Sheet Rev. 002

1. PURPOSE

This calculation will determine the toxic, flammable and explosive minimum safe distances, control room (CR) concentrations, and overpressure values due to explosions, using the Areal Locations of Hazardous Atmospheres (ALOHA®) software, for the proposed V.C. Summer Unit 2 from chemicals associated with Unit 1 at the V.C. Summer nuclear facility.

For toxic vapor clouds it is necessary to determine the maximum distance at which the Immediately Dangerous to Life or Health (IDLH) value, or other toxicity limit, exists for a given amount of a chemical (NRC 2001). This distance represents the minimum safe distance that a nuclear power plant can operate, without protection, when near a toxic chemical. The distance depends on the prevailing meteorological conditions, wind speed, toxicity of the chemical and the quantity of chemical released. It is also necessary to determine the concentration inside the CR to ascertain the effects of a spill on the operators.

For flammable vapor clouds it is necessary to determine the distances at which lower flammability limits (LFL) exist. Once the concentration is below the LFL the vapor is no longer flammable. The distance to the outer edge of the LFL section of the cloud is the minimum distance that a nuclear power plant can operate from the chemical source when near a flammable chemical.

For explosive vapor clouds it is necessary to determine the maximum distance at which the peak overpressure is less than or equal to 1 psi (NRC 1978). This is the minimum safe distance for explosions. A peak overpressure of 1 psi will shatter glass but not do any significant structural damage to buildings (NRC 1978). The peak overpressure at the nearest safety related structure (NSRS) is also established. The Unit 2 CR is the NSRS for all chemicals in this calculation.

ALOHA® is capable of modeling all of these scenarios.

7. CONCLUSIONS

None of the analyzed chemicals presented any design based hazards to the proposed V.C. Summer Unit 2 or Unit 3 CRs. The highlighted values in section 6 are the worst case values for each chemical and are summarized in Table 7.1. For most of the chemicals, F stability class, 1 m/s wind speed and an ambient temperature of 94.2 °F were the predominant conditions that produced the worst case scenarios. There were two cases where the indoor concentration was worse at F stability class and 2 m/s, for gasoline and hydrazine. Comparing the runs that occurred during daylight to the runs that occurred during darkness, it can be seen that the dominant effect is the stability class and wind speed versus the solar radiation. Temperature also plays a large role, as can be seen by comparing the F stability class and 1 m/s second runs at 25°C (77°F) and 94.2°F. Increasing the ambient temperature had a significant effect on the evaporation rate and thus the total quantity released and the concentration at the control room as well as having a minor effect on dispersion within the plume. Given the selection of either F or E stability, which occur at night time with a cloud cover fraction of $\leq 3/8$, 25°C would be a conservative selection (Seinfeld 1986), however as shown, even with an ambient air temperature of 94.2°F, no hazards exist at the CR. As stated in section 5.1, wind speeds less than 1.5 m/s occur 2.18% annually (ABS 2009a, 2009b), thus the selection of F stability class with 1 m/s wind speed is overly conservative.
