				REV. 2
				PAGE NO. 1 of 53
Title:	MITS004 – Probable Maximum Flood Calculation for Comanche Peak Nuclear Power Plant Units 3 and 4 (HEC-HMS & HEC-RAS)			Client: Luminant Project: MITS063 – Luminant COLA
Item	Cover Sheet Items	Yes	No	
1	Does this calculation contain any open assumptions that require confirmation? (If YES, identify the assumptions) _____		X	
2	Does this calculation serve as an "Alternate Calculation"? (If YES, identify the design verified calculation.) Design Verified Calculation No. _____		X	
3	Does this calculation supersede an existing calculation? (If YES, identify the superseded calculation.) Superseded Calculation No. _____		X	
Scope of Revision: The calculation has been revised to account for non-linear basin response for Squaw Creek and Paluxy River watersheds. The spillway discharge rating curves were revised to account for tailwater conditions. The HEC-HMS model was updated to include maximum baseflow instead of minimum baseflow. The calculation has been also revised to include a sensitivity analysis to account for different time to peak in determining backwater at toe of the Squaw Creek Reservoir Dam. The PMF elevation was adjusted in the end to account for different datum's used.				
Revision Impact on Results: The critical storm centers for Paluxy and Squaw Creek watershed remain unchanged. However, the critical temporal distribution for the Paluxy River watershed has been changed to be center. The PMF elevation at the CPNPP site is increased to 793.66 ft (NAVD 88) and the revised backwater elevation at the toe of the dam is 761.05 ft (NAVD 88).

Calculation Design Verification Plan: Apply CSP Number 3.01 Revision 6, Section 4.5a Design Review Methods and to include at a minimum: 1. Review the changes due to Revision 2 and determine if the calculation provides a reasonable estimate of the PMF and the resulting water surface elevation. 2. Review the design methodology and determine if it is appropriate, correctly applied, and accurate.		
<i>(Print Name and Sign for Approval – mark "N/A" if not required)</i>		
Approver: Joe Mancinelli	Date: 6/24/10	
Calculation Design Verification Summary: After reviewing the Comanche Peak PMF calculation Revision 2, we have come to the following conclusions: 1. Revision 2 provides a recalculation of the PMF to account for non-linear basin response, revises the HEC-HMS model to include the maximum baseflow, revises the spillway rating curve for tailwater conditions, and datum conversion; 2. The methodology applied to this set of calculations is appropriate and has been applied correctly; 3. The calculation provides a reasonable estimate of the PMF for the Comanche Peak from the Paluxy River and Squaw Creek watersheds; 4. The Originator has considered all recommendations given during the review process and has made appropriate revisions; 5. The calculations were independently checked and any errors that were discovered have been corrected in the final version of the calculation sheets; 6. The Revision 2 calculation methodology, assumptions and inputs applied are reasonable and are in accordance with CSP Number 3.01 Revision 6. Based on the above summary, the calculation is determined to be acceptable.

1.0 Purpose And Scope

To determine the Probable Maximum Flood (PMF) at Comanche Peak Nuclear Power Plant (CPNPP) Units 3 and 4 using HEC-HMS computer software (Reference 7) and HEC-RAS computer software (Reference 8). The calculation also estimates the water surface elevation at the confluence of Brazos River and Paluxy River, resulting from flows due to the Dam Break Analysis (Reference 4) and PMF on Squaw Creek and Paluxy River watersheds using HEC-RAS computer software.

2.0 Summary Of Results And Conclusions

The results from the HEC-HMS analysis indicate that due to the PMF at the Squaw Creek Reservoir (SCR) the maximum inflow is 319,000 cubic feet per second (cfs) with a water surface elevation of 793.00 feet (ft). Thus, the maximum outflow from the reservoir is 206,000 cfs. Additionally to account for datum differences, the PMF water surface elevation is increased by 0.66 ft. Therefore, the resulting PMF water surface elevation is 793.66 ft (793.0 ft + 0.66 ft)

The results from the HEC-RAS analysis indicate that the resulting maximum backwater flow on the downstream side of the Squaw Creek dam is 100,440 cfs with a water surface elevation of 760.39 ft. The water surface elevation at the downstream side of the Squaw Creek dam with adjustment due to different datum will be 761.05 ft (760.39 ft + 0.66 ft).

The plant grade for all CPNPP Units 3 and 4 safety related structures is set at 822 ft (Reference 5). Therefore, neither the PMF on the upstream side or the backwater will not impact any safety related structures at CPNPP Units 3 and 4.

4.0 Assumptions

The following assumption was made for this analysis:

- The tailwater at the Squaw Creek Reservoir is assumed to be at an elevation of 776 feet, which is one foot above the spillway crest. The discharge coefficient for the spillway was reduced in accordance with Figure 9-28 (Reference 27), which will result in a higher water surface elevation in the SCR. This elevation will be compared with the water surface elevation at the downstream end of the SCR dam calculated with the HEC-RAS software. If the calculated water surface elevation is found to be lower than the assumed tailwater elevation of 776 feet, the assumed elevation will provide a conservative value for the PMF elevation in the SCR, and will be used for the calculations.

5.0 Design Inputs

The U.S. Army Corps of Engineers (USACE), Hydrologic Engineering Center-Hydrologic Modeling System (HEC-HMS) software (Reference 7) was used for the rainfall runoff calculation. The inputs to the HEC-HMS are: the Probable Maximum Precipitation (PMP) estimates as described in Section 7.0 Calculations, rainfall distribution, drainage basin characteristics loss rates, unit hydrographs, base flow, reservoir stage discharge, elevation discharge curves, channel slope, reach length, channel cross sections, and roughness coefficients. The methodology and inputs used in determining PMP estimates are explained in detail within the separate Enercon Calculation entitled "TXUT-001-FSAR 2.4.3-CALC-011, Probable Maximum Precipitation Calculation for Comanche Peak Nuclear Power Plant Units 3 and 4 using HMR 51 & HMR 52" (Reference 3), hereafter referred as Enercon PMP Calculation. The source code for the HEC-HMS software has been maintained by USACE.

The U.S. Army Corps of Engineers River Analysis System (HEC-RAS) software, version 3.1.3 (Reference 8) was used to calculate the effects of backwater from the confluence of the Squaw Creek, the Paluxy River and the Brazos Rivers due to the PMF and upstream dam failures. Input to the HEC-RAS consists of flow hydrographs obtained from HEC-HMS, cross section geometry,

	CALCULATION CONTROL SHEET	CALC. NO. TXUT-001-FSAR 2.4.3-CALC-012
		REV. 2
		PAGE NO. 10 of 53

channel length, channel slope, roughness coefficients, and inline structure geometry. Cross-section geometry, channel length, channel slope and inline structure geometry were the inputs obtained from the Dam Breach Analysis and are explained in Section 7.0. The source code for the HEC-RAS software has been maintained by USACE.

6.0 Methodology

The following listed design guides were considered in evaluating the PMF Calculation for CPNPP Units 3 and 4 using HEC-HMS & HEC-RAS computer software. All other procedures, instructions and design guides listed in Section 5.4 of Project Planning Document (PPD No. TXUT-001, Rev. 3) are not specifically applicable in evaluating the PMF calculation.

- U.S. Nuclear Regulatory Commission, "Standard Review Plan," NUREG-0800, March 2007 (Reference 23).
- U.S. Nuclear Regulatory Commission, "Design Basis Floods for Nuclear Power Plants, Alternative Methods of Estimating Probable Maximum Floods," Regulatory Guide 1.59, August 1977 (Reference 18).
- American Nuclear Society, "Determining Design Basis Flooding at Power Reactor Sites," ANSI/ANS-2.8-1992, July 28, 1992 (Reference 19).
- U.S. Nuclear Regulatory Commission, "Standard Format and Content of Safety Analysis Reports for Nuclear Power Plants", Regulatory Guide 1.70, November 1978 (Reference 20).
- U.S. Nuclear Regulatory Commission, "Flood Protection for Nuclear Power Plants", Regulatory Guide 1.102, September 1976 (Reference 21).
- U.S. Nuclear Regulatory Commission, "Combined License Applications for Nuclear Power Plants (LWR Edition)," Regulatory Guide 1.206, June 2007 (Reference 22).
- U.S. Nuclear Regulatory Commission, "Early Site Permits; Standard design Certifications; and Combined Licenses for Nuclear Power Plants", 10 CFR Part 52, August 2007 (Reference 24).
- U.S. Nuclear Regulatory Commission, "Industry Guidelines for Combined License Applicants under 10 CFR Part 52", NEI 04-05, October 2005 (Reference 25).

The Regulatory Guide 1.59 (Reference 18) indicates use of ANSI N170-1976 "Standards for Determining Design Basis Flooding at Power Reactor Sites." ANSI/ANS-2.8-1992 (Reference 19) was issued to supersede ANSI N170-1976. Although ANSI/ANS-2.8-1992 has been withdrawn, as of June 2010 a replacement standard has not been issued by American Nuclear Society. The NRC NUREG-0800, March 2007 (Reference 23), includes ANSI/ANS-2.8-1992 as a historical technical reference.

The drainage areas for Paluxy River and Squaw Creek watersheds are referenced from the Squaw Creek Dam TXU 04627 Breach Analysis (Reference 2), hereafter referred to as the Dam Breach Analysis. The drainage area boundaries shown in the Dam Breach Analysis were digitized in AutoCAD and scaled to represent the respective drainage areas for the four drainage sub-basins. The watershed shape and areas were compared by superimposing the United States Geological Survey's (USGS) topographical map on AutoCAD drawing. USGS topographic maps were obtained from the USDA's Geospatial Data Gateway (Reference 26), and the drainage basin boundaries were mapped using ArcGIS software (Reference 1). The coordinates were verified by comparing the drainage areas with the USGS topographic map. The drainage areas reported for the sub-basins in the Dam Breach Analysis were verified to be an acceptable representation for the watershed.

	CALCULATION CONTROL SHEET	CALC. NO. TXUT-00-FSAR 2.4.3-CALC-012
		REV. 2
		PAGE NO. 11 of 53

HEC-HMS version 3.4 modeling software and HEC-RAS version 3.1.3 modeling software were used to calculate the rainfall runoff and resulting water surface elevation. The methodology used within the HEC-HMS computer software includes Snyder's unit hydrograph, which allows for a 20 percent increase to the peak of the unit hydrograph to account for non-linearity (Reference 31), Muskingum-Cunge channel routing, Lag Time and Peaking Coefficient, Initial and Constant loss model, constant monthly base flow model and Muskingum-Cunge 8-point cross section routing model. The remaining ordinates of the unit hydrograph were adjusted to maintain a smooth unit hydrograph and the standard characteristics of 1 inch of runoff. The ordinates were adjusted through trial and error using Microsoft Excel.

The methodology used within the HEC-RAS computer software includes the Unsteady NETwork Simulator (UNET) equation solver for unsteady flow momentum equations. The unsteady flow analysis allows the user to view the change in depth as a function of both time and space. The UNET simulates one-dimensional unsteady flow through a network of open channels. In addition to solving the network, UNET provides the ability to apply external and internal boundary conditions. The HEC-RAS uses an unsteady solver at each node for each time step, and data were organized for each cross-section. The unsteady analysis gives the flexibility to view the dynamics of a flood wave as it moves downstream.

The HEC-HMS, HEC-RAS, AutoCAD 2010 (Reference 16), Microsoft Excel, and ArcGIS software are validated per CSP 3.02, Revision 5. The validation and verification documents are maintained by Enercon as part of the Quality Assurance program.

USGS quadrangles and other locations and elevations discussed herein are relative to the Texas State Plane coordinate system, North American Datum of 1927 (NAD 27), and National Geodetic Vertical Datum of 1929 (NGVD 29) unless noted otherwise. The plant site grading plan is based on the Texas State Plane coordinate system, North American Datum of 1983 (NAD 83), and North American Vertical Datum of 1988 (NAVD 88).

According to the National Geodetic Survey (Reference 32) and as shown in Figure 6-1, the datum shift of NAVD 88 – NGVD 29 is between 0 and +20 cm for the CPNPP Site and upstream areas in the vicinity of the dams analyzed. Therefore, it is conservative to use the maximum conversion value when comparing water surface elevations determined from USGS quadrangles (NGVD 29) to elevations at the site (NAVD 88). Therefore, the PMF water surface elevation and the backwater elevation at the toe of the Squaw Creek Dam are increased by 0.66 ft (+20cm) to account for the datum differences.

Figure 6-1. NAVD 88 Minus NGVD 29 Datum Shift Contours

7.0 Calculations

Background

The Squaw Creek Dam and the Paluxy River watersheds were analyzed in detail within the Texas Utilities Services Inc., Comanche Peak Steam Electric Station Units 1 and 2 CPSES SSI Dam Design Calculation and Calculation Check, Volume 1 and 2 (Reference 11 and Reference 12), hereafter referred as the SSI Dam Design Calculation. The Squaw Creek Dam watershed was further studied within the Dam Breach Analysis. The SSI Dam Design Calculation and Dam Breach Analysis were reviewed by Enercon.

Watershed

CPNPP Units 3 and 4 are located within the Squaw Creek watershed. Squaw Creek is a tributary of the Paluxy River, and in turn the Paluxy River is a tributary of the Brazos River. The Squaw Creek and the Paluxy River watersheds are divided into four basins, as shown in Figure 7-1. Basins 1 and 2 represent the Squaw Creek watershed, and Basins 3 and 4 represent the Paluxy River watershed. The area upstream of the SCR is steeper and has different basin properties compared to the area around and within the SCR. Due to the variation of slope, Basin 1 has been further subdivided into three sub-basins: 1a, 1b and 1c. Basin 1a represents the drainage area above SCR, Basin 1b represents the contributing area adjacent to SCR, and Basin 1c represents SCR. Basin 2 represents the Squaw Creek watershed downstream of the Squaw Creek Dam to the confluence of the Squaw Creek and the Paluxy River. Basin 3 represents the Paluxy River watershed from the confluence of Squaw Creek to the city of Glen Rose. Basin 4 represents the drainage area north of Glen Rose. The general drainage pattern is flowing to the southeast and ultimately drains into the Brazos River.

Figure 7-1 – Squaw Creek and Paluxy River watersheds

Rainfall Distribution

The rainfall estimates were obtained from the Enercon PMP Calculation. An antecedent storm equal to 40 percent of the PMP precedes the PMP storm with a 3 day dry period between the storms, as described in Nuclear Regulatory Commission (NRC) Regulatory Guide 1.59 (Reference 18) and ANSI/ANS-2.8-1992 (Reference 19), and was considered for the PMF analysis. A sensitivity analysis was performed for various storm center locations within each watershed in determining the critical storm center for the PMP. The hyetograph resulting in the greatest runoff flow and highest elevation was used for the critical storm center. The trial storm center locations are shown in Figure

7-1. The critical storm centers for the Squaw Creek and the Paluxy watersheds are SC X and PR Y, respectively. The critical temporal distribution of the PMP at the critical storm center is determined by watershed rainfall runoff analysis using HEC-HMS. In order to reduce the number of distributions for evaluation, four distributions were chosen that bracket the range of possible hyetographs. The four distributions are one-third peaking event, center peaking event, two-thirds peaking event, and end peaking event. The analysis indicates that the two-thirds and the center temporal distributions are the critical temporal distributions for the Squaw Creek and the Paluxy River watersheds, respectively. The PMP distributions are explained in detail within the Enercon PMP calculation (Reference 3) and are not repeated here.

Baseflow

Baseflow information for USGS gage 08091750 was obtained from the USGS website (Reference 6). Prior to completion of the Squaw Creek Dam, USGS gage 08091700 was located upstream of CPNPP Units 3 and 4 on Panter Branch, a tributary of Squaw Creek. The flow measurement period of record available for gage 08091700 is from 1966 to 1973. Gage 08091750 has a period of record from 1977 to present. Gage 08091750 represents the more current data and is used to represent the Squaw Creek and the Paluxy River watersheds. The gage locations are shown in Figure 7-2. The area that drains to gage 08091750 is 70.3 square miles (sq mi). The average monthly flows for gage 08091750 were obtained from the USGS website (Reference 6). The highest of these monthly flows was used as the baseflow. The highest monthly baseflow of 46 cfs was for the month of June. Since the basin areas are different from gage area (70.3 sq mi), the baseflow of 46 cfs was adjusted on the basis of the ratio of basin drainage area to the gage area as shown in Tables 7-1 and 7-2 below. The adjusted baseflow was then applied as a constant baseflow for all months in the HEC-HMS model. Basin 1 has a total area of 64.2 sq mi. The baseflow is calculated for total area of Basin 1 and is applied to sub-basins 1a, 1b and 1c. This baseflow will be more than individual baseflow for sub-basins 1a, 1b and 1c, and will result in higher runoff to the Squaw Creek Reservoir.

Table 7-1: Average monthly baseflow for USGS Gage 08091750

Month	Average Baseflow (cfs)	Month	Average Baseflow (cfs)
January	12	July	9.7
February	18	August	13
March	28	September	11
April	21	October	13
May	44	November	13
June	46	December	24

Figure 7-2 – USGS Gage locations

Table 7-2: Adjusted baseflow for PMF analysis

	Area (sq mi)	Multiplication Factor (Basin Area/ Gage Area)	Adjusted Baseflow (46* Multiplication factor) (cfs)
Basin1a, 1b & 1c	64.2	$64.2/70.3 = 0.91$	42.01
Basin2	10.65	$10.65/70.3 = 0.15$	6.97
Basin3	24.3	$24.3/70.3 = 0.35$	15.90
Basin4	410	$410/70.3 = 5.83$	268.28

Note: Adjusted Baseflow values were calculated without rounding the multiplication factors.

Unit Hydrograph

The unit hydrographs for the Squaw Creek and the Paluxy River watershed were derived using Snyder's Method (Reference 10). This is consistent with the method used in the original Dam Breach Analysis, and the area of each of the basins in the current model falls within the applicable range for Snyder's method.

The Snyder's unit hydrograph method was used within the HEC-HMS model to calculate runoff.

$$Q_p = 640C_p A/t_p \quad \text{(Equation 1) (Reference 10)}$$

where:

Q_p = peak discharge of the unit hydrograph (cfs)

A = Drainage area (sq mi)

C_p = Peaking coefficient ranging from 0.4 to 0.8 where, larger values of C_p are associated with smaller values of C_t

t_p = Basin Lag Time (hr)

The Basin Lag Time for Snyder's method is defined as:

$$t_p = C_t (LL_{ca})^{0.3} \quad \text{(Equation 2)(Reference 10)}$$

where:

t_p = Basin Lag (hr)

L = Length of the main stream from the outlet to divide (mi)

L_{ca} = Length along the main stream to a point nearest the watershed centroid (mi)

C_t = coefficient usually ranging from 1.8 to 2.2 (C_t has found to vary from 0.4 in mountainous areas to 8.0 along the Gulf of Mexico)

The higher values of C_p (0.8) and lower values of C_t (0.4), result in higher runoff and will be more conservative. Therefore, unit hydrographs were derived using a C_p value of 0.8 and a C_t value of 0.4.

L is the length of the main stream from the most upstream point to the most downstream point on the reach within the basin, and was calculated using ArcGIS (Reference 1) . The calculated values of L and those obtained from the Dam Breach Analysis are shown in Table 7-3. The calculated values of L are smaller than the L values obtained from the Dam Breach Analysis. It is assumed that the Dam Breach Analysis used L as channel length from basin outlet to the most upstream watershed boundary or the longest travel time length. However, the smaller length will reduce the routing distance and time, which will result in higher runoff. Therefore, the calculated values of L were used in Lag time estimates.

L_{ca} is the length along the main stream to a point nearest the watershed centroid and was calculated using ArcGIS. The watershed centroid locations for Basins 1 through 4 were determined using HMR52. The HMR52 methodology and inputs are explained in detail in the Enercon PMP Calculation. The centroid location was plotted on AutoCAD using centroid co-ordinates. The length on the main stream nearest the centroid location was then calculated using ArcGIS. The calculated L_{ca} lengths are shown in Table 7-3. The L_{ca} values were compared to those found in the Dam Breach Analysis. The calculated values of L_{ca} for Squaw Creek & Paluxy River watersheds are the same as used in the Dam Breach Analysis and the SSI Dam Design, and these values are shown in Table 7-3.

	CALCULATION CONTROL SHEET	CALC. NO. TXUT-00-FSAR 2.4.3-CALC-012
		REV. 2
		PAGE NO. 17 of 53

Table 7-3: Calculated and Referenced values of L and L_{ca}

Basin	Calculated L (mi)	Calculated L _{ca} (mi)	Dam Breach Analysis L (mi)	Dam Breach Analysis L _{ca} (mi)
Basin 1a	13.7	6.5	13.7	6.5
Basin 1b	5.3	2.5	5.3	2.5
Basin 1c	-	-	-	-
Basin 2	4.6	3.0	6.3	3.0
Basin 3	4.9	5.6	12.2	5.6
Basin 4	59.3	25.8	60.6	25.8

The time base T_b for the Snyder's unit hydrograph was estimated using following equation.

$$T_b = 3 + t_p/8 \quad \text{(Equation 3)(Reference 10)}$$

where:

T_b = Time base of the unit hydrograph (hr)

t_p = Basin Lag (hr)

For small watersheds T_b should be replaced by a value 3 to 5 times the value of t_p (Reference 10).

To better estimate T_b , a multiplication factor of 3 was chosen.

$$T_b = 3 * t_p \quad \text{(Equation 4) (Reference 10)}$$

The shape of the Snyder hydrograph is further defined by the width equations at 50 percent and 75 percent of Q_p and are as follows:

$$W_{75} = 440 (Q_p/A)^{-1.08} \quad \text{(Equation 5) (Reference 10)}$$

$$W_{50} = 770 (Q_p/A)^{-1.08} \quad \text{(Equation 6) (Reference 10)}$$

where:

Q_p = peak discharge of the unit hydrograph (cfs)

A = Drainage area (sq mi)

Nonlinear Basin Response

To account for nonlinear basin response at high rainfall rates the Snyder's unit hydrograph was modified by increasing the peak of the unit hydrograph by 20 percent. The unit hydrograph was then adjusted to maintain the 1 in. of runoff characteristic for unit hydrographs.

Table 7-4: Snyder's Unit Hydrograph Parameters

Basin	Area	C_t	C_p	L (mi)	L _{ca} (mi)	Q_p (cfs)	t_p (hr)	$3 * t_p$ (hr)	T_b (hr)	W_{75} (hr)	W_{50} (hr)
Basin 1a & 1c	43.9	0.4	0.8	13.7	6.5	14,615	1.54	4.61	3.19	0.83	1.45

Loss Rates

The initial constant loss method was applied in the runoff calculation through HEC-HMS. The initial loss rate of 0.0 has been used for each sub-basin. A uniform loss rate of 0.0 inch (in)/hour (hr) for the entire watershed has been used to calculate runoff using HEC-HMS.

Reservoir

Elevation Storage

SCR is the only significant reservoir within the watersheds. The storage-elevation for SCR was obtained from the following two sources:

The storage-elevation data for elevation 775 ft and below was obtained from the 2007 Texas Water Development Board (TWDB) Volumetric Survey for Squaw Creek Reservoir (Reference 13), hereafter referred as TWDB Volumetric Survey.

The storage-elevation data for elevations above 775 ft was obtained from the Operation and Maintenance Procedures for Squaw Creek Dam, which was prepared by Freese and Nichols in 1997 (Reference 14), hereafter referred as Operation and Maintenance Procedure.

The elevation-storage data is shown in Table 7-10 and plotted as shown in Figure 7-8.

Table 7-10: Elevation-Storage data for Squaw Creek Reservoir

Elevation (ft)	Volume (acre-ft)	Elevation (ft)	Volume (acre-ft)	Elevation (ft)	Volume (ac-ft)

Figure 7-8 – Squaw Creek Reservoir Elevation - Storage Curve

Elevation Discharge

The discharge values for the service and emergency spillways were estimated using Design of Small Dams (Reference 27) and HDS No.5 (Reference 28). The spillway discharge curve for SCR was initially developed by Freese and Nichols (Reference 30, hereafter referred to as Freese & Nichols Design Discharge Document) and was published in the Operation and Maintenance Procedure. The published values only extend to elevation 790. Discharge data for elevations above 790 were estimated using the methods in these references.

The estimated values were compared to the published values to ensure that conservative estimates were used in the PMF determination. The published values for elevation-discharge data are shown in Table 7-11.

Service Spillway: The service spillway is an uncontrolled structure with an ogee crest weir. The service spillway is 100 ft wide and the crest of the weir is at elevation 775 ft. The depth of the approach channel is 12 feet below the crest of the spillway or at elevation 763 ft (Reference 29). The service spillway discharge rating curve was developed in the Freese & Nichols Design Discharge Document (Reference 30) based on the U.S. Army Corps of Engineers publication EM 1110-2-1603, and is hereafter referred to as the existing discharge rating curve. The revised service spillway discharge rating curve was developed using guidance from the Design of Small Dams (Reference 27), and is hereafter referred to as the revised discharge rating curve. The revised discharge rating curve was extended up to elevation 795 feet to account for spillway discharges resulting from the higher PMF elevation and tailwater depth.

The design parameters for the service spillway are as follows:

Spillway Width $L = 100\text{ft}$

Assumed Design Elevation = 800 ft

Design Head $H_o = 800\text{ ft} - 775\text{ ft} = 25\text{ ft}$

Crest Elevation = 775 ft

Approach height $P = 775\text{ ft} - 763\text{ ft} = 12\text{ ft}$

The design head of 25 ft is higher than the design head reported in Freese & Nichols Design Discharge Document (Reference 30) of 14.6 ft. The higher design head reduces the discharge coefficient resulting in less overtopping and a higher PMF elevation. The discharge coefficient for a vertical faced ogee crest was estimated using Figures 9-23 thru 9-25 (Reference 27). The discharge coefficient was then adjusted for ratio of head to approach height using Figure 9-24 (Reference 27). The ogee weir used in this design has a 45° sloping upstream face instead of a vertical face. The discharge coefficient was then adjusted to account for the sloping upstream face using Figure 9-25 (Reference 27).

The tailwater is assumed to be elevation 776 ft, which is one foot above the spillway crest. The discharge coefficient for the spillway was adjusted in accordance with Figure 9-28 (Reference 27), which will result in a higher water surface elevation in the SCR. Using the HEC-RAS software, the water surface elevation at the downstream end of the SCR dam was determined to be 758.52. This elevation is lower than the assumed tailwater elevation of 776 ft, therefore the assumed elevation is conservative. The higher tailwater elevation will reduce the overflow from the spillway and ultimately result in a higher PMF elevation at SCR. A detailed discussion of the HEC-RAS models is contained in the sections of this calculation titled "HEC-RAS Steady Flow Routing" and "HEC-RAS Unsteady Flow Routing."

Table 7-12 contains the calculations of the adjusted discharge coefficients for the SCR Service Spillway.

(7) Obtained from Reference 30

The estimated values of discharge are lower than both the published values and the values listed in Freese & Nichols Design Discharge Document (Reference 30). The estimated and published values for discharge are also shown in Figure 7-9. Lower values of discharge overtopping the spillway will result in higher water surface elevations, which in turn results in a higher PMF. Since the published discharge curves do not include values for elevations above 790 feet, the estimated discharge values, which extend to an elevation of 795 feet, will result in a more conservative value for the calculated PMF elevation. Therefore, the revised discharge rating curve was used in HEC-HMS for determining the PMF elevation.

**Service Spillway
(Estimated Vs Published Rating Curve)**

Figure 7-9 – SCR Service Spillway Elevation-Discharge Curve (Estimated Vs Published)

Emergency Spillway: The emergency spillway provides additional discharge capacity during extreme floods. The emergency spillway is a broad-crested weir with crest elevation at 783.0 ft and 2200 ft wide. The Squaw Creek Dam record drawings (Reference 29) indicate a concrete cap on top of the spillway.

The published emergency spillway discharge rating curve was developed by Freese & Nichols Design Discharge Document (Reference 30) using a backwater computer program and is hereafter referred to as the existing discharge rating curve. The revised emergency spillway discharge rating curve was developed using guidance provided by HDS No. 5 (Reference 28) and is hereafter referred to as the emergency spillway revised discharge rating curve.

The revised discharge rating curve was calculated for elevations up to 795 ft to account for a higher PMF elevation and tailwater depth.

The design parameters for the service spillway are as follows:

Spillway Length $L = 2200$ ft
 Crest Width $L_r = 50$ ft
 Crest Elevation = 783 ft

	CALCULATION CONTROL SHEET	CALC. NO. TXUT-001-FSAR 2.4.3-CALC-012
		REV. 2
		PAGE NO. 31 of 53

The discharge over the spillway is estimated using the following equation:

$$Q = C_d L H_{Wr}^{1.5} \quad (\text{Equation 7}) \quad (\text{Reference 28})$$

Where:

Q = Overtopping flow rate (cfs)

C_d = Overtopping Discharge Coefficient

L = Length of spillway crest (ft)

H_{Wr} = upstream depth (ft)

The overtopping discharge coefficient can be estimated using discharge coefficient, C_r , and a correction factor for downstream submergence, k_t , as shown in Equation 8.

$$C_d = k_t C_r \quad (\text{Equation 8}) \quad (\text{Reference 28})$$

The discharge coefficient, C_r , was estimated based on the submergence ratio h_t/H_{Wr} (Figure III-11, Reference 28), which is the ratio of the depth of the tailwater to the headwater over the spillway crest. Figure III-11 in Reference 28 estimates C_r with two curves, A and B. Curve A is utilized when $H_{Wr}/L_r > 0.15$, while curve B is utilized when $H_{Wr}/L_r \leq 0.15$. The discharge coefficient, C_r , is then adjusted for submergence based on the correction factor, k_t , to obtain the overtopping discharge coefficient, C_d .

From Equations 7 and 8, it is evident that lower values of k_t can result in lower C_d values. The lower C_d values result in a reduction in the overtopping discharge, thus increasing the PMF elevations. Values for k_t were obtained from the submergence factor, h_t/H_{Wr} , where h_t and H_{Wr} are based on the channel and reservoir water surface elevations obtained from the Freese & Nichols Design Discharge document (Reference 30). Using the submergence factor curve (Figure III-11(c), Reference 28), values for k_t were determined to range from 0.5 to 1.0. Given the discharge coefficient, C_r , and the k_t value, an overtopping discharge coefficient can be obtained from Equation 8.

The crest of the emergency spillway is at elevation 783 ft, which is higher than the assumed tailwater elevation of 776 ft, indicating that the emergency spillway is not directly affected by the assumed tailwater elevation. However, submergence of the channel downstream of the emergency spillway due to the assumed tailwater elevation will impact the water surface elevation at the emergency spillway. Therefore, in order to account for the effects of the downstream channel submergence, the emergency spillway will also be analyzed as a submerged weir. This will also be consistent with Freese & Nichols Design Discharge Document (Reference 30) analysis, which indicates that the backwater computer program accounts for downstream channel conditions.

		REV. 2
		PAGE NO. 32 of 53

Table 7-14: SCR Emergency Spillway Submergence Factor from Design Document

Water Surface Elevation at Channel Downstream of Emergency Spillway (ft)	Reservoir Water Surface Elevation (ft)	ht/Hwr
783.5	783.5	1
783.7	783.7	1
784.2	784.2	1
784.7	784.7	1
785.5	785.6	0.96
786.1	786.3	0.94
786.7	786.9	0.95
787.2	787.5	0.93
787.6	788.0	0.92
788.5	789.0	0.92
789.2	789.8	0.91
789.9	790.7	0.90

The reservoir elevations are interpolated to obtain submergence ratio at whole number elevations as shown in Table 7-15. The values corresponding to channel elevations 785.5 ft and 786.1 ft were averaged to obtain the submergence ratio at elevation 786.0 ft. Similarly, the values for elevations 786.7 ft and 787.2 ft were averaged to obtain the submergence ratio at elevation 787.0 ft. The value corresponding to reservoir water surface elevation of 789.8 ft was used for 790 ft. Similarly, the value corresponding to a reservoir water surface elevation of 790.7 ft was used for 791 ft. The elevation, corresponding submergence ratio and kt values are shown in Table 7-15. Table 7-16 shows the calculation of the discharge values for the emergency spillway.

Table 7-15: SCR Emergency Spillway Submergence Factor from Design Document & corresponding kt values

Elevation (ft)	Submergence Ratio ht/Hwr	kt*
783	1	0.50
784	1	0.50
785	1	0.50
786	$0.96 + 0.94 / 2 = 0.95$	0.78

The values of kt used in estimating discharge were compared to those obtained using data from Freese & Nichols Design Discharge Document (Reference 30). The kt values used to estimate discharge are lower than those in Table 7-15 for the corresponding elevations. Therefore, the kt values used in Table 7-16 are conservative for estimating PMF elevation. From Table 7-15, it is evident that as the values for kt continue to increase so does the water surface elevations; however, the kt values used herein will be capped at 0.87 for the higher water surface elevation in order to remain conservative. The discharge values for the emergency spillway are shown in Table 7-17 and Figure 7-10. The estimated values of discharge are lower than those published in the Operational and Maintenance Procedure (Reference 14), thus resulting in higher PMF elevations.

Channel Geometry

The cross-section data used for the HEC-RAS analysis were obtained from the Dam Breach Analysis. The Dam Breach Analysis cross-section data was verified with the USGS topographic maps and found to be the same. The USGS topographic maps do not contain a level of detail sufficient to show the depth and width of the channel. However, this is not considered significant because the capacity of the actual channel is negligible when compared to the volume of runoff from a PMF event. The cross section data for the Squaw Creek, the Paluxy River and the Brazos River as applied within the HEC-RAS analysis are included in Appendix A.

Roughness Coefficient

Manning's roughness coefficients range from 0.06 to 0.09 for the Squaw Creek, from 0.045 to 0.07 for the Paluxy River, and from 0.045 to 0.065 for the Brazos River in the Dam Breach Analysis. Reference 15 suggests a Manning's roughness coefficient of 0.10 for major streams with irregular and rough section (Reference 15, Table 5-6, Page 113). To account for the variability and uncertainty in the Manning's roughness coefficient, it was increased by 50 percent to 0.15, which corresponds to natural streams with very weedy reaches, weedy deep pools, or floodways with a heavy stand of timber and underbrush (Reference 15, Table 5-6). The higher roughness coefficient results in a higher water surface elevation, which produces a more conservative approach. Therefore, a Manning's roughness coefficient of 0.15 has been used within the HEC-HMS and HEC-RAS analyses.

Snowmelt

Snowmelt does not historically contribute significantly to river floods in the state of Texas (Reference 17). It was deemed appropriate not to include snowmelt to be a factor in modeling the PMF event.

HEC-HMS Analysis

The watersheds are modeled with the HEC-HMS model as shown in Figure 7-12. The reaches are modeled using Muskingum-Cunge routing method. The eight-point cross-section shape has been used for the reaches. The channel cross-sections used in HEC-RAS are modified to represent the eight-point data sets. The modified cross-sections for Reaches 2 and 4 are shown in Table 7-19 and Figure 7- 13. Flows from the sub-basins of Basin 1 will flow to SCR. The discharge from the SCR is then routed along Reach 2 to Junction 1. The flow from Basin 4 is routed along Reach 4 to Junction 1. The routed Basin 4 flow is combined with the runoff from Basin 3 at Junction 1. The routed discharge from the SCR is combined with the runoff from Basin 2 at Junction 1.

Reach 2

Reach 4

Figure 7-13: Eight-Point cross-section geometry for HEC-HMS Analysis

The length and slopes for the reaches are determined from the topographic maps. The overall slope for the reach is determined by dividing the difference in elevation of the most upstream point and most downstream point by the total distance for that reach. Upper portions of the Squaw Creek are flatter than the area downstream of the Squaw Creek Dam. The slope used to represent Basin 2 has been used to represent Basins 1a and 1b, to be more conservative.

The HEC-HMS analysis was performed for two-third and center temporal distributions at critical storm centers SC X and PR Y respectively, as described in Enercon PMP Calculation. The critical center SC X results in higher runoff for Basin 1 and Basin 2. The critical storm center PR Y results in higher runoff for Basin 3 and Basin 4. The results of the critical storm scenario from the HEC-HMS analysis that produces the greatest peak discharges for the Squaw Creek and the Paluxy River watersheds are summarized in Table 7-21.

Table 7-21: HEC-HMS Analysis Results

Basin/Station	Area (mi ²)	Peak flow (cfs)
Basin 1a & 1c	43.90	215,00
Basin 1b	20.30	129,000
Squaw Creek Reservoir	-	319,000*
Basin 2	10.65	37,600
Basin 3	24.30	85,000
Basin 4	410.0	945,000

*This value is the peak inflow into the SCR

The inflow and outflow from the SCR will be maximized with the storm center at SC X. The flow values at the SCR for the critical storm center at Squaw Creek watershed (Basin 1) are shown in Table 7-22. The SCR PMF Inflow Hydrograph is presented in Figure 7- 14 and the SCR PMF Outflow Hydrograph is presented in Figure 7-15. The SCR PMF Elevation Hydrograph is presented in Figure 7-16.

Table 7-22: HEC-HMS output for Squaw Creek Reservoir

HEC-HMS Analysis					
Basin/Station	Peak Storage Volume (acre-ft)	Peak Inflow (cfs)	Peak Outflow (cfs)	Time to Peak (hrs)	Peak Elev. (ft.l)
Squaw Creek Reservoir	216,000	319,000	206,000	194.9	793.0

The water surface elevation at the Squaw Creek Reservoir with adjustment due to different datum will be 793.66 ft (793 ft + 0.66 ft).

HEC-RAS Steady Flow Routing

A steady flow hydraulic analysis was performed to determine the water surface elevation at the confluence of Paluxy River and Brazos River. HEC-RAS was used to route the peak PMF flows from the HEC-HMS model. As discussed earlier, a roughness coefficient of 0.15 was used to obtain higher water surface elevations for the Squaw Creek, Paluxy River, and Brazos River watersheds. The cross-sections for Brazos River were determined using USGS Topographic Maps (Reference 26). The location of the cross-sections are identified in Figure 7-17.

Figure 7-17– Brazos River Cross-section Location

The confluence of Squaw Creek with the Paluxy River is approximately 4200 feet upstream of the confluence of the Paluxy River and the Brazos River. The portion of the Paluxy River downstream of Squaw Creek is referred to as Lower Paluxy in the HEC-RAS model. The HEC-RAS schematic for Squaw Creek, the Paluxy River, and the Brazos River is shown in Figure 7-18. The Brazos River is modeled as the Upper Brazos and Lower Brazos.

The peak outflow from SCR obtained from the HEC-HMS analysis was used as a boundary condition at the upstream end of Squaw Creek (station 24757). The peak outflows from Basin 2 and SCR were combined and used as a downstream boundary condition (station 1164) for Squaw Creek. The peak outflow from Basin 4 was used as a boundary condition for Paluxy River (station 25092). The combined peak outflow from Basin 4, Basin 2 and SCR was used as a boundary condition at the confluence of Squaw Creek and the Paluxy River. Figure 7-18 indicates the boundary condition flows used in HEC-RAS steady state analysis.

	CALCULATION CONTROL SHEET	CALC. NO. TXUT-001-FSAR 2.4.3-CALC-012
		REV. 2
		PAGE NO. 43 of 53

The flow of 6.73 million cfs at the Brazos River and the Paluxy River confluence was due to the hydrologically sequential failures of the Fort Phantom Hill Dam, the proposed Cedar Ridge Reservoir Dam, the Morris Sheppard Dam, and the De Cordova Bend Dam coincident with the PMF and the simultaneous failure of the Lake Stamford Dam. The methodology and inputs used in the dam failure analysis are explained in detail within the separate Enercon Calculation entitled “TXUT-001-FSAR 2.4.4-CALC-015, Brazos River Dam Failure Analysis for Comanche Peak Nuclear Power Plant Units 3 and 4” (Reference 4), and hereafter referred to as the Enercon Dam Failure Calculation. The combined flows from the Paluxy River, Squaw Creek, the Brazos River and Basin 3 were used as boundary conditions for the Lower Brazos River (station 268430).

Figure 7-18– HEC-RAS Schematic – Steady State Analysis

The normal depth boundary condition was used for downstream end of Lower Brazos River. Figure 7-17 shows the locations where 570 ft and 560 ft contours cross the Brazos River. The distance between the two locations is approximately 31,159 ft. Therefore, the slope is approximately 0.00032 ft/ft.

Cross-sections, as determined by the Dam Breach Analysis (Reference 2), were further interpolated to stabilize the HEC-RAS model for the PMF analysis. The HEC-RAS analysis extends the cross-sections vertically to accommodate the flows. Extending the cross-sections vertically will prevent the river/creek flow from spreading out into the flood plain or to its actual width within the cross-section. This will result in a higher, more conservative water surface elevation at the confluence of the Brazos River and the Paluxy River.

	CALCULATION CONTROL SHEET	CALC. NO. TXUT-001-FSAR 2.4.3-CALC-012
		REV. 2
		PAGE NO. 44 of 53

The peak elevation on the downstream side of the Squaw Creek Dam (station 24757), downstream end of Lower Paluxy River (station 814), and downstream end of upper Brazos River (station 276887) are shown in Table 7-23. The steady state HEC-RAS analysis inputs and outputs are included in Appendix A.

Table 7-23: HEC-RAS Results (Steady State Analysis)

HEC-RAS Analysis (Steady State)		
Reach	Upstream End Peak Elevation (ft)	Downstream End Peak Elevation (ft)
Squaw Creek	758.22	758.14
Paluxy River	759.18	758.10
Lower Paluxy River	758.05	757.89
Upper Brazos River	760.05	759.66
Lower Brazos River	759.50	758.83

As expected, the cross-section at the upstream end of the Upper Brazos River indicates the highest water surface elevation. Therefore, that value is used in the unsteady analysis to maximize the backwater estimates at the toe of the Squaw Creek Dam. A plot of the Lower Brazos River cross-section 268430 near the confluence of the Brazos River and the Lower Paluxy River is shown below in Figure 7-19. Figure 7-20 shows the plot of the Upper Brazos River Cross Section 276887.

HEC-RAS Unsteady Flow Routing

An unsteady flow hydraulic analysis was performed to assess the backwater flows downstream of the Squaw Creek Dam. HEC-RAS computer software was used to route the 72 hr PMF hydrographs from the HEC-HMS model. To obtain a conservative estimate of the backwater at toe of the Squaw Creek dam, the channel cross-section and Manning's roughness coefficient are the same as were used in the steady state analysis. Manning's coefficient of 0.15 was used to maximize the effects of backwater. Additional considerations were made such as energy losses due to contraction or expansion of flow due to change in the cross-section. These energy losses are higher if there is an abrupt change, for example in cases of bridges and culverts. The analysis does not include any structures such as bridges and culverts within the HEC-RAS model. The relative change in cross-section shape for the Squaw Creek and the Paluxy River is gradual. Therefore, the contraction and expansion coefficients are based on gradual transitions. The HEC-RAS manual (Reference 9) suggests a contraction and expansion coefficients of 0.10 and 0.30 respectively, for gradual transitions.

The confluence of Squaw Creek with the Paluxy River is approximately 4200 feet upstream of the confluence of the Paluxy River and the Brazos River. The portion of the Paluxy River downstream of Squaw Creek is referred to as Lower Paluxy in HEC-RAS Model. The HEC-RAS schematic for Squaw Creek and the Paluxy River is shown in Figure 7-21.

The hydrographs from the HEC-HMS analysis at the SCR and for each sub-basin were routed using the HEC-RAS software. As discussed earlier, the two-thirds temporal distribution for storm center SC X results in a higher runoff for Basin 1 and Basin 2. The center temporal distribution for storm center PR Y results in maximum runoff at the confluence of the Paluxy River and Squaw Creek. The maximum runoff at the confluence of the Paluxy River and Squaw Creek may result in maximum water surface elevation at the confluence of Brazos River and Paluxy River. Therefore, hydrographs obtained due to the center temporal distribution for storm center PR Y were used as the input hydrographs for the HEC-RAS analysis. The outflow hydrograph from the SCR (shown in Figure 7-22), resulting from the HEC-HMS analysis with storm center at PR Y, was used as a flow boundary condition for Squaw Creek at upstream end of the Squaw Creek (station 24757). The HEC-HMS outflow hydrograph for Basin 2 (shown in Figure 7-20), resulting from the HEC-HMS analysis with storm center at PR Y, was applied as a lateral inflow boundary condition at the downstream end of Squaw Creek (station 1214). The HEC-HMS outflow hydrograph for Basin 4 (shown in Figure 7-21), resulting from the HEC-HMS analysis with storm center at PR Y, was applied as a flow boundary condition at the upstream end of the Paluxy River (station 25092) in the HEC-RAS analysis. The HEC-HMS output hydrograph for Basin 3 (shown in Figure 7-22), resulting from the HEC-HMS analysis with storm center at PR Y, was applied as a lateral inflow boundary condition for the Lower Paluxy River (station 924) in the HEC-RAS analysis.

A stage hydrograph with constant elevation of 760.05 ft was used as the boundary condition for the Lower Paluxy River (station 874). The elevation of 760.05 feet is the highest of the elevations for the Brazos River listed in Table 7-23. The higher elevation at the confluence of the Brazos River and the Paluxy River results in a higher elevation at the toe of the SCR. The water surface elevation of 760.05 ft at the confluence of the Brazos River and the Paluxy River was due to the hydrologically sequential failures of the Fort Phantom Hill Dam, the proposed Cedar Ridge Reservoir Dam, the Morris Sheppard Dam, and the De Cordova Bend Dam coincident with the PMF and the simultaneous failure of the Lake Stamford Dam. The initial flow was assumed to be zero for Squaw Creek and the Paluxy River as the base flows are already applied within HEC-HMS analysis.

Figure 7-25– Lower Paluxy River (station 924) inflow hydrograph from HEC-HMS (Basin 3, storm center at PR Y)

The cross-sections for the HEC-RAS model were taken from the Dam Breach Analysis. Due to the distance between the input cross-sections, additional, interpolated cross-sections were required to allow the HEC-RAS model for the PMF analysis to properly balance. The HEC-RAS analysis extends the cross-sections vertically to accommodate the flows. Extending the cross-sections vertically will prevent the river/creek flow from spreading out into the flood plain or to its actual width within the cross-section. This will result in a higher water surface elevation at the downstream end of the Squaw Creek Dam. The peak flow and the peak elevation on the downstream side of the Squaw Creek dam are shown in Table 7-24. A 5-minute computation interval was used along with a 5-minute detailed hydrograph output interval. The HEC-RAS analysis inputs and outputs are included in Appendix B. The results from the HEC-RAS analysis are summarized in Table 7-24.

Table 7-24: HEC-RAS Results (Unsteady State Analysis)

HEC-RAS Analysis		
Location	Peak Flow (cfs)	Peak Elev. (ft)
Downstream of Squaw Creek Dam	100,440	760.39

The HEC-RAS outputs at downstream side of the Squaw Creek Dam (station 24757) and the downstream end of the Lower Paluxy River (station 874) are shown in Figures 7-26 and 7-27, respectively. The stage hydrograph is at the constant stage of 760.05 ft, which is obtained from the Enercon Dam Failure Calculation (Reference 4). The HEC-RAS model calculates the elevation at the downstream end of the Squaw Creek dam, due to the PMF at the Squaw Creek and the Paluxy River watersheds and higher stage at the confluence of the Brazos River and the Paluxy River.

HEC-RAS Sensitivity Analysis

The existing HEC-RAS model discussed above uses the HEC-HMS output with the storm center at PR Y with center temporal distributions. The center distribution with the storm center at PR Y results in a higher runoff at the confluence of the Brazos River and Squaw Creek. The two-thirds temporal distribution with the storm center at SC X results in higher water surface elevation for Basins 1 and 2. It should be noted that the Basin 1 PMP calculations include only the Basin 1 areas, while the Basin 2 PMP is based on the combined hydrographs from the SCR and Basin 2. The change in timing of the two storms may alter the water surface elevation at toe of the Squaw Creek Dam. Therefore, a sensitivity analysis was performed by revising the inflow hydrographs in HEC-RAS analysis

The outflow hydrograph from the SCR, resulting from the HEC-HMS analysis with the storm center at SC X, was used as a flow hydrograph boundary condition for Squaw Creek at the upstream end of Squaw Creek (station 24757). The HEC-HMS output hydrograph for Basin 2, resulting from the HEC-HMS analysis with the storm center at SC X, was applied as a lateral inflow hydrograph boundary condition at the downstream end of Squaw Creek (station 1214). The HEC-HMS output hydrograph for Basin 4, resulting from the HEC-HMS analysis with storm center at PR Y, was applied as a flow hydrograph boundary condition at the upstream end of the Paluxy River (station 25092) in the HEC-RAS analysis. The HEC-HMS output hydrograph for Basin 3, resulting from the HEC-HMS analysis with the storm center at PR Y, was applied as a lateral inflow hydrograph boundary condition for the Lower Paluxy River (station 924) in the HEC-RAS analysis. The HEC-RAS sensitivity analysis inputs and outputs are included in Appendix C.

An unsteady analysis similar to the analysis described above was performed to obtain the backwater elevation at the toe of the Squaw Creek Dam. The results from the HEC-RAS sensitivity analysis are summarized in Table 7-25.

Table 7-25: HEC-RAS Results (Sensitivity Analysis)

HEC-RAS Analysis		
Location	Peak Flow (cfs)	Peak Elev. (ft)
Downstream of Squaw Creek Dam	5500	760.31

The results of the sensitivity analysis indicate that the water surface elevation at the downstream end of the Squaw Creek Dam is 760.31 ft., which is less than the elevation of 760.39 ft listed in Table 7-24. Therefore, the resulting water surface elevation at the toe of the Squaw Creek Dam due to the PMF on Squaw Creek and the Paluxy River, including the effect of upstream existing and proposed dam failures, is 760.39 ft.

The water surface elevation at the downstream side of the Squaw Creek dam with adjustment due to different datum will be 761.05 ft (760.39 ft + 0.66 ft).
