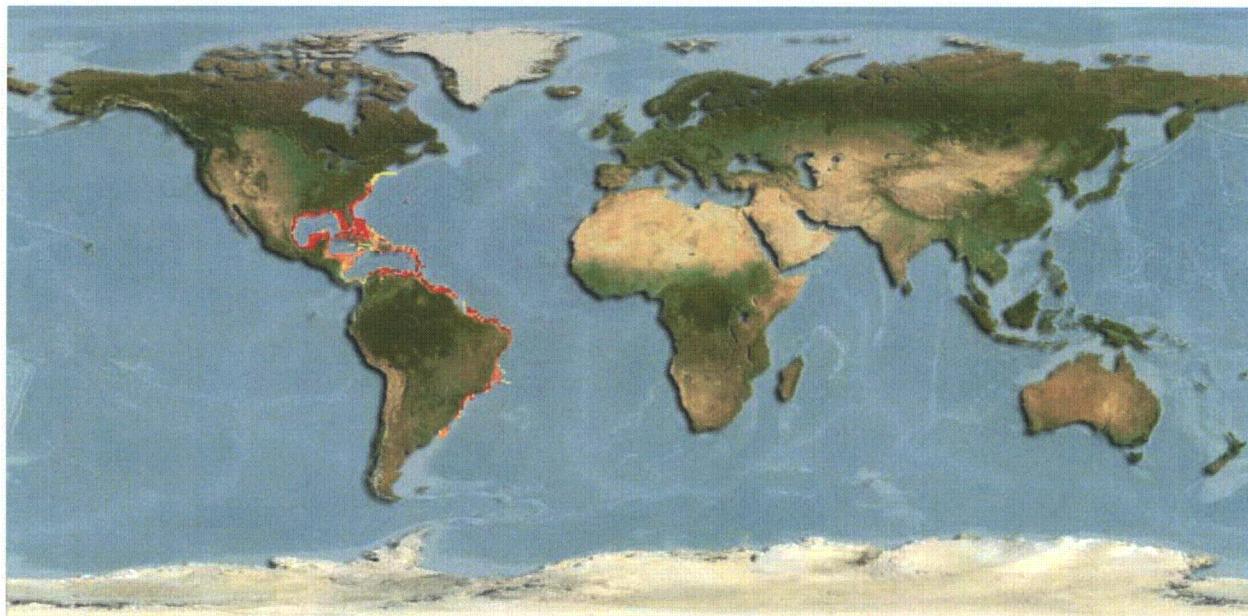

Figure 2. Range of distribution of *Opisthonema oglinum*, Atlantic threadfin herring (photo from Fishbase.org).

The Atlantic threadfin herring, *Opisthonema oglinum* (Figure 1), is distinguished by its filamentous last dorsal fin ray (1). It has a silvery body, with a bluish or greenish back and 6-7 lengthwise dark streaks on side. The species has a dark spot above the opercle and a larger dark spot behind this bone, followed by a row of dark spots caudally (2).

The Atlantic threadfin herring inhabits marine coastal waters, often associated with reef structure in the Gulf of Maine (USA), Bermuda, Gulf of Mexico, Caribbean and West Indies and Brazil (Figure 2). It is considered a tropical species with its range of distribution being 41°N - 37°S, 98°W - 33°W. A freshwater population inhabits the St. Johns River, Florida (3). Schools of this species are normally found in harbors and shallow coastal areas (1), filter- feeding on plankton (copepods), but occasionally feeding on small fishes, crabs and shrimps. The Western North Atlantic (USA) population is reported to live up to eight years (Tmax = 8 yrs) with a maximum length, L_{max} = 30 cm (4). It spawns in May – June.

The Atlantic threadfin herring is commonly used as bait, but is also marketed fresh, frozen and salted. It is a common raw material for the fishmeal industry (5).

***Anchoa mitchilli*, Bay anchovy
(Order Clupeiformes, Family Engraulidae)**

Figure 3. A photograph of the bay anchovy, *Anchoa mitchilli* (photo from Fishbase.org).

Figure 4. Range of distribution of the bay anchovy, *Anchoa mitchilli* (photo from Fishbase.org).

The bay anchovy, *Anchoa mitchilli* (Figure 3), varies in size among populations within its range of distribution, with more slender bodied individuals in northern populations. It is distinguishable by having a fairly blunt snout, about half its eye diameter. It has a long and pointed upper jaw, reaching posteriorly past the border of the pre-operculum.

The bay anchovy occurs along the coasts of the Western Atlantic (Figure 4), from Maine to Florida, and throughout the entire Gulf of Mexico. It is a subtropical species widely distributed along 42°N - 16°N, 99°W - 72°W, often found associated with reef structure and is considered amphidromous (6). It is also commonly found in shallow tidal areas with muddy bottoms and brackish waters, tolerating a wide range of salinities. It is found only in spring and summer in the tidal portion of the Ochlockonee River, Florida. It feeds mostly on *Mysis* and copepods, but occasionally forages on small fishes, gastropods and isopods. It spawns off the US coasts in April to September. The bay anchovy population in US waters has an estimated maximum size (L_{max}) of 11 cm and lives up to T_{max} = 3 yrs (7).

It has a minor commercial importance as bait and used to make anchovy paste (7).

***Orthopristis chrysoptera*, pigfish
(Order Perciformes, Family Haemulidae)**

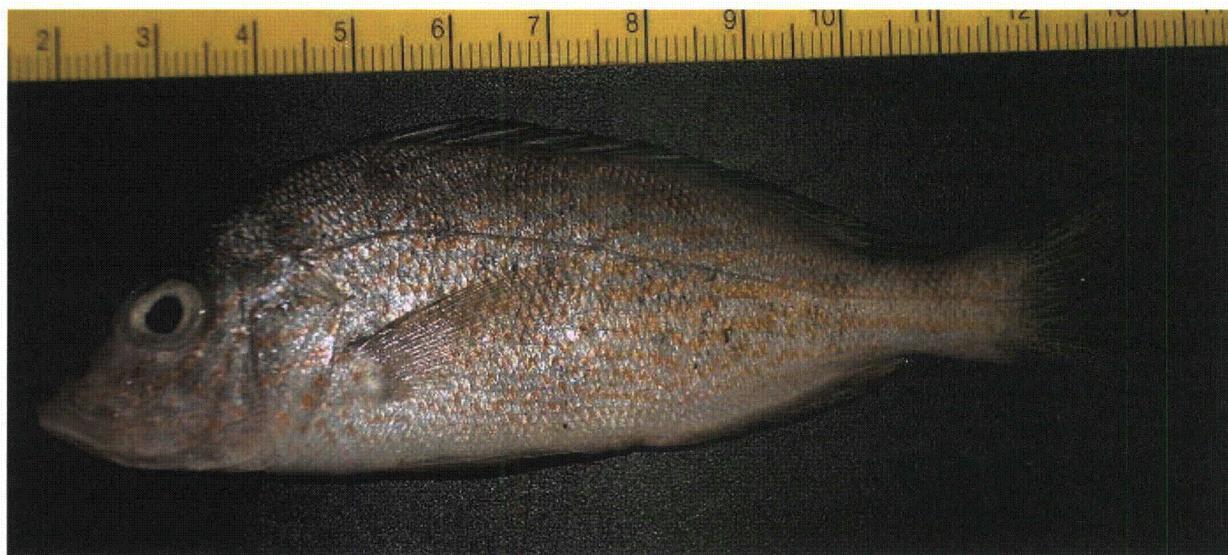

Figure 5. A photograph of the pigfish, *Orthopristis chrysoptera*, caught in the collecting screens of the Progress Energy Nuclear and Coal Power Plants in Crystal River, Florida.

Figure 6. Range of distribution of *Orthopristis chrysoptera*, pigfish (photo from Fishbase.org).

The pigfish, *Orthopristis chrysoptera* (Fig. 5), is morphologically distinguishable by its elevated back, long and tapered snout and a little oblique mouth. Its natural range of distribution includes the Western Atlantic, from New York, USA and Bermuda to Mexico. It is an oceanodromous (8), demersal species. The pigfish has a reported maximum size of 46.0 cm SL, maximum weight of 900 g and a maximum age of 4 years (9).

Pigfish populations are found in coastal waters, over sand and mud bottoms. They form schools, feeding on crustaceans and smaller fishes. The species undergoes seasonal migration as well as local nocturnal-diurnal foraging migrations (9). It spawns from January to July in the USA waters.

The pigfish as a minor commercial importance, marketed as aquarium fish and as bait.

***Lagodon rhomboides*, pinfish
(Order Perciformes; Family Sparidae)**

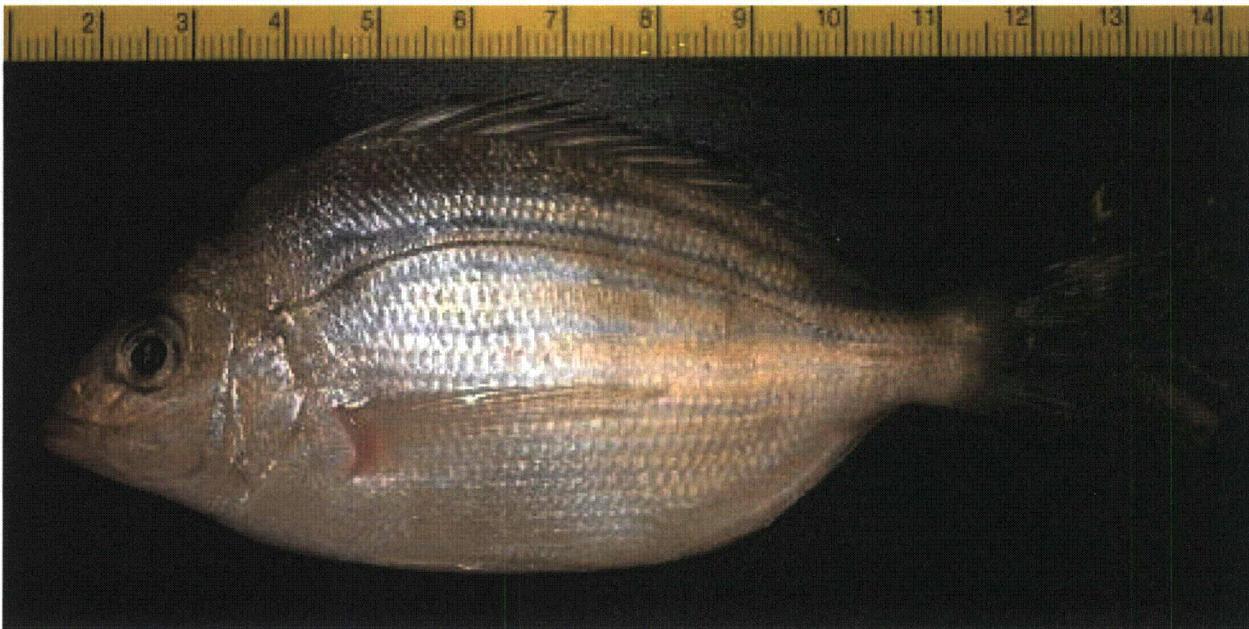

Figure 7. A photograph of the pinfish, *Lagodon rhomboides*, caught in the collecting screens of the Progress Energy Nuclear and Coal Power Plants in Crystal River, Florida.

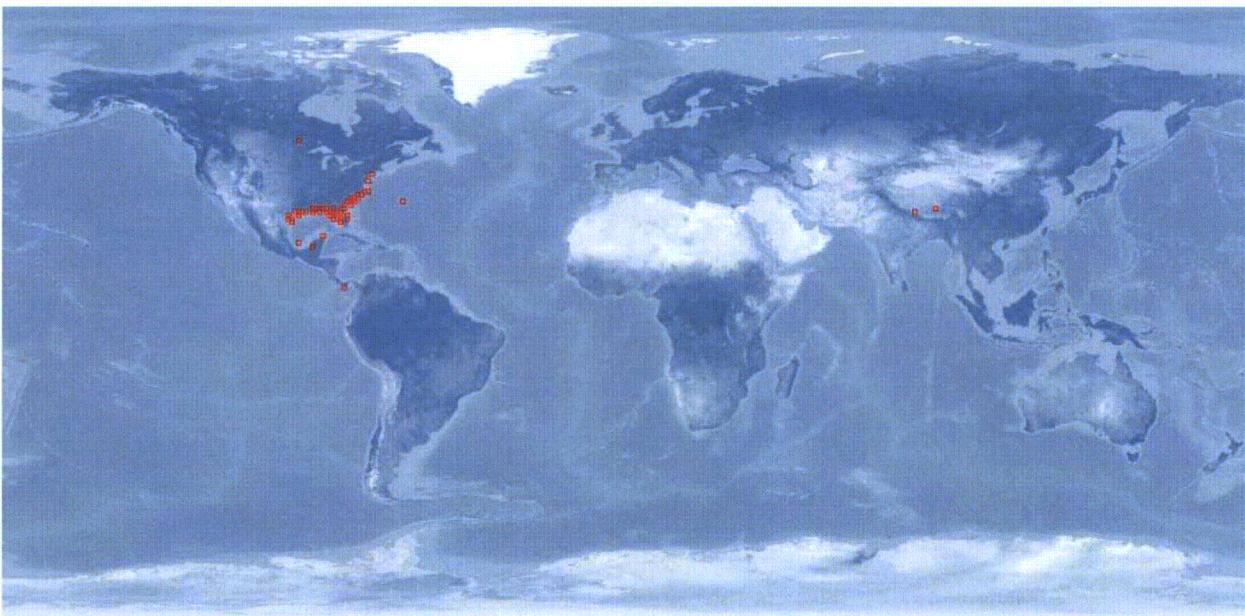

Figure 8. Range of distribution of the pinfish, *Lagodon rhomboides* (photo from Fishbase.org).

The pinfish is commonly found on vegetated bottoms, occasionally over rocky bottoms and in mangrove areas. Individuals often form large aggregations, feeding mainly on small animals, especially crustaceans, but also takes mollusks, worms and occasionally small fishes that are associated with the grassy habitat. Pinfish populations are found in freshwater, brackish and marine habitats. It naturally occurs in the Western Atlantic, from Massachusetts (USA), Bermuda, and northern Gulf of Mexico to Florida Keys, USA and Yucatan, Mexico. Also in northern coast of Cuba, but absent in Bahamas or rest of Antilles (10). It spawns October to November in Tampa Bay and adjacent waters of the Gulf of Mexico. Pinfish reaches a maximum size of 40.0 cm TL (11), maximum weight of 1,510 g (12) and a maximum age of 6 years.

Pinfish has a minor commercial importance, marketed as aquarium fish and as bait.

***Ogcocephalus cubifrons*, polka-dot batfish
(Order Lophiiformes; Family Ogcocephalidae)**

Figure 9. A photograph of the polka-dot batfish, *Ogcocephalus cubifrons*, caught in the collecting screens of the Progress Energy Nuclear and Coal Power Plants in Crystal River, Florida.

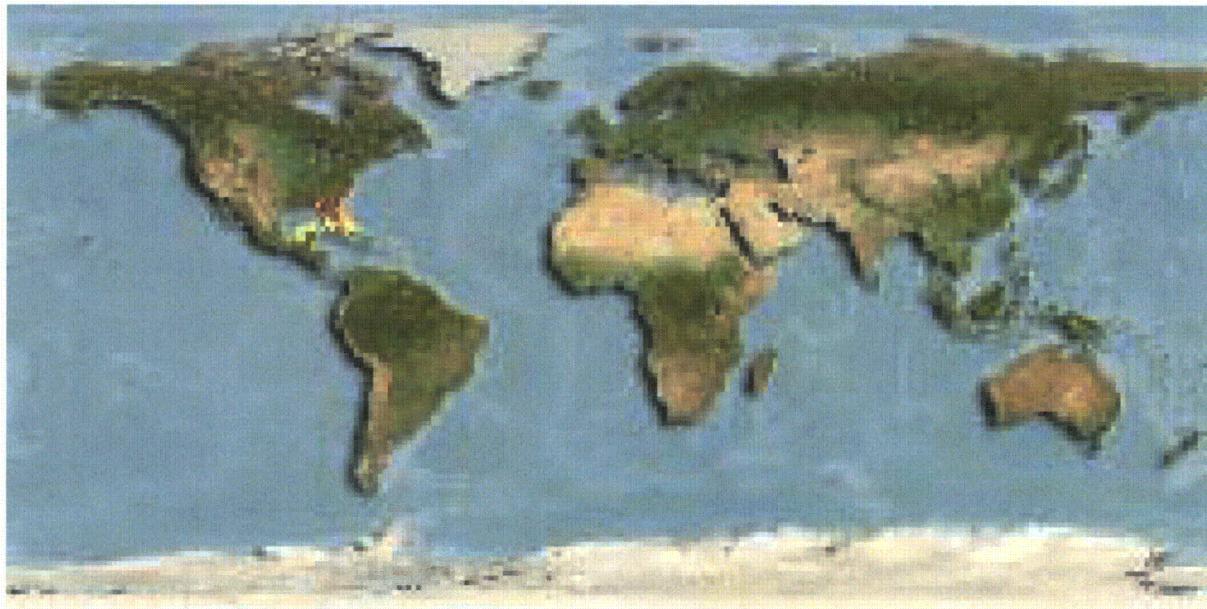

Figure 10. Range of distribution of the polka-dot batfish, *Ogcocephalus cubifrons* (photo from Fishbase.org).

Morphologically, the polka-dot batfish, *Ogcocephalus cubifrons* (Fig. 9), is distinguishable by its bright pattern of dark spots on its pale pectoral fins and small mouth (13). It naturally occurs in the Western Central Atlantic, ranging from North Carolina (USA), Bahamas and northwest Florida to Campeche Bank (Yucatan). It is considered a rare species, found on sandy, muddy, or rocky bottoms from 0-70m deep.

The polka-dot batfish has no known commercial importance.

***Harengula jaguana*, scaled sardine
(Order Clupeiformes, Family Clupeidae)**

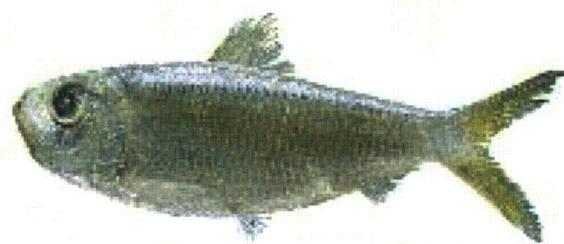

Figure 11. A photograph of the scaled sardine, *Harengula jaguana* (photo from Fishbase.org).

Figure 12. Range of distribution of the scaled sardine, *Harengula jaguana* (photo from Fishbase.org).

The scaled sardine is distinguishable morphologically by the presence of a tooth plate on tongue (basihyal and basibranchial tooth plates) (14). This species lacks a dark pigment on dorsal fin tip (14) nor an orange or red spot at the opercle (15). It naturally occurs in the Western Atlantic, from New Jersey, USA and Bermuda southward to Florida (USA), Gulf of Mexico, Caribbean, and southern Brazil. The scaled sardine inhabits marine, often associated with reef structure s and estuarine waters, over mud sand bottoms. It has been reported to reach a maximum length of 21.2 cm TL (16) and a maximum age of 6 years. The scaled sardine spawns in February to July around Miami, Florida, USA.

The scaled sardine has a minor commercial importance, marketed fresh or canned.

***Bairdiella chrysoura*, silver perch
(Order Perciformes; Family Sciaenidae)**

Figure 13. A photograph of the silver perch, *Bairdiella chrysoura*, caught in the collecting screens of the Progress Energy Nuclear and Coal Power Plants in Crystal River, Florida.

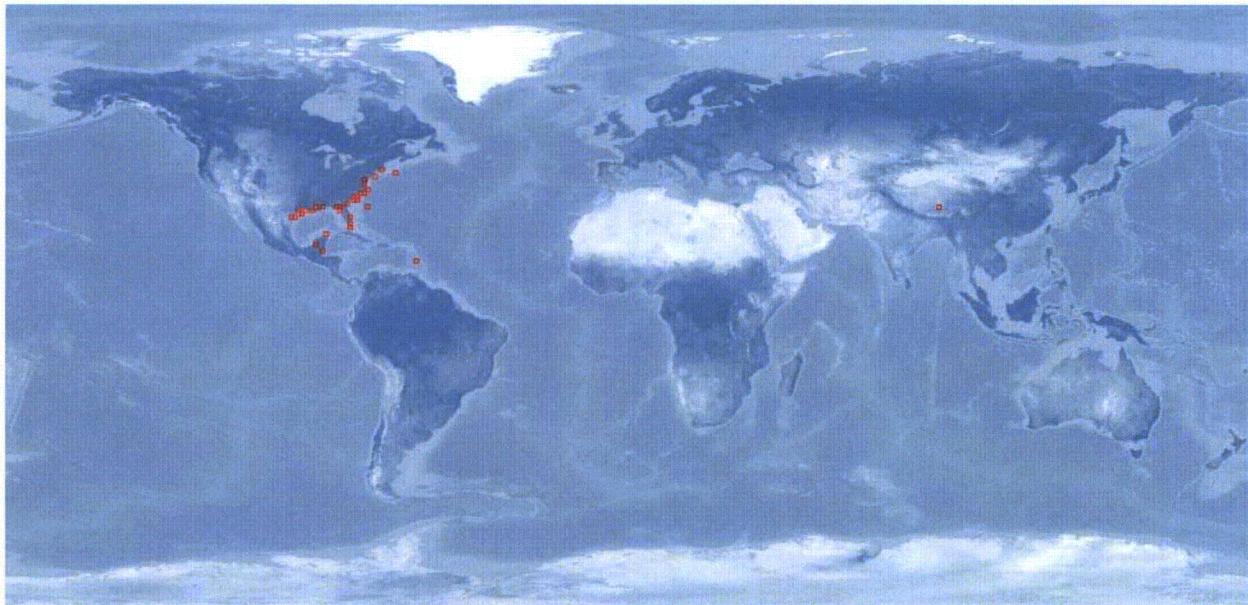

Figure 14. Range of distribution of the silver perch, *Bairdiella chrysoura* (photo from Fishbase.org).

The silver perch, *Bairdiella chrysoura* (Fig. 13), has a silvery body with greenish or bluish coloration in the dorsal half of the body and bright silvery to yellowish on the belly. Pelvic and anal fins are mostly yellowish to dusky. It has a terminal mouth, moderately large and oblique, and with 6 mental pores in the chin (17). It occurs in the Western Atlantic (Fig. 14), ranging from New York to southern Florida in USA, and eastern and northern Gulf of Mexico to northern Mexico.

The silver perch is commonly found in coastal marine and estuarine waters over sandy and muddy bottoms. Individuals move to estuarine habitat in the summer to forage on crustaceans, worms and occasionally, fishes. The species is known to live for up to 4 years at a maximum size of 30 cm (18) in the Gulf of Mexico, where they spawn in January to September.

The silver perch has a minor commercial, marketed as bait.

***Eucinostomus argenteus*, spotfin mojarra
(Order Perciformes; Family Gerreidae)**

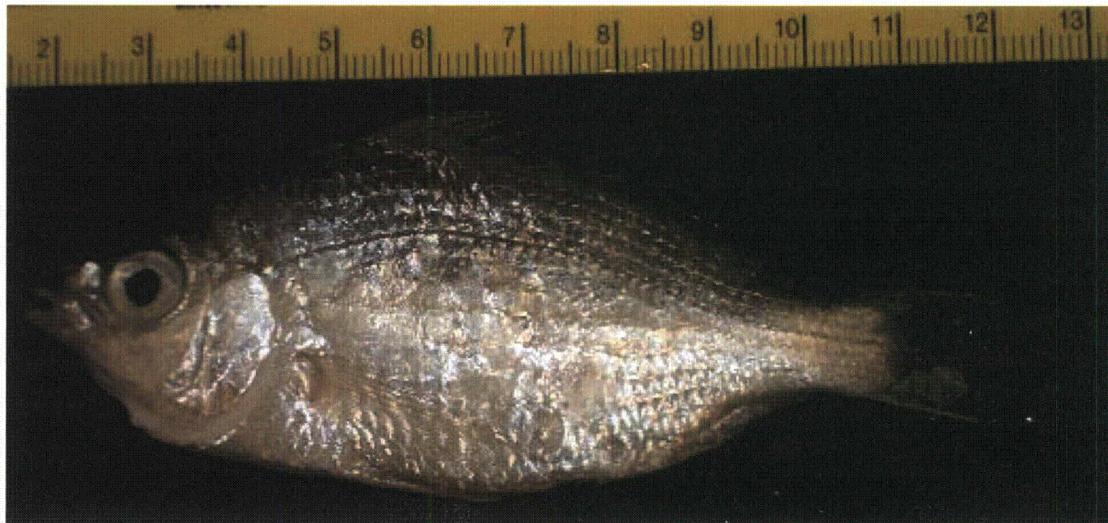

Figure 15. A photograph of the spotfin mojarra, *Eucinostomus argenteus*, caught in the collecting screens of the Progress Energy Nuclear and Coal Power Plants in Crystal River, Florida.

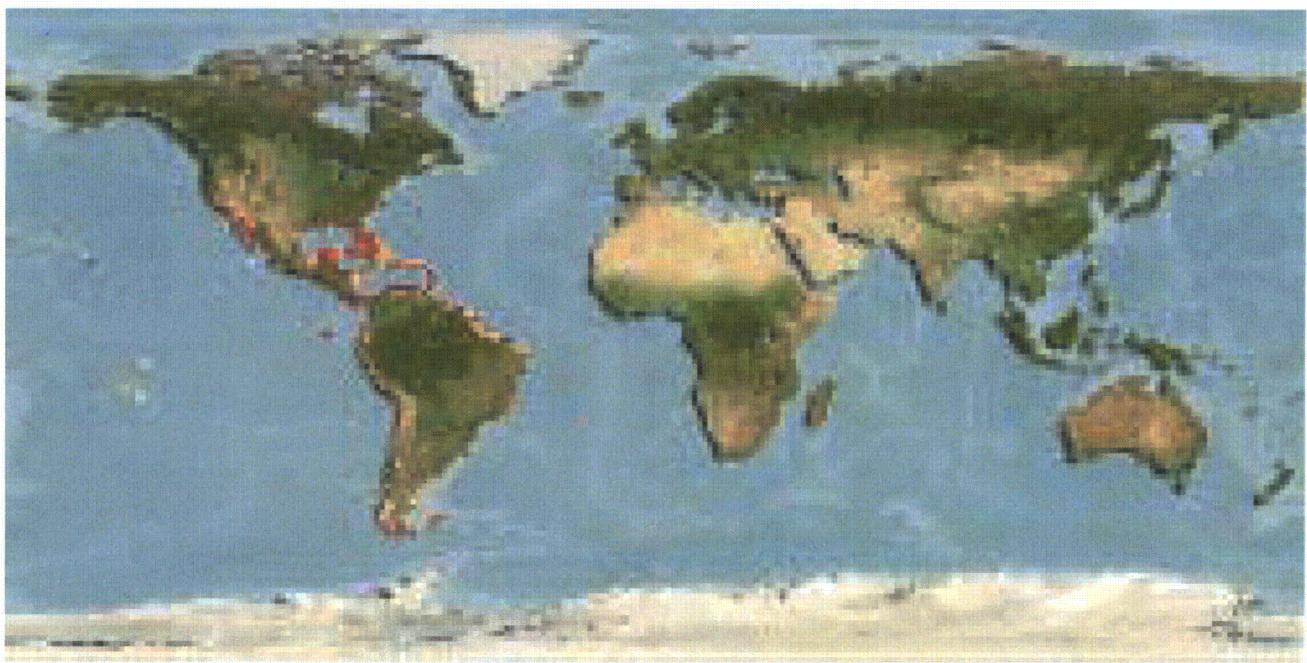

Figure 16. Range of distribution of the spotfin mojarra, *Eucinostomus argenteus* (photo from Fishbase.org).

The spotfin mojarra is distinguishable from its closest relatives by the presence of a premaxillary groove that is continuous, but narrow, bordered by scales anteriorly (19). It occurs in the Eastern Pacific ranging from Anaheim Bay in southern California, USA southward to Peru, including the Galapagos Islands. Populations in the Western Atlantic range from New Jersey, USA and Bermuda through the Gulf of Mexico and the Caribbean to southeastern Brazil (20). They inhabit soft bottoms of bays and shallow inshore areas, often along sand beaches (21). They also enter freshwater (20). Juveniles are encountered in lagoons of mangroves. The spotfin mojarra is an omnivore (22). The largest recorded body size of spotfin mojarra is 20.0 cm TL (21) and age 4 years in the Gulf of Mexico. Adult spotfin mojarra spawn in January to September in the Gulf of Mexico..

Spotfin mojarra has a minor commercial importance, marketed as fresh and frozen bait (23). Marketed fresh but not highly esteemed; processed into fish meal and used as live bait in the snapper fishery.

Anchoa hepsetus, striped anchovy
(Order Clupeiformes; Family Engraulidae)

Figure 17. A photograph of the striped anchovy, *Anchoa hepsetus* (photo from Fishbase.org).

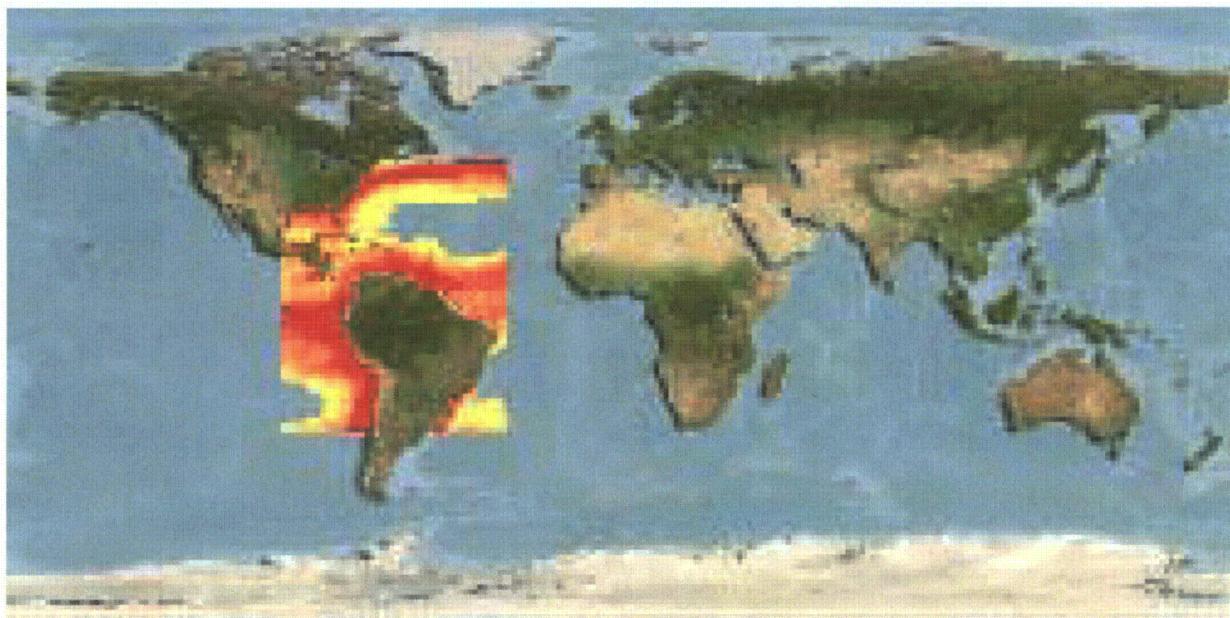

Figure 18. Range of distribution of the striped anchovy, *Anchoa hepsetus* (photo from Fishbase.org).

The striped anchovy, *Anchoa hepsetus* (Fig. 17) is morphologically distinguishable by having a pointed snout about 3/4 its eye diameter. Its long maxilla reach posteriorly beyond the border of pre-operculum. It has a silver stripe along its flank (a dark line above) that is of uniform width, but narrowed immediately behind the band (24). Melanophores outline all dorsal scales in the striped anchovy (25).

The striped anchovy occurs in the Western Atlantic (Fig. 18), ranging from Massachusetts, USA perhaps occasionally straying north to Maine or even Nova Scotia (Canada), south to Fort Pierce, Florida (but not Florida Keys) and at least northern Gulf of Mexico; also from Gulf of Venezuela south to Uruguay. It forms dense schools, often in shallow waters close to shore. Some populations can tolerate a wide range of salinities, from hypersaline to almost fresh. They feed on copepods when young, then on gastropods, foraminifers and occasionally ostracods and annelids as juveniles and adults.

The largest recorded size of the striped anchovy 15.3 cm TL; maximum age is 4 years in the Gulf of Mexico (24). Spawns in May to August in US waters (24).

The striped anchovy has a minor commercial importance, marketed as bait.

***Eugerres plumieri*, striped mojarra
(Order Perciformes; Family Gerreidae)**

Figure 19. A photograph of the striped mojarra, *Eugerres plumieri* (photo from Fishbase.org).

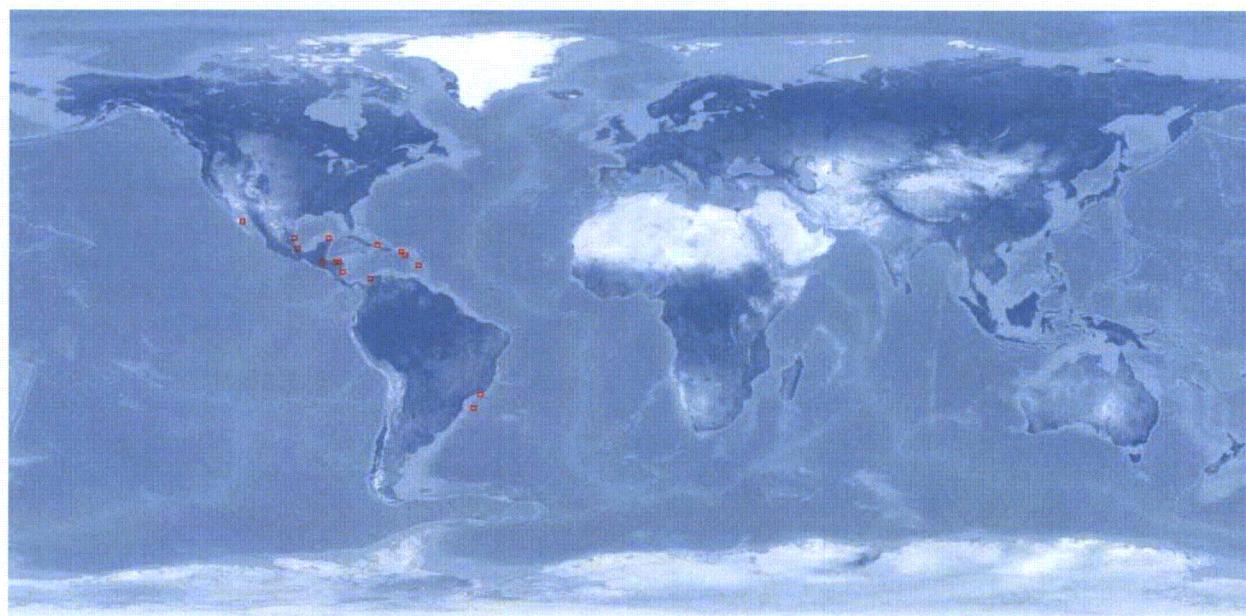

Figure 20. Range of distribution of the striped mojarra, *Eugerres plumieri* (photo from Fishbase.org).

The striped mojarra, *Eugerres plumieri* (Fig. 19) occurs in the Western Atlantic (Fig. 20), ranging from South Carolina to western Florida, USA and the entire Gulf of Mexico to Brazil (26). They inhabit shallow marine and estuarine waters (27), commonly found in muddy, mangrove-lined creeks and lagoons (28). Striped mojarra are omnivorous, feeding on aquatic insects, crustaceans, micro-bivalves and detritus (27).

The largest recorded size of the striped mojarra is 40.0 cm TL (28); maximum recorded weight is 1,020 g (29).

The striped mojarra has a minor commercial importance as a gamefish, and marketed fresh and processed into fishmeal (28).
