1.0 INTRODUCTION

This report has been prepared in response to the Nuclear Regulatory Commission (NRC) Safety Evaluation Report (SER) [1], concerning environmental qualification of safety related equipment for the Monticello Nuclear Generating Plant. This report addresses all concerns identified by the NRC in the Monticello SER.

The Equipment Qualification Branch of the Office of Nuclear Reactor Regulation, Nuclear Regulatory Commission (NRC), has required all licensees of operating reactors to submit a re-evaluation of the qualification of safety related electrical equipment which may be exposed to a harsh environment. This requirement was implemented primarily by the issuance, on January 14, 1980, of IE Bulletin No 79-01B [10] with subsequent clarifying supplements in February, September, and October, 1980.

The Bulletin required that a master list of safety related systems and equipment be generated, all accident service conditions be defined, and the equipment be evaluated in accordance with guidelines in the Bulletin.

Northern States Power Company has provided three responses to the Bulletin in May 1980, August 1980 and November 1980. The May 27, 1980 response included identification and evaluation of safety related electrical equipment. In particular, the environments for equipment outside containment were identified and a general plan was developed to complete the qualification of equipment.

The August 27, 1980 response incorporated newly acquired qualification data. Additionally the normal and accident environments for equipment both inside and outside containment were finalized. The November 1, 1980 response [2] summarized additional evaluations that had been performed. This response completely superceded all previous responses. Also, plans were described, which had been developed to assure the qualification of equipment identified as having "outstanding items."

On June 3, 1981, the NRC issued the Monticello Nuclear Generating Plant Safety Evaluation Report (SER) [1], which summarized their assessment of the November 1, 1980 response and also requested additional information. A summary of all Monticello Nuclear Generating Plant environmental qualification activities is provided in this report.

This response incorporates newly acquired equipment qualification data. All remaining outstanding items have also been identified and plans developed for their resolution. Plans are described to establish necessary maintenance and surveillance programs to identify age degraded equipment. Also, justification for continued operation of the Monticello Plant is provided.

All work concerning the evaluation and response to evaluation deficiencies of environmental qualification have been fully documented in accordance with the procedures and requirements of the EDS Quality Assurance Program, so as to provide an auditable package. This program complies with 10CFR50, Appendix B, ANSI N45.2 and applicable daughter standards.

2.0 SUMMARY

This document summarizes the evaluation of environmental qualification of safety related electrical equipment performed in response to IE Bulletin No 79-01B. It provides documentation of the Environmental Qualification Program that is being undertaken by Northern States Power Company. The program ensures that all safety related equipment is capable of performing its safety related function during postulated accident conditions.

The present status of the evaluation is as follows:

- All safety related plant systems have been identified.
- The safety related electrical equipment in these systems has been identified.
- Equipment qualification service conditions have been developed for all areas of the plant.
- Information sources have been contacted in order to obtain qualification documentation.
- Type-test reports have been received for most safety related components. This data has been evaluated for compliance with the required qualification standards.
- A summary of the current evaluation status of all equipment for which qualification documentation has been obtained is presented.
- Responses to all deficiencies identified in the SER are presented.
- Corrective action plans to resolve any remaining outstanding qualification items are presented. These plans are currently being implemented by Northern States Power.

This report is submitted as a final response to the NRC Safety Evaluation Report concerning environmental qualifications to safety related electrical equipment at Monticello.

3.0 GENERAL CONCERNS

Section 3.0 of the Safety Evaluation Report [1] identified various general concerns. The following present our responses to these concerns.

3.1 Safety Related Equipment List

The NRC staff's review of the Safety Related Equipment List determined that the equipment list provided by Northern States Power was acceptable with one exception. The exception was that a complete list of all display instrumentation mentioned in the LOCA and HELB Emergency Procedures was not provided. Display instrumentation is discussed in Section 3.1.1.

Subsequent to the previous IE Bulletin 79-01B submittal for Monticello [2], the Safety Related Equipment List was reevaluated. The review determined that some components could be deleted from the list of equipment required to function in harsh environments. Deleted equipment is discussed in Section 3.1.2.

3.1.1 Display Instrumentation

Display instrumentation mentioned in the Monticello LOCA and HELB emergency procedures and subject to harsh environmental conditions was included in our November 1, 1980 submittal [2]. Each item was listed with its appropriate system. For clarity, these items are listed in Table 3-1 by system, plant ID number, and function. For consistency, the component evaluation worksheets for these instruments are included in their appropriate system.

3.1.2 Deleted Equipment

A review of the safety related equipment list for Monticello indicated that various components in three systems could be deleted from the list of equipment requiring qualification to harsh environmental service conditions. It was determined that various components in the following systems could be deleted.

1. Reactor Core Isolation Cooling System (RCIC)
2. Containment System
3. Nuclear Boiler Vessel Instrumentation System

Equipment deleted from these systems is discussed below.

3.1.2.1 Reactor Core Isolation Cooling System

In our previous submittal [2] the limiting accident in the RCIC Room was assumed to be a RCIC steamline break. A review of FSAR [6] Section 7.2.3.2 determined that a RCIC steamline break would disable the RCIC system due to initiation of the RCIC steamline isolation by the RCIC system temperature sensors in either the RCIC room or the torus compartment. The other HELB that could possibly affect the RCIC room is a HPCI steamline break in the torus compartment. However, this break will also disable the RCIC system due to steamline isolation by the RCIC system temperature sensors in the torus area. Therefore, qualification of the equipment listed in Table 3-2 for the environment resulting from a HELB is not required.

Also, in the FSAR analysis, the equipment in Table 3-2 was not assumed to operate to mitigate the consequences of a LOCA. Therefore, qualification to LOCA induced environmental conditions such as radiation is not required.

The previous discussion indicates that the equipment listed in Table 3-2 is not required to be qualified to harsh environmental conditions. This equipment is now considered to be located in a mild environment and will be included in the mild environment equipment qualification evaluation.

Level transmitters LT 1358 and LT 1359 provide indication of condensate storage tank level. Operator use of these non-safety related instruments has been reviewed. It was determined by Northern States Power that post-accident failure would not mislead the operator. Therefore, qualification of these instruments is not required. This position is consistent with the requirements of Reg. Guide 1.97, Revision 2 [9], in which these instruments are identified as Category 3.

3.1.2.2 Containment System

Level transmitter LT 2996 provides indication of Torus water level. As dictated by TMI lessons learned requirements, qualified wide range Torus level transmitters (LT 7338A,B) have been installed. Because these new instruments provide the same indication function as LT 2996, they will supercede this instrument on the safety related equipment master list. Therefore, qualification of LT 2996 is not required and it has been deleted from the response.

3.1.2.3 Nuclear Boiler Vessel Instrumentation

Level transmitters LT 6-52A,B provide indication of reactor water level. Operator use of the information provided by these level transmitters has been reevaluated. It was determined that the same information provided by LT 6-52A,B is provided by redundant level transmitters LITS 2-3-59A,B. Therefore, qualification of LT 6-52A,B is not required and they have been deleted from the response.

3.2 Service Conditions Inside Containment

The NRC staff identified four service conditions inside containment that were considered deficient or required further justification. These service conditions are as follows:

1. Pressure Conditions
2. Temperature Conditions
3. Chemical Spray
4. Radiation Conditions

The NRC staff identified the reported submergence condition inside containment as being acceptable. These five service conditions are discussed below.

3.2.1 Pressure Conditions

The containment pressure profile in the FSAR was confirmed in the Mark 1 Containment Program plant unique load definition report for Monticello [3]. Calculation techniques used in this analysis are described in the Mark 1 Containment Program Load Definition Report [4] and are equivalent to those used in GESSAR Appendix 3B. These techniques were accepted by the NRC in the Safety Evaluation Report, Mark 1 Containment Long-Term Program, NUREG 0661 [5].

For the Monticello plant, the plant unique Mark 1 containment load analysis of drywell pressure predicts a peak of 41.1 psig, which is consistent with the value of 41.5 psig used for equipment qualification. Additionally, the peak calculated drywell temperature during the LOCA is 282°F, which compares favorably with the 289°F reported to the NRC.

The previous discussion justifies our use of FSAR Figure 5-2-14, Containment Pressure Response, for equipment qualification. The pressure profile used

for equipment qualification inside containment is shown in Figure B.1, of Appendix B. Temperature conditions are discussed below.

3.2.2 Temperature Conditions

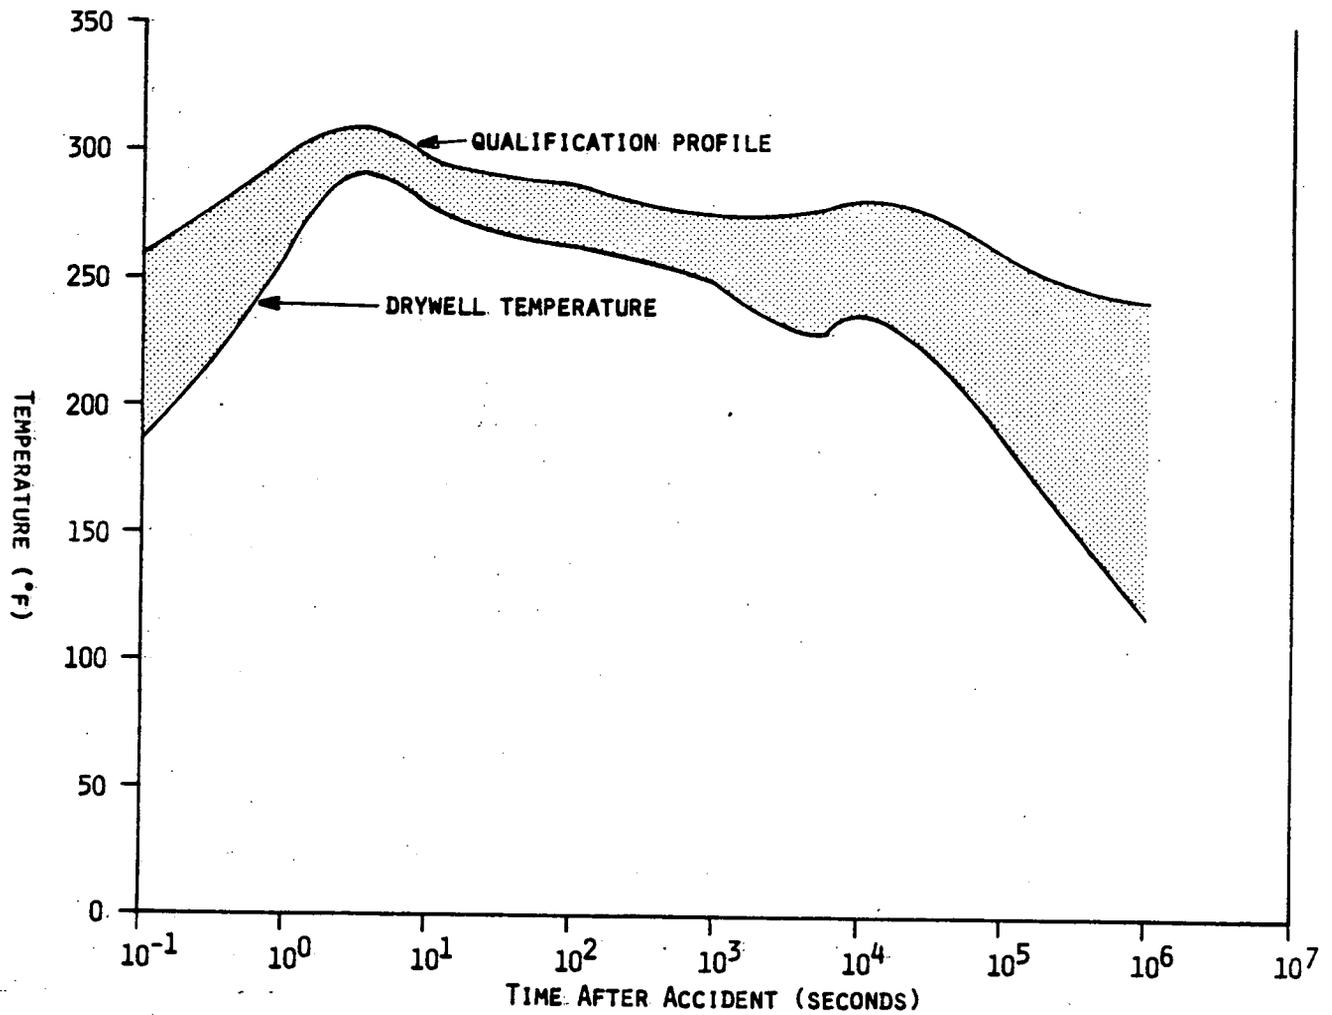

The NRC staff concluded that the minimum temperature profile for equipment qualification should include a margin to account for analytical uncertainties in the calculated temperature profiles for postulated accidents. A margin of 20°F above steam saturation temperature is considered to be appropriate for either a postulated LOCA or MSLB, whichever is controlling as to potential adverse environmental effects on equipment.

The limiting accident inside containment analyzed in the FSAR is a double ended recirculation line break. The pressure response for this accident is shown in FSAR 5-2-14 [6]. The calculated temperature response for this accident is shown in FSAR Figure 5-2-15 [6] and was used for equipment qualification. To satisfy the new NRC temperature margin requirement a new temperature profile was used. This new profile is the steam saturation temperature plus 20°F corresponding to the pressure curve shown in FSAR Figure 5-2-14 [6]. Figure 3-1 illustrates the temperature margin resulting from the new temperature profile. The temperature profile used for equipment qualification inside containment is shown in Figure B.1, of Appendix B.

3.2.3 Chemical Spray

In our previous submittal [2], the containment spray system was not considered safety-related and credit for its use was not taken in the analysis. The NRC staff concluded that because the system is available and could be used, any equipment upon which the spray impinges must be qualified for the spray parameter.

FIGURE 3-1

To satisfy the chemical spray requirement, all components located inside containment were reevaluated. All equipment potentially impinged by the spray solution of demineralized water were determined to be qualified for this condition.

3.2.4 Radiation Conditions

During the environmental equipment qualification meeting in Bethesda, July 7 through 10, 1981, the NRC staff presented their "screening value" for radiation service conditions inside containment. The staff's screening value was 4.0×10^7 Rads of gamma plus beta radiations. This new radiation requirement includes the 2.0×10^7 Rad accident gamma dose previously provided in the DOR Guidelines [10] plus an assumed 2.0×10^7 Rad normal gamma and accident beta dose.

The radiation condition used in our previous submittal [2] for equipment qualification inside containment was a maximum accident dose of 3.3×10^7 Rads Gamma. However, lower doses were specified for equipment with shorter operating time requirements. The radiation specification of 3.3×10^7 Rads used in our previous submittal was determined using the assumptions presented in TID 14844 and compares favorably with the new NRC screening value. Therefore, we feel this specification is adequate and the gamma radiation specifications inside containment have not been revised.

However, the radiation service conditions inside containment have been revised to account for beta radiation. As indicated in the DOR Guidelines [10], an unshielded surface beta radiation dose of 2.0×10^8 Rads was assumed. The beta radiation was considered simultaneously with the previously described gamma radiation. All equipment potentially exposed to the beta radiation has been reevaluated. The results of these reevaluations are included on the component evaluation worksheets in Appendix C of this report.

3.2.5. Submergence

Our previous submittal [2] identified a flood elevation of 922 ft. inside containment. No equipment inside containment was found to be subject to submergence. The NRC staff found this acceptable.

3.3 Service Conditions Outside Containment

3.3.1 Thermal Hydraulic Conditions

Temperature, pressure and relative humidity conditions as a result of a High Energy Line Break (HELB) outside containment were previously submitted for the following plant areas:

1. Steam Chase
2. Turbine Building
3. Torus Compartment
4. HPCI Room
5. RCIC Room
6. RHR Rooms
7. RWCU Pump Room
8. RWCU Heat Exchanger Room
9. Open Space at Elevations 935 ft. and 962 ft. 6 in.

The environmental service conditions provided for these areas were deemed acceptable by the NRC staff.

The thermal hydraulic service conditions have been reevaluated for many areas of the Monticello Plant. The open spaces at elevations 935 ft. and 962 ft. 6 in. were modeled in more detail. This effort was performed in order to more accurately

define the required accident service conditions for future equipment installation, relocation and replacement.

The results of the refined thermal hydraulic analyses are presented in Reference 7. Plant layout drawings depicting the layout of thermal-hydraulic control volumes for the environmental analyses are shown in Figures B.18 through B.21, of Appendix B.

In addition, the environmental conditions in the HPCI room due to a RCIC steamline break in the torus compartment were analyzed. The results of this analysis are presented in reference 8.

The temperature and pressure profiles used for equipment qualification outside containment are shown in Figure B.2 through B.17, of Appendix B. The post accident relative humidity condition for each of these locations is assumed to be 100% as indicated on the Component Evaluation Worksheet.

3.3.2 Submergence

Flooding analyses in support of our equipment qualification efforts identified the following flood elevations for areas outside containment:

1. HPCI Room: 4 feet above floor
2. Steam Chase: 4 feet above floor

No equipment outside containment required to operate during submerged conditions was identified. The NRC staff found this acceptable.

3.3.3 Radiation

The radiation conditions for equipment located outside containment were deemed acceptable by the NRC staff. Therefore, no changes were required in the radiation levels for equipment outside containment.

However, the radiation levels specified in our previous submittal [2] for the Standby Gas Treatment (SBGT) Room did not account for the distance from the radiation source to each component. This resulted in overly conservative radiation specifications for many components. The radiation conditions have been reevaluated for the SBGT room in Reference 11. This reevaluation resulted in more accurate radiation specifications for equipment in this room. The appropriate radiation specification from this analysis is given on the SBGT system Component Evaluation Worksheets.

3.4 Aging

When Northern States Power Company received their operating license for Monticello, aging was not required for equipment qualification. Therefore, aging was not addressed in the original equipment qualification efforts.

The DOR Guidelines presented in the IE Bulletin No. 79-01B [10] required that component aging be addressed in the evaluation of equipment qualification. While the DOR Guidelines do not require a qualified life be established for all safety related equipment, the following actions are required:

1. Make a detailed comparison of existing equipment and the materials identified in Appendix C of the DOR Guidelines. The first supplement to IEB 79-01B requires licensees to utilize the table in Appendix C and identify any additional materials as the result of their effort.

2. Establish an ongoing program to review surveillance and maintenance records to identify potential age related degradations.
3. Establish component maintenance and replacement schedules which include considerations of aging characteristics of the installed components.

At this time, efforts required by Action Item (1) have been completed. An extensive amount of manpower was spent in these efforts. Although primary emphasis was placed on evaluating the affects of thermal aging, other significant aging mechanisms were addressed. The following steps were involved in performing the aging evaluations:

1. Identify the potentially age susceptible subcomponents of an equipment item. This was done by listing all non-metallic parts. It was assumed that metallic components were not susceptible to significant age related degradation.
2. Identify the specific non-metallic component materials. In most cases, a bill of materials provided by the equipment vendor defined these materials. However, many components were of a vintage such that the vendor could not accurately identify the actual materials of construction. In these cases, typical materials used in similar applications were listed and the material most susceptible to aging was assumed.
3. Identify aging properties of the previously identified materials. This involved an extensive literature search. Data sources included:
 - a. Appendix C of the DOR Guidelines
 - b. Material Manufacturer Information
 - c. EPRI Report No. NP-1558
 - d. U.L. Temperature Ratings
 - e. Test Lab Data
 - f. Other Sources

The data was reviewed to determine whether it applied to the geometry (i.e., bulk, thin film, etc.) and material property of concern, such as retention of elongation for a cyclic diaphragm. The aging data utilized incorporated conservative definitions of material failure relative to retention of a critical property.

4. Determine susceptibility to age related degradation. The literature search indicated that certain materials, such as thermosetting plastics and silicons, were not susceptible to significant thermal degradation. This determination was made only when adequate basis was present in the literature. It should be noted that this conclusion was made for very few materials.

The Arrhenius Model was used to evaluate the affects of thermal aging for materials that were determined to be potentially susceptible to significant thermal degradation. The Arrhenius evaluations extrapolated test conditions and published materials information to determine a qualified life for a material in a certain application. Conservatism was included in all Arrhenius calculations in the following manner:

- a. The lowest listed apparent activation energy for a material was used unless a specific justification for a higher value was provided.
- b. A conservatively high normal operating temperature was used to calculate a qualified life.
- c. A conservative activation energy of 0.5 eV was assumed for materials where adequate aging data was unavailable.
- d. A conservatively high material temperature was assumed when evaluating equipment that generate heat such as solenoids and motors.

5. Evaluate effect of material degradation. When a qualified life for a material was less than required, the affect of the material failure was evaluated. If it was determined that failure of this material or subcomponent would not affect the functionability of the component, this material was no longer considered the limiting material and the next most limiting material was used to establish the qualified life. An example of this situation would be a cover gasket on a component not subject to harsh temperature, pressure or relative humidity conditions. In this situation, failure of the cover gasket due to age related degradation would not have a deleterious affect on the component's functionability.

Also, for equipment exposed to zero or small accident temperature transients, the normal age related degradation will not be significantly accelerated during post accident conditions. Therefore, catastrophic failure due to thermal aging under these circumstances is very unlikely.

4.0 COMPONENT DEFICIENCIES

Section 4.0 of the Safety Evaluation Report [1] separated the safety related equipment into three categories. These three categories are discussed below:

4.1 Equipment Requiring Immediate Action

No safety related equipment at Monticello was included in this category.

4.2 Equipment Requiring Additional Information

Appendix B of the Safety Evaluation Report [1] lists equipment requiring additional information and/or corrective action. Ninety six percent of the safety related equipment in the previous submittal [2] was included in this category. Various deficiencies were identified for these components.

Information obtained during the Environmental Equipment Qualification meeting in Bethesda, Maryland, through discussions with the NRC, and by reviewing the identified deficiencies against the Component Evaluation Worksheets indicates that only additional information is required. We have attempted to identify what additional information was necessary by a component by component comparison of the Component Evaluation Worksheets and the identified deficiency. This additional information is included on the revised worksheets included in Appendix C of this report.

4.3 Equipment Considered Conditionally Acceptable

Appendix C of the Safety Evaluation Report [1] lists equipment considered conditionally acceptable. All equipment listed in the category have aging identified as the only deficiency.

Because the number of components in this category is small and the aging deficiency is not significantly different than those discussed in Section 4.2, the revised Component Evaluation Worksheets for these components are included in Appendix C of this report. The additional information describing each aging evaluation is included on the worksheets.

5.0 CORRECTIVE ACTIONS

Corrective actions required to resolve outstanding items identified during the equipment qualification evaluations have been developed. These corrective actions are discussed below.

5.1 Component Specific Items

Component specific corrective action plans have been developed to resolve outstanding qualification items. The corrective action plans include the following:

1. Component Replacement
2. Component Relocation
3. Component Modification
4. Component Testing

The specific action plan for each component is indicated on the component evaluation worksheets included in Appendix C.

5.2 Aging

The NRC staff requested additional information regarding aging of all safety related equipment. Section 3.4 of this report describes the analysis methods used to address the aging requirement.

As required by the NRC, a program is being established at Monticello to review component maintenance and surveillance records to identify potential age related degradations. Information obtained from this review program and the specific component aging analyses is being incorporated into existing component maintenance and replacement schedules.

Maintenance and surveillance procedures currently in effect track the degradation of many components. Also, replacement schedules exist for components with known aging problems. These procedures are being reviewed to determine the impact of the recently compiled and ongoing aging evaluations being performed by Northern States Power Company. Component specific maintenance and surveillance procedures will be modified or developed as required by our evaluations.

6.0 JUSTIFICATION FOR CONTINUED OPERATION

Justification for continued plant operation has been provided for all components for which complete qualification documentation could not be obtained. These justifications are found as notes to the applicable Component Evaluation Worksheets included in Appendix C.

For components where no environmental test data has been found, justification is based on discussions with the vendor, review of the materials of construction, design specifications, operating experience and similarity to qualified equipment. Additionally, when applicable, justification included consideration of the distance between the equipment and the location of the postulated HELB and the availability of redundant qualified equipment.

Temperature Exposure

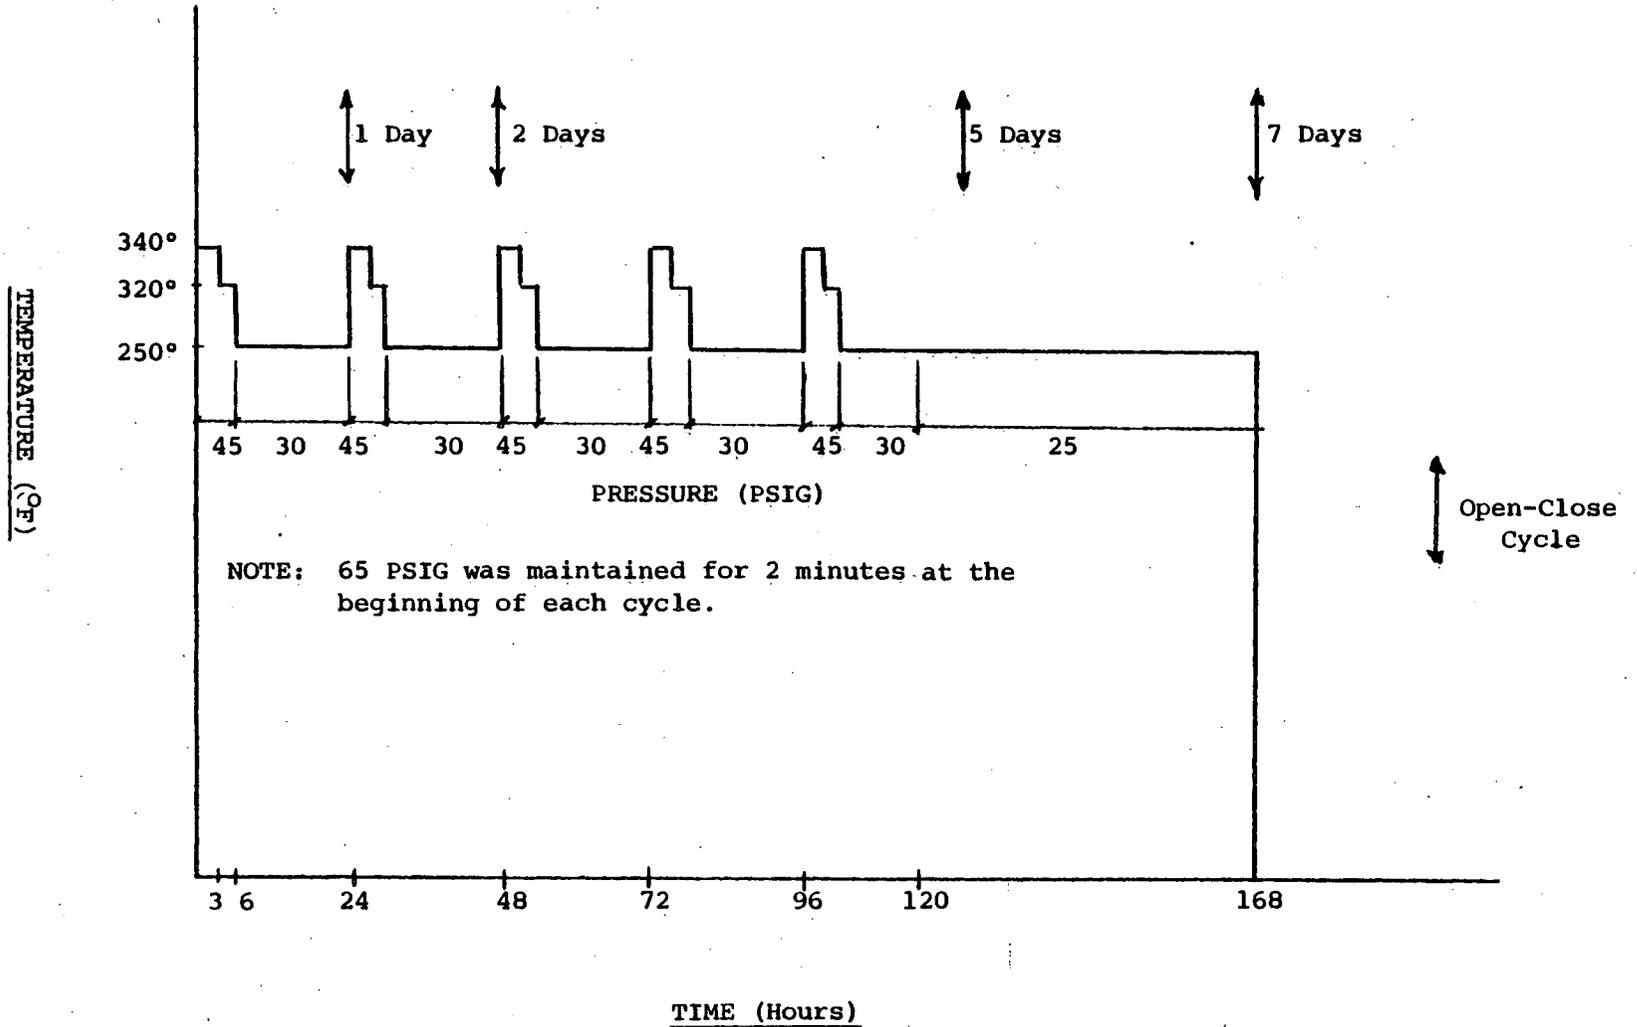

The following is a tabulation of total temperature exposure above 250°F commenced on August 27, 1970 on the Automatic valves.

- a. Time above 250°F: 9.3 hours
- b. Time above 310°F: 5.5 hours
- c. Time above 340°F: 3.3 hours

Saturated steam conditions were maintained during the test.

TEMPERATURE AND PRESSURE PROFILE

LIMITORQUE VALVE ACTUATORS-FRANKLIN REPORT F-C3117

NOTES

1. In the FSAR, aging was not considered an environmental parameter. The effect of aging on this equipment has been evaluated as required by Action Item 4 of IE Bulletin 79-01B.
2. Through vendor correspondence, similarity of these valve operators to radiation qualified operators was established. Also, all radiation susceptible materials in this equipment were identified. A literature search was then performed and the results indicated that all identified materials have radiation thresholds greater than the radiation dose specified for this equipment.
3. All materials in this equipment susceptible to thermal aging were identified. A literature search was performed to identify the thermal properties of these materials. The Arrhenius method was then used in conjunction with these properties to extrapolate existing test results to encompass the specification temperature.

NOTES	NOTES	CORRECTIVE ACTION
<p>1. In the FSAR, aging was not considered an environmental parameter. The effect of aging on this equipment has been evaluated as required by Action Item 4 of IE Bulletin 79-01B.</p> <p>2. For this qualification to completely apply, the mercury switches within these models must be replaced with snap switches. However, the mercury switches have qualified to similar environmental conditions.</p> <p>3. In FSAR Section 14-10.1.3, the post-accident cooling capability is evaluated for 180 days. This equipment could be required to operate for that period.</p> <p>4. All materials in this equipment susceptible to thermal aging were identified. A literature search was performed to identify the thermal properties of these materials. The Arrhenius method was then used in conjunction with these properties to extrapolate existing test results to encompass the required operating time, including margin.</p>	<p>5. The level switch housing is not sealed. Therefore, no significant pressure differential will exist across the switch housing. The pressure transient of 0.6 psi is sufficiently short as not to impair the integrity of the mercury switch in this equipment. No credible failure mode of the mercury switch has been demonstrated for pressures of this magnitude. Therefore, engineering judgement indicates that these components are qualified for the pressure condition.</p> <p>6. All radiation susceptible materials in this equipment were identified. A literature search was then performed and the results indicated that all identified materials have radiation thresholds greater than the radiation dose specified for this equipment.</p> <p>7. All materials in this equipment susceptible to thermal aging were identified. A literature search was performed to identify the thermal properties of these materials. The Arrhenius method was then used in conjunction with these properties to extrapolate existing test results and demonstrate that none of these materials are susceptible to significant thermal degradation at the specific temperature.</p>	<p>Replacement of the mercury switches will be evaluated.</p> <p><u>JUSTIFICATION FOR CONTINUED OPERATION</u></p> <p>Yarway Instruments with identical mercury switches have been qualified by testing. Engineering judgement based on previous testing, discussions with the vendor and the materials of construction indicate that this component is qualified for the specified environmental conditions.</p>

NOTES

1. In the FSAR, aging was not considered an environmental parameter. The effect of aging on this equipment has been evaluated as required by Action Item 4 of IE Bulletin 79-01B.
2. No specific operating time requirement is available for this equipment. The operating time specification was derived from LOCA and HELB analyses.
3. The penetration of the switch housing is sealed with electrical conduit. The switch case is rated NEMA 4 and has sufficiently small surface area such that the effect of the 0.6 psig pressure transient is negligible.

NOTES

4. All radiation susceptible materials in this equipment were identified. A literature search was then performed and the results indicated that all identified materials have radiation thresholds greater than the radiation dose specified for this equipment.
5. All materials in this equipment susceptible to thermal aging were identified. A literature search was performed to identify the thermal properties of these materials. The Arrhenius method was then used in conjunction with these properties to extrapolate existing test results to encompass the specification temperature.

NOTES	NOTES	REFERENCES (Continued)
<p>1. In the FSAR, aging was not considered an environmental parameter. The effect of aging on this equipment has been evaluated as required by Action Item 4 of IE Bulletin 79-01B.</p> <p>2. No operating time is available for this equipment. Specification derived from HELB Analysis Report "Postulated Pipe Failures Outside Containment," submitted by letter to A. Grambusso (AED) by C. E. Ward (NSP), dated September 7, 1973.</p> <p>3. Engineering Analysis was used to supplement test data. Analysis showed that pressure transients of this magnitude are not a credible failure mode. Therefore, the pressure condition is satisfied.</p>	<p>4. All materials in this equipment susceptible to thermal aging were identified. A literature search was performed to identify the thermal properties of these materials. The Arrhenius method was then used in conjunction with these properties to extrapolate existing test results to encompass the specification temperature.</p>	<p>4. Temperature Exposure

The following is a tabulation of total temperature exposure above 250°F commended on August 27, 1970 on the Automatic Valves.

- a. Time above 250°F: 9.3 hours
- b. Time above 310°F: 5.5 hours
- c. Time above 340°F: 3.3 hours

Saturated steam conditions were maintained during the test.

TEMPERATURE AND PRESSURE PROFILE

TEST PROFILE FOR ASCO HVA-90

NOTES

1. In the FSAR, aging was not considered an environmental parameter. The effect of aging on this equipment has been evaluated as required by Action Item 4 of IE Bulletin 79-01B.
2. The operating time requirement was derived from LOCA and HELB analyses. No specific specification is available for this equipment.
3. Engineering analysis was used to evaluate pressure qualification of this valve. The maximum pressure rise experienced by this valve during normal or accident is 0.4 psig for less than 5 seconds. No credible failure mode due to a pressure of this magnitude is expected.

NOTES

4. All radiation susceptible materials in this equipment were identified. A literature search was then performed and the results indicated that all identified materials have radiation thresholds greater than the radiation dose specified for this equipment.
5. Operating experience, as outlined in NRC Bulletins 78-14, indicates that the life of the limiting material, BUNA 'N' to be 7 years. A regular replacement schedule for these materials has been established to insure that they remain in proper operating condition throughout their 40-year design life.

NOTES

1. In the FSAR, aging was not considered an environmental parameter. The effect of aging on this equipment has been evaluated as required by Action Item 4 of IE Bulletin 79-01B.
2. No operating time is available for this equipment. Specification derived from HELB Analysis Report "Postulated Pipe Failures Outside Containment," submitted by letter to A. Grambusso (AEC) by E. C. Ward (NSP), dated September 7, 1973.
3. The instruments must function to mitigate the consequences of a LOCA inside containment. This event does not result in harsh pressure, temperature, or relative humidity conditions at the installed location.

NOTES

4. All materials in this equipment susceptible to thermal aging were identified. A literature search was performed to identify the thermal properties of these materials. The Arrhenius method was then used in conjunction with these properties to extrapolate existing test results to encompass the specification temperature.

 - EDS File No. 11, Rev. 2, "Barton Pressure Switch," Monticello Nuclear Plant, EDS Job No. 0910-001-451.

NOTES

1. In the FSAR, aging was not considered an environmental parameter. The effect of aging on this equipment has been evaluated as required by Action Item 4 of IE Bulletin 79-01B.
2. No specific operating time requirement is available for this equipment. The operating time specification was derived from LOCA and HELB analyses.
3. Engineering analysis was used to supplement test data for pressure qualification of this switch. Electrical conduit penetration effectively seals the switch housing so that internal components do not experience a pressure differential. Cases are rated NEMA 4 and have a sufficiently small surface area that the effect of an external 0.6psig pressure rise for only a few seconds is negligible. Therefore, this switch is pressure qualified.

NOTES

4. All radiation susceptible materials in this equipment were identified. A literature search was then performed and the results indicated that all identified materials have radiation thresholds greater than the radiation dose specified for this equipment.
5. All materials in this equipment susceptible to thermal aging were identified. A literature search was performed to identify the thermal properties of these materials. The Arrhenius method was then used in conjunction with these properties to extrapolate existing test results to encompass the specification temperature.

YARWAY LEVEL INDICATING SWITCH

NOTE: 100% RH WAS MAINTAINED
THROUGHOUT THE TEST

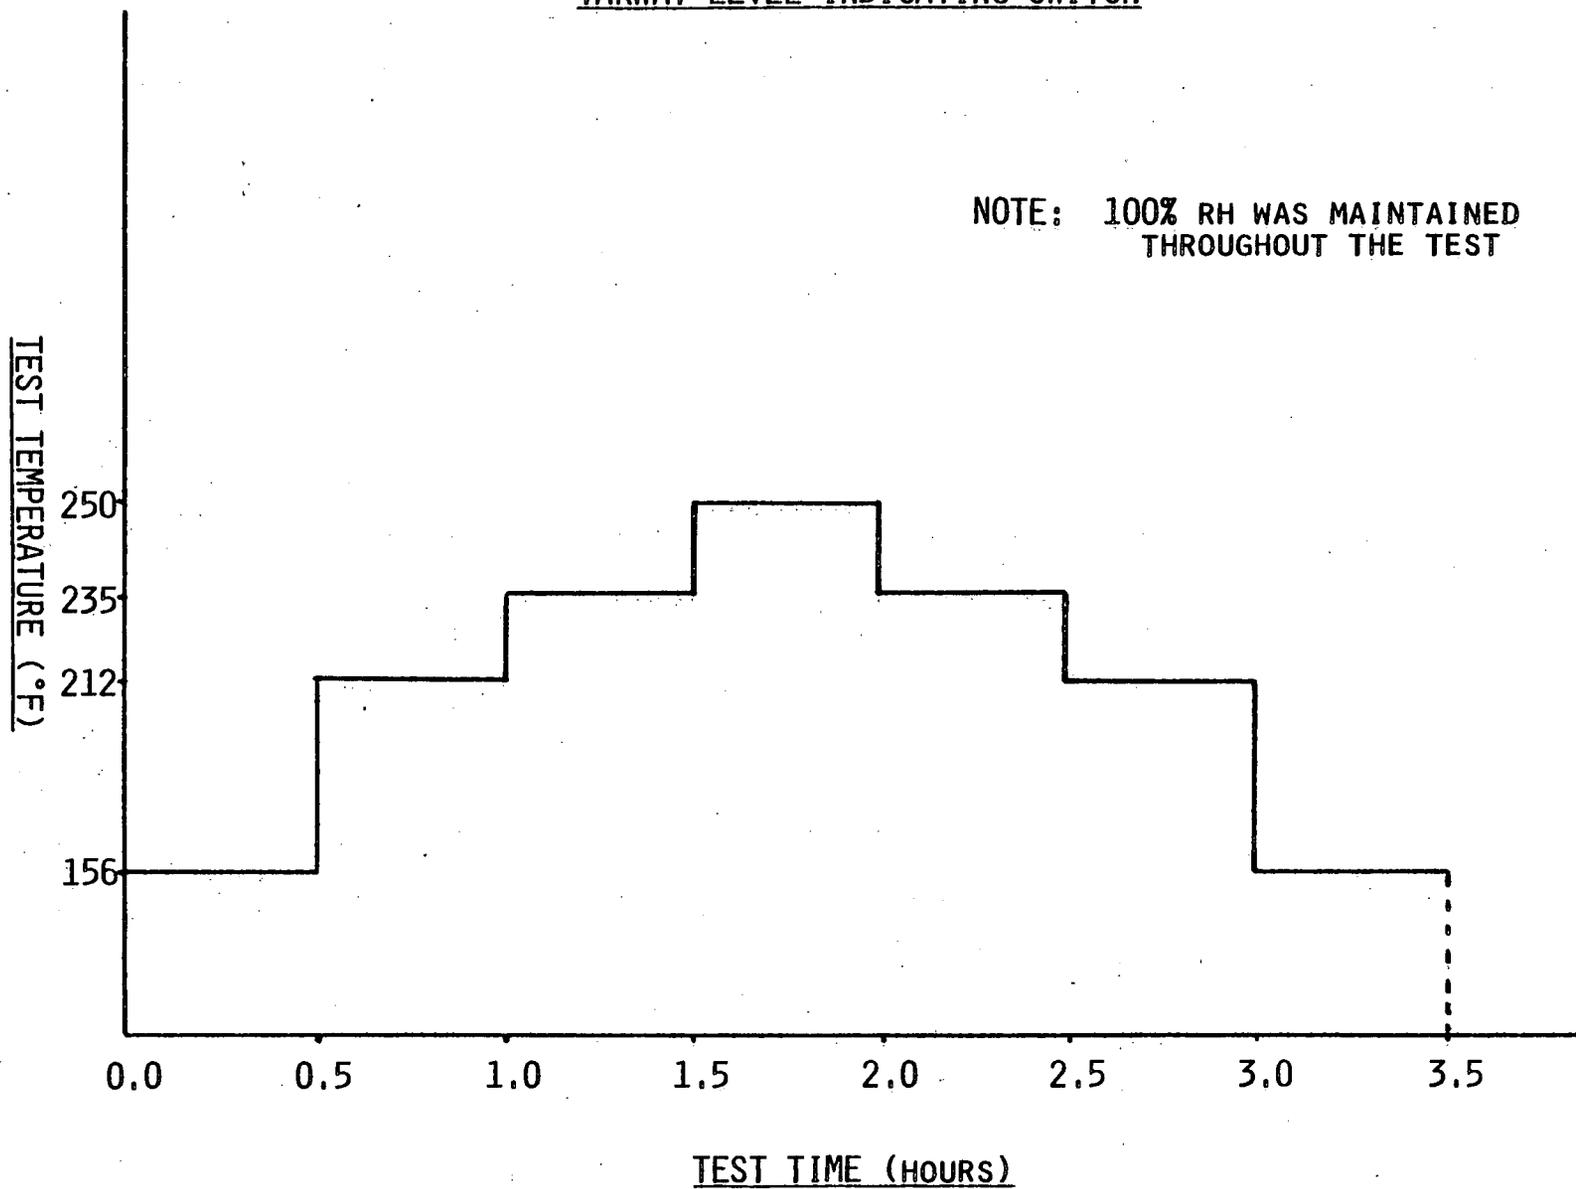

NOTES	NOTES	CORRECTIVE ACTION
<p>1. In the FSAR, aging was not considered an environmental parameter. The effect of aging on this equipment has been evaluated as required by Action Item 4 of IE Bulletin 79-01B.</p> <p>2. For this qualification to completely apply, the mercury switches within these models must be replaced with snap switches. However, the mercury switches have qualified to similar environmental conditions.</p> <p>3. In FSAR Section 14-10.1.3, the post-accident cooling capability is evaluated for 180 days. This equipment could be required to operate for that period.</p> <p>4. All materials in this equipment susceptible to thermal aging were identified. A literature search was performed to identify the thermal properties of these materials. The Arrhenius method was then used in conjunction with these properties to extrapolate existing test results to encompass the required operating time, including margin.</p>	<p>5. The level switch housing is not sealed. Therefore, no significant pressure differential will exist across the switch housing. The pressure transient of 0.6 psi is sufficiently short as not to impair the integrity of the mercury switch in this equipment. No credible failure mode of the mercury switch has been demonstrated for pressures of this magnitude. Therefore, engineering judgement indicates that these components are qualified for the pressure condition.</p> <p>6. All radiation susceptible materials in this equipment were identified. A literature search was then performed and the results indicated that all identified materials have radiation thresholds greater than the radiation dose specified for this equipment.</p> <p>7. All materials in this equipment susceptible to thermal aging were identified. A literature search was performed to identify the thermal properties of these materials. The Arrhenius method was then used in conjunction with these properties to extrapolate existing test results and demonstrate that none of these materials are susceptible to significant thermal degradation at the specific temperature.</p>	<p>Replacement of the mercury switches will be evaluated.</p> <p><u>JUSTIFICATION FOR CONTINUED OPERATION</u></p> <p>Yarway Instruments with identical mercury switches have been qualified by testing. Engineering judgement based on previous testing, discussions with the vendor and the materials of construction indicate that this component is qualified for the specified environmental conditions.</p>

LIMITORQUE VALVE ACTUATORS-FRANKLIN REPORT F-C3117

NOTES

1. In the FSAR, aging was not considered an environmental parameter. The effect of aging on this equipment has been evaluated as required by Action Item 4 of IE Bulletin 79-01B.
2. Through vendor correspondence, similarity of these valve operators to radiation qualified operators was established. Also, all radiation susceptible materials in this equipment were identified. A literature search was then performed and the results indicated that all identified materials have radiation thresholds greater than the radiation dose specified for this equipment.
3. All materials in this equipment susceptible to thermal aging were identified. A literature search was performed to identify the thermal properties of these materials. The Arrhenius method was then used in conjunction with these properties to extrapolate existing test results to encompass the specification temperature.

LIMITORQUE VALVE ACTUATORS-FRANKLIN REPORT F-C3117

NOTES

1. In the FSAR, aging was not considered an environmental parameter. The effect of aging on this equipment has been evaluated as required by Action Item 4 of IE Bulletin 79-01B.
2. Through vendor correspondence, similarity of these value operators to radiation qualified operators was established. Also, all radiation susceptible materials in this equipment were identified. A literature search was then performed and the results indicated that all identified materials have radiation thresholds greater than the radiation dose specified for this equipment.
3. All materials in this equipment susceptible to thermal aging were identified. A literature search was performed to identify the thermal properties of these materials. The Arrhenius method was then used in conjunction with these properties to extrapolate existing test results to encompass the specification temperature.

- REFERENCES:
- "Environmental Effects Due to Pipe Rupture," Monticello Nuclear Plant, EDS Report No. 01-0910-1137, Rev. 0, December 1980.
 - Monticello Nuclear Plant FSAR Table 14-10-4.

NOTES

1. In the FSAR, aging was not considered an environmental parameter. The effect of aging on this equipment has been evaluated as required by Action Item 4 of IE Bulletin 79-01B.
2. No specific operating time requirement is available for this equipment. The operating time specification was derived from LOCA and HELB analyses.
3. Engineering analysis was used to supplement test data for pressure qualification of this switch. Electrical conduit penetration effectively seals the switch housing so that internal components do not experience a pressure differential. Cases are rated NEMA 4 and have a sufficiently small surface area that the effect of an external 0.5psig pressure rise for only a few seconds is negligible. Therefore, this switch is pressure qualified.

NOTES

4. All radiation susceptible materials in this equipment were identified. A literature search was then performed and the results indicated that all identified materials have radiation thresholds greater than the radiation dose specified for this equipment.
5. All materials in this equipment susceptible to thermal aging were identified. A literature search was performed to identify the thermal properties of these materials. The Arrhenius method was then used in conjunction with these properties to extrapolate existing test results to encompass the specification temperature.
6. This component was type-tested for 6.5 hours at a maximum temperature of 212°F. The accident profile shows that temperatures in excess of the test temperature last only a few seconds and exceed it by only one degree. The thermal capacitance of the housing is sufficient to prevent the internal components from experiencing the 213°F temperature rise, therefore adequate margin exists for temperature qualification.

NOTES

1. In the FSAR, aging was not considered an environmental parameter. The effect of aging on this equipment has been evaluated as required by Action Item 4 of IE Bulletin 79-01B.
2. No specific operating time requirement is available for this equipment. The operating time specification was derived from LOCA and HELB analyses.
3. Engineering analysis was used to supplement test data for pressure qualification of this switch. Electrical conduit penetration effectively seals the switch housing so that internal components do not experience a pressure differential. Cases are rated NEMA 4 and have a sufficiently small surface area that the effect of an external 0.5psig pressure rise for only a few seconds is negligible. Therefore, this switch is pressure qualified.

NOTES

4. All radiation susceptible materials in this equipment were identified. A literature search was then performed and the results indicated that all identified materials have radiation thresholds greater than the radiation dose specified for this equipment.
5. All materials in this equipment susceptible to thermal aging were identified. A literature search was performed to identify the thermal properties of these materials. The Arrhenius method was then used in conjunction with these properties to extrapolate existing test results to encompass the specification temperature.
6. This component was type-tested for 6.5 hours at a maximum temperature of 212°F. The accident profile shows that temperatures in excess of the test temperature last only a few seconds and exceed it by only one degree. The thermal capacitance of the housing is sufficient to prevent the internal components from experiencing the 213°F temperature rise, therefore adequate margin exists for temperature qualification.

NOTES

7. Components susceptible to thermal degradation were identified and an Arrhenius calculation was performed to evaluate the equivalent operating time based on test and accident temperature profiles. The equivalent operating time of this equipment was 11 hours. This is greater than the required 10 hours, including margin.

NOTES	NOTES	
<p>1. In the FSAR, aging was not considered an environmental parameter. The effect of aging on this equipment has been evaluated as required by Action Item 4 of IE Bulletin 79-01B.</p> <p>2. In FSAR Section 14-10.1.3, the post-accident cooling capability is evaluated for 180 days. This equipment could be required to operate for that period.</p> <p>3. The Arrhenius method, in conjunction with test data, has shown that the test conditions have enveloped the operating time requirement.</p> <p>4. The Arrhenius method in conjunction with test data has provided a life for this equipment. This life will be coordinated with a surveillance and maintenance program to insure qualification is maintained for the life of the plant.</p>	<p>5. Since this motor is open and the pressure transient sufficiently short, the motor will not be subjected to a significant pressure differential which could impair its functioning.</p> <p>6. All radiation susceptible materials in this equipment were identified. A literature search was then performed and the results indicated that all identified materials have radiation thresholds greater than the radiation dose specified for this equipment.</p>

NOTES	NOTES	REFERENCES (Continued)
<p>1. In the FSAR, aging was not considered an environmental parameter. The effect of aging on this equipment has been evaluated as required by Action Item 4 of IE Bulletin 79-01B,</p> <p>2. Engineering analysis was used to supplement test data for pressure qualification of this switch. Electrical conduit penetration effectively seals the switch housing so that internal components do not experience a pressure differential. Cases are rated NEMA 4 and have a sufficiently small surface area that the effect of an external 1.8 psig pressure rise for only a few seconds is negligible. Therefore, this switch is pressure qualified.</p>	<p>3. All radiation susceptible materials in this equipment were identified. A literature search was then performed and the results indicated that all identified materials have radiation thresholds greater than the radiation dose specified for this equipment.</p> <p>4. All materials in this equipment susceptible to thermal aging were identified. A literature search was performed to identify the thermal properties of these materials. The Arrhenius method was then used in conjunction with these properties to extrapolate existing test results to encompass the specification temperature.</p> <p>5. Components susceptible to thermal degradation were identified and an Arrhenius calculation was performed to evaluate the equivalent operating time based on test and accident temperature profiles. The equivalent operating time of this equipment was 11 hours. This is greater than the required 10 hours, including margin.</p>	<p>5. NOTES	CORRECTIVE ACTION	JUSTIFICATION FOR CONTINUED OPERATION
<p>1. In the FSAR, aging was not considered an environmental parameter. The effect of aging on this equipment has been evaluated as required by Action Item 4 of IE Bulletin 79-01B.</p> <p>2. In FSAR Section 14-10.1.3, the post-accident cooling capability is evaluated for 180 days. This equipment could be required to operate for that period.</p>	<p>Qualification documentation is unavailable for this equipment. It will be either relocated to a less severe environment or replaced.</p>	<p>Justification for continued operation is made on the basis of past operating experience and the short duration of the harsh portion of the accident environment. Engineering judgement indicates this equipment will function during the postulated accident.</p>

NOTES	CORRECTIVE ACTION	JUSTIFICATION FOR CONTINUED OPERATION
<p>1. In the FSAR, aging was not considered an environmental parameter. The effect of aging on this equipment has been evaluated as required by Action Item 4 of IE Bulletin 79-01B.</p> <p>2. All radiation susceptible materials in this equipment were identified. A literature search was then performed and the results indicated that all identified materials have radiation thresholds greater than the radiation dose specified for this equipment.</p> <p>3. All materials in this equipment susceptible to thermal aging were identified. A literature search was performed to identify the thermal properties of these materials. The Arrhenius method was then used in conjunction with these properties to show that none of these materials are susceptible to significant thermal degradation at the specification temperature.</p>	<p>This equipment will be replaced with an already qualified pressure switch.</p>	<p>Based on vendor contact and previous operating experience, as well as the short duration of the post accident environment, engineering judgement indicates this equipment is capable of functioning for the required post-accident operating time.</p>

NOTES

1. In the FSAR, aging was not considered an environmental parameter. The effect of aging on this equipment has been evaluated as required by Action Item 4 of IE Bulletin 79-01B.
2. All materials in the equipment susceptible to thermal aging were identified. A literature search was performed to identify the thermal properties of these materials. The Arrhenius method was then used in conjunction with these properties to extrapolate existing test results to encompass the required operating time.
3. The penetration of the switch housing is sealed with electrical conduit. The switch case is rated NEMA 4 and has sufficiently small surface area such that the effect of the 1.8 psig pressure transient is negligible.

NOTES

4. All radiation susceptible materials in this equipment were identified. A literature search was then performed and the results indicated that all identified materials have radiation thresholds greater than the radiation dose specified for this equipment.
5. All materials in this equipment susceptible to thermal aging were identified. A literature search was performed to identify the thermal properties of these materials. The Arrhenius method was then used in conjunction with these properties to extrapolate existing test results to encompass the specification temperature.

 3. EDS File No. 48, Rev. 2, "GE RHR and CS Pump Motors," Monticello Nuclear Plant, EDS Job #0910-001-451.
 4. Monticello Nuclear Plant FSAR, Table 14-10-4.

NOTES

1. In the FSAR, aging was not considered an environmental parameter. The effect of aging on this equipment has been evaluated as required by Action Item 4 of IE Bulletin 79-01B.
2. In FSAR Section 14-10.1.3, the post-accident cooling capability is evaluated for 180 days. This equipment could be required to operate for that period.
3. The Arrhenius method, in conjunction with test data, has shown that the test conditions have enveloped the operating time requirement.
4. The Arrhenius method in conjunction with test data has provided a life for this equipment. This life will be coordinated with a surveillance and maintenance program to insure qualification is maintained for the life of the plant.

NOTES

5. Since this motor is open and the pressure transient sufficiently short, the motor will not be subjected to a significant pressure differential, that would impair the equipments functionality.
6. All radiation susceptible materials in this equipment were identified. A literature search was then performed and the results indicated that all identified materials have radiation thresholds greater than the radiation dose specified for this equipment.

NOTES

1. In the FSAR, aging was not considered an environmental parameter. The effect of aging on this equipment has been evaluated as required by Action Item 4 of IE Bulletin 79-01B.
2. Through vendor correspondence, similarity of these valve operators to radiation qualified operators was established. Also, all radiation susceptible materials in this equipment were identified. A literature search was then performed and the results indicated that all identified materials have radiation thresholds greater than the radiation dose specified for this equipment.
3. All materials in this equipment susceptible to thermal aging were identified. A literature search was performed to identify the thermal properties of these materials. The Arrhenius method was then used in conjunction with these properties to extrapolate existing test results to encompass the specification temperature.

NOTES		CORRECTIVE ACTION
<p>1. In the FSAR, aging was not considered an environmental parameter. The effect of aging on this equipment has been evaluated as required by Action Item 4 of IE Bulletin 79-01B.</p> <p>2. These actuators employ motor brakes for which complete qualification documentation does not exist. The motor and actuator have been qualified to 2×10^7 rads. See corrective action and justification for continued operation.</p> <p>3. All materials in this equipment susceptible to thermal aging were identified. A literature search was performed to identify the thermal properties of these materials. The Arrhenius method was then used in conjunction with these properties to extrapolate existing test results to encompass the specification temperature.</p>		<p>Information necessary to analytically qualify the motor brakes is currently being investigated. If qualification cannot be established, one of the following actions will be taken: 1) brake removal, 2) motor operator modification, 3) motor operator replacement.</p> <hr/> <p><u>JUSTIFICATION FOR CONTINUED OPERATION</u></p> <p>Motor brakes have been environmentally tested but have failed after exposure to high levels of radiation. Because the radiation specification for the component is relatively low, engineering judgement indicates the component will function in the postulated accident environment.</p>

NOTES	NOTES	
<p>1. In the FSAR, aging was not considered an environmental parameter. The effect of aging on this equipment has been evaluated as required by Action Item 4 of IE Bulletin 79-01B.</p> <p>2. Accident Profile B.6 indicates the maximum accident temperature and pressure transient at this location is +2°F and +0.4 psig. In addition, this location is isolated from the postulated pipe break by a tank room which will prevent the relative humidity parameter from being significantly affected. Thus, the postulated maximum accident for this location is considered non-harsh and qualification for the temperature, pressure and relative humidity parameters is not required.</p> <p>3. Since the component is qualified for a 12 hour TID following a LOCA, and since all other accidents result in mild environment conditions at this location, the component is qualified for a 12-hour operating time.</p>	<p>4. Radiation was qualified by showing that the radiation thresholds for all non-mettalic parts are greater than the specified radiation dose.</p> <p>5. All materials in this equipment susceptible to thermal aging were identified. A literature search was performed to identify the thermal properties of these materials. The Arrhenius method was then used in conjunction with these properties to extrapolate existing test results to encompass the specification temperature.</p>

NOTES	NOTES	
<p>1. In the FSAR, aging was not considered an environmental parameter. The effect of aging on this equipment has been evaluated as required by Action Item 4 of IE Bulletin 79-01B.</p> <p>2. Accident Profile B.6 indicates the maximum accident temperature and pressure transient at this location is +2°F and +0.4 psig. In addition, this location is isolated from the postulated pipe break by a tank room which will prevent the relative humidity parameter from being significantly affected. Thus, the postulated maximum accident for this location is considered non-harsh and qualification for the temperature, pressure and relative humidity parameters is not required.</p> <p>3. The 8 hour operating time specification is based on a HELB. This results in mild environment conditions as discussed in Note 2. The radiation specification is the 12 hour TID due to a LOCA. Qualification for this 12 hour TID has been established.</p>	<p>4. All radiation susceptible materials in this equipment were identified. A literature search was then performed and the results indicated that all identified materials have radiation thresholds greater than the radiation dose specified for this equipment.</p> <p>5. All materials in this equipment susceptible to thermal aging were identified. A literature search was performed to identify the thermal properties of these materials. The Arrhenius method was then used in conjunction with these properties to show that none of these materials are susceptible to significant thermal degradation at the specification temperature.</p>

NOTES	CORRECTIVE ACTION	JUSTIFICATION FOR CONTINUED OPERATION
<p>1. In the FSAR, aging was not considered an environmental parameter. The effect of aging on this equipment has been evaluated as required by Action Item 4 of IE Bulletin 79-01B.</p> <p>2. Accident Profile B.6 indicates the maximum accident temperature and pressure transient at this location is +2°F and +0.4 psig. In addition, this location is isolated from the postulated pipe break by a tank room which will prevent the relative humidity parameter from being significantly affected. Thus, the postulated maximum accident for this location is considered non-harsh and qualification for the temperature, pressure and relative humidity parameters is not required.</p>	<p>Information has been requested from the manufacturer of this component. When this information is obtained, the component can then be qualified.</p>	<p>The limiting accident for which this equipment could be expected to operate is a RCIC line break in the Torus compartment. Figure B.6 illustrates that the accident produces a mild environment in the HPCI room. Therefore the normal and accident temperatures will have minimal thermal impact on the equipment. Also, these units have operated satisfactorily over a ten year period.</p>

NOTES	NOTES	JUSTIFICATION FOR CONTINUED OPERATION
<ol style="list-style-type: none"> 1. In the FSAR, aging was not considered an environmental parameter. The effect of aging on this equipment has been evaluated as required by Action Item 4 of IE Bulletin 79-01B. 2. The mercury switch installed in the Model 249-C is to be replaced with a dry contact, snap acting switch. 3. The maximum accident pressure is significantly short not to affect the functioning of the level switch. 4. During testing, all materials were serviceable to a radiation dose of 10^7 rads. 5. All materials in this equipment susceptible to thermal aging were identified. A literature search was performed to identify the thermal properties of these materials. The Arrhenius method was then used in conjunction with these properties 	<p>to show that none of these materials are susceptible to significant thermal degradation at the specification temperature.</p> <p><u>CORRECTIVE ACTION</u></p> <p>To insure qualification for the pressure condition, the mercury switch is to be replaced with a qualified snap switch. If a qualified snap switch is not available, the entire unit will be replaced.</p>	<p>The only outstanding item for this component is qualification for the pressure condition. The postulated transient equals 17 psia, which is an increase of 2.3 psi. Continued operation is justified for the following reasons:</p> <ol style="list-style-type: none"> 1) The design and materials of this unit are similar to other qualified units. 2) The pressure transient of 2.3 psi is of low enough magnitude to have insignificant impact on the equipment. Therefore, engineering judgement indicates that these components will pose no threat to safety until they are replaced.

NOTES

1. In the FSAR, aging was not considered an environmental parameter. The effect of aging on this equipment has been evaluated as required by Action Item 4 of IE Bulletin 79-01B.
2. All radiation susceptible materials in this equipment were identified. A literature search was then performed and the results indicated that all identified materials have radiation thresholds greater than the radiation dose specified for this equipment.
3. All materials in this equipment susceptible to thermal aging were identified. A literature search was performed to identify the thermal properties of these materials. The Arrhenius method was then used in conjunction with these properties to extrapolate existing test results to encompass the specification temperature.

NOTES

1. In the FSAR, aging was not considered an environmental parameter. The effect of aging on this equipment has been evaluated as required by Action Item 4 of IE Bulletin 79-01B.
2. All radiation susceptible materials in this equipment were identified. A literature search was then performed and the results indicated that all identified materials have radiation thresholds greater than the radiation dose specified for this equipment.
3. Accident Profile B.6 indicates the maximum accident temperature and pressure transient at this location is +2°F and +0.4 psig. In addition, this location is isolated from the postulated pipe break by a tank room which will prevent the relative humidity parameter from being significantly affected. Thus, the postulated maximum accident for this location is considered non-harsh and qualification for the temperature, pressure and relative humidity parameters is not required.

NOTES

4. All materials in this equipment susceptible to thermal aging were identified. A literature search was performed to identify the thermal properties of these materials. The Arrhenius method was then used in conjunction with these properties to show that none of these materials are susceptible to significant thermal degradation at the specification temperature.

NOTES

1. In the FSAR, aging was not considered an environmental parameter. The effect of aging on this equipment has been evaluated as required by Action Item 4 of IE Bulletin 79-01B.
2. Through vendor correspondence, similarity of these valve operators to radiation qualified operators was established. Also, all radiation susceptible materials in this equipment were identified. A literature search was then performed and the results indicated that all identified materials have radiation thresholds greater than the radiation dose specified for this equipment.
3. All materials in this equipment susceptible to thermal aging were identified. A literature search was performed to identify the thermal properties of these materials. The Arrhenius method was then used in conjunction with these properties to extrapolate existing test results to encompass the specification temperature.

NOTES	NOTES	REFERENCES (Continued)
<p>1. In the FSAR, aging was not considered an environmental parameter. The effect of aging on this equipment has been evaluated as required by Action Item 4 of IE Bulletin 79-01B.</p> <p>2. No operating time is available for this equipment. Specification derived from HELB Analysis Report "Postulated Pipe Failures Outside Containment" submitted by letter to A. Grambusso (AEC) by E. C. Ward (NSP) dated September 7, 1973.</p> <p>3. Engineering analysis was used to supplement test data for pressure qualification of this switch. The surface area of this switch is sufficiently small that the effect of a 0.6 psig pressure rise for a few seconds is negligible. Therefore, this switch is pressure qualified.</p>	<p>4. All materials in this equipment susceptible to thermal aging were identified. A literature search was performed to identify the thermal properties of these materials. The Arrhenius method was then used in conjunction with these properties to extrapolate existing test results to encompass the specification temperature.</p>	<p>5. IEEE 344-1975 Seismic and Radiation Qualification Test for ITT Barton Differential Pressure Indicating Switches 288A and 289A, Report No. R3-288A-1.</p>

NOTES	NOTES	CORRECTIVE ACTION
<p>1. In the FSAR, aging was not considered an environmental parameter. The effect of aging on this equipment has been evaluated as required by Action Item 4 of IE Bulletin 79-01B,</p> <p>2. No specific operating time requirement is available for this equipment. The operating time specification was derived from LOCA and HELB analyses.</p> <p>3. In the FSAR, this equipment was not assumed to function to mitigate a LOCA. Therefore, qualification to LOCA induced environments (such as radiation) is not required.</p>	<p>4. These instruments are essentially identical to Barksdale Model B2T-A12SS Pressure switches. The Barksdale pressure switches have been qualified to environment more severe than those conditions specified for these instruments. We contend that these Meletron instruments are qualified on the basis of similarity to qualified Barksdale Instruments.</p> <p>5. It was not possible to identify all materials in this component susceptible to thermal aging. However, operating experience and similarity to Barksdale's B2T-A12SS instruments indicate that thermal aging does not constitute a significant failure mode. Calibration procedures currently in effect will identify any age related failure of this component.</p>	<p>No corrective action is required.</p> <p><u>JUSTIFICATION FOR CONTINUED OPERATION</u></p> <p>On the basis of construction and similarity to qualified equipment, engineering judgement indicates that these components are qualified for their intended service conditions.</p>

NOTES	NOTES	REFERENCES (Continued)
<p>1. In the FSAR, aging was not considered an environmental parameter. The effect of aging on this equipment has been evaluated as required by Action Item 4 of IE Bulletin 79-01B.</p> <p>2. In the FSAR analyses, this equipment is not assumed to operate to mitigate the consequences of a LOCA. Therefore, qualification to LOCA induced environmental conditions, i.e., radiation, is not required.</p> <p>3. All materials in this equipment susceptible to thermal aging were identified. A literature search was performed to identify the thermal properties of these materials. The Arrhenius method was then used in conjunction with these properties to extrapolate existing test results to encompass the specification temperature.</p>	<p>4. Simultaneous testing was used in conjunction with engineering analysis to show that the 5 second temperature spike to 298°F would not impact the actuator qualification. The justification for this is: 1) the actuator will not experience a significant temperature rise due to the 5 second spike and 2) the total thermal input due to the test exceeds that due to the accident (as shown with Arrhenius calculations).</p>	<p>3. NOTES		CORRECTIVE ACTION
<p>1. In the FSAR, aging was not considered an environmental parameter. The effect of aging on this equipment has been evaluated as required by Action Item 4 of IE Bulletin 79-01B.</p> <p>2. These actuators employ motor brakes for which complete qualification documentation does not exist. The motor and actuator have been qualified to 2×10^7 rads. See corrective action and justification for continued operation.</p> <p>3. All materials in this equipment susceptible to thermal aging were identified. A literature search was performed to identify the thermal properties of these materials. The Arrhenius method was then used in conjunction with these properties to extrapolate existing test results to encompass the specification temperature.</p>	<p>4. Simultaneous testing was used in conjunction with engineering analysis to show that the 5 second temperature spike to 298°F would not impact the actuator qualification. The justification for this is 1) the actuator will not experience a significant temperature rise due to the 5 second spike and 2) the total thermal input due to the test exceeds that due to the accident (as shown with Arrhenius calculations).</p>	<p>Information necessary to analytically qualify the motor brakes is currently being investigated. If qualification cannot be established, one of the following actions will be taken: 1) brake removal, 2) motor operator modification, 3) motor operator replacement.</p> <hr/> <p><u>JUSTIFICATION FOR CONTINUED OPERATION</u></p> <p>Motor brakes have been environmentally tested but have failed after exposure to high levels of radiation. Because the radiation specification for the component is relatively low, engineering judgement indicates the component will function in the postulated accident environment.</p>

NOTES		NOTES
<p>1. In the FSAR, aging was not considered an environmental parameter. The effect of aging on this equipment has been evaluated as required by Action Item 4 of IE Bulletin 79-01B.</p> <p>2. Accident Profile B.6 indicates the maximum accident temperature and pressure transient at this location is +2°F and +0.4 psig. In addition, this location is isolated from the postulated pipe break by a tank room which will prevent the relative humidity parameter from being significantly affected. Thus, the postulated maximum accident for this location is considered non-harsh and qualification for the temperature, pressure and relative humidity parameters is not required.</p> <p>3. Since the component is qualified for a 12 hour TID following a LOCA, and since all other accidents result in mild environment conditions at this location, the component is qualified for a 12-hour operating time.</p>		<p>4. Radiation was qualified by showing that the radiation thresholds for all non-metallc parts are greater than the specified radiation dose.</p> <p>5. All materials in this equipment susceptible to thermal aging were identified. A literature search was performed to identify the thermal properties of these materials. The Arrhenius method was then used in conjunction with these properties to extrapolate existing test results to encompass the specification temperature.</p>

 2. BWR Owners' Group Summary Report No. QSR-096-A-01.
 3. EDS File No. 9, Revision 2, "ASCO Solenoid Valve" Monticello Nuclear Generating Plant, EDS Job #0910-001-451.

NOTES

1. In the FSAR, aging was not considered an environmental parameter. The effect of aging on this equipment has been evaluated as required by Action Item 4 of IE Bulletin 79-01B.
2. This equipment is located in the SGTS room, connected to the Reactor Building by double air lock doors which are always closed. Since there are no high energy lines running through this room, this area is isolated from the temperature, pressure and humidity effects of a HELB or a LOCA. Thus, the only relevant accident parameter is radiation.
3. An operating time specification for this equipment is not available. Since the only accident parameter of concern is radiation, use of the 180 day total integrated dose values of Reference [1] as a qualification requirement provides adequate consideration of operating time.

NOTES

4. All radiation susceptible materials in this equipment were identified. A literature search was then performed and the results indicated that all identified materials have radiation thresholds greater than the radiation dose specified for this equipment.
5. Extensive operating experience exists for these components. The current maintenance procedures for these valves predict pending age related failures and will assure safe operation of these valves for the plant life.

PLANT: Monticello Nuclear Plant												
DOCKET No.: 50-263												
REVISION: 1	DATE: 11/01/81											

NOTES

1. In the FSAR, aging was not considered an environmental parameter. The effect of aging on this equipment has been evaluated as required by Action Item 4 of IE Bulletin 79-01B.
2. This equipment is located in the SGTS room, connected to the Reactor Building by double air lock doors which are always closed. Since there are no high energy lines running through this room, this area is isolated from the temperature, pressure and humidity effects of a HELB or a LOCA. Thus, the only relevant accident parameter is radiation.
3. An operating time specification for this equipment is not available. Since the only accident parameter of concern is radiation, use of the 180 day total integrated dose values of Reference [1] as a qualification requirement provides adequate consideration of operating time.

NOTES

4. All radiation susceptible materials in this equipment were identified. A literature search was then performed and the results indicated that all identified materials have radiation thresholds greater than the radiation dose specified for this equipment.
5. The temperature service conditions in the SBT system room are not affected by a LOCA/HELB. The primary concern of the thermal aging parameter is to avoid common mode failure of components due to the harsh accident temperatures. Because this location is isolated from harsh accident temperatures, any age related failures would be of a random nature. Further investigation of the susceptibility to thermal aging of the non-metallic components is in progress. In addition vendor information indicates that these motors will last for 40 years.

Radiation is an open item.</p> <p>5. All radiation susceptible materials in this equipment were identified. A literature search was then performed and the results indicated that not all identified materials have radiation thresholds greater than the radiation dose specified for this equipment.</p> <p>6. The temperature service conditions in the SBT system room are not affected by a LOCA/HELB. The primary concern of the thermal aging parameter is to avoid common mode failure of components due to the harsh accident temperatures. Because this location is isolated from harsh accident temperatures, any age related failures would be of a random nature. Further investigation of the susceptibility to thermal aging of the non-metallic components is in progress. In addition vendor information indicates that these motors will last for 40 years.</p>	<p>Adequate documentation to qualify this component is not available. This motor will be shielded, relocated, or replaced.</p> <p><u>JUSTIFICATION FOR CONTINUED OPERATION</u></p> <p>The limiting materials are inside the motor and surrounded by a metal shell which would partially shield them from the total radiation dose. In addition, engineering judgement based upon typical materials of construction for motors of this type indicates this motor will perform its intended function in the postulated accident environment.</p>

NOTES	NOTES	CORRECTIVE ACTION										
<p>1. In the FSAR, aging was not considered an environmental parameter. The effect of aging on this equipment has been evaluated as required by Action Item 4 of IE Bulletin 79-01B.</p> <p>2. This equipment is located in the SGTS room, connected to the Reactor Building by double air lock doors which are always closed. Since there are no high energy lines running through this room, this area is isolated from the temperature, pressure and humidity effects of a HELB or a LOCA. Thus, the only relevant accident parameter is radiation.</p> <p>3. An operating time specification for this equipment is not available. Since the only accident parameter of concern is radiation, use of the 180 day total integrated dose values of Reference [1] as a qualification requirement provides adequate consideration of operating time.</p>	<p>4. All radiation susceptible materials in this equipment were identified. A literature search was then performed and the results indicated that all identified materials have radiation thresholds greater than the radiation dose specified for this equipment, except for one material. Teflon was given a radiation threshold of 1.7×10^4 rads. This is based on mechanical rather than electrical properties. Components employing teflon as an electrical insulator have been qualified to over 2×10^7 rads, however an auditable data source for this information has not been found.</p> <p>5. All materials in this equipment susceptible to thermal aging were identified. A literature search was performed to identify the thermal properties of these materials. The Arrhenius method was then used in conjunction with these properties to show that none of these materials are susceptible to significant thermal degradation at the specification temperature.</p>	<p>These components will be shielded, relocated, or replaced.</p> <p><u>JUSTIFICATION FOR CONTINUED OPERATION</u></p> <p>Based on the design and construction of these instruments coupled with existing test data for similar equipment, engineering judgement indicates these components will function in the postulated accident conditions.</p>

NOTES	NOTES	REFERENCES (Continued)
<p>1. In the FSAR, aging was not considered an environmental parameter. The effect of aging on this equipment has been evaluated as required by Action Item 4 of IE Bulletin 79-01B.</p> <p>2. All materials in this equipment susceptible to thermal aging were identified. A literature search was performed to identify the thermal properties of these materials. The Arrhenius method was then used in conjunction with these properties to extrapolate existing test results to encompass the specification temperature.</p>	<p>3. Maximum accident pressure is 17.04 psia. Since the operator housing is made of steel and totally sealed, pressure transients of this magnitude are not a credible failure mode. Therefore, this equipment is qualified for the pressure condition.</p> <p>4. A thermal capacitance heat transfer calculation was performed and concluded that the high temperature transient is short enough so that performance of this equipments required function is not impaired.</p>	<p>4. NOTES

1. In the FSAR, aging was not considered an environmental parameter. The effect of aging on this equipment has been evaluated as required by Action Item 4 of IE Bulletin 79-01B.
2. Through vendor correspondence, similarity of these value operators to radiation qualified operators was established. Also, all radiation susceptible materials in this equipment were identified. A literature search was then performed and the results indicated that all identified materials have radiation thresholds greater than the radiation dose specified for this equipment.
3. All materials in this equipment susceptible to thermal aging were identified. A literature search was performed to identify the thermal properties of these materials. The Arrhenius method was then used in conjunction with these properties to extrapolate existing test results to encompass the specification temperature.

NOTES	NOTES	REFERENCES (Continued)										
<p>1. In the FSAR, aging was not considered an environmental parameter. The effect of aging on this equipment has been evaluated as required by Action Item 4 of IE Bulletin 79-01B.</p> <p>2. This solenoid valve is qualified to NEMA 4 specifications, indicating protection from splashing water and hose-directed water. Thus, this solenoid valve is qualified for containment spray conditions.</p>	<p>3. Qualification for gamma radiation was by testing. Qualification for beta radiation was done by analysis which showed that the amount of Beta radiation which penetrates existing shielding is less than 10% of the Gamma qualification dose.</p> <p>4. All materials in this equipment susceptible to thermal aging were identified. A literature search was performed to identify the thermal properties of these materials. The Arrhenius method was then used in conjunction with these properties to extrapolate existing test results to encompass the specification temperature.</p>	<p>5. General Electric Plant Equipment Design Memo #126-62, "Environmental Testing of MSS/RV Air Control Valves."</p> <p>6. Assumed conservative surface dose.</p>

NOTES	NOTES	
<p>1. In the FSAR, aging was not considered an environmental parameter. The effect of aging on this equipment has been evaluated as required by Action Item 4 of IE Bulletin 79-01B.</p> <p>2. No specific operating time requirement is available for this equipment. The operating time specification was derived from LOCA and HELB analyses.</p> <p>3. In the FSAR, this equipment was not assumed to function to mitigate a LOCA. Therefore, qualification to LOCA induced environments (such as radiation) is not required.</p> <p>4. The postulated accident profile exceeds the test conditions by 4°F for less than 30 seconds. The thermal capacitance of the switch housing is sufficient to prevent the internal components from experiencing a temperature in excess of 212°F during this short duration.</p>	<p>5. The penetration of the switch housing is sealed with electrical conduit. The switch case is rated NEMA 4 and has sufficiently small surface area such that the effect of the 1.4 psig pressure transient is negligible.</p> <p>6. All radiation susceptible materials in this equipment were identified. A literature search was then performed and the results indicated that all identified materials have radiation thresholds greater than the radiation dose specified for this equipment.</p> <p>7. All materials in this equipment susceptible to thermal aging were identified. A literature search was performed to identify the thermal properties of these materials. The Arrhenius method was then used in conjunction with these properties to extrapolate existing test results to encompass the specification temperature.</p>

NOTES	NOTES	
<p>1. In the FSAR, aging was not considered an environmental parameter. The effect of aging on this equipment has been evaluated as required by Action Item 4 of IE Bulletin 79-01B.</p> <p>2. No specific operating time requirement is available for this equipment. The operating time specification was derived from LOCA and HELB analyses.</p> <p>3. Engineering analysis was used to supplement test data for pressure qualification of this switch. Electrical conduit penetration effectively seals the switch housing so that internal components do not experience a pressure differential. Cases are rated NEMA 4 and have a sufficiently small surface area that the effect of an external 0.5psig pressure rise for only a few seconds is negligible. Therefore, this switch is pressure qualified.</p>	<p>4. All radiation susceptible materials in this equipment were identified. A literature search was then performed and the results indicated that all identified materials have radiation thresholds greater than the radiation dose specified for this equipment.</p> <p>5. All materials in this equipment susceptible to thermal aging were identified. A literature search was performed to identify the thermal properties of these materials. The Arrhenius method was then used in conjunction with these properties to extrapolate existing test results to encompass the specification temperature.</p> <p>6. This component was type-tested for 6.5 hours at a maximum temperature of 212°F. The accident profile shows that temperatures in excess of the test temperature last only a few seconds and exceed it by only one degree. The thermal capacitance of the housing is sufficient to prevent the internal components from experiencing the 213°F temperature rise, therefore adequate margin exists for temperature qualification.</p>

NAMCO LIMIT SWITCH - SL SERIES

NOTES	NOTES	NOTES
<p>1. In the FSAR, aging was not considered an environmental parameter. The effect of aging on this equipment has been evaluated as required by Action Item 4 of IE Bulletin 79-01B.</p> <p>2. In FSAR Section 14-10.1.3, the post-accident cooling capability is evaluated for 180 days. This equipment could be required to operate for that period.</p> <p>3. All materials in this equipment susceptible to thermal aging were identified. A literature search was performed to identify the thermal properties of these materials. The Arrhenius method was then used in conjunction with these properties to show that none of these materials are susceptible to significant thermal degradation at the specification temperature.</p>	<p>4. Reference [4] indicated the BZ switching block internal to the BZE6-2RN limit switch was not susceptible to radiation damage from a gamma dose less than 1.0×10^7 rads. For the remaining components of this switch, all radiation susceptible materials were identified. A literature search was then performed and the results indicated that all identified materials have radiation thresholds greater than the radiation dose specified for this switch.</p> <p>5. This limit switch is a sealed unit designed to provide protection against splashing water and will also withstand a limited steam exposure. Engineering judgement indicates this switch will function for the humidity condition of 100%.</p> <p>6. The maximum postulated accident at this location causes the temperature to rise to 214°F then quickly fall to below 140°F. Because this switch has a thick cast aluminum housing, the temperature sensitive materials internal to the switch will be effectively shielded from temperature spike.</p>	<p>7. The operating time condition was evaluated by using the Arrhenius method (see note 3). Margin was included by using the highly-conservative assumption that the temperature remains at 140°F for the entire 180 day post accident period.</p>

NOTES	NOTES	NOTES
<p>1. In the FSAR, aging was not considered an environmental parameter. The effect of aging on this equipment has been evaluated as required by Action Item 4 of IE Bulletin 79-01B.</p> <p>2. In FSAR Section 14-10.1.3, the post-accident cooling capability is evaluated for 180 days. This equipment could be required to operate for that period.</p> <p>3. All materials in this equipment susceptible to thermal aging were identified. A literature search was performed to identify the thermal properties of these materials. The Arrhenius method was then used in conjunction with these properties to show that none of these materials are susceptible to significant thermal degradation at the specification temperature.</p>	<p>4. Reference [4] indicated the BZ switching block internal to the BZE6-2RQ2 limit switch was not susceptible to radiation damage from a gamma dose less than 1.0×10^7 rads. For the remaining components of this switch, all radiation susceptible materials were identified. A literature search was then performed and the results indicated that all identified materials have radiation thresholds greater than the radiation dose specified for this switch.</p> <p>5. Since this switch is not a sealed unit, the pressure spike will not create a pressure differential across the switch casing. Because the pressure spike is of such a small magnitude and of such a short duration, the material properties will not be affected and the functioning of the switch will not be impaired.</p> <p>6. The maximum postulated accident at this location causes the temperature to rise to 214°F then quickly fall to below 140°F. Because this switch has a thick cast aluminum housing, the temperature sensitive materials internal to the switch will be effectively shielded from the temperature spike.</p>	<p>7. The operating time condition was evaluated by using the Arrhenius method (See Note 3). Margin was included by using the highly-conservative assumption that the temperature remains at 140°F for the entire 180 day post-accident period.</p>
		<p style="text-align: center;"><u>CORRECTIVE ACTION</u></p> <p>This limit switch will be tested or replaced.</p> <p style="text-align: center;"><u>JUSTIFICATION FOR CONTINUED OPERATION</u></p> <p>Engineering judgement, based on discussions with the vendor, qualifications of similar switches, and the short duration of the harsh portion of the postulated accident indicates that this switch will be able to perform its intended function as needed.</p>

NOTES	NOTES	CORRECTIVE ACTION																		
<p>1. In the FSAR, aging was not considered an environmental parameter. The effect of aging on this equipment has been evaluated as required by Action Item 4 of IE Bulletin 79-01B.</p> <p>2. All materials in this equipment susceptible to thermal aging were identified. A literature search was performed to identify the thermal properties of these materials. The Arrhenius method was then used in conjunction with these properties to extrapolate existing test results to encompass the specification temperature.</p> <p>3. All radiation susceptible materials in this equipment were identified. A literature search was then performed and the results indicated that all identified materials have radiation thresholds greater than the radiation dose specified for this equipment.</p>	<p>4. No specific operating time requirement is available for this equipment. The operating time specification was derived from LOCA and HELB analyses.</p> <p>5. All materials in this equipment susceptible to temperature degradation were identified. A literature search was performed and indicated that this equipment will withstand the specification temperature.</p> <p>6. Qualification based on analysis of the construction and location of the connectors compared to possible effects of high relative humidity.</p> <p>7. Qualification based on Engineering Analysis comparing components and materials of banana plugs to those of the temperature switches they support.</p> <p>8. Comparison based on comparison of worst case accident pressure profile to the design of the connectors and their location. Pressure transients of this magnitude will not affect the operation of these connectors.</p>	<p>None.</p> <p><u>JUSTIFICATION FOR CONTINUED OPERATION</u></p> <p>These plugs are considered completely qualified based on the analysis presented in Reference 2. The short operating time; rugged, simple construction; and added protection of a junction box housing provide adequate justification for continuous operation in the postulated accident environment.</p> <p style="text-align: center;"><u>NOTES (Continued)</u></p> <p>9. NOTES	CORRECTIVE ACTION	JUSTIFICATION FRO CONTINUED OPERATION
<p>1. In the FSAR, aging was not considered an environmental parameter. The effect of aging on this equipment has been evaluated as required by Action Item 4 of IE Bulletin 79-01B.</p> <p>2. The flood level of 900' in this location results from a feed water line break in the steam chase. Reference [3] concluded that this motor control center is not required to operate for this accident condition.</p> <p>3. Accident Profile B.6 indicates the maximum accident temperature and pressure transient at this location is +2°F and +0.4 psig. In addition, this location is isolated from the postulated pipe break by a tank room which will prevent the relative humidity condition from being significantly affected. Thus, the postulated maximum accident for this location is considered non-harsh and qualification for the temperature, pressure and relative humidity parameters is not required.</p>	<p>This equipment will be shielded, relocated, or tested.</p>	<p>Engineering judgement, based on testing of similar equipment, discussion with the vendor, and on a conservative definition of the accident environment indicates these motor control centers will perform their required function during the accident environment.</p>
