

The Reactor Shield Building (RSB) completely encloses the Reactor Containment Building (RCB) and provides a second containment barrier to the release of airborne radioactive material. The space between the RSB and RCB forms an annulus, which is maintained at a subatmospheric pressure and is filtered by the annulus ventilation system (AVS).

6.2.3.1 Design Bases

The RSB functions as a secondary containment to prevent the uncontrolled release of radioactivity to the environment following a postulated accident.

The RSB and AVS provide the secondary containment function under the environmental conditions of normal operation, maintenance, testing, and postulated accidents, including protection against dynamic effects resulting from equipment failures (GDC 4).

The AVS maintains the annulus at a subatmospheric pressure during normal operations and following postulated accidents, establishing a barrier against uncontrolled release of radioactivity to the environment (GDC 16).

The AVS filters leakage from the primary containment following a postulated accident before releasing it to the environment.

The AVS maintains the ambient air temperature in the annulus to avoid significant boron precipitation in piping that traverses the annulus.

The AVS is designed to permit periodic inspection and functional testing to confirm barrier integrity and the operability of the secondary containment ventilation system (GDC 43). RSB inspection is addressed in Section 3.8.4. Containment leakage testing in accordance with 10 CFR 50, Appendix J is described in Section 6.2.6.

6.2.3.2 System Description

6.2.3.2.1 General Description

The RSB is a reinforced concrete shell structure consisting of an upright cylinder capped with a spherical dome. The RSB is concentric with, and completely encloses the RCB, creating an annular region approximately six feet in width. The RSB is surrounded by the Safeguard Buildings and the Fuel Building. Section 3.8.1 contains plan and elevation views of the Reactor Building.

The primary function of the RSB is to protect the RCB from damage due to external events. The RSB also functions as a secondary containment to prevent the

uncontrolled release of radioactivity to the environment. The design description and performance criteria of the RSB are presented in Section 3.8.4.

The annulus ventilation system collects and filters airborne radioactive material that may leak from the primary containment by maintaining a subatmospheric pressure in the annulus.

6.2.3.2.2 Annulus Ventilation System

The AVS is designed to contain leakage from the primary containment by maintaining a subatmospheric pressure in the annulus. The AVS consists of three trains: one train is used during normal plant operation; two trains are used to mitigate potential accidents. AVS design and performance parameters are presented in Table 6.2.3-1.

Table 3.2.2-1 provides the seismic and other design classifications of the components in the AVS.

Refer to Section 12.3.6.5.6 for ventilation system design features which demonstrate compliance with the requirements of 10 CFR 20.1406.

6.2.3.2.2.1 AVS Normal Operation Train

The normal operation filtration train is shown in Figure 6.2.3-1. The full capacity normal operation filtration train is designed to maintain a subatmospheric pressure in the annulus, to maintain the annulus temperature above 45°F to prevent boron precipitation in the extra borating system piping, and to provide conditioned air in the annulus for personnel accessibility.

During normal operation, the conditioned air is drawn from the Nuclear Auxiliary Building ventilation supply shaft (See Section 9.4.3) through a fire damper, a motoroperated control damper, and two motor-operated isolation dampers. The supply air is distributed in the bottom of the annulus to four different locations. A subatmospheric pressure of less than or equal to -0.8 inches water gauge is maintained in the annulus during normal operation by regulating the control damper with two redundant pressure sensors located in the annulus.

The exhaust air is drawn from the top of annulus by the Nuclear Auxiliary Building ventilation system exhaust fans through two motor-operated isolation dampers and a fire damper. The exhaust air is filtered by the Nuclear Auxiliary Building filtration trains and discharged through the vent stack.

The normal operation filtration train is in service during normal plant operation and plant shutdown conditions. The two accident trains are available as backup if the normal operation train is not able to maintain the subatmospheric pressure in the annulus.

The motor-operated air-tight dampers—located on the normal operation filtration train supply and exhaust ducts—isolate the secondary containment in case of a postulated accident. The redundant dampers in the supply and exhaust trains are powered by different electrical divisions backed by separate emergency diesel generators. The dampers can be operated automatically or manually from the main control room (MCR). In the event of a station blackout (SBO), these dampers are automatically closed by batteries.

The fire dampers on both supply and exhaust trains are located at the wall penetration between the Fuel Building and the annulus. These dampers are equipped with thermal sensors for automatic closing, and can be closed or re-opened remotely if not released by the thermal sensor.

6.2.3.2.2.2 AVS Accident Trains

The AVS accident filtration trains are shown on Figure 6.2.3-2. The filtration trains are engineered safety feature (ESF) filters and are used during postulated accidents to contain leakage from the primary containment by maintaining a subatmospheric pressure in the annulus. The exhaust air from the annulus is filtered before release to the environment via the vent stack.

There are two full capacity ESF trains, each consists of an air-tight motor-controlled damper, an electrical heater, a pre-filter, an upstream HEPA filter, an iodine absorber, a downstream HEPA filter, an air-tight motor controlled damper, a fan, and a back-draft damper. The filter system components are designed in accordance with Regulatory Guide 1.52, and are described in Section 6.5.1.

During a postulated accident, the ESF filtration trains collect the containment leakage from the annulus, remove airborne radioactivity through the filtration train, and release the filtered air to the vent stack. The AVS accident trains reduce the pressure in the annulus to at least -0.25 inches water gauge or less and maintain the lower subatmospheric pressure. The system is capable of maintaining a uniform negative pressure throughout the secondary containment structure following the design basis loss of coolant accident (LOCA).

The exhaust air is monitored and sampled for radiation levels before release to the vent stack, as described in Section 11.5.3.1.10 and Table 11.5-1, Monitors R-27 and R-28.

The two ESF trains are physically separated by being installed in separate rooms of the Fuel Building, which are also in separate fire areas. The two ESF trains are powered by different electrical divisions backed by separate emergency diesel generators.

6.2.3.2.2.3 System Operation

The normal operation filtration train is in service during normal plant operation, including cold shutdown and outages. During normal operation, the isolation dampers are in the open position and the annulus is continuously vented. The subatmospheric pressure inside the annulus is maintained by regulating the control damper located on the supply side of the normal operation filtration train. The supply air from the AVS maintains the annulus temperature between 45°F and 113°F.

A failure of the normal operation filtration train leads to the loss of supply and exhaust air to the annulus. In this case, one of the accident filtration trains is started, and the two isolation dampers on the supply and exhaust side of the normal filtration train are closed to isolate the normal operation filtration train and maintain the leak tightness of the annulus.

In case of a postulated accident, a containment isolation signal causes the normal filtration train to automatically stop. The normal filtration train supply air isolation dampers close immediately and the exhaust isolation dampers close with a delay, to maintain the annulus negative pressure during the switchover to the accident filtration trains. Both accident filtration trains start on receipt of a containment isolation signal and an alarm is issued in the MCR.

6.2.3.2.3 Bypass Leakage

Certain containment penetrations introduce the potential for primary containment leakage to bypass the filtered annulus and escape directly to the environment. Potential bypass leakage paths exist through the double seals of the equipment hatch, personnel airlocks, fuel transfer tube, and containment ventilation system isolation valves.

The leak-off system provides a means to capture bypass leakage and route it to the annulus to be processed. The leak-off system is located in the Reactor Containment Building, Reactor Building Annulus, Fuel Building, and Safegurard Buildings 2 and 3, and consists of valves, sensors and piping. It is composed of three main subsystems: containment leakage exhaust subsystem (CLES), containment inflating/deflating subsystem (CIDS), and containment leak-tightness test subsystem (CLTS). The CLES collects leaks from various systems and components in the Reactor Containment Building, Fuel Building, and Safegurard Buildings, and transports the leakage to the Reactor Building Annulus. The CIDS is used for the pressurization, depressurization, and evacuation of the Reactor Containment Building in order to test the structural integrity and leak-tightness of the Reactor Containment Building. The CLTS uses sensors in the Reactor Containment Building, Fuel Building Annulus and the environment to estimate the leak-tightness of the Reactor Containment Building.

The CLES contains piping to collect leakage from components located at containment penetrations at the interface boundary between the Reactor Containment Building and Reactor Building Annulus, the Reactor Building Annulus and the environment, and the Fuel Building and Safegurard Building 3. During normal operation, the CLES collects leakage in leak-off lines and routes the leakage to the Reactor Building Annulus. Subatmospheric pressure in the Reactor Building Annulus, provided by the annulus ventilation system (AVS), creates a pressure differential, which drains the CLES leakage. Discharge piping from the CLES is routed to a floor drain in the nuclear island drain and vent system located in the Reactor Building Annulus.

The leak-off system is functional during normal operation and postulated accidents. During design basis accidents, valves in the CLES are open. Leaks from components (valves, hatch seals) are collected and drained to the Reactor Building Annulus by the pressure differential created by the AVS. Leak-off system component classifications are presented in Section 3.2.

Containment penetrations that are paths for potential bypass leakage terminate in areas of the surrounding buildings that are filtered during a postulated accident. Section 6.2.6.5 addresses the treatment of bypass leakage for containment leakage rate testing.

6.2.3.3 Safety Evaluation

The AVS system components are located inside the Fuel Building, which is a Seismic Category I structure. The two AVS accident filtration trains are designed to withstand the safe shutdown earthquake and are classified as Seismic Category I.

The safety-related components of the AVS system remain functional and perform their intended function following a postulated internal hazard (e.g., fire, flood, internal missiles, pipe breaks). The two accident filtration trains are physically separated from each other to prevent common mode failures. Since the accident filtration trains are completely redundant and are both full capacity, one train alone can collect and process radioactive material that may leak from the primary containment following an accident. The supply and exhaust trains of the normal filtration train can be isolated with two redundant dampers in series.

Guard pipes surround high energy lines passing through the annulus to protect against pipe failures that could compromise the integrity of the secondary containment. Design criteria for guard pipes are presented in Section 3.6.2.2. Containment penetrations are listed in Section 6.2.4. Doors and hatches leading to the annulus are maintained under administrative control.

If a fire is detected in the annulus during normal operation, the continuous ventilation of the annulus is stopped manually from the MCR by closing the fire dampers located

at the wall penetration between the Fuel Building and Nuclear Auxiliary Building ventilation supply and exhaust shafts to reduce the possibility for fire propagation.

Analyses have demonstrated the ability of the AVS to depressurize and maintain a subatmospheric pressure in the annulus during normal operation and following a design basis LOCA. The LOCA is assumed to occur concurrent with a loss of off-site power, and a loss of one of the accident trains. The total thermal and pressure expansion of the primary containment structure is assumed to occur prior to the start of the remaining accident train, resulting in a starting pressure of 14.712 psia. The drawdown of the annulus is started 60 seconds after the start of the postulated accident. Analytical results indicate that the pressure in the annulus reaches a subatmospheric pressure sufficient for the AVS to perform its safety function with substantial margin. Analytical specifications and results are presented in Table 6.2.3-2.

6.2.3.4 Inspection and Testing Requirements

The AVS major components, such as dampers, motors, fans, filters, heaters, and ducts are located to provide access for initial and periodic testing to verify their integrity.

Initial in-place acceptance testing of the AVS is performed as described in Section 14.2 (test abstracts #077 and #203), Initial Plant Test Program, to verify the system is built in accordance with applicable programs and specifications.

The AVS is designed with adequate instrumentation for differential pressure, temperature, and flow indicating devices to enable testing and verification of equipment function, heat transfer capability and air flow monitoring.

During normal plant operation, periodic testing of AVS is performed to demonstrate system and component operability and integrity.

Isolation dampers are periodically inspected and damper seats replaced as required.

Per IEEE 334 (Reference 17), type tests of continuous duty class 1E motors for AVS are conducted to confirm ESF system operation and availability.

Fans are tested by manufacturer in accordance with Air Movement and Control Association (AMCA) standards (References 18, 19, and 20). Air filters are tested in accordance with the American Society of Heating, Refrigerating and Air-Conditioning Engineers (ASHRAE) standards (Reference 21).

Housings and ductwork are leak-tested in accordance with the Sheet Metal and Air Conditioning Contractors' National Association (SMACNA) technical manual "HVAC Air Duct Leakage Test Manual" (Reference 22), American Society of Mechanical Engineers, ASME N510 (Reference 23), ASME AG-1 (Reference 24), and RG 1.52 (Reference 25).

Heaters are tested in accordance with ASME AG-1, Section CA (Reference 24).

Emergency filtration units are tested by manufacturer for housing leakage, filter bypass leakage and airflow performance. Periodically and subsequent to each filter or adsorber material replacement, the unit is inspected and tested in-place in accordance with the requirements of RG 1.52 (Reference 25), ASME N510 (Reference 23) and ASME AG-1 (Reference 24). The charcoal adsorber samples are tested for efficiency in accordance with RG 1.52 (Reference 25) and ASTM D3803 (Reference 26). Air filtration and adsorption unit heaters are tested in accordance with ASME N510 (Reference 23).

Periodic testing and inspections identify systems and components requiring corrective maintenance, and plant maintenance programs correct deficiencies.

In-service test program and test frequency requirements are described in Section 16, "Technical Specification" Subsections 3.6.6, 3.6.7 and per Ventilation Filter Test Program (VFTP) described in Section 16, "Technical Specification" Subsection 5.5.10.

6.2.3.5 Instrumentation Requirements

Indication of the operational status of the AVS equipment, position of dampers, instrument indications and alarms are provided in the MCR. Fans, motor-operated dampers, and heaters are operable from the MCR. Local instruments are provided to measure differential pressure across filters, flow, temperature and pressure. The fire detection and sensors information is delivered to the fire detection system. The radiation instrumentation requirements for controlling airborne radioactivity releases via the vent stack are addressed in Section 11.5.

The minimum instrumentation, indications, and alarms for the AVS ESF filter systems is provided in Table 6.2.3-3 per the requirements of ASME N509 (Reference 27).

I

Design Feature	Value
Maximum annulus pressure during normal operation ²	< -0.8 inches water gauge
Maximum annulus pressure during postulated accidents ²	≤ -2.5 inches water gauge
Minimum annulus temperature (all modes)	45°F
Maximum relative humidity at iodine filters (postulated accident)	70%
Design pressure	2.77 inches water gauge
Design temperature	212°F
Electrical heater power (each train)	6 kW
Minimum rated efficiency – Pre-filter	55-65%
Minimum rated efficiency – HEPA filters	99.95%
Minimum rated efficiency – Iodine adsorbers ¹	99%
Fan design air flow	60 – 1177 cfm

Table 6.2.3-1—Design and Performance of Annulus Ventilation System

Note:

- Laboratory test results for both elemental iodine and organic iodine, based on four (4) inch deep bed of carbon.
- 2. The subatmospheric pressure in the annulus will be equal to or lower than the value listed.

Design Feature ³	Value	
Annulus temperature	Initial	86.6°F
	After 24 hours	< 92°F
Annulus pressure	Start of drawdown	0.44 inches water gauge
	At 305 seconds	-0.25 inches water gauge
	After 565 seconds	≥ -2.5 inches water gauge
Annulus volume	Initial	706,299 ft ³
	After compression and at start of drawdown analysis	704,737 ft ³
Heat transfer coefficients ^{1, 2}	N/A ⁴	
Conductive heat transfer ¹	N/A ⁴	
Radiant heat transfer ¹	N/A ⁴	
Compressive effect of primary containment ¹	Volume reduction of 1556 ft ³	
Secondary containment in-leakage assumed ¹	0.25% of containment free volume per day	
Secondary containment out-leakage assumed 1	Zero leakage out of the secondary containment	
Heat loads generated within annulus ¹	Negligible	

Table 6.2.3-2—Secondary Containment Response Analysis

Notes:

- 1. During postulated accident in primary containment.
- 2. Heat transfer calculated by methods provided in BTP 6-2.
- 3. Secondary containment response analysis based on worst single failure.
- 4. An infinite heat transfer coefficient was assumed such that the surface temperature in contact with primary containment is at the design maximum value from time zero.

Table 6.2.3-3—Instrumentation, Indication, and Alarm Features for AVS (Accident Filtration Trains)

Sensing Location	Local Indication / Alarm	MCR Indication / Alarm
Unit Inlet Moisture Separator	Pressure Drop Indication	
Electric Heater Inlet	Temperature Indication	
Electric Heater	Status Indication	Status Indication
Electric Heater Outlet	Temperature Indication	Temperature Indication / High Temperature Alarm
Prefilter	Pressure Drop Indication / High Alarm	
Upstream-HEPA	Pressure Drop Indication / High Alarm	
Adsorber	Pressure Drop Indication / High Alarm	
Adsorber Outlet	Temperature Indication	Temperature Indication / High Temperature Alarm
Post-filter	Pressure Drop Indication / High Alarm	
System Filters Inlet to Outlet		Summation of pressure drop across entire filtration train (Indication / High Pressure Drop Alarm)
Fan	Pressure Drop Indication	Handswitch / Status Indication
Damper / Operator	Position Indication	Position Indication
Unit Outlet	Flow Rate Indication	Flow Rate (recorded indication, high alarm signal)
Unit Outlet	Radiation Indication	Radiation Indication / High Radiation Alarm
