I. DESCRIPTION

NRC Form 366A (9-83)

> On July 5, 1989, with the plant operating at 100% power, the Reactor Core Isolation Cooling (RCIC) (EIIS System Code BN) inboard isolation valve (BN-ISV-2400, DAEC M02400) closed following receipt of the "B" logic isolation signal. The isolation signal was generated during performance of the RCIC Steam Leak Detection System (SLDS) (EIIS System Code JM) Surveillance Test Procedure (STP) at 1642 hours following lifting of input leads to a temperature switch (JM-TDS-2450B, DAEC TDS2450B). Prior to lifting instrument input leads the Instrument Technician working the STP failed to put the appropriate keylock test switch in the test position. This allowed the temperature switch to feed a trip signal to the downstream trip logic when the input leads were lifted.

II. CAUSE OF EVENT:

The root cause of this event was personnel error on the part of the utility apprentice instrument technician who lifted the temperature switch input leads prior to completing the procedure steps which place the appropriate keylock test switch in the test position. A major contributing factor in this event was a communication error between the journeyman instrument technician and the apprentice. Prior to momentarily leaving the area the journeyman instructed the apprentice to re-terminate the input leads on the instrument they had just finished calibrating and de-terminate the input leads on the next instrument. What had been intended by this statement was "complete the STP steps up to and including the step which de-terminates the next instrument." What was actually performed was de-termination of the next instrument on the Temporary Modification Clearance Form immediately following re-termination of the previously worked instrument. Another contributing factor was the fact that the apprentice, although trained in general on performing STPs, had not performed this specific test previously.

III. ANALYSIS OF EVENT:

This event had no effect on the safe operation of the plant. The isolation of RCIC was immediately identified and the appropriate actions were taken. The RCIC isolation valve responded as expected to the inadvertent isolation signal. During any other plant conditions this event would have had no effect on the safe operation of the plant as the RCIC system could rapidly be unisolated and put into service if required. In addition, no credit is taken for RCIC performance in the DAEC Emergency Core Cooling System analysis.
