INTRODUCTION

A regional-scale map of the water table configuration beneath SRS and its surrounding area has been developed. The water table beneath the SRS is in continuous connection with the water table in areas immediately surrounding SRS and thus justifies extending the coverage some distance outside the SRS boundary. The direction of groundwater flow in the water table aquifer is determined from the configuration of the water table. Flow directions are perpendicular to the contour lines in the direction of decreasing hydraulic head. Knowledge of the water table configuration in the region surrounding SRS will allow for more accurate delineation of areas where there is lateral flow of groundwater across the site boundary. Understanding the direction of movement of shallow groundwater has particular significance for projecting the movement of any contaminants that may have been released to the subsurface.

The configuration of the water table is illustrated in the 11" x 17" map contained in the attachment to this document. In general, the configuration of the water table is a subdued expression of the land surface configuration. The areas of lower water table correspond to the lowest land surface elevations, along surface drainageways, while the areas of highest water table elevation correspond to the areas of highest land surface elevation, between the drainageways. Continually flowing surface drainageways gain water from the groundwater flow system and thus represent areas of groundwater discharge. The areas of groundwater mounding between the surface drainageways represent areas of recharge via the infiltration of precipitation. The resulting directions of groundwater movement are from areas of recharge toward the areas of discharge.

The regional-scale map is expected to provide a frame of reference for interpretation of well information on the local scale and assist individuals engaged in construction of water table maps at more local scales within the SRS boundary. The water table contours have been incorporated as an ARC/INFO coverage, in order to facilitate future modifications to the coverage and to provide an easy means of distribution to potential users. ArcView layouts have already been created and customized for several sizes, including a 34" x 44" plot size. The layouts can be made available in the form of a PostScript file. ArcView layouts are actively "linked" to the coverage so that the ability to "zoom" to any sub-zone within the region is maintained. The water table coverage will be maintained and updated within SRTC/ESS although the water table coverage and other ARC/INFO themes used to generate the maps actually reside on the computer system in EPD/EMS GIS Laboratory.

METHOD OF DEVELOPMENT

Information Sources

Information types utilized to develop the water table configuration map include the following:

- Water levels measured in wells
- Land surface topography
- Continuously flowing stream reaches

A total of 617 water level measurements from wells, all within the boundaries of SRS, were utilized to develop water table contours. From the SRS data base of field information for monitoring wells, water level measurements for individual wells that fell between the base of the well screen and a distance of 5 feet above the top of the screen were regarded as representative of the water table. Wells having measurements slightly above the screen zone were still utilized because these fluid levels are still very close to the actual water table and deviate only by the amount of head loss occurring over the vertical distance above the screen top. Vertical gradients are not high in individual aquifers, but even under relatively high vertical gradients, 0.1 to 0.15, the maximum deviation from the water table would only be 0.5 to 0.75 ft. This tolerance is regarded as acceptable for a regional water table map.

Water level measurements were restricted to those acquired during the first quarter of 1995. The measurements were not "time-synchronous" other than having been made in the same quarter. Time-synchronous measurements would be a slightly more accurate reflection of water table conditions but deviations due to the lack of temporal uniformity are not likely to be more than 1.5 feet and are probably less. This tolerance is regarded as adequate for a regional scale map. A listing of the wells utilized is presented in a table in the Attachment. The table contains information on well location, screen elevation, and water table elevation for each well.

The land surface elevation information was acquired from the U.S.G.S. 7.5 minute quadrangle sheets. Land surface elevation is used because it defines an upper surface above which the water table cannot exist and this information was utilized as a guide during development of the water table map, particularly in the vicinity of streams. A common error in construction of water table contours is to project contours across stream valleys which are located between adjacent wells.

Surface drainageways, when they have continuously flowing water, define areas where the land surface elevation is coincident with the water table elevation. Information on continuously flowing, or perennial, streams is available on the 7.5 minute quadrangle sheets. This information is not always accurate, especially in the upper reaches of minor tributaries to the major surface water drainageways. To supplement the 7.5 minute quadrangle information, a field survey was conducted to verify the map information. This survey was conducted by driving to every location where a road or trail crossed the headwaters of a minor stream and making a visual check. The survey was conducted

both on the SRS and also in the area immediately surrounding SRS, although no survey was conducted on the Georgia side of the Savannah River. The map information on that side of the river was assumed to be accurate in regard to flowing stream reaches.

Knowledge of the relationship of the water table to topography and perennial stream reaches has allowed a significant enhancement of the accuracy of the water table configuration in the vicinity of flowing streams. These locations generally have few wells from which to obtain measurements. This approach, along with the extended map coverage beyond the actual SRS boundary, has allowed a significant improvement to be made over previous maps of the regional water table at SRS.

Contour Interval

A 20-foot contour interval was selected to represent the water table configuration at the regional scale and is adequate for illustrating the configuration at this map scale. While a much finer contour interval can be justified in certain parts of the SRS where many wells have been installed, the 20-foot interval is more appropriate in other areas where little or no well information exists and the configuration must be inferred exclusively from surface topography and flowing stream reaches.

Contouring Methodology

Initial contouring of the water table was done on the U.S.G.S 7.5 minute Quadrangle sheets covering the SRS and its surrounding area. These contours were then digitized, built into an ARC/INFO coverage, and brought in as an ArcView (version 2.1) theme. A well data file was created and loaded into an information table within ArcView. An ArcView project was created, and the applicable themes loaded into the project. These themes include the following coverages:

- Water table contour lines
- Lakes (Par and L Ponds)
- Roads
- Wells
- Streams
- SRS boundary
- Hypsography (land surface contours)

Adjustments were made to the water table contour lines within ArcView. The water table elevation values were posted and the hypsography and streams overlain. The editing capability in ArcView was used to adjust the contour lines and made so as to maximize conformance with well measurements and land surface topography, according to the relationships previously described.

Relative Certainty

Although the water table contours are thought to be accurate there is some variation in certainty from location to location on the map. The relative certainty in the water table surface is greatest in areas where numerous wells exist. Other areas of greater certainty are in the vicinity of continually flowing streams, especially where field verification was

performed. Areas of somewhat less certainty are in interstream divide areas where the water table has mounded and there are no wells or flowing streams to verify the water table elevation.

FUTURE REFINEMENT

This map represents an initial effort to define the configuration of the regional water table at SRS. Even though all currently available data was utilized, additional water level information will become available in the future as new wells and piezometers are installed. New information will be incorporated in future revisions of the water table coverage. Also, the revisions will incorporate future water level measurements that are expected to be made in existing wells.

The following improvements will be undertaken at some point in the future:

- A decrease of the 20-foot contour interval to a 10-foot contour interval throughout the region.
- Development of 5-foot contours where well information is sufficient to justify this level of detail.
- Revision of the perennial stream reach file to more accurately reflect field conditions.
- Development of similar ARC/INFO coverages of potentiometric levels of the deeper hydrostratigraphic units beneath SRS.

AVAILABILITY OF COVERAGE

ArcView layouts of the regional water table coverage have been customized at the following standard sizes: 8.5"x11", 11"x17", and 34"x44". These layouts can be made into PostScript files. Customization for individual requests can easily be accommodated. Each of the layouts has been constructed with an "active" link to the actual coverage. This means that there is the capability to "zoom" to sub-areas and customize the water table map layout at the standard sizes. The coverages can be printed in color if the user has access to a color printer or plotter. Requests for existing PostScript files or for individual customization should be made to the author, who will coordinate with the EPD/EMS GIS Laboratory to satisfy requests.
