Soil Survey of Converse County, Wyoming, Northern Part, U.S. Soil Conservation Service
Order 1-2 Baseline Soil Assessment, 1997

APPENDIX D-7 SOILS

1.0 HISTORIC SOIL SURVEYS

The soil baseline study for the western portion of the permit area was assembled in 1990. This study, as agreed to with the WDEQ staff at the November 17, 1989 meeting is comprised of the Soil Survey of Converse County, Wyoming, Northern Part published by the U.S. Soil Conservation Service (SCS). The soil survey conducted by the SCS was an Order 3 survey.

The following information is included with the study:

- **Plate D7-1 in Addendum D-7 B2** which shows the various SCS soil types in the entire permit area and adjacent lands.
- Detailed SCS map unit descriptions for the soil types found within and adjacent to the entire permit area and adjacent lands, in **Addendum D-7 B3**.
- Typical SCS soil profile descriptions of each series in **Addendum D-7 B3**.
- Engineering index properties in **Addendum D-7 B3**.
- Physical and chemical properties in **Addendum D-7 B3**.

Soil samples were collected in 1986 for areas contained in the eastern portion of the permit area. Chemical analyses were conducted on 13 samples. These data are included in **Addendum D-7 B3**. The locations of the soil sampling sites are shown on **Plates D7-1 and D7-2 of Addendum D-7 B2**. The suitability of the soils sampled for topsoil is also shown on **Table 1 of Addendum D7-B3**. All soils are shown to be suitable or marginally suitable as topsoil.

Baseline soil studies performed for the proposed Reynolds Ranch amendment area include an Order 3 soil survey conducted by the U.S. Soil Conservation Service (SCS) in 1982 and an Order 1-2 soil assessment conducted by BKS Environmental Associates, Inc. in 1997 for Rio Algom Mining Corporation.

The soil survey conducted by the SCS included all of Converse County, including the Reynolds Ranch amendment area. Applicable portions of this survey are contained in Addendum D-7 C and include detailed SCS map unit descriptions, typical SCS soil profile descriptions of each series, engineering index properties, and physical and chemical properties. Plate D7-1 shows the delineation of the SCS soil unit boundaries for the Reynolds Ranch amendment area.

The 1997 soil assessment is contained in Addendum D-7 C3. This assessment was a higher intensity Order 1-2 survey and includes mechanical and chemical analysis of several sampling locations throughout the amendment area, additional soil unit descriptions, and reclamation suitability analysis. An area soils map was also developed during this survey utilizing previous mapping and soil unit information and information gained during the 1997 survey. Figure D7-1 provides the complete permit boundary, including the Proposed Reynolds Ranch Amendment area. Notes on the index map indicate when individual plates and figures for Smith ranch, highland or Reynolds can be found in the addenda.

2.0 IMPACTS TO SOIL RESOURCES

The ISR mine unit facilities will disturb only a limited amount of surface. The impact to the topsoil resource in the western portion of the ISR permit area is relatively minor when compared to a typical surface mine operation. The soils within the western portion of the proposed permit area have been mapped based upon data developed by the Converse County Soil Conservation Service for the permit area. See **Table D-7.1** of **Addendum D-7 A1** for the mapping unit designations, approximate percentage of slope and approximate depth of topsoil material. **Addendum D-7 A3** contains a discussion of each mapping unit. The mapping unit locations are shown on **Figure D-7.1** of **Addendum D-7 A2**.

In general the well installation process may produce a short term disturbance to soils, but topsoil and land recovery is initiated as soon as practicable following well completion. Soil disturbance of mine units typically lasts approximately six months. Topsoil conservation methods to be employed during construction and operation are discussed in **Section 3.2.2 of the Operations Plan**.

Table D-7.1
SOLUTION MINING PERMIT AREA SOILS SURVEY

Unit	U.S. Department of Agriculture Soil Conservation Service Mapping Unit	Approximate Percent Slope	Approximate Depth of A, B, & C Horizons (Ft)	Typical Topsoil Depths ¹ (In)

¹Range of typical surface layer depths.

Clarkelen-Draknab Complex, 0-3 percent slopes (Mapping Unit 5)

Clarkelen - Typically, the surface layer is sandy loam about 3 inches thick. The substratum is stratified sandy clay loam to loamy sand to a depth of 60 inches or more.

Draknab - Typically the surface layer is loamy sand about 21 inches thick. The substratum is fine sand stratified with thin lenses of sandy loam to a depth of 60 inches.

These soils may have low available water capacity and should be managed to control wind erosion. Lower lying areas are subject to occassional flooding.

Capability - IVe

Range Site - Lowland

Clarkelen-Haverdad-Bigwin Variant Complex, 0-3 percent slopes (Mapping Unit 6)

Clarkelen - Typically, the surface layer is sandy loam about 3 inches thick. The substratum is stratified sandy clay loam to loamy sand to a depth of 60 inches or more. Lowland

Haverdad - Typically, the surface layer is fine sandy loam about 6 inches thick. The substratum is loam stratified with thin lenses of clay loam and fine sandy loam to a depth of 60 inches or more. Lowland

Bigwin - Typically, the surface layer is fine sandy loam about 6 inches thick. The substratum is sandy loam stratified with lenses of loamy sand and loam sand is at a depth of 19 inches. Subirrigated

Capability - IVe

Range Site - Clarkelen & Haverdad - Lowland
Bigwin Variant - Subirrigated

Bahl Savageton Complex, 0-6 percent slopes (Mapping Unit 35)

Bahl - Typically, the surface layer is clay about 14 inches thick. The substratum to a depth of 60 inches or more is clay.

Savageton - Typically, the surface layer is clay loam about 2 inches thick. The substratum is clay about 30 inches thick. Shale is at a depth of 32 inches.

These soils should be managed to control water erosion.

Capability - IVe

Range Site - Clayey

Dwyer - Orpha Complex, 3-15 percent slopes (Mapping Unit 64)

Dwyer - Typically, the surface layer is loamy sand about 5 inches thick. The substratum is loamy sand to a depth of 60 inches.

Orpha - Typically, the surface layer is loamy sand about 6 inches thick. The substratum is sand to a depth of 60 inches.

These soils have low available water capacity. These soils should be managed to control both water and wind erosion.

Capability - IVe

Range Site - Sandy

Zigweid-Cambria Association, 0-6 percent slopes (Mapping Unit 158)

Zigweid - Typically, the surface layer is clay loam about 3 inches thick. The substratum is clay to a depth of 60 inches or more.

The soil should be managed to control water erosion.

Cambria - Typically, the surface layer is fine sandy loam about 2 inches thick. The subsoil is sandy clay loam about 12 inches thick. The substratum is loam and sandy loam to a depth of 60 inches or more.

This soil should be managed to control wind erosion.

Capability - IVE

Range Site - Loamy

Zigweid-Cambria-Theedle Association, 6-15 percent slopes (Mapping Unit 158C)

Zigweid - Typically, the surface layer is loam about 4 inches thick. The substratum is clay loam to a depth of 60 inches or more.

This soil should be managed to control water erosion.

Cambria - Typically, the surface layer is sandy loam about 4 inches thick. The subsoil is loam about 11 inches thick. The substratum is loam to a depth of 60 inches or more.

This soil should be managed to control water erosion.

Theedle - Typically, the surface layer is loam about 5 inches thick. The substratum is loam and clay loam about 23 inches thick. Shale is at a depth of 28 inches.

This soil should be managed to control water erosion.

Capability - VIe

Range Site - Loamy

Zigweid-Bahl Association, 0-6 percent slopes (Mapping Unit 163)

Zigweid - Typically, the surface layer is loam about 2 inches thick. The substratum is clay loam to a depth of 60 inches or more.

This soil should be managed to control water erosion.

Bahl - Typically, the surface layer is clay about 24 inches thick. The substratum is clay to a depth of 60 inches or more.

This soil has low permeability which causes seasonal ponding in some areas. This soil should be managed to control water erosion.

Capability - IVe

Range Site - Zigweid - Loamy
 Bahl - Clayey

Theedle-Kishona Association, 0-6 percent slopes (Mapping Unit 177)

Theedle - Typically, the surface layer is loam about 5 inches thick. The substratum is clay loam about 23 inches thick. Interbedded shale and sandstone is at a depth of 28 inches.

Theedle soils should be managed to control water erosion. Management of Thedalund soils should take into consideration low available water capacity.

Kishona - Typically, the surface layer is loam about 3 inches thick. The substratum is clay loam to a depth of 60 inches or more.

Kishona soils should be managed to control water erosion.

Capability - IV

Range Site - Loamy

Gullied Land, 3-45 percent slopes (Mapping Unit 247)

Gullied Land - Typically, the original soil material has been lost through erosion. Depth of the soil material ranges from 10 to more than 60 inches. Soil textures range from sandy loam to clay loam.

These soils should be managed to control water erosion. Extensive gullying in this unit limits use.

Capability - VIIe

Range Site - Sandy Loam Clay Loam

Forkwood-Ulm Complex, 0-6 percent slopes (Mapping Unit 331)

Forkwood - Typically, the surface layer is fine sandy loam about 4 inches thick. The subsoil is fine sandy loam and clay loam about 16 inches thick. The substratum is clay loam to 60 inches or more.

Ulm - Typically, the surface layer is loam about 5 inches thick. The subsoil is clay loam and clay about 31 inches thick. The substratum is clay loam to 60 inches or more.

These soils should be managed to control water erosion.

Capability - IVe

Range Site - Loamy

Forkwood-Ulm-Renohill Complex, 6-15 percent slopes (Mapping Unit 331C)

Forkwood - Typically, the surface layer is fine sandy loam about 4 inches thick. The subsoil is fine sandy loam and clay loam about 16 inches thick. The substratum is clay loam to 60 inches or more.

Ulm - Typically, the surface layer is clay loam about 4 inches thick. The subsoil is clay loam about 21 inches thick. The substratum is clay loam to 60 inches or more.

Renohill - Typically, the surface layer is clay loam about 5 inches thick. The subsoil is clay loam about 20 inches thick. Calcareous gritty shale is at a depth of 25 inches.

These soils should be managed to control water erosion.

Capability - VIe

Range Site - Forkwood - Loamy
 Ulm - Clayey
 Renohill - Clayey

Cushman-Terro Complex, 0-6 percent slopes (Mapping Unit 332)

Cushman - Typically, the surface layer is loam about 4 inches thick. The subsoil is clay loam about 14 inches thick. The substratum is loam about 8 inches thick over interbedded sandstone and shale.

Terro - Typically, the surface layer is sandy loam about 4 inches thick. The subsoil is sandy loam and loamy sand about 12 inches thick. The substratum is sandy loam about 18 inches thick. Soft calcareous sandstone is at a depth of 34 inches.

These soils should be managed to control both water and wind erosion.

Capabiliy - IVE

Range Site - Cushman - Loamy
 Terro - Sandy

Terro-Tullock-Orpha Complex, 6-15 percent slopes (Mapping Unit 322C)

Terro - Typically, the surface layer is sandy loam about 4 inches thick. The subsoil is sandy loam and loamy sand about 12 inches thick. The substratum is sandy loam about 18 inches thick. Soft sandstone is at a depth of 34 inches.

Tullock - Typically, the surface layer is loamy sand about 5 inches thick. The substratum is sand and loamy sand about 26 inches thick. Soft sandstone is at a depth of 31 inches.

Orpha - Typically, the surface layer is loamy sand about 5 inches thick. The substratum to a depth of 60 inches is sand.

These soils have low or very low available water capacity and should be managed to control wind and water erosion.

Capability - VIe

Range Site - Terro - Sandy
 Tullock - Orpha - Sands

Forkwood-Cambria Complex, 0-6 percent slopes (Mapping Unit 336)

Forkwood - Typically, the surface layer is fine sandy loam about 4 inches thick. The subsoil is loam and clay loam about 25 inches thick. The substratum is loam to 60 inches or more.

Cambria - Typically, the surface layer is fine sandy loam about 2 inches thick. The subsoil is loam and clay loam about 12 inches thick. The substratum is loam to 60 inches or more.

These soils should be managed to control water erosion.

Capability - IVE

Range Site - Loamy

Forkwood-Cambria-Cushman Complex, 6-15 percent slopes (Mapping Unit 336C)

Forkwood - Typically, the surface layer is sandy loam about 2 inches thick. The subsoil is clay loam and loam about 23 inches thick. The substratum is loam to 60 inches or more.

Cambria - Typically, the surface layer is loam about 4 inches thick. The subsoil is loam about 11 inches thick. The substratum is loam to 60 inches or more.

Cushman - Typically, the surface layer is loam about 3 inches thick. The subsoil is clay loam about 14 inches thick. The substratum is loam about 8 inches thick over soft interbedded shale and sandstone.

These soils should be managed to control water erosion.

Capability - VIe

Range Site - Loamy

Haverdad-Lohmiller Complex, 0-6 percent slopes (Mapping Unit 341)

Haverdad - Typically, the surface layer is fine sandy loam about 6 inches thick. The substratum to a depth of 60 inches or more is stratified loam, clay loam and fine sandy loam.

Lohmiller - Typically, the surface layer is clay loam about 3 inches thick. The substratum to a depth of 60 inches or more is stratified clay, sandy clay loam and sandy loam.

These soils are subject to occasional flooding.

Capability - IVE

Range Site - Lowland

Shingle-Rock Outcrop-Samday Complex, 10-30 percent slopes (Mapping Unit 347)

Shingle - Typically, the surface layer is clay loam about 4 inches thick. The substratum is clay loam about 9 inches thick. Soft interbedded shale and sandstone is at a depth of 13 inches.

Rock Outcrop - Typically is exposures of calcareous soft to hard shale.

Samday - Typically, the surface layer is clay loam about 2 inches thick. The substratum is clay about 16 inches thick. Interbedded shale and sandstone is at a depth of 18 inches.

These soils should be managed to control water erosion. Very shallow soil or exposed rock occur in about 30 percent of this unit.

Capability - VIIe

Range Site - Shingle - Shallow Loamy
 Samday - Shallow Clayey

Silhouette-Holdt Association, 0-6 percent slopes (Mapping Unit 375)

Silhouette - Typically, the surface layer is clay loam about 2 inches thick. The subsoil is clay about 16 inches thick. The substratum is clay to a depth of 60 inches or more.

Holdt - Typically, the surface layer is clay loam about 4 inches thick. The subsoil is clay to a depth of 48 inches or more.

Low permeability and in some soils, occasional flooding on parts of this unit should be considered in management of these soils.

Capability - IVe

Range Site - Clayey

Clarkelen-Dwyer-Orpha Association, 0-10 percent slopes (Mapping Unit 351)

Clarkelen - Typically, the surface layer is sandy loam about 3 inches thick. The substratum is stratified sandy loam to loamy sand to a depth of 60 inches or more.

This soil should be managed to control wind erosion.

Dwyer - Typically, the surface layer is loamy sand about 5 inches thick. The substratum is loamy sand to a depth of 60 inches or more.

This soil has low available water capacity and should be managed to control wind erosion.

Orpha - Typically, the surface layer is loamy sand about 5 inches thick. The substratum is sand to a depth of 60 inches or more.

This soil has low available water capacity and should be managed to control wind erosion.

Capability - VIe

Range Site - Clarkelen - Lowland
Dwyer & Orpha - Sands

Kishona-Dwyer-Orpha Association, 0-10 percent slopes (Mapping Unit 353)

Kishona - Typically, the surface layer is loam about 3 inches thick. The substratum is clay loam to 60 inches or more.

This soil should be managed to control water erosion.

Dwyer - Typically, the surface layer is loamy sand about 5 inches thick. The substratum is loamy sand to a depth of 60 inches or more.

This soil has low available water capacity and should be managed to control wind erosion.

Orpha - Typically, the surface layer is loamy sand about 5 inches thick. The substratum is loamy sand to a depth of 60 inches or more.

This soil has low available water capacity and should be managed to control wind erosion.

Capability - Kishona - IVe
Dwyer & Orpha - VIe

Range Site - Kishona - Loamy
Dwyer & Orpha - Sands

Ulm-Renohill Complex, 0-6 percent slopes (Mapping Unit 365)

Ulm - Typically, the surface layer is loam about 5 inches thick. The subsoil is clay loam and clay about 31 inches thick. The substratum is sandy clay loam to 60 inches or more.

Renohill - Typically, the surface layer is fine sandy loam about 5 inches thick. The subsoil is clay and clay loam about 31 inches thick. Calcareous shale is at a depth of 36 inches.

These soils should be managed to control water erosion.

Capability - IVe

Range Site - Ulm - Clayey
Renohill - Loamy

Ulm-Renohill Complex, 6-15 percent slopes (Mapping Unit 365C)

Ulm - Typically, the surface layer is clay loam about 4 inches thick. The subsoil is clay loam about 21 inches thick. The substratum is clay loam to 60 inches or more.

Renohill - Typically, the surface layer is clay loam about 5 inches thick. The subsoil is clay loam about 20 inches thick. Calcareous, gritty shale is at a depth of 25 inches.

These soils should be managed to control water erosion.

Capability - VIe

Range Site - Clayey

Hiland-Bowbac Complex, 0-6 percent slopes (Mapping Unit 380)

Hiland - Typically, the surface layer is sandy loam about 5 inches thick. The subsoil is sandy clay loam about 25 inches thick. The substratum is sandy loam to a depth of 60 inches or more.

Bowbac - Typically, the surface layer is sandy loam about 3 inches thick. The subsoil is sandy clay loam about 23 inches thick. The substratum is sandy loam about 10 inches thick over soft sandstone.

These soils should be managed to control wind and water erosion.

Capability - IVe

Range Site - Loamy

Hiland-Bowbac Complex, 6-15 percent slopes (Mapping Unit 380C)

Hiland - Typically, the surface layer is sand clay loam about 3 inches thick. The subsoil is sandy loam and sandy clay loam about 21 inches thick. The substratum is sandy clay loam to a depth of 60 inches or more.

Bowbac - Typically, the surface layer is sandy loam about 4 inches thick. The subsoil is sandy clay loam about 11 inches thick. The substratum is fine sandy loam about 13 inches thick. Soft sandstone is at a depth of 28 inches.

These soils should be managed to control water erosion.

Capability - VIe

Range Site - Loamy

Vonalee-Terro Complex, 0-6 percent slopes (Mapping Unit 381)

Vonalee - Typically, the surface layer is loamy sand about 4 inches thick. The subsoil is loamy sand and sandy loam about 19 inches thick. The substratum is loamy sand and loam to a depth of 60 inches or more.

Terro - Typically, the surface layer is sandy loam about 4 inches thick. The subsoil is sandy loam and loamy sand about 12 inches thick. The substratum is sandy loam about 18 inches thick. Calcareous sandstone is at a depth of 34 inches.

These soils should be managed to control wind and water erosion.

Capability - VIe

Range Site - Sandy

Vonalee-Terro Complex, 6-15 percent slopes (Mapping Unit 381C)

Vonalee - Typically, the surface layer is loamy sand about 3 inches thick. The subsoil is sandy loam about 21 inches thick. The substratum to a depth of 60 inches is loamy sand.

Terro - Typically, the surface layer is sandy loam about 4 inches thick. The subsoil is sandy loam and loamy sand about 12 inches thick. The substratum is sandy loam about 18 inches thick. Calcareous sandstone is at a depth of 34 inches.

These soils should be managed to control wind and water erosion.

Capability - VIe

Range Site - Sandy

Renohill-Worfka-Shingle Complex, 6 to 15 percent slopes (Mapping Unit 393)

Renohill - Typically, the surface layer is clay loam about 5 inches thick. The subsoil is clay loam about 20 inches thick. Calcareous gritty shale is at a depth of 25 inches.

Worfka - Typically, the surface layer is fine sandy loam about 3 inches thick. The subsoil is clay and clay loam about 11 inches thick. Interbedded shale and sandstone is at a depth of 14 inches.

Shingle - Typically, the surface layer is clay loam about 4 inches thick. The substratum is clay loam about 14 inches thick. Shale is at a depth of 18 inches.

These soils should be managed to control erosion. Erosion control is significant because much of the unit has bedrock between 10 to 20 inches.

Capability - VIIe

Range Site - Renohill - Clayey
 Worfka - Shallow Clayey
 Shingle - Shallow Loamy

Worf-Shingle-Tassel Complex, 3-30 percent slopes (Mapping Unit 401)

Worf - Typically, the surface layer is loamy sand about 2 inches thick. The subsoil is clay loam about 13 inches thick. Calcareous shale and sandstone is at a depth of 15 inches.

Shingle - Typically, the surface layer is clay loam about 4 inches thick. The substratum is clay loam about 14 inches thick. Shale is at a depth of 18 inches.

Tassel - Typically, the surface layer is sandy loam about 3 inches thick. The substratum is sandy loam about 11 inches thick. Soft sandstone is at a depth of 14 inches.

These soils are shallow and have low and very low available water capacity. These soils should be managed to control both water and wind erosion.

Capability - VIIe

Range Site - Worf - Shallow Loamy
 Shingle - Shallow Loamy
 Tassel - Shallow Loamy

Tassel-Shingle Complex, 3-30 percent slopes (Mapping Unit 402)

Tassel - Typically, the surface layer is sandy loam about 3 inches thick. The substratum is sandy loam about 11 inches thick. Soft sandstone is at a depth of 14 inches.

Shingle - Typically, the surface layer is clay loam about 4 inches thick. The substratum is clay loam about 14 inches thick. Soft shale is at a depth of 18 inches.

These soils should be managed to control erosion.

Capability - VIIe

Range Site - Tassel - Shallow Sandy
 Shingle - Shallow Loamy

Tassel-Tullock-Vonalee Association, 6-30 percent slopes (Mapping Unit 404)

Tassel - Typically, the surface layer is loamy fine sand about 5 inches thick. The substratum is sandy loam about 11 inches thick. Soft calcareous sandstone is at a depth of 16 inches.

Tassel soils have very low available water capacity and should be managed to control a water erosion.

Tullock - Typically, the surface layer is loamy sand about 5 inches thick. The substratum is sand and loamy sand about 26 inches thick. Soft sandstone is at a depth of 31 inches.

Tullock soils have very low or low available water capacity and should be managed to control wind and water erosion.

Vonalee - Typically, the surface layer is loamy sand about 3 inches thick. The subsoil is sandy loam about 21 inches thick. The substratum is to a depth of 60 inches is loamy sand.

Vonalee soils should be managed to control wind and water erosion.

Capability - Tassel - VIIe
Tullock & Vonalee - VIe

Range Site - Tassel - Shallow Sandy
Tullock - Sands
Vonalee - Sandy

Tassel-Terro-Rock Outcrop Complex, 15-30 percent slopes (Mapping Unit 405)

Tassel - Typically, the surface layer is loamy fine sand about 5 inches thick. The substratum is sandy loam about 11 inches thick. Calcareous sandstone is at a depth of 16 inches.

Terro - Typically, the surface layer is sandy loam about 4 inches thick. The subsoil is sandy loam and loamy sand about 12 inches thick. The substratum is sandy loam about 18 inches thick. Calcareous sandstone is at a depth of 34 inches.

Rock Outcrop - Exposures of sandstone bedrock occurring as knobs and narrow ridges.

These soils should be managed to control wind and water erosion. Very shallow soil or exposed rock occurs in about 25 percent of this unit.

Capability = VIIe

Range Site - Tassel - Shallow Sandy
 Terro - Sandy

Samday-Shingle-Worf Complex, 3-15 percent slopes (Mapping Unit 409)

Samday - Typically, the surface layer is clay loam about 2 inches thick. The substratum is clay about 16 inches thick. Shale is at a depth of 18 inches.

Shingle - Typically, the surface layer is clay loam about 4 inches thick. The substratum is clay loam about 14 inches thick. Shale is at a depth of 18 inches.

Worf - Typically, the surface layer is fine sandy loam about 2 inches thick. The subsoil is sandy clay loam about 12 inches thick. The substratum is sandy clay loam about 4 inches thick. Interbedded shale and sandstone is at a depth of 18 inches.

These soils should be managed to control water erosion.

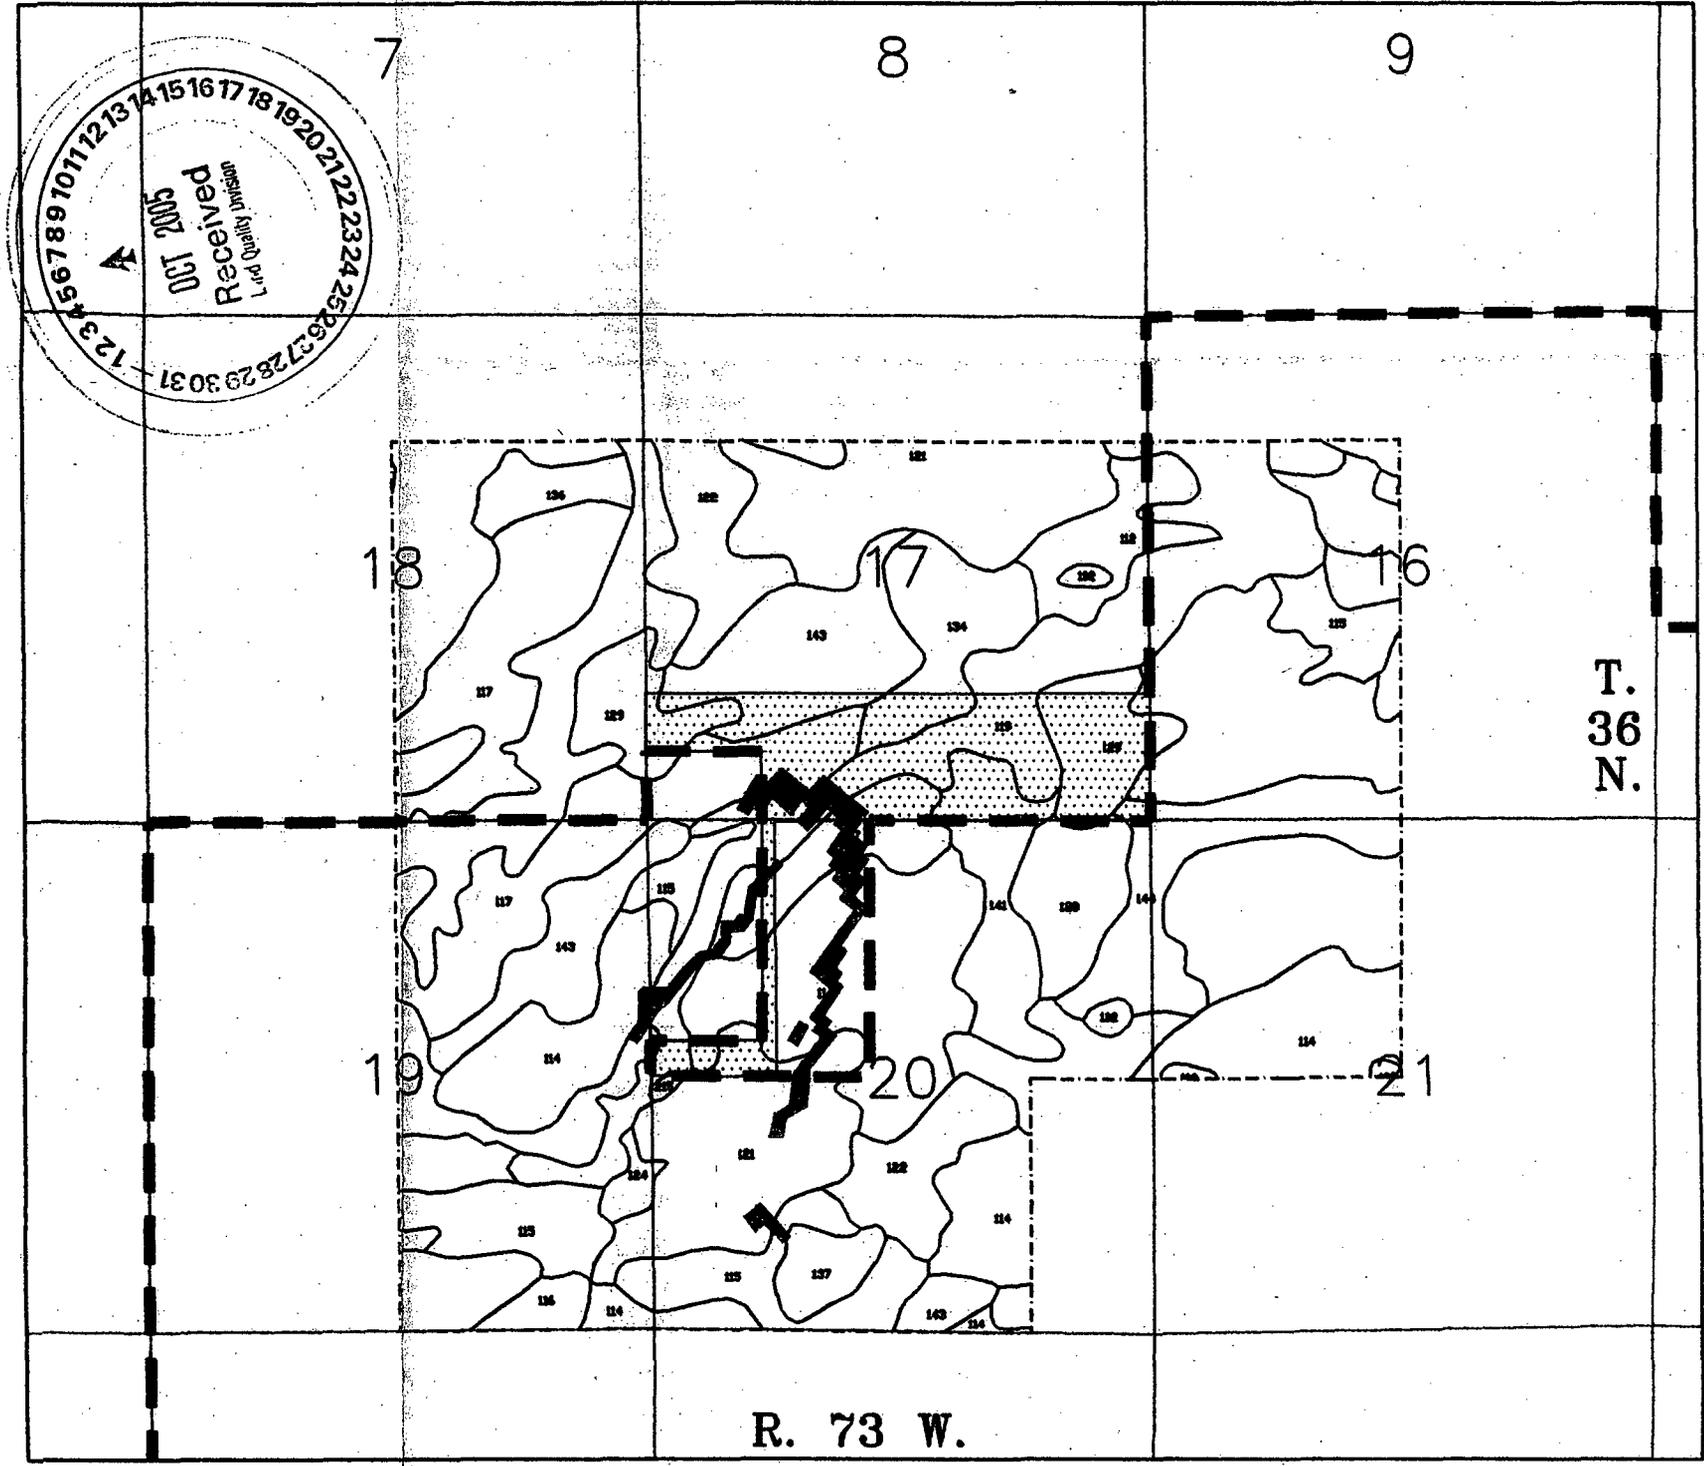

Capability = VIIe

Range Site - Samday - Shallow Clayey
 Shingle - Shallow Loam
 Worf - Shallow Clayey

The following 2 Drawings specifically referenced Appendix D7 Table of Contents have been processed into ADAMS.

APPENDIX D7 - SOILS

1.0 GENERAL

The impact to the topsoil resource at the Highland Uranium Project is relatively minor when compared to a typical surface mine operation as the in situ mining process results in very limited topsoil disturbance. Accordingly, most of the required topsoil salvage is restricted to major roads and building sites. Topsoil is not regularly salvaged and stockpiled from wellfield sites as disturbance is minimal and the wellfield sites are revegetated shortly after well construction is completed.

2.0 SOIL BASELINE STUDY

The soil baseline study was assembled in 1990 and covers the entire permit area of the Highland Uranium Project and includes lands within the proposed West Highland Amendment. This study, as agreed to with the WDEQ staff at the November 17, 1989 meeting is comprised of the Soil Survey of Converse County, Wyoming, Northern Part recently published by the U.S. Soil Conservation Service (SCS). The soil survey conducted by the SCS is an Order 3 survey.

The following are also included with the study:

- Plate D7-1 which shows the various SCS soil types in the entire permit area and adjacent lands.
- Detailed SCS map unit descriptions for the soil types found within and adjacent to the entire permit area and adjacent lands.
- Typical SCS soil profile descriptions of each series.
- Engineering index properties.
- Physical and chemical properties.

3.0 SOIL CHEMICAL ANALYSES

Soil samples were collected in 1986 for areas contained in the original permit application. Chemical analyses were conducted on 13 samples. These data are included in Addendum D7-1. The locations of the soil sampling sites are shown on Plate D7-1. The suitability of the soils sampled for topsoil is also shown in Addendum D7-1, in Table 1. All soils are shown to be suitable or marginally suitable as topsoil.

Detailed Soil Map Units

The map units delineated on the detailed maps at the back of this survey represent the soils or miscellaneous areas in the survey area. The map unit descriptions in this section, along with the maps, can be used to determine the suitability and potential of a unit for specific uses. They also can be used to plan the management needed for those uses. More information on each map unit is given under "Use and Management of the Soils."

A map unit delineation on a map represents an area dominated by one or more major kinds of soil or miscellaneous areas. A map unit is identified and named according to the taxonomic classification of the dominant soils or miscellaneous areas. Within a taxonomic class there are precisely defined limits for the properties of the soils. On the landscape, however, the soils and miscellaneous areas are natural phenomena, and they have the characteristic variability of all natural phenomena. Thus, the range of some observed properties may extend beyond the limits defined for a taxonomic class. Areas of soils of a single taxonomic class rarely, if ever, can be mapped without including areas of other taxonomic classes. Consequently, every map unit is made up of the soils or miscellaneous areas for which it is named and some "included" areas that belong to other taxonomic classes.

Most included soils have properties similar to those of the dominant soil or soils in the map unit, and thus they do not affect use and management. These are called noncontrasting, or similar, inclusions. They may or may not be mentioned in the map unit description. Other included soils and miscellaneous areas, however, have properties and behavior divergent enough to affect use or to require different management. These are called contrasting, or dissimilar, inclusions. They generally are in small areas and could not be mapped separately because of the scale used. Some small areas of strongly contrasting soils or miscellaneous areas are identified by a special symbol on the maps. The included areas of contrasting soils or miscellaneous areas are mentioned in the map unit descriptions. A few included areas may not have been observed, and consequently they are not mentioned in the descriptions, especially where the pattern was so complex that it was impractical to make thorough observations to identify all the soils and miscellaneous areas on the landscape.

The presence of included areas in a map unit in no way diminishes the usefulness or accuracy of the data. The objective of mapping is not to delineate pure taxonomic classes but rather to separate the landscape into segments that have similar use and management requirements. The delineation of such landscape segments on the map provides sufficient information for the development of resource plans, but if intensive use of small areas is planned, onsite investigation to precisely define and locate the soils and miscellaneous areas is needed.

An identifying symbol precedes the map unit name in the map unit descriptions. Each description includes general facts about the unit and gives the principal hazards and limitations to be considered in planning for specific uses.

Soils that have profiles that are almost alike make up a *soil series*. Except for differences in texture of the surface layer or of the underlying layers, all the soils of a series have major horizons that are similar in composition, thickness, and arrangement.

Soils of one series can differ in texture of the surface layer or of the underlying layers. They also can differ in characteristics that affect their use. On the basis of such differences, a soil series is divided into *soil phases*. Most of the areas shown on the detailed soil maps are phases of soil series. The name of a soil phase commonly indicates a feature that affects use or management. For example, Shingle loam, thin solum, is one of several phases in the Shingle series.

Most map units are made up of two or more major soils or miscellaneous areas. These map units are complexes or associations.

A *complex* consists of two or more soils or miscellaneous areas in such an intricate pattern or in such small areas that they cannot be shown separately on the maps. The pattern and proportion of the soils or miscellaneous areas are somewhat similar in all areas. Ulm-Renohill complex, 0 to 6 percent slopes, is an example.

An *association* is made up of two or more geographically associated soils or miscellaneous areas that are shown as one unit on the maps. Because of present or anticipated uses of the map units in the survey area, it was not considered practical or necessary to map the soils or miscellaneous areas separately. The pattern and relative proportion of the soils or

LANDQUALITY DIVISION

RECEIVED MAR 11 1991

miscellaneous areas are somewhat similar. Zigweid-Cambria association, 0 to 6 percent slopes, is an example.

This survey includes *miscellaneous areas*. Such areas have little or no soil material and support little or no vegetation. Rock outcrop is an example.

Table 3 gives the acreage and proportionate extent of each map unit. Other tables (see "Summary of tables") give properties of the soils and the limitations, capabilities, and potentials for many uses. The Glossary defines many of the terms used in describing the soils or miscellaneous areas.

Map Unit Descriptions

101—Absted-Arvada-Bone complex, 0 to 6 percent slopes. This map unit is in nearly level to undulating areas on toe slopes, alluvial flats, and stream terraces. Slopes are medium in length and are plane. The native vegetation is mainly salt tolerant grasses, shrubs, and woody plants.

This unit is 40 percent Absted fine sandy loam, 25 percent Arvada loam, and 20 percent Bone clay loam. The components of this unit are so intricately intermingled that it was not practical to map them separately at the scale used.

Included in this unit are small areas of Ulm loam, Lohmiller clay loam, Haverdad fine sandy loam, and Bahl clay. Included areas make up about 15 percent of the total acreage. The percentage varies from one area to another.

The Absted soil is deep and well drained. It formed in clayey alluvium derived dominantly from sedimentary rock. Typically, the surface layer is pale brown fine sandy loam about 3 inches thick. The upper 23 inches of the subsoil is brown and grayish brown clay, and the lower 34 inches or more is light brownish gray clay. In a few areas soft bedrock is at a depth of 20 to 60 inches.

Permeability of the Absted soil is slow. Available water capacity is moderate. Effective rooting depth is 60 inches or more. Runoff is slow, and the hazard of water erosion is moderate. The hazard of wind erosion is moderate. Excess sodium or soluble salts are at an average depth of 15 inches.

The Arvada soil is deep and well drained. It formed in clayey alluvium derived dominantly from sedimentary rock. Typically, the surface layer is light brownish gray loam about 3 inches thick. The subsoil is pale brown and light brownish gray clay about 19 inches thick. The substratum to a depth of 60 inches or more is pale brown clay.

Permeability of the Arvada soil is very slow. Available water capacity is low. Effective rooting depth is 60 inches or more. Runoff is slow, and the hazard of water erosion is moderate. The hazard of wind erosion is moderate. Excess sodium or soluble salts are in the upper part of the subsoil.

The Bone soil is deep and well drained. It formed in clayey alluvium derived dominantly from sedimentary rock. Typically, the surface layer is pale brown clay loam about 2 inches thick. The upper 3 inches of the subsoil is light brownish gray clay loam, and the lower 5 inches is light gray clay loam. The substratum to a depth of 60 inches or more is very pale brown clay loam and clay.

Permeability of the Bone soil is very slow. Available water capacity is low. Effective rooting depth is 60 inches or more. Runoff is slow, and the hazard of water erosion is moderate. The hazard of wind erosion is moderate. Excess sodium or soluble salts occur throughout the profile.

Most areas of this unit are used for livestock grazing and wildlife habitat. A few areas are used for hay production.

The potential plant community on this unit is mainly inland saltgrass, western wheatgrass, Indian ricegrass, and Gardner saltbush. The Bone soil commonly does not support any significant amount of vegetation. As the range condition deteriorates, greasewood increases. As the range condition further deteriorates, annuals invade. The potential plant community produces about 500 pounds of air-dry vegetation in normal years. Production varies from 650 pounds in favorable years to 250 pounds in unfavorable years.

Some areas of this unit east of Wyoming Highway 59, immediately adjacent to the Cheyenne River, support different species and significantly higher levels of plant production than is typical for this unit. Alkali sacaton and western wheatgrass dominate these areas, and yields may range from 1,200 to 2,000 pounds of air-dry vegetation per year. These sites are on the lower parts of stream terraces and receive runoff from river tributaries.

The production of forage in most areas is limited by salinity or alkalinity and low annual precipitation. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

Range seeding is suitable if the range is in poor condition. The main limitations are salinity or alkalinity and lack of suitable adapted species for use in reclamation. The areas of this unit on the lower parts of stream terraces have fair suitability for seeding. These areas also can be improved by mechanical or chemical treatment if heavily infested with undesirable plants.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

This unit is poorly suited to homesite development. The main limitations are high shrink-swell potential, slow and very slow permeability, and slow runoff. Backfilling excavations with coarser textured material reduces the shrink-swell potential. Constructing a larger absorption

LANDQUALITY DIVISION

RECEIVED MAR 11 1961

1/173 PERMIT

or using selected material will help compensate for the slow and very slow permeability.

This map unit is in capability subclass VI_s. Most of the unit is in the Saline Upland, 10- to 14-inch ppt., Northern Plains range site. The areas on the lower parts of stream terraces adjacent to the Cheyenne River are in Saline Lowland, 10- to 14-inch ppt., Northern Plains range site.

102—Aeric Haplaquepts, 0 to 3 percent slopes.

These deep, poorly drained soils are in areas of centripetal drainage in playas. The soils formed in clayey local alluvium derived dominantly from sedimentary rock. Slopes are concave and are short or medium in length. Areas are generally oval in shape and are 1 to 100 acres in size. The native vegetation is mainly grasses.

Included in this unit are small areas of Silhouette clay loam, Savageton clay loam, and Bahl clay. Also included are small intermittent ponds. Included areas make up about 25 percent of the total acreage. The percentage varies from one area to another.

No single profile of Aeric Haplaquepts is typical, but one commonly observed in the survey area has a surface layer of light gray and light brownish gray clay loam about 8 inches thick. The underlying material to a depth of 48 inches or more is light gray and pale brown clay with yellow and yellowish red mottles. In some of the smaller areas of these soils, soft sedimentary bedrock is at a depth of 20 to 60 inches.

Permeability of the Aeric Haplaquepts is very slow.

Available water capacity is high. Effective rooting depth is 60 inches for water-tolerant plants but is limited to depths between 0 and 12 inches for non-water-tolerant plants. Runoff is very slow, and the hazard of water erosion is slight. The hazard of wind erosion is slight. A seasonal high water table fluctuates between depths of 0 and 24 inches from March through July. Some areas of this unit are covered by water from snowmelt, intense rain showers, and runoff from adjacent areas.

This unit is used for livestock grazing and wildlife habitat.

The potential plant community on this unit is mainly basin wildrye, green needlegrass, western wheatgrass, and Canada wildrye. As the range condition deteriorates, needleleaf sedge and Sandberg bluegrass increase. As the range condition further deteriorates, annual forbs invade. The potential plant community produces about 2,300 pounds of air-dry vegetation in normal years. Production varies from 2,800 pounds in favorable years to 1,900 pounds in unfavorable years. The types of vegetation in the larger playas also include those of wetland and subirrigated range sites in the lower positions and no vegetation in the lowest positions because of intermittent ponding.

The production of forage is limited by low annual precipitation. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore,

livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of this unit for rangeland seeding is good. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds. Larger areas of this unit are used temporarily by migratory shore birds.

This unit is not suited to homesite development because of ponding.

This map unit is in capability subclass VI_w. Most of this unit is in the Clayey Overflow, 10- to 14-inch ppt., Northern Plains range site.

103—Bahl-Savageton complex, 0 to 6 percent slopes.

This map unit is in nearly level to undulating areas on toe slopes and alluvial flats. Slopes are medium in length and are plane to slightly concave. The native vegetation is mainly grasses.

This unit is 40 percent Bahl clay and 35 percent Savageton clay loam. The components of this unit are so intricately intermingled that it was not practical to map them separately at the scale used.

Included in this unit are small areas of Ulm loam and Zigweid clay loam. Included areas make up about 25 percent of the total acreage. The percentage varies from one area to another.

The Bahl soil is deep and well drained. It formed in clayey local alluvium derived dominantly from calcareous shale. Typically, the surface layer is pale olive clay about 4 inches thick. The underlying material to a depth of 60 inches or more is pale olive clay.

Permeability of the Bahl soil is slow. Available water capacity is high. Effective rooting depth is 60 inches or more. Runoff is medium, and the hazard of water erosion is moderate. The hazard of wind erosion is slight.

The Savageton soil is moderately deep and well drained. It formed in clayey local alluvium and residuum derived dominantly from calcareous shale. Typically, the surface layer is gray clay loam about 2 inches thick. The subsoil is light brownish gray and grayish brown clay about 30 inches thick. Platy shale is at a depth of 32 inches.

Permeability of the Savageton soil is very slow. Available water capacity is low. Effective rooting depth is 20 to 40 inches. Runoff is medium, and the hazard of water erosion is moderate. The hazard of wind erosion is slight.

This unit is used for livestock grazing and wildlife habitat.

The potential plant community on this unit is mainly western wheatgrass, green needlegrass, and thickspike wheatgrass. As the range condition deteriorates, big sagebrush and blue grama increase. As the range condition further deteriorates, cactus and broom

LANDQUALITY DIVISION

MAR 11 1991

snakeweed invade. The potential plant community produces about 1,300 pounds of air-dry vegetation in normal years. Production varies from 1,800 pounds in favorable years to 750 pounds in unfavorable years.

The production of forage is limited by low annual precipitation. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of this unit for rangeland seeding is good. Chiseling or other such practices can be used to improve areas of deteriorated rangeland. Such practices increase water infiltration, reduce plant competition, and allow the desirable native plants to increase. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

This unit is poorly suited to homesite development. The main limitations are high shrink-swell potential, slow and very slow permeability, and the depth of the the Savageton soil to soft bedrock. Backfilling excavations with coarser textured material reduces the limitation of shrink-swell potential. Constructing a larger absorption field or using selected material helps to overcome the slow permeability of the Bahl soil. Areas of the Savageton soil are not suitable for use as septic tank absorption fields.

This map unit is in capability subclass IVe. It is in the Clayey, 10- to 14-inch ppt., Northern Plains range site.

104—Cambria-Cushman complex, 0 to 6 percent slopes. This map unit is on toe slopes and ridge crests of rolling uplands. Slopes are medium in length and are slightly convex to plane. The native vegetation is mainly grasses and shrubs.

This unit is 60 percent Cambria fine sandy loam and 30 percent Cushman loam. The components of this unit are so intricately intermingled that it was not practical to map them separately at the scale used.

Included in this unit are small areas of Ulm loam and Renohill sandy loam. Included areas make up about 10 percent of the total acreage. The percentage varies from one area to another.

The Cambria soil is deep and well drained. It formed in loamy local alluvium and residuum derived dominantly from sedimentary rock. Typically, the surface layer is grayish brown fine sandy loam about 2 inches thick. The upper 8 inches of the subsoil is brown sandy clay loam, and the lower part to a depth of 60 inches or more is pale brown loam. In some areas soft bedrock is at a depth of 40 to 60 inches.

Permeability of the Cambria soil is moderate. Available water capacity is high. Effective rooting depth is 60 inches or more. Runoff is medium, and the hazard of water erosion is moderate. The hazard of wind erosion is moderate.

The Cushman soil is moderately deep and well drained. It formed in loamy residuum derived dominantly from calcareous shale and sandstone. Typically, the surface layer is brown loam about 4 inches thick. The upper 11 inches of the subsoil is yellowish brown and light yellowish brown clay loam, and the lower 18 inches is pale brown clay loam and very pale brown sandy clay loam. Interbedded shale and sandstone are at a depth of 33 inches.

Permeability of the Cushman soil is moderate. Available water capacity is moderate. Effective rooting depth is 20 to 40 inches. Runoff is medium, and the hazard of water erosion is moderate. The hazard of wind erosion is moderate.

This unit is used for livestock grazing and wildlife habitat.

The potential plant community on this unit is mainly western wheatgrass, thickspike wheatgrass, and needleandthread. As the range condition deteriorates, big sagebrush and blue grama increase. As the range condition further deteriorates, cacti, annuals, and broom snakeweed invade. The potential plant community produces about 1,500 pounds of air-dry vegetation in normal years. Production varies from 2,000 pounds in favorable years to 850 pounds in unfavorable years.

The production of forage is limited by low annual precipitation. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of this unit for rangeland seeding is good. Chiseling or other such practices can be used to improve areas of deteriorated rangeland. Such practices increase water infiltration, reduce plant competition, and allow the desirable native plants to increase.

This unit is limited for livestock watering ponds and other water impoundments because of the seepage potential.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

If this unit is used for homesite development, the main limitations are moderate shrink-swell potential and the depth of the Cushman soil to soft bedrock. Backfilling excavations with coarser textured material reduces the limitation of shrink-swell potential. Areas of the Cushman soil are not suitable for use as septic tank absorption fields.

This map unit is in capability subclass IVe. It is in the Loamy, 10- to 14-inch ppt., Northern Plains range site.

105—Cambria-Cushman complex, 6 to 15 percent slopes. This map unit is on back slopes of rolling uplands and on adjacent foot slopes. Slopes are short and are mostly convex. The native vegetation is mainly grasses and shrubs.

LANDQUALITY DIVISION

RECEIVED MAR 11 1991

This unit is 50 percent Cambria sandy loam and 30 percent Cushman loam. The components of this unit are so intricately intermingled that it was not practical to map them separately at the scale used.

Included in this unit are small areas of Renohill clay loam and Worf fine sandy loam. Included areas make up about 20 percent of the total acreage. The percentage varies from one area to another.

The Cambria soil is deep and well drained. It formed in loamy local alluvium and residuum derived dominantly from sedimentary rock. Typically, the surface layer is brown sandy loam about 4 inches thick. The upper 4 inches of the subsoil is yellowish brown loam, and the lower part to a depth of 60 inches or more is pale brown loam. In some areas soft bedrock is between depths of 40 and 60 inches.

Permeability of the Cambria soil is moderate. Available water capacity is high. Effective rooting depth is 60 inches or more. Runoff is medium, and the hazard of water erosion is severe. The hazard of wind erosion is moderate.

The Cushman soil is moderately deep and well drained. It formed in loamy residuum derived dominantly from calcareous shale and sandstone. Typically, the surface layer is pale brown loam about 3 inches thick. The upper 14 inches of the subsoil is pale brown and light gray clay loam, and the lower 8 inches is pale yellow loam. Interbedded shale and sandstone are at a depth of 25 inches.

Permeability of the Cushman soil is moderate. Available water capacity is low. Effective rooting depth is 20 to 40 inches. Runoff is medium, and the hazard of water erosion is severe. The hazard of wind erosion is moderate.

This unit is used for livestock grazing and wildlife habitat.

The potential plant community on this unit is mainly western wheatgrass, thickspike wheatgrass, and needleandthread. As the range condition deteriorates, big sagebrush and blue grama increase. As the range condition further deteriorates, cacti, annuals, and broom snakeweed invade. The potential plant community produces about 1,500 pounds of air-dry vegetation in normal years. Production varies from 2,000 pounds in favorable years to 850 pounds in unfavorable years.

The production of forage is limited by low annual precipitation. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of this unit for rangeland seeding is fair. The main limitation is the hazard of water erosion. Chiseling or other such practices can be used to improve soil of deteriorated rangeland. Such practices increase soil infiltration, reduce plant competition, and allow the

desirable native plants to increase. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

If this unit is used for homesite development, the main limitations are moderate shrink-swell potential, slope, and the depth of the Cushman soil to soft bedrock. Backfilling with coarser textured material reduces the limitation of shrink-swell potential. Areas of the Cushman soil are not suitable for use as septic tank absorption fields.

This map unit is in capability subclass VIe. It is in the Loamy, 10- to 14-inch ppt., Northern Plains range site.

106—Cambria Variant-Forkwood Variant complex, 0 to 6 percent slopes. This map unit is in nearly level to undulating areas on toe slopes and alluvial flats. Slopes are long and plane. The native vegetation is mainly grasses and shrubs.

This unit is 45 percent Cambria Variant fine sandy loam and 35 percent Forkwood Variant clay loam. The components of this unit are so intricately intermingled that it was not practical to map them separately at the scale used.

Included in this unit are small areas of Hiland sandy loam and Ulm loam. Also included are small areas of soils that have a stratified substratum. Included areas make up about 20 percent of the total acreage. The percentage varies from one area to another.

The Cambria Variant soil is deep and well drained. It formed in loamy alluvium derived dominantly from interbedded sandstone and shale. Typically, the surface layer is light gray fine sandy loam about 2 inches thick. The upper 14 inches of the subsoil is light brownish gray clay loam and loam, and the lower 32 inches is light brownish gray stratified loam, clay loam, and sandy clay loam to a depth of 60 inches or more.

Permeability of the Cambria Variant soil is moderate. Available water capacity is high. Effective rooting depth is 60 inches or more. Runoff is slow, and the hazard of water erosion is moderate. The hazard of wind erosion is moderate.

The Forkwood Variant soil is deep and well drained. It formed in loamy alluvium derived dominantly from interbedded sandstone and shale. Typically, the surface layer is light gray clay loam about 3 inches thick. The upper 13 inches of the subsoil is pale brown clay loam, and the lower part to a depth of 60 inches or more is light gray stratified loam, clay loam, and fine sandy loam.

Permeability of the Forkwood Variant soil is moderate. Available water capacity is high. Effective rooting depth is 60 inches or more. Runoff is medium, and the hazard of water erosion is moderate. The hazard of wind erosion is slight.

This unit is used for livestock grazing and wildlife habitat.

LAND QUALITY DIVISION

The potential plant community on this unit is mainly western wheatgrass, thickspike wheatgrass, and needleandthread. As the range condition deteriorates, big sagebrush and blue grama increase. As the range condition further deteriorates, cacti, annuals, and broom snakeweed invade. The potential plant community produces about 1,500 pounds of air-dry vegetation in normal years. Production varies from 2,000 pounds in favorable years to 850 pounds in unfavorable years.

The production of forage is limited by low annual precipitation. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of this unit for rangeland seeding is good. Chiseling or other such practices can be used to improve areas of deteriorated rangeland. Such practices increase water infiltration, reduce plant competition, and allow the desirable native plants to increase.

This unit is limited for livestock watering ponds and other water impoundments because of the seepage potential.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

If this unit is used for homesite development, the main limitation is moderate shrink-swell potential. Backfilling excavations with coarser textured material helps to overcome this limitation.

This map unit is in capability subclass IVe. It is in the Loamy, 10- to 14-inch ppt., Northern Plains range site. There are inclusions of Clayey Overflow, 10- to 14-inch ppt., Northern Plains range site in areas where runoff water collects.

107—Clarkelen-Draknab complex, 0 to 3 percent slopes. This map unit is on flood plains. Slopes are long and plane. The native vegetation is mainly grasses and woody plants.

This unit is 50 percent Clarkelen sandy loam and 35 percent Draknab loamy sand. The components of this unit are so intricately intermingled that it was not practical to map them separately at the scale used.

Included in this unit are small areas of Keeline sandy loam, Haverdad fine sandy loam, and Bigwin fine sandy loam. Included areas make up about 15 percent of the total acreage. The percentage varies from one area to another.

The Clarkelen soil is deep and somewhat excessively drained. It formed in loamy recently deposited alluvium derived dominantly from sedimentary rock. Typically, the surface layer is pale brown and grayish brown sandy loam about 3 inches thick. The underlying material to a depth of 60 inches or more is highly stratified light brownish gray sand, sandy loam, sandy clay loam, and silt loam.

Permeability of the Clarkelen soil is moderately rapid. Available water capacity is moderate. Effective rooting depth is 60 inches or more. Runoff is slow, and the hazard of water erosion is moderate. The hazard of wind erosion is moderate. This soil is subject to flooding during prolonged, high-intensity storms. Channeling and deposition occur along streambanks.

The Draknab soil is deep and excessively drained. It formed in sandy recently deposited alluvium derived dominantly from sandstone. Typically, the surface layer is yellowish brown loamy sand about 2 inches thick. The underlying material to a depth of 60 inches or more is pale brown and very pale brown, stratified sand, coarse sand, loamy sand, and loamy coarse sand.

Permeability of the Draknab soil is rapid. Available water capacity is low. Effective rooting depth is 60 inches or more. Runoff is very slow, and the hazard of water erosion is slight. The hazard of wind erosion is severe. This soil is subject to flooding during prolonged, high-intensity storms. Channeling and deposition occur along streambanks.

This unit is used for livestock grazing and wildlife habitat.

The potential plant community on this unit is mainly western wheatgrass, slender wheatgrass, needleandthread, and cottonwood trees. As the range condition deteriorates, silver sagebrush, rubber rabbitbrush, and snowberry increase. As the range condition further deteriorates, annual forbs and cheatgrass invade. The potential plant community produces about 2,500 pounds of air-dry vegetation in normal years. Production varies from 3,000 pounds in favorable years to 2,000 pounds in unfavorable years.

The production of forage is limited by low annual precipitation and the hazard of flooding. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of this unit for rangeland seeding is good. Chiseling or other such practices can be used to improve areas of deteriorated rangeland. Such practices increase water infiltration, reduce plant competition, and allow the desirable native plants to increase.

This unit is limited for livestock watering ponds and other water impoundments because of the seepage potential.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds. Cottonwood trees commonly provide important riparian habitat for birds and small mammals.

This unit is poorly suited to homesite development. The main limitations are the hazard of excavations caving in and the hazard of flooding. Constructing dikes reduces the risk of flooding. Use of septic tank

LANDQUALITY DIVISION

RECEIVED MAR 11 1991

2 1/173 PERMIT

absorption fields could create a hazard of polluting ground water.

This map unit is in capability subclass IVe. It is in the Lowland, 10- to 14-inch ppt., Northern Plains range site.

108—Clarkelen-Dwyer-Orpha association, 0 to 10 percent slopes. This map unit is in gently sloping areas on flood plains and in undulating to gently rolling areas on dunes that are superimposed on stream terraces. The Clarkelen soil is on flood plains, and the Dwyer and Orpha soils are on terrace dunes. Slopes are medium in length and are plane, or they are short and convex. The native vegetation is mainly grasses and woody plants.

This unit is 40 percent Clarkelen sandy loam, 25 percent Dwyer loamy sand, and 20 percent Orpha loamy sand.

Included in this unit are small areas of Haverdad fine sandy loam, Draknab loamy sand, Keeline sandy loam, and Kishona loam. Included areas make up about 15 percent of the total acreage. The percentage varies from one area to another.

The Clarkelen soil is deep and somewhat excessively drained. It formed in loamy recently deposited alluvium derived dominantly from sedimentary rock. Typically, the surface layer is pale brown and grayish brown sandy loam about 3 inches thick. The underlying material to a depth of 60 inches or more is highly stratified, light brownish gray sand, sandy loam, sandy clay loam, and loam that contain carbonates.

Permeability of the Clarkelen soil is moderately rapid. Available water capacity is moderate. Effective rooting depth is 60 inches or more. Runoff is slow, and the hazard of water erosion is severe. The hazard of wind erosion is moderate. This soil is subject to flooding during prolonged, high-intensity storms. Channeling and deposition are common along streambanks.

The Dwyer soil is deep and excessively drained. It formed in eolian sand derived from mixed sources. Typically, the surface layer is brown loamy sand about 5 inches thick. The underlying material to a depth of 60 inches or more is pale brown loamy sand that contains carbonates within a depth of 40 inches.

Permeability of the Dwyer soil is rapid. Available water capacity is low. Effective rooting depth is 60 inches or more. Runoff is slow, and the hazard of water erosion is moderate. The hazard of wind erosion is severe.

The Orpha soil is deep and excessively drained. It formed in eolian sand derived from mixed sources. Typically, the surface layer is pale brown loamy sand about 5 inches thick. The underlying material to a depth of 60 inches or more is light yellowish brown loamy sand.

Permeability of the Orpha soil is very rapid. Available water capacity is low. Effective rooting depth is 60 inches or more. Runoff is slow, and the hazard of water erosion is slight. The hazard of wind erosion is severe.

This unit is used for livestock grazing and wildlife habitat.

The potential plant community on the Clarkelen soil is mainly needleandthread, slender wheatgrass, western wheatgrass, and cottonwood trees. As the range condition deteriorates, silver sagebrush, rubber rabbitbrush, and snowberry increase. As the range condition further deteriorates, annual forbs and cheatgrass invade. The potential plant community produces about 2,500 pounds of air-dry vegetation in normal years. Production varies from 3,000 pounds in favorable years to 2,000 pounds in unfavorable years.

The production of forage on the Clarkelen soil is limited by low annual precipitation and the hazard of flooding. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community. The suitability of this soil for rangeland seeding is good. Chiseling or other such practices can be used to improve areas of deteriorated rangeland. Such practices increase water infiltration, reduce plant competition, and allow the desirable native plants to increase. This soil is limited for livestock watering ponds and other water impoundments because of the seepage potential.

The potential plant community on the Dwyer and Orpha soils is mainly prairie sandreed, sand bluestem, needleandthread, and Indian ricegrass. As the range condition deteriorates, sageworts increase. As the range condition further deteriorates, annuals and broom snakeweed invade. The potential plant community produces about 2,000 pounds of air-dry vegetation in normal years. Production varies from 2,500 pounds in favorable years to 1,400 pounds in unfavorable years.

The production of forage on the Dwyer and Orpha soils is limited by droughtiness. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community. The suitability of these soils for rangeland seeding is poor. The main limitations are the hazard of wind erosion and droughtiness. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment. These soils are limited for livestock watering ponds and other water impoundments because of the seepage potential.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds. Cottonwood trees commonly provide important riparian habitat for birds and small mammals.

The Clarkelen soil is poorly suited to homesite development. The main limitation is the hazard of flooding. Use of septic tank absorption fields could

EQUALITY DIVISION

RECEIVE

Addendum D7 B3

Page 20

1/

create a hazard of polluting ground water. If the Dwyer and Orpha soils are used for homesite development, the main limitations are slope, the hazard of excavations caving in, and sand blowing.

The Clarkelen soil is in capability subclass IVe. The Dwyer and Orpha soils are in capability subclass VIe. The Clarkelen soil is in the Lowland, 10- to 14-inch ppt., Northern Plains range site. The Dwyer and Orpha soils are in the Sands, 10- to 14-inch ppt., Northern Plains range site.

109—Clarkelen-Haverdad-Bigwinder complex, 0 to 3 percent slopes. This map unit is on flood plains and low terraces of major streams. Slopes are medium in length and are plane. The native vegetation is mainly grasses, sedges, and woody plants.

This unit is 35 percent Clarkelen sandy loam, 25 percent Haverdad fine sandy loam, and 25 percent Bigwinder fine sandy loam. The components of this unit are so intricately intermingled that it was not practical to map them separately at the scale used.

Included in this unit are small areas of Draknab loamy sand, Keeline sandy loam, and Dwyer loamy sand. Included areas make up about 15 percent of the total acreage. The percentage varies from one area to another.

The Clarkelen soil is deep and somewhat excessively drained. It formed in loamy recently deposited alluvium derived dominantly from sedimentary rock. Typically, the surface layer is pale brown and grayish brown sandy loam about 3 inches thick. The underlying material to a depth of 60 inches or more is highly stratified, light brownish gray sand, sandy loam, sandy clay loam, and silt loam.

Permeability of the Clarkelen soil is moderately rapid. Available water capacity is moderate. Effective rooting depth is 60 inches or more. Runoff is slow, and the hazard of water erosion is moderate. The hazard of wind erosion is moderate. This soil is subject to flooding during prolonged, high-intensity storms. Channeling and deposition are common along streambanks.

The Haverdad soil is deep and well drained. It formed in loamy recently deposited alluvium derived dominantly from sedimentary rock. Typically, the surface layer is grayish brown fine sandy loam about 6 inches thick. The underlying material to a depth of 60 inches or more is light brownish gray loam with lenses of clay loam and fine sandy loam.

Permeability of the Haverdad soil is moderate. Available water capacity is moderate. Effective rooting depth is 60 inches or more. Runoff is slow, and the hazard of water erosion is moderate. The hazard of wind erosion is moderate. This soil is subject to flooding during prolonged, high-intensity storms. Channeling and deposition occur along streambanks.

The Bigwinder soil is deep and poorly drained. It formed in loamy alluvium derived dominantly from

sedimentary rock. Typically, the surface layer is light brownish gray fine sandy loam about 3 inches thick. It has strong brown mottles. The upper 21 inches of the underlying material is stratified, light gray loam, sandy loam, and loamy sand, and the lower part to a depth of 60 inches or more is stratified, light gray and reddish yellow loamy sand and sand.

Permeability of the Bigwinder soil is moderate to moderately rapid to a depth of 24 inches and is rapid below this depth. Available water capacity is high. Effective rooting depth is 60 inches or more. Runoff is slow, and the hazard of water erosion is moderate. The hazard of wind erosion is moderate. This soil is subject to flooding during prolonged, high-intensity storms. Channeling and deposition occur along streambanks.

This unit is used mainly for livestock grazing and wildlife habitat. It is also used as hayland.

The potential plant community on the Clarkelen and Haverdad soils is mainly needleandthread, slender wheatgrass, green needlegrass, and cottonwood trees (fig. 2). As the range condition deteriorates, silver sagebrush, rubber rabbitbrush, and snowberry increase. As the range condition further deteriorates, annual forbs and cheatgrass invade. The potential plant community produces about 2,500 pounds of air-dry vegetation in normal years. Production varies from 3,000 pounds in favorable years to 2,000 pounds in unfavorable years.

The production of forage on these soils is limited by low annual precipitation and the hazard of flooding. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of these soils for rangeland seeding is good. Chiseling or other such practices can be used to improve areas of deteriorated rangeland. Such practices increase water infiltration, reduce plant competition, and allow the desirable native plants to increase.

The potential plant community on the Bigwinder soil is mainly Nebraska sedge, basin wildrye, slender wheatgrass, and willows. As the range condition deteriorates, western wheatgrass, mat muhly, and spike sedge increase. As the range condition further deteriorates, annual forbs invade. The potential plant community produces about 4,000 pounds of air-dry vegetation in normal years. Production varies from 4,500 pounds in favorable years to 3,500 pounds in unfavorable years.

The production of forage on this soil is limited by wetness and the hazard of flooding. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

Figure 2.—Area of Clarkelen-Haverdad-Bigwinder complex, 0 to 3 percent slope, along Box Creek. This area supports scattered cottonwood trees.

The suitability of this soil for rangeland seeding is good. The main limitations are wetness and the hazard of flooding.

This unit is limited for livestock watering ponds and other water impoundments because of the seepage potential.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds. Cottonwood trees commonly provide important riparian habitat for birds and small mammals.

This unit is poorly suited to homesite development. The main limitations are the hazard of flooding and wetness. Construction of dikes reduces the risk of flooding. Use of septic tank absorption fields could create a hazard of polluting ground water.

This map unit is in capability subclass IVe. The Clarkelen and Haverdad soils are in the Lowland, 10- to 14-inch ppt., Northern Plains range site. The Bigwinder soils are in the Subirrigated, 10- to 14-inch ppt., Northern Plains range site.

110—Cushman-Terro complex, 0 to 6 percent slopes. This map unit is on pediment slopes of nearly level to undulating dissected uplands. Slopes are medium in length and are convex. The native vegetation is mainly grasses and shrubs.

This unit is 45 percent Cushman loam and 40 percent Terro sandy loam. The components of this unit are so intricately intermingled that it was not practical to map them separately at the scale used.

Included in this unit are small areas of Shingle clay loam in the more highly dissected areas. Also included are small areas of Hiland sandy loam. Included areas make up about 15 percent of the total acreage. The percentage varies from one area to another.

The Cushman soil is moderately deep and well drained. It formed in loamy residuum derived dominantly from calcareous shale and sandstone. Typically, the surface layer is brown loam about 4 inches thick. The upper 11 inches of the subsoil is yellowish brown and light yellowish brown clay loam, and the lower 18 inches

LAND QUALITY DIVISION

RECEIVED

Addendum D7 B3

Page 22

is pale brown clay loam and very pale brown loam. Interbedded sandstone and shale are at a depth of 33 inches.

Permeability of the Cushman soil is moderate. Available water capacity is moderate. Effective rooting depth is 20 to 40 inches. Runoff is medium, and the hazard of water erosion is moderate. The hazard of wind erosion is moderate.

The Terro soil is moderately deep and somewhat excessively drained. It formed in loamy residuum derived dominantly from calcareous sandstone. Typically, the surface layer is brown sandy loam about 4 inches thick. The upper 19 inches of the subsoil is brown and pale brown sandy loam, and the lower 11 inches is light gray sandy loam. Soft sandstone is at a depth of 34 inches. In some areas soft bedrock is at a depth of 40 to 60 inches or more.

Permeability of the Terro soil is moderately rapid. Available water capacity is low. Effective rooting depth is 20 to 40 inches. Runoff is slow, and the hazard of water erosion is moderate. The hazard of wind erosion is moderate.

This unit is used for livestock grazing and wildlife habitat.

The potential plant community on the Cushman soil is mainly western wheatgrass, thickspike wheatgrass, and needleandthread. As the range condition deteriorates, big sagebrush and blue grama increase. As the range condition further deteriorates, cacti, annuals, and broom snakeweed invade. The potential plant community produces about 1,500 pounds of air-dry vegetation in normal years. Production varies from 2,000 pounds in favorable years to 850 pounds in unfavorable years.

The potential plant community on the Terro soil is mainly needleandthread, prairie sandreed, Indian ricegrass, and little bluestem. As the range condition deteriorates, sageworts and needleleaf sedge increase. As the range condition further deteriorates, annuals and broom snakeweed invade. The potential plant community produces about 1,600 pounds of air-dry vegetation in normal years. Production varies from 2,100 pounds in favorable years to 1,000 pounds in unfavorable years.

The production of forage on this unit is limited by low annual precipitation. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of this unit for rangeland seeding is good. The main limitation is the hazard of wind erosion. Chiseling or other such practices can be used to improve areas of deteriorated rangeland. Such practices increase water infiltration, reduce plant competition, and allow the desirable native plants to increase. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

This unit is limited for livestock watering ponds and other water impoundments because of the seepage potential.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

If this unit is used for homesite development, the main limitations are depth to soft bedrock and shrink-swell potential. Backfilling excavations with coarser textured material helps to overcome the problem of shrink-swell potential. It may be necessary to construct a mounded absorption field to compensate for the restricted depth to bedrock.

This map unit is in capability subclass IVe. The Cushman soil is in the Loamy, 10- to 14-inch ppt., Northern Plains range site. The Terro soil is in the Sandy, 10- to 14-inch ppt., Northern Plains range site.

111—Cushman-Terro complex, 6 to 15 percent slopes. This map unit is on shoulder slopes and back slopes of rolling uplands. Slopes are short and convex. The native vegetation is mainly grasses and shrubs.

This unit is 55 percent Cushman loam and 30 percent Terro sandy loam. The components of this unit are so intricately intermingled that it was not practical to map them separately at the scale used.

Included in this unit are small areas of Shingle clay loam and Worf fine sandy loam on shoulder slopes. Also included are small areas of Hiland sandy loam on back slopes. Included areas make up about 15 percent of the total acreage. The percentage varies from one area to another.

The Cushman soil is moderately deep and well drained. It formed in loamy residuum derived dominantly from calcareous shale and sandstone. Typically, the surface layer is pale brown loam about 3 inches thick. The upper 14 inches of the subsoil is pale brown and light gray clay loam, and the lower 8 inches is pale yellow loam. Interbedded sandstone and shale are at a depth of 25 inches. In some areas soft bedrock is at a depth of 40 to 60 inches or more.

Permeability of the Cushman soil is moderate. Available water capacity is low. Effective rooting depth is 20 to 40 inches. Runoff is medium, and the hazard of water erosion is severe. The hazard of wind erosion is moderate.

The Terro soil is somewhat excessively drained. It formed in loamy residuum derived dominantly from calcareous sandstone. Typically, the surface layer is brown sandy loam about 4 inches thick. The upper 19 inches of the subsoil is brown and pale brown sandy loam, and the lower 11 inches is light gray sandy loam. Soft sandstone is at a depth of 34 inches. In some areas soft bedrock is at a depth of 40 to 60 inches or more.

Permeability of the Terro soil is moderately rapid. Available water capacity is low. Effective rooting depth is 20 to 40 inches. Runoff is slow, and the hazard of water

LANDQUALITY DIVISION

...ion is moderate. The hazard of wind erosion is moderate.

This unit is used for livestock grazing and wildlife habitat.

The potential plant community on the Cushman soil is mainly western wheatgrass, thickspike wheatgrass, and needleandthread. As the range condition deteriorates, big sagebrush and blue grama increase. As the range condition further deteriorates, cacti, annuals, and broom snakeweed invade. The potential plant community produces about 1,500 pounds of air-dry vegetation in normal years. Production varies from 2,000 pounds in favorable years to 850 pounds in unfavorable years.

The potential plant community on the Terro soil is mainly needleandthread, prairie sandreed, Indian ricegrass, and little bluestem. As the range condition deteriorates, sageworts and needleleaf sedge increase. As the range condition further deteriorates, annuals and broom snakeweed invade. The potential plant community produces about 1,600 pounds of air-dry vegetation in normal years. Production varies from 2,100 pounds in favorable years to 1,000 pounds in unfavorable years.

The production of forage on this unit is limited by low annual precipitation. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in a plant community.

The suitability of this unit for rangeland seeding is fair. The main limitations are the hazards of wind and water erosion. Chiseling or other such practices can be used to improve areas of deteriorated rangeland. Such practices increase water infiltration, reduce plant competition, and allow the desirable native plants to increase. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

If this unit is used for homesite development, the main limitations are depth to soft bedrock, slope, and the moderate shrink-swell potential of the Cushman soil, which can be overcome by backfilling with coarser textured material. It may be necessary to construct a mounded absorption field to compensate for the limited depth to bedrock.

This map unit is in capability subclass VIe. The Cushman soil is in the Loamy, 10- to 14-inch ppt., Northern Plains range site. The Terro soil is in the Sandy, 10- to 14-inch ppt., Northern Plains range site.

112—Cushman-Worf association, 6 to 15 percent slopes. This map unit is on ridges, shoulder slopes, and back slopes of rolling uplands. Slopes are convex and of medium in length. The native vegetation consists mainly of grasses and shrubs.

This unit is 50 percent Cushman loam, 6 to 10 percent slopes, and 35 percent Worf fine sandy loam, 10 to 15 percent slopes. The Cushman soil is on back slopes, and the Worf soil is on ridges and shoulder slopes.

Included in this unit are small areas of Worfka fine sandy loam and Shingle loam intermingled with areas of the Worf soil. Also included are small areas of Forkwood sandy loam on concave slopes bordering areas of the Cushman soil. Included areas make up about 15 percent of the total acreage. The percentage varies from one area to another.

The Cushman soil is moderately deep and well drained. It formed in loamy residuum derived dominantly from interbedded sandstone and shale. Typically, the surface layer is pale brown loam about 3 inches thick. The upper 14 inches of the subsoil is pale brown and light gray clay loam, and the lower 8 inches is pale yellow loam. Interbedded shale and sandstone are at a depth of 25 inches.

Permeability of the Cushman soil is moderate. Available water capacity is low. Effective rooting depth is 20 to 40 inches. Runoff is medium to rapid, and the hazard of water erosion is severe. The hazard of wind erosion is moderate.

The Worf soil is shallow and well drained. It formed in residuum derived dominantly from calcareous shale. Typically, the surface layer is grayish brown fine sandy loam about 2 inches thick. The subsoil is brown and light yellowish brown sandy clay loam about 16 inches thick. Soft, calcareous shale is at a depth of 18 inches.

Permeability of the Worf soil is moderate. Available water capacity is low. Effective rooting depth is 8 to 20 inches. Runoff is medium to rapid, and the hazard of water erosion is severe. The hazard of wind erosion is moderate.

This unit is used for livestock grazing and wildlife habitat.

The potential plant community on the Cushman soil is mainly western wheatgrass, thickspike wheatgrass, and needleandthread. As the range condition deteriorates, big sagebrush and blue grama increase. As the range condition further deteriorates, cacti, annuals, and broom snakeweed invade. The potential plant community produces about 1,500 pounds of air-dry vegetation in normal years. Production varies from 2,000 pounds in favorable years to 850 pounds in unfavorable years. The production of forage is limited by low annual precipitation. The suitability of this soil for rangeland seeding is good.

The potential plant community on the Worf soil is mainly western wheatgrass, green needlegrass, and bluebunch wheatgrass. As the range condition deteriorates, birdfoot sagebrush and big sagebrush increase. As the range condition further deteriorates, broom snakeweed and annuals invade. The potential plant community produces about 900 pounds of air-dry vegetation in normal years. Production varies from 1,200

RECEIVED MAR 11 1991
WATER PERMIT

pounds in favorable years to 450 pounds in unfavorable years.

The production of forage on this unit is limited by restricted rooting depth and droughtiness. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of this unit for rangeland seeding is poor. The main limitations are the limited rooting depth and the hazard of water erosion. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

This unit is limited for livestock watering ponds and other water impoundments because of the seepage potential.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

If this unit is used for homesite development, the main limitations are slope, depth to soft bedrock, and moderate shrink-swell potential. Backfilling excavations with coarser textured material helps to overcome the limitation of moderate shrink-swell potential. Construction of a mounded absorption field may be needed to compensate for the depth to rock.

This map unit is in capability subclass VIe. The Cushman soil is in the Loamy, 10- to 14-inch ppt., Northern Plains range site. The Worf soil is in the Shallow Clayey, 10- to 14-inch ppt., Northern Plains range site.

113—Dwyer-Orpha loamy sands, 3 to 15 percent slopes. This map unit is on undulating to rolling dunes superimposed on stream terraces and alluvial flats. Slopes are short and convex. The native vegetation is mainly grasses and shrubs.

This unit is 50 percent Dwyer loamy sand and 30 percent Orpha loamy sand. The components of this unit are so intricately intermingled that it was not practical to map them separately at the scale used.

Included in this unit are small areas of Keeline sandy loam, Vonalee loamy sand, and Hiland sandy loam in swales and other depressional areas. Included areas make up about 20 percent of the total acreage. The percentage varies from one area to another.

The Dwyer soil is deep and excessively drained. It formed in sandy eolian material derived from mixed sources. Typically, the surface layer is brown loamy sand about 5 inches thick. The underlying material to a depth of 60 inches or more is pale brown loamy sand. Carbonates are within 40 inches of the surface. In some areas buried loamy strata are at a depth of 40 inches or more. In a few areas calcareous sandstone is at a depth of 20 to 60 inches.

Permeability of the Dwyer soil is rapid. Available water capacity is low. Effective rooting depth is 60 inches or

more. Runoff is slow, and the hazard of water erosion is moderate. The hazard of wind erosion is severe.

The Orpha soil is deep and excessively drained. It formed in sandy eolian material derived from mixed sources. Typically, the surface layer is grayish brown loamy sand about 6 inches thick. The underlying material to a depth of 60 inches or more is light brownish gray sand. Carbonates are below a depth of 40 inches. In some areas buried loamy strata are at a depth of 40 inches or more.

Permeability of the Orpha soil is very rapid. Available water capacity is low. Effective rooting depth is 60 inches or more. Runoff is slow, and the hazard of water erosion is slight. The hazard of wind erosion is severe.

This unit is used for livestock grazing and wildlife habitat.

The potential plant community on this unit is mainly prairie sandreed, Indian ricegrass, needleandthread, and little bluestem. As the range condition deteriorates, sageworts and needleleaf sedge increase. If the vegetation further deteriorates, annuals and snakeweed invade. The potential plant community produces about 1,600 pounds of air-dry vegetation in normal years. Production varies from 2,100 pounds in favorable years to 1,000 pounds in unfavorable years.

The production of forage is limited by low annual precipitation. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of this unit for rangeland seeding is fair. The main limitations are the hazards of erosion by wind and water. Chiseling or other such practices can be used to improve areas of deteriorated rangeland. Such practices increase water infiltration, reduce plant competition, and allow the desirable native plants to increase. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment. This unit is limited for livestock watering ponds and other water impoundments because of the seepage potential.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

If this unit is used for homesite development, the main limitations are the hazard of excavations caving in, slope, and sand blowing.

This map unit is in capability subclass VIIe. It is in the Sandy, 10- to 14-inch ppt., Northern Plains range site. In some of the steeper areas are inclusions of Sands, 10- to 14-inch ppt., Northern Plains range site.

114—Forkwood-Cambria fine sandy loams, 0 to 6 percent slopes. This map unit is in nearly level to undulating areas of foot slopes and toe slopes of rolling

LANDQUALITY DIVISION

1. Slopes are long and plane. The native vegetation is mainly grasses and shrubs.

This unit is 55 percent Forkwood fine sandy loam and 30 percent Cambria fine sandy loam. The components of this unit are so intricately intermingled that it was not practical to map them separately at the scale used.

Included in this unit are small areas of Ulm loam and Zigweid clay loam. Included areas make up about 15 percent of the total acreage. The percentage varies from one area to another.

The Forkwood soil is deep and well drained. It formed in loamy local alluvium derived dominantly from calcareous shale. Typically, the surface layer is pale brown fine sandy loam about 7 inches thick. The upper 7 inches of the subsoil is pale brown clay loam, and the lower part to a depth of 60 inches or more is light brownish gray and light gray clay loam. In some areas bedrock is at a depth of 20 to 60 inches.

Permeability of the Forkwood soil is moderate. Available water capacity is high. Effective rooting depth is 60 inches or more. Runoff is slow, and the hazard of water erosion is slight. The hazard of wind erosion is moderate.

The Cambria soil is deep and well drained. It formed in loamy local alluvium and residuum derived dominantly from sedimentary rock. Typically, the surface layer is grayish brown fine sandy loam about 2 inches thick. The upper 8 inches of the subsoil is brown sandy clay loam, and the lower part to a depth of 60 inches or more is pale brown loam.

Permeability of the Cambria soil is moderate. Available water capacity is high. Effective rooting depth is 60 inches or more. Runoff is medium, and the hazard of water erosion is moderate. The hazard of wind erosion is moderate.

This unit is used for livestock grazing and wildlife habitat.

The potential plant community on this unit is mainly western wheatgrass, thickspike wheatgrass, and needleandthread. As the range condition deteriorates, big sagebrush and blue grama increase. As the range condition further deteriorates, cacti, annuals, and broom snakeweed invade. The potential plant community produces about 1,500 pounds of air-dry vegetation in normal years. Production varies from 2,000 pounds in favorable years to 850 pounds in unfavorable years.

The production of forage is limited by low annual precipitation. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of this unit for rangeland seeding is good. Chiselplow or other such practices can be used to improve areas of deteriorated rangeland. Such practices increase water infiltration, reduce plant competition, and

allow the desirable native plants to increase. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

This unit is well suited to homesite development. It has few limitations. Backfilling excavations with coarser textured material helps to overcome the limitation of shrink-swell potential. Septic tank absorption fields operate most effectively if placed deep in the subsoil.

This map unit is in capability subclass IVe. It is in the Loamy, 10- to 14-inch ppt., Northern Plains range site.

115—Forkwood-Cambria-Cushman complex, 6 to 15 percent slopes. This map unit is on ridge crests, back slopes, and foot slopes of rolling uplands. Slopes are short and are mostly convex. The native vegetation is mainly grasses and shrubs.

This unit is 30 percent Forkwood fine sandy loam, 30 percent Cambria sandy loam, and 30 percent Cushman loam. The components of this unit are so intricately intermingled that it was not practical to map them separately at the scale used.

Included in this unit are small areas of Ulm loam and Worf fine sandy loam. Included areas make up about 10 percent of the total acreage. The percentage varies from one area to another.

The Forkwood soil is deep and well drained. It formed in loamy local alluvium derived dominantly from calcareous shale. Typically, the surface layer is pale brown fine sandy loam about 5 inches thick. The upper 13 inches of the subsoil is light yellowish brown clay loam, and the lower part to a depth of 60 inches or more is pale yellow and light gray loam.

Permeability of the Forkwood soil is moderate. Available water capacity is high. Effective rooting depth is 60 inches or more. Runoff is medium, and the hazard of water erosion is moderate. The hazard of wind erosion is moderate.

The Cambria soil is deep and well drained. It formed in loamy local alluvium and residuum derived dominantly from sedimentary rock. Typically, the surface layer is brown sandy loam about 4 inches thick. The upper 4 inches of the subsoil is yellowish brown loam, and the lower part to a depth of 60 inches or more is pale brown loam.

Permeability of the Cambria soil is moderate. Available water capacity is high. Effective rooting depth is 60 inches or more. Runoff is medium, and the hazard of water erosion is severe. The hazard of wind erosion is moderate.

The Cushman soil is moderately deep and well drained. It formed in loamy residuum derived dominantly from calcareous shale. Typically, the surface layer is pale brown loam about 3 inches thick. The upper 14 inches of the subsoil is pale brown and light gray clay loam, and the lower 8 inches is pale yellow loam over

LAND QUALITY DIVISION

REC

Addendum D7 B3

interbedded shale and sandstone. Soft bedrock is at a depth of 25 inches.

Permeability of the Cushman soil is moderate. Available water capacity is moderate. Effective rooting depth is 20 to 40 inches. Runoff is medium, and the hazard of water erosion is severe. The hazard of wind erosion is moderate.

This unit is used for livestock grazing and wildlife habitat.

The potential plant community on this unit is mainly western wheatgrass, thickspike wheatgrass, and needleandthread. As the range condition deteriorates, big sagebrush and blue grama increase. As the range condition further deteriorates, cacti, annuals, and broom snakeweed invade. The potential plant community produces about 1,500 pounds of air-dry vegetation in normal years. Production varies from 2,000 pounds in favorable years to 850 pounds in unfavorable years.

The production of forage is limited by low annual precipitation. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of this unit for rangeland seeding is fair. The main limitation is the hazard of water erosion. Chiseling or other such practices can be used to improve areas of deteriorated rangeland. Such practices increase water infiltration, reduce plant competition, and allow the desirable native plants to increase. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

If this unit is used for homesite development, the main limitations are moderate shrink-swell potential and the depth of the Cushman soil to soft bedrock. Backfilling excavations with coarser textured material helps to overcome the limitation of moderate shrink-swell potential. Septic tank absorption fields operate most effectively if placed deep in the subsoil of the Cambria and Forkwood soils; areas of the Cushman soil are not suitable for this use.

This map unit is in capability subclass VIe. It is in the Loamy, 10- to 14-inch ppt., Northern Plains range site.

116—Forkwood-Ulm complex, 0 to 6 percent slopes. This map unit is on foot slopes and toe slopes. Slopes are plane and are medium to long. The native vegetation is mainly grasses and shrubs.

This unit is 50 percent Forkwood fine sandy loam and 40 percent Ulm loam. The components of this unit are so intricately intermingled that it was not practical to map them separately at the scale used.

Included in this unit are small areas of Bidman sandy loam. Included areas make up about 10 percent of the

total acreage. The percentage varies from one area to another.

The Forkwood soil is deep and well drained. It formed in loamy local alluvium derived dominantly from calcareous shale. Typically, the surface layer is pale brown fine sandy loam about 7 inches thick. The upper 16 inches of the subsoil is pale brown clay loam, and the lower part to a depth of 60 inches or more is light brownish gray and light gray clay loam. In some areas the subsoil is sandy clay loam.

Permeability of the Forkwood soil is moderate. Available water capacity is high. Effective rooting depth is 60 inches or more. Runoff is slow, and the hazard of water erosion is slight. The hazard of wind erosion is moderate.

The Ulm soil is deep and well drained. It formed in clayey local alluvium derived dominantly from calcareous shale. Typically, the surface layer is brown loam about 5 inches thick. The upper 16 inches of the subsoil is brown clay loam and clay, and the lower part to a depth of 60 inches or more is pale brown clay loam and light yellowish brown sandy clay loam.

Permeability of the Ulm soil is slow. Available water capacity is high. Effective rooting depth is 60 inches or more. Runoff is slow, and the hazard of water erosion is moderate. The hazard of wind erosion is slight.

This unit is used for livestock grazing and wildlife habitat.

The potential plant community on this unit is mainly western wheatgrass, thickspike wheatgrass, and needleandthread. As the range condition deteriorates, big sagebrush and blue grama increase. As the range condition further deteriorates, cacti, annuals, and broom snakeweed invade. The potential plant community produces about 1,500 pounds of air-dry vegetation in normal years. Production varies from 2,000 pounds in favorable years to 850 pounds in unfavorable years.

The production of forage is limited by low annual precipitation. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of this unit for rangeland seeding is good. Chiseling or other such practices can be used to improve areas of deteriorated rangeland. Such practices increase water infiltration, reduce plant competition, and allow the desirable native plants to increase. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

If this unit is used for homesite development, the main limitations are high shrink-swell potential and the slow permeability of the Ulm soil. Backfilling excavations with coarser textured material helps to overcome the

LA QUALITY DIVISION

RECEIVED MAR 11 1991

1/173 PERMIT

ation of shrink-swell potential. Constructing a larger septic tank absorption field helps to compensate for the slow permeability of the Ulm soil. Absorption lines operate most effectively if they are placed deep in the subsoil.

This map unit is in capability subclass IVe. It is in the Loamy, 10- to 14-inch ppt., Northern Plains range site.

117—Forkwood-Ulm-Renohill complex, 6 to 15 percent slopes. This map unit is on foot slopes, back slopes, and ridges of rolling uplands. Slopes are short and are convex to plane. The native vegetation is mainly grasses and shrubs.

This unit is 35 percent Forkwood fine sandy loam, 30 percent Ulm clay loam, and 20 percent Renohill clay loam. The components of this unit are so intricately intermingled that it was not practical to map them separately at the scale used.

Included in this unit are small areas of Cushman loam, Bidman sandy loam, and Worfka fine sandy loam. Included areas make up about 15 percent of the total acreage. The percentage varies from one area to another.

The Forkwood soil is deep and well drained. It formed in loamy local alluvium derived dominantly from calcareous shale. Typically, the surface layer is pale brown fine sandy loam about 7 inches thick. The upper 7 inches of the subsoil is pale brown clay loam, and the lower part to a depth of 60 inches or more is light brownish gray and light gray clay loam.

Permeability of the Forkwood soil is moderate. Available water capacity is high. Runoff is medium, and the hazard of water erosion is moderate. Effective rooting depth is 60 inches or more. The hazard of wind erosion is moderate.

The Ulm soil is deep and well drained. It formed in clayey local alluvium derived dominantly from calcareous shale. Typically, the surface layer is light brownish gray clay loam about 4 inches thick. The upper 12 inches of the subsoil is brown clay loam, and the lower part to a depth of 60 inches or more is light gray clay loam.

Permeability of the Ulm soil is slow. Available water capacity is high to very high. Effective rooting depth is 60 inches or more. Runoff is medium, and the hazard of water erosion is severe. The hazard of wind erosion is slight.

The Renohill soil is moderately deep and well drained. It formed in clayey residuum derived dominantly from calcareous shale. Typically, the surface layer is light brownish gray clay loam about 5 inches thick. The subsoil is light brownish gray clay loam about 20 inches thick. Calcareous gritty shale is at a depth of 25 inches.

Permeability of the Renohill soil is slow. Available water capacity is low. Effective rooting depth is 20 to 40 inches. Runoff is medium, and the hazard of water erosion is severe. The hazard of wind erosion is slight.

This unit is used for livestock grazing and wildlife habitat.

The potential plant community on the Forkwood soil is mainly western wheatgrass, thickspike wheatgrass, and needleandthread. As the range condition deteriorates, big sagebrush and blue grama increase. As the range condition further deteriorates, cacti, annuals, and broom snakeweed invade. The potential plant community produces about 1,500 pounds of air-dry vegetation in normal years. Production varies from 2,000 pounds in favorable years to 850 pounds in unfavorable years.

The potential plant community on the Ulm and Renohill soils is mainly western wheatgrass, thickspike wheatgrass, and green needlegrass. As the range condition deteriorates, big sagebrush and blue grama increase. As the range condition further deteriorates, broom snakeweed and cacti invade. The potential plant community produces about 1,300 pounds of air-dry vegetation in normal years. Production varies from 1,800 pounds in favorable years to 750 pounds in unfavorable years.

The production of forage on this unit is limited by low annual precipitation. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of this unit for rangeland seeding is fair. The main limitation is the hazard of water erosion. Chiseling or other such practices can be used to improve areas of deteriorated rangeland. Such practices increase water infiltration, reduce plant competition, and allow the desirable native plants to increase. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

This unit is poorly suited to homesite development. The main limitations are high shrink-swell potential, slope, slow permeability of the Ulm and Renohill soils, and the depth of the Renohill soil to soft bedrock. Backfilling excavations with coarser textured material helps to overcome the limitation of shrink-swell potential. Constructing a larger absorption field helps to compensate for the slow permeability of the Ulm and Renohill soils. Absorption fields are most effective if they are placed deep in the subsoil of the Forkwood soil; the Renohill soil is not suitable for use as absorption fields.

This map unit is in capability subclass VIe. The Forkwood soil is in the Loamy, 10- to 14-inch ppt., Northern Plains range site. The Ulm and Renohill soils are in the Clayey, 10- to 14-inch ppt., Northern Plains range site.

118—Gateson Variant-Tassel Variant association, 10 to 45 percent slopes. This map unit is on upland

LANDQUALITY DIVISION

ridges, shoulder slopes, and back slopes on the northern end of Pine Ridge. Slopes are convex and are medium in length. The native vegetation in the steeper areas is mainly conifers with an understory of grasses, and in the less sloping areas it is mainly grasses with scattered conifers. Sandstone and ironstone channery fragments and flagstones cover as much as 50 percent of the surface in some areas.

This unit is 45 percent Gateson Variant loamy sand and 35 percent Tassel Variant very fine sandy loam. The Gateson Variant soil is on steep back slopes, and the Tassel Variant soil is on ridges.

Included in this unit are small areas of Worf fine sandy loam, Tullock loamy sand, and Terro loamy fine sand. Included areas make up about 20 percent of the total acreage. The percentage varies from one area to another.

The Gateson Variant soil is shallow and well drained. It formed in loamy residuum derived dominantly from noncalcareous sandstone. Typically, the surface is covered with a mat of pine needles and other forest litter about 2 inches thick. The surface layer is pinkish gray loamy sand about 4 inches thick. The subsoil is reddish yellow sandy clay loam about 7 inches thick. The substratum is pinkish gray clay about 5 inches thick over soft, noncalcareous, interbedded sandstone and shale. Soft bedrock is at a depth of 15 to 24 inches.

Permeability of the Gateson Variant soil is moderate. Available water capacity is very low. Effective rooting depth is 10 to 20 inches. Runoff is rapid, and the hazard of water erosion is moderate. The hazard of wind erosion is severe.

The Tassel Variant soil is very shallow and well drained. It formed in loamy residuum derived dominantly from calcareous sandstone. Typically, the surface layer is light yellowish brown very fine sandy loam about 4 inches thick. The underlying material to a depth of 9 inches is gray loam. Soft, calcareous sandstone is at a depth of 9 inches.

Permeability of the Tassel Variant soil is moderate. Available water capacity is very low. Effective rooting depth is 5 to 10 inches. Runoff is rapid, and the hazard of water erosion is severe. The hazard of wind erosion is moderate.

Most areas of this unit are used for livestock grazing and wildlife habitat. A few areas are used as a source of wood products.

The Gateson Variant soil is poorly suited to the production of ponderosa pine. The site index for ponderosa pine ranges from 35 to 50. This soil can produce 12 cords per acre in a stand of trees that average 5 inches in diameter at a height of 1 foot. The main concerns in producing and harvesting timber are shallow soil depth, slow regeneration of trees, the hazard of erosion, and difficulty of harvesting on the steeper slopes. Plant competition delays natural regeneration but does not prevent the eventual development of a fully

stocked, normal stand of trees. The very low available water capacity generally influences seedling survival in areas where understory plants are numerous. Conventional methods of harvesting timber are difficult to use because of slope.

The potential understory plant community on the Gateson Variant soil is mainly Idaho fescue and yarrow. The woodland understory produces about 650 pounds of air-dry vegetation in normal years. Production varies from 800 pounds in favorable years to 400 pounds in unfavorable years.

The potential plant community on the Tassel Variant soil is mainly needleandthread, prairie sandreed, little bluestem, and bluebunch wheatgrass. As the range condition deteriorates, threadleaf sedge and fringed sagewort increase. As the range condition further deteriorates, broom snakeweed and annuals invade. The potential plant community produces about 1,300 pounds of air-dry vegetation in normal years. Production varies from 1,600 pounds in favorable years to 1,000 pounds in unfavorable years.

The production of forage on this soil is limited by restricted rooting depth and droughtiness. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of the Tassel Variant soil for rangeland seeding is poor. The main limitations are limited rooting depth and the hazards of erosion by wind and water. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

This unit is limited for livestock watering ponds and other water impoundments because of the seepage potential.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

This unit is poorly suited to homesite development. The main limitations are slope, shrink-swell potential, and depth to soft bedrock. Backfilling excavations with coarser textured material reduces the limitation of shrink-swell potential. Absorption fields should be constructed of selected material.

This map unit is in capability subclass VIIe. The Gateson Variant soil is not placed in a range site. The Tassel Variant soil is in the Shallow Sandy, 15- to 17-inch ppt., Northern Plains range site.

119—Gullied land. This map unit is in rolling to steep areas where gullies have downcut into friable soil material. The remaining soil material is shallow to deep and is well drained. It was derived from sedimentary residuum and local alluvium. Slopes are short and convex. This unit is essentially barren.

Typically, the original surface layer and subsoil have been lost through erosion. The remaining soil material is

LAND QUALITY DIVISION

RECEIVED MAR 11 1991

NO. 2 1/173 PERMIT

60 inches thick or more over bedrock. Texture ranges from sandy loam to clay loam.

Included in this unit are small areas of Shingle clay loam, Theedle loam, Samday clay loam, and Savageton clay loam. Also included are small areas of exposed sandstone and shale. Included areas make up about 15 percent of the total acreage. The percentage varies from one area to another.

Permeability of the soil material in this unit is slow to moderate. Available water capacity is low to moderate. Effective rooting depth is 10 to 60 inches. Runoff is rapid, and the hazard of water erosion is severe. The hazard of wind erosion is moderate.

This unit is used mainly for wildlife habitat. The included areas are also used for livestock grazing.

The vegetation on the included areas in this unit provides some food for antelope, deer, small mammals, and birds.

This map unit is in capability subclass VIIIe. It is not placed in a range site.

120—Haverdad-Lohmiller complex, 0 to 6 percent slopes. This map unit is on flood plains. Slopes are short and plane. The native vegetation is mainly grasses, woody shrubs, and scattered cottonwood trees. This unit is subject to flooding during prolonged, high-intensity storms. Channeling and deposition are common along streambanks.

This unit is 50 percent Haverdad fine sandy loam and 50 percent Lohmiller clay loam. The components of this unit are so intricately intermingled that it was not practical to map them separately at the scale used.

Included in this unit are small areas of Draknab loamy sand on flood plains and small areas of Kishona loam and Bahl clay on alluvial flat remnants. Included areas make up about 20 percent of the total acreage. The percentage varies from one area to another.

The Haverdad soil is deep and well drained. It formed in loamy recently deposited alluvium derived dominantly from sedimentary rock. Typically, the surface layer is grayish brown fine sandy loam about 6 inches thick. The underlying material to a depth of 60 inches or more is light brownish gray loam with lenses of clay loam and fine sandy loam.

Permeability of the Haverdad soil is moderate. Available water capacity is high. Effective rooting depth is 60 inches or more. Runoff is slow, and the hazard of water erosion is slight. The hazard of wind erosion is moderate. A slight accumulation of soluble salts is in the surface layer and the upper part of the subsoil in some areas.

The Lohmiller soil is deep and well drained. It formed in stratified, clayey, recently deposited alluvium derived dominantly from shale. Typically, the surface layer is grayish brown clay loam about 3 inches thick. The next layer is brown clay 13 inches thick. Below this to a depth

of 60 inches or more is stratified, light yellowish brown and brown sandy clay loam, sandy loam, and sandy clay.

Permeability of the Lohmiller soil is slow to moderately slow. Available water capacity is moderate. Effective rooting depth is 60 inches or more. Runoff is medium, and the hazard of water erosion is moderate. The hazard of wind erosion is moderate.

This unit is used for livestock grazing and wildlife habitat.

The potential plant community on this unit is mainly green needlegrass, slender wheatgrass, needleandthread, and cottonwood trees. As the range condition deteriorates, woody plants such as snowberry, silver sagebrush, and rubber rabbitbrush increase. As the range condition further deteriorates, annual forbs and cheatgrass invade. The potential plant community produces about 2,500 pounds of air-dry vegetation in normal years. Production varies from 3,000 pounds in favorable years to 2,000 pounds in unfavorable years.

The production of forage is limited by low annual precipitation and the hazard of flooding. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of this unit for rangeland seeding is good. Chiseling or other such practices can be used to improve areas of deteriorated rangeland. Such practices increase water infiltration, reduce plant competition, and allow the desirable native plants to increase. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds. Cottonwood trees commonly provide important riparian habitat for birds and small mammals.

This unit is poorly suited to homesite development. The main limitations are the hazard of flooding and shrink-swell potential. Construction of dikes reduces the risk of flooding. Backfilling excavations with coarser textured material helps to overcome the limitation of shrink-swell potential.

This map unit is in capability subclass IVw. It is in the Lowland, 10- to 14-inch ppt., Northern Plains range site. In some areas are inclusions of Clayey Overflow, 10- to 14-inch ppt., Northern Plains range site.

121—Hiland-Bowbac sandy loams, 0 to 6 percent slopes. This map unit is on foot slopes and pediment slopes. Slopes are convex and are medium in length. The native vegetation is mainly grasses and shrubs.

This unit is 70 percent Hiland sandy loam and 20 percent Bowbac sandy loam. The components of this unit are so intricately intermingled that it was not practical to map them separately at the scale used.

LANDQUALITY DISTRICT

Addendum D7 B3
Page 30

Included in this unit are small areas of Ulm loam, Vonalee loamy sand, and Terro sandy loam. Included areas make up about 10 percent of the total acreage. The percentage varies from one area to another.

The Hiland soil is deep and well drained. It formed in loamy residuum, local alluvium, and eolian material derived dominantly from calcareous sandstone. Typically, the surface layer is pale brown sandy loam about 5 inches thick. The upper 25 inches of the subsoil is pale brown and light yellowish brown sandy clay loam, and the lower part to a depth of 60 inches or more is very pale brown sandy loam. In some areas the subsoil is loam or light clay loam.

Permeability of the Hiland soil is moderate. Available water capacity is moderate. Effective rooting depth is 60 inches or more. Runoff is slow, and the hazard of water erosion is slight. The hazard of wind erosion is moderate.

The Bowbac soil is moderately deep and well drained. It formed in loamy residuum derived dominantly from calcareous sandstone. Typically, the surface layer is brown sandy loam about 3 inches thick. The upper 15 inches of the subsoil is brown sandy clay loam, and the lower 18 inches is brown and light yellowish brown sandy loam. Soft, calcareous sandstone is at a depth of 36 inches. In some areas the subsoil is loam or light clay loam.

Permeability of the Bowbac soil is moderate. Available water capacity is low. Effective rooting depth is 20 to 40 inches. Runoff is medium, and the hazard of water erosion is moderate. The hazard of wind erosion is moderate.

Most areas of this unit are used for livestock grazing and wildlife habitat. A few areas where water is available from small reservoirs are used for irrigated alfalfa.

The potential plant community on this unit is mainly western wheatgrass, thickspike wheatgrass, and needleandthread. As the range condition deteriorates, big sagebrush and blue grama increase. As the range condition further deteriorates, cacti, annuals, and broom snakeweed invade. The potential plant community produces about 1,500 pounds of air-dry vegetation in normal years. Production varies from 2,000 pounds in favorable years to 850 pounds in unfavorable years.

The production of forage is limited by low annual precipitation. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of this unit for rangeland seeding is good. Chiseling or other such practices can be used to improve areas of deteriorated rangeland. Such practices increase water infiltration, reduce plant competition, and allow the desirable native plants to increase. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment. Alfalfa

yields average about 2.0 to 2.5 tons per acre with a moderate level of management.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

If this unit is used for homesite development, the main limitation is depth to soft bedrock in the Bowbac soil. Areas of Hiland soil should be selected for absorption fields.

This map unit is in capability subclass IVe, irrigated and nonirrigated. It is in the Loamy, 10- to 14-inch ppt. Northern Plains range site.

122—Hiland-Bowbac complex, 6 to 15 percent slopes. This map unit is on ridges and back slopes of rolling uplands. Slopes are short and convex. The native vegetation is mainly grasses and shrubs.

This unit is 60 percent Hiland sandy clay loam and 3 percent Bowbac sandy loam. The components of this unit are so intricately intermingled that it was not practical to map them separately at the scale used.

Included in this unit are small areas of Vonalee loam sand, Renohill clay loam, Terro sandy loam, and Worff fine sandy loam. Included areas make up about 10 percent of the total acreage. The percentage varies from one area to another.

The Hiland soil is deep and well drained. It formed in loamy residuum and eolian material derived dominantly from calcareous sandstone. Typically, the surface layer is brown sandy clay loam about 3 inches thick. The upper 21 inches of the subsoil is brown sandy loam and sandy clay loam, and the lower part to a depth of 60 inches or more is grayish brown and light brownish gray sandy loam and sandy clay loam. In some areas the subsoil is loam or light clay loam.

Permeability of the Hiland soil is moderate to moderately rapid. Available water capacity is moderate. Effective rooting depth is 60 inches or more. Runoff is medium, and the hazard of water erosion is moderate. The hazard of wind erosion is moderate.

The Bowbac soil is moderately deep and well drained. It formed in loamy residuum derived dominantly from calcareous sandstone. Typically, the surface layer is brown sandy loam about 4 inches thick. The upper 11 inches of the subsoil is brown and dark yellowish brown sandy clay loam, and the lower 13 inches is light yellowish brown fine sandy loam. Soft calcareous sandstone is at a depth of 28 inches. In some areas the subsoil is loam or light clay loam.

Permeability of the Bowbac soil is moderate. Available water capacity is low. Effective rooting depth is 20 to 4 inches. Runoff is medium, and the hazard of water erosion is moderate. The hazard of wind erosion is moderate.

This unit is used for livestock grazing and wildlife habitat.

The potential plant community on this unit is mainly western wheatgrass, thickspike wheatgrass, and

LANDQUALITY DIVISION

RECEIVED MAR 11 1991

2 1/173 PERMIT

needleandthread. As the range condition deteriorates, big sagebrush and blue grama increase. As the range condition further deteriorates, cacti, annuals, and broom snakeweed invade. The potential plant community produces about 1,500 pounds of air-dry vegetation in normal years. Production varies from 2,000 pounds in favorable years to 850 pounds in unfavorable years.

The production of forage is limited by low annual precipitation. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of this unit for rangeland seeding is fair. The main limitation is the hazard of water erosion. Chiseling or other such practices can be used to improve areas of deteriorated rangeland. Such practices increase water infiltration, reduce plant competition, and allow the desirable native plants to increase. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

If this unit is used for homesite development, the main limitations are slope and the depth of the Bowbac soil to soft bedrock. Areas of the Bowbac soil are not suitable absorption fields.

This map unit is in capability subclass VIe. It is in the Loamy, 10- to 14-inch ppt., Northern Plains range site.

123—Keeline-Tassel-Turnback complex, 6 to 15 percent slopes. This map unit is on rolling uplands. Slopes are short to medium in length and are mostly convex. The native vegetation is mainly grasses.

This unit is 35 percent Keeline sandy loam, 25 percent Tassel loamy fine sand, and 20 percent Turnback loamy fine sand. The components of this unit are so intricately intermingled that it was not practical to map them separately at the scale used.

Included in this unit are small areas of Tullock loamy sand, Orpha loamy sand, and Dwyer loamy sand on ridge crests and on lee slopes where windblown sand collects. Included areas make up about 20 percent of the total acreage. The percentage varies from one area to another.

The Keeline soil is deep and somewhat excessively drained. It formed in loamy, wind-worked residuum derived dominantly from calcareous sandstone. Typically, the surface layer is yellowish brown sandy loam about 3 inches thick. The subsoil is pale brown sandy loam about 5 inches thick. The underlying material to a depth of 60 inches or more is very pale brown sandy loam.

Permeability of the Keeline soil is moderately rapid. Available water capacity is moderate. Effective rooting depth is 60 inches or more. Runoff is slow, and the

hazard of water erosion is slight. The hazard of wind erosion is moderate.

The Tassel soil is shallow and well drained. It formed in loamy residuum derived dominantly from calcareous sandstone. Typically, the surface layer is light brownish gray loamy fine sand 2 inches thick. The underlying material to a depth of 16 inches is pale brown fine sandy loam. Soft sandstone is at a depth of 16 inches.

Permeability of the Tassel soil is moderately rapid. Available water capacity is very low. Effective rooting depth is 6 to 20 inches. Runoff is medium, and the hazard of water erosion is moderate. The hazard of wind erosion is severe.

The Turnback soil is moderately deep and well drained. It formed in loamy, wind-worked residuum derived dominantly from calcareous sandstone. Typically, the surface layer is pale brown loamy fine sand about 4 inches thick. The subsoil is light yellowish brown and pale yellow sandy loam about 26 inches thick. Soft sandstone is at a depth of 30 inches.

Permeability of the Turnback soil is moderately rapid. Available water capacity is very low to low. Effective rooting depth is 20 to 40 inches. Runoff is slow, and the hazard of water erosion is moderate. The hazard of wind erosion is severe.

This unit is used for livestock grazing and wildlife habitat.

The potential plant community on the Keeline and Turnback soils is mainly needleandthread, prairie sandreed, Indian ricegrass, and little bluestem. As the range condition deteriorates, sageworts and needleleaf sedge increase. As the range condition further deteriorates, annuals and broom snakeweed invade. The potential plant community produces about 1,600 pounds of air-dry vegetation in normal years. Production varies from 2,100 pounds in favorable years to 1,000 pounds in unfavorable years.

The production of forage is limited by low annual precipitation. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of these soils for rangeland seeding is fair. The main limitation is the hazard of wind erosion. Chiseling or other such practices can be used to improve areas of deteriorated rangeland. Such practices increase water infiltration, reduce plant competition, and allow the desirable native plants to increase. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

These soils are limited for livestock watering ponds and other water impoundments because of the seepage potential.

The potential plant community on the Tassel soil is mainly needleandthread, prairie sandreed, Indian

RECEIVED MAR 11 1991

ricegrass, and little bluestem. As the range condition deteriorates, threadleaf sedge and fringed sagewort increase. As the range condition further deteriorates, broom snakeweed and annuals invade. The potential plant community produces about 1,000 pounds of air-dry vegetation in normal years. Production varies from 1,400 pounds in favorable years to 600 pounds in unfavorable years.

The production of forage on this soil is limited by restricted rooting depth and droughtiness. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of this soil for rangeland seeding is poor. The main limitations are limited rooting depth and the hazards of wind and water erosion. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

This soil is limited for livestock watering ponds and other water impoundments because of the seepage potential.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

If the Keeline soil is used for homesite development, the main limitation is slope. The Tassel and Turnback soils are limited by depth to soft bedrock. They are not suitable for absorption fields.

This map unit is in capability subclass VIe. The Keeline and Turnback soils are in the Sandy, 10- to 14-inch ppt., Northern Plains range site. The Tassel soil is in the Shallow Sandy, 10- to 14-inch ppt., Northern Plains range site.

124—Kishona-Dwyer-Orpha association, 0 to 10 percent slopes. This map unit is on nearly level to undulating alluvial flats and gently rolling dunes superimposed on stream terraces. Slopes are long and plane or short and convex. The Kishona soils are on alluvial flats, and the Dwyer and Orpha soils are on terrace dunes. The native vegetation is mainly grasses.

This unit is 35 percent Kishona loam, 25 percent Dwyer loamy sand, and 15 percent Orpha loamy sand.

Included in this unit are small areas of Draknab loamy sand and Haverdad fine sandy loam on flood plains and Bahl clay on alluvial flats. Included areas make up about 25 percent of the total acreage. The percentage varies from one area to another.

The Kishona soil is deep and well drained. It formed in loamy local alluvium derived dominantly from calcareous shale. Typically, the surface layer is brown loam about 3 inches thick. The underlying material to a depth of 60 inches or more is light yellowish brown and light gray clay loam. Carbonates are disseminated throughout the soil.

Permeability of the Kishona soil is moderate. Available water capacity is high. Effective rooting depth is 60 inches or more. Runoff is medium, and the hazard of water erosion is moderate. The hazard of wind erosion is moderate.

The Dwyer soil is deep and excessively drained. It formed in eolian sand derived dominantly from mixed sources. Typically, the surface layer is brown loamy sand about 5 inches thick. The underlying material to a depth of 60 inches or more is pale brown loamy sand. Carbonates are at a depth of less than 40 inches.

Permeability of the Dwyer soil is rapid. Available water capacity is low. Effective rooting depth is 60 inches or more. Runoff is slow, and the hazard of water erosion is moderate. The hazard of wind erosion is severe.

The Orpha soil is deep and excessively drained. It formed in eolian sand derived from mixed sources. Typically, the surface layer is pale brown loamy sand about 5 inches thick. The underlying material to a depth of 60 inches or more is light yellowish brown loamy sand. Depth to carbonates is less than 40 inches.

Permeability of the Orpha soil is very rapid. Available water capacity is low. Effective rooting depth is 60 inches or more. Runoff is slow, and the hazard of water erosion is slight. The hazard of wind erosion is severe.

This unit is used for livestock grazing and wildlife habitat.

The potential plant community on the Kishona soil is mainly western wheatgrass, thickspike wheatgrass, and needleandthread. As the range condition deteriorates, big sagebrush and blue grama increase. As the range condition further deteriorates, cacti, annuals, and broom snakeweed invade. The potential plant community produces about 1,500 pounds of air-dry vegetation in normal years. Production varies from 2,000 pounds in favorable years to 850 pounds in unfavorable years.

The production of forage on the Kishona soil is limited by low annual precipitation. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increase. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of this soil for rangeland seeding is good. Chiseling or other such practices can be used to improve areas of deteriorated rangeland. Such practices increase water infiltration, reduce plant competition, and allow the desirable native plants to increase. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

The potential plant community on the Dwyer and Orpha soils is mainly prairie sandreed, sand bluestem, needleandthread, and Indian ricegrass. As the range condition deteriorates, sageworts increase. As the range condition further deteriorates, annuals and broom snakeweed invade. The potential plant community produces about 2,000 pounds of air-dry vegetation in

LANDQUALITY DIVISION

RECEIVED MAR 11 1981

2 1/1 23 PERCOT

1 years. Production varies from 2,500 pounds in favorable years to 1,400 pounds in unfavorable years.

The production of forage is limited by droughtiness. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of these soils for rangeland seeding is poor. The main limitations are the hazard of wind erosion and droughtiness. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

These soils are limited for livestock watering ponds and other water impoundments because of the seepage potential.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

If the Kishona soil is used for homesite development, the main limitation is moderate shrink-swell potential. If the Dwyer and Orpha soils are used for homesite development, the main limitations are the hazard of cutbanks caving in, sand blowing, and slope. Backfilling excavations with coarser textured material helps to overcome the limitation of shrink-swell potential in the Kishona soil.

The Kishona soil is in capability subclass IVe, and the Dwyer and Orpha soils are in capability subclass VIe. The Kishona soil is in the Loamy, 10- to 14-inch ppt., Northern Plains range site. The Dwyer and Orpha soils are in the Sands, 10- to 14-inch ppt., Northern Plains range site.

125—Orella-Rock outcrop-Samday complex, 3 to 30 percent slopes. This map unit is on ridgetops, shoulders, and back slopes of undulating to steep uplands. Slopes are medium in length and are convex. The native vegetation is mainly grasses and forbs.

This unit is 35 percent Orella clay loam, 25 percent Rock outcrop, and 25 percent Samday clay loam. The components of this unit are so intricately intermingled that it was not practical to map them separately at the scale used.

Included in this unit are small areas of Shingle clay loam, Tassel sandy loam, and Theedle loam. Included areas make up about 15 percent of the total acreage. The percentage varies from one area to another.

The Orella soil is shallow and well drained. It formed in clayey residuum derived dominantly from sodic shale. The surface layer is light gray clay loam about 4 inches thick. The underlying material to a depth of 20 inches is light gray and light brownish gray clay. Fragmented shale is at a depth of 20 inches.

Permeability of the Orella soil is very slow. Available water capacity is very low. Effective rooting depth is 10 to 15 inches. Runoff is rapid, and the hazard of water

erosion is severe. The hazard of wind erosion is moderate.

Rock outcrop is exposures of multicolored, calcareous and noncalcareous, soft and moderately hard shale and siltstone.

The Samday soil is shallow and well drained. It formed in clayey residuum derived dominantly from calcareous shale. Typically, the surface layer is light brownish gray clay loam about 2 inches thick. The underlying material to a depth of 18 inches is light brownish gray clay. Soft shale is at a depth of 18 inches.

Permeability of the Samday soil is slow. Available water capacity is very low. Effective rooting depth is 6 to 20 inches. Runoff is rapid, and the hazard of water erosion is severe. The hazard of wind erosion is slight.

This unit is used for livestock grazing and wildlife habitat.

The potential plant community on this unit is mainly western wheatgrass, green needlegrass, and bluebunch wheatgrass. As the range condition deteriorates, birdfoot sagebrush and big sagebrush increase. As the range condition further deteriorates, broom snakeweed and annuals invade. The potential plant community produces about 900 pounds of air-dry vegetation in normal years. Production varies from 1,200 pounds in favorable years to 450 pounds in unfavorable years.

The production of forage is limited by restricted rooting depth and droughtiness. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of this unit for rangeland seeding is poor. The main limitations are limited rooting depth and the hazard of water erosion. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

This unit is limited for livestock watering ponds and other water impoundments because of the seepage potential.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

This unit is poorly suited to homesite development. The main limitations are high shrink-swell potential, slope, and depth to shale. Backfilling excavations with coarser textured material helps to overcome the limitation of shrink-swell potential.

This map unit is in capability subclass VIIe. The Orella and Samday soils are in the Shallow Clayey, 10- to 14-inch ppt., Northern Plains range site.

126—Pits, mine. This map unit consists of open pits and spoil material from small- and moderate-sized uranium operations. None of these areas are currently being mined, and reclamation plans have not been developed. These areas support little if any vegetation.

CONVERSE COUNTY DIVISION

RECEIVED MAF

Addendum D7 B3

FN 2 1/173 PL

Page 34

Open pits are vertical or very steep excavations into sedimentary rock consisting of rippable sandstone with some interbedded shale and coal seams. Physical and chemical properties of the pit wall and displaced spoil banks are highly variable. The spoil material is mixed, and it is extremely acid to moderately alkaline. The material commonly is sandy, but some layers are loamy and clayey.

Onsite investigation of individual areas is necessary to determine reclamation potential. Backfilling excavations and reshaping cut slopes reduce the risk of erosion. Backfilling with suitable topsoil aids revegetation.

127—Renohill-Worfka-Shingle complex, 0 to 6 percent slopes. This map unit is on upland summits and back slopes. Slopes are medium in length and are convex. The native vegetation is mainly grasses and shrubs.

This unit is 35 percent Renohill fine sandy loam, 30 percent Worfka fine sandy loam, and 20 percent Shingle clay loam. The components of this unit are so intricately intermingled that it was not practical to map them separately at the scale used.

Included in this unit are small areas of Samday clay loam, Worf fine sandy loam, and Bidman sandy loam. Included areas make up about 15 percent of the total acreage. The percentage varies from one area to another.

The Renohill soil is moderately deep and well drained. It formed in clayey residuum derived dominantly from soft shale. Typically, the surface layer is pale brown fine sandy loam about 5 inches thick. The upper 15 inches of the subsoil is brown clay, and the lower 16 inches is pale brown clay loam. Calcareous shale is at a depth of 36 inches. In some areas depth to soft bedrock ranges from 40 to 60 inches or more.

Permeability of the Renohill soil is slow. Available water capacity is moderate. Effective rooting depth is 20 to 40 inches. Runoff is medium, and the hazard of water erosion is moderate. The hazard of wind erosion is moderate.

The Worfka soil is shallow and well drained. It formed in clayey residuum derived dominantly from calcareous shale and sandstone. Typically, the surface layer is pale brown fine sandy loam about 6 inches thick. The upper 6 inches of the subsoil is light brownish gray clay, and the lower 6 inches is light yellowish brown clay loam. Soft interbedded shale and sandstone are at a depth of 18 inches.

Permeability of the Worfka soil is slow. Available water capacity is very low to low. Effective rooting depth is 7 to 20 inches. Runoff is medium, and the hazard of water erosion is moderate. The hazard of wind erosion is moderate.

The Shingle soil is shallow and well drained. It formed in loamy residuum derived dominantly from calcareous shale. Typically, the surface layer is light brownish gray

clay loam about 4 inches thick. The underlying material to a depth of 18 inches is light brownish gray clay loam. Soft shale is at a depth of 18 inches.

Permeability of the Shingle soil is moderate. Available water capacity is low. Effective rooting depth is 4 to 20 inches. Runoff is medium, and the hazard of water erosion is moderate. The hazard of wind erosion is slight.

This unit is used for livestock grazing, nonirrigated crops, and wildlife habitat.

The potential plant community on the Renohill soil is mainly western wheatgrass, thickspike wheatgrass, and needleandthread. As the range condition deteriorates, big sagebrush and blue grama increase. As the range condition further deteriorates, cacti, annuals, and brown snakeweed invade. The potential plant community produces about 1,500 pounds of air-dry vegetation in normal years. Production varies from 2,000 pounds in favorable years to 850 pounds in unfavorable years.

The production of forage on the Renohill soil is limited by low annual precipitation. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of this soil for rangeland seeding is good. Chiseling or other such practices can be used to improve areas of deteriorated rangeland. Such practices increase water infiltration, reduce plant competition, and allow the desirable native plants to increase. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

The potential plant community on the Worfka and Shingle soils is mainly western wheatgrass, bluebunch wheatgrass, needleandthread, and little bluestem. As the range condition deteriorates, blue grama and threadleaf sedge increase. As the range condition further deteriorates, broom snakeweed and cacti invade. The potential plant community produces about 900 pounds of air-dry vegetation in normal years. Production varies from 1,200 pounds in favorable years to 450 pounds in unfavorable years.

The production of forage is limited by restricted rooting depth and droughtiness. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of these soils for rangeland seeding is poor. The main limitations are limited rooting depth and the hazard of water erosion. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment. This unit is limited for livestock watering ponds and other water impoundment because of the seepage potential.

few small, nearly level areas of this unit have a smaller percentage of Renohill soil than is typical; these areas are used for nonirrigated wheat. Yield averages about 15 to 20 bushels per acre every other year with a moderate level of management. Because precipitation is not sufficient for annual cropping, a cropping system that includes small grain and summer fallow is most suitable. Crop residue left on or near the surface helps to conserve moisture, maintain tilth, and control erosion.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

This unit is poorly suited to homesite development. The main limitations are high shrink-swell potential and depth to soft bedrock. Backfilling excavations with coarser textured material helps to overcome the limitation of shrink-swell potential.

This map unit is in capability subclass VIe. The Renohill soil is in the Loamy, 10- to 14-inch ppt., Northern Plains range site. The Worfka and Shingle soils are in the Shallow Loamy, 10- to 14-inch ppt., Northern Plains range site.

128—Renohill-Worfka-Shingle complex, 6 to 15 percent slopes. This map unit is on back slopes of rolling uplands. Slopes are short to medium in length and are convex. The native vegetation is mainly grasses and shrubs.

This unit is 35 percent Renohill clay loam, 30 percent Worfka fine sandy loam, and 20 percent Shingle clay loam. The components of this unit are so intricately intermingled that it was not practical to map them separately at the scale used.

Included in this unit are small areas of Samday clay loam, Worf fine sandy loam, and Cushman loam. Included areas make up about 15 percent of the total acreage. The percentage varies from one area to another.

The Renohill soil is moderately deep and well drained. It formed in clayey residuum derived dominantly from soft shale. Typically, the surface layer is light brownish gray clay loam about 5 inches thick. The subsoil is light brownish gray clay loam 20 inches thick. Calcareous, gritty shale is at a depth of 25 inches. In some areas soft bedrock is at a depth of 40 to 60 inches or more.

Permeability of the Renohill soil is slow. Available water capacity is low. Effective rooting depth is 20 to 40 inches. Runoff is medium, and the hazard of water erosion is severe. The hazard of wind erosion is slight.

The Worfka soil is shallow and well drained. It formed in clayey residuum derived dominantly from calcareous shale and sandstone. Typically, the surface layer is grayish brown fine sandy loam about 3 inches thick. The upper 5 inches of the subsoil is pale brown clay, and the lower 6 inches is light yellowish brown clay loam. Interbedded shale and sandstone are at a depth of 14 inches.

Permeability of the Worfka soil is slow. Available water capacity is very low. Effective rooting depth is 7 to 20 inches. Runoff is medium, and the hazard of water erosion is moderate. The hazard of wind erosion is moderate.

The Shingle soil is shallow and well drained. It formed in loamy residuum derived dominantly from calcareous shale. Typically, the surface layer is light brownish gray clay loam about 4 inches thick. The underlying material to a depth of 18 inches is light brownish gray clay loam. Soft shale is at a depth of 18 inches.

Permeability of the Shingle soil is moderate. Available water capacity is low. Effective rooting depth is 4 to 20 inches. Runoff is medium, and the hazard of water erosion is severe. The hazard of wind erosion is slight.

This unit is used for livestock grazing and wildlife habitat.

The potential plant community on the Renohill soil is mainly western wheatgrass, green needlegrass, and thickspike wheatgrass. As the range condition deteriorates, big sagebrush and blue grama increase. As the range condition further deteriorates, cacti and broom snakeweed invade. The potential plant community produces about 1,300 pounds of air-dry vegetation in normal years. Production varies from 1,800 pounds in favorable years to 750 pounds in unfavorable years.

The production of forage on the Renohill soil is limited by low annual precipitation. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of this soil for rangeland seeding is fair. The main limitation is the hazard of water erosion. Chiseling or other such practices can be used to improve areas of deteriorated rangeland. Such practices increase water infiltration, reduce plant competition, and allow the desirable native plants to increase. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

The potential plant community on the Worfka soil is mainly western wheatgrass, green needlegrass, and bluebunch wheatgrass. As the range condition deteriorates, birdfoot sagebrush and big sagebrush increase. As the range condition further deteriorates, broom snakeweed and annuals invade. The potential plant community produces about 900 pounds of air-dry vegetation in normal years. Production varies from 1,200 pounds in favorable years to 450 pounds in unfavorable years.

The potential plant community on the Shingle soil is mainly western wheatgrass, bluebunch wheatgrass, needleandthread, and little bluestem. As the range condition deteriorates, blue grama and threadleaf sedge increase. As the range condition further deteriorates, broom snakeweed and cacti invade. The potential plant

community produces about 900 pounds of air-dry vegetation in normal years. Production varies from 1,200 pounds in favorable years to 450 pounds in unfavorable years.

The production of forage on the Worfka and Shingle soils is limited by restricted rooting depth and droughtiness. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of these soils for rangeland seeding is poor. The main limitations are limited rooting depth and the hazard of water erosion. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

This unit is limited for livestock watering ponds and other water impoundments because of the seepage potential.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

This unit is poorly suited to homesite development. The main limitations are high shrink-swell potential, slope, and depth to soft bedrock. Backfilling excavations with coarser textured material helps to overcome the limitation of shrink-swell potential.

This map unit is in capability subclass VIIe. The Renohill soil is in the Clayey, 10- to 14-inch ppt., Northern Plains range site. The Worfka soil is in the Shallow Clayey, 10- to 14-inch ppt., Northern Plains range site. The Shingle soil is in the Shallow Loamy, 10- to 14-inch ppt., Northern Plains range site.

129—Samday-Shingle-Worf complex, 3 to 15 percent slopes. This map unit is on summits and ridges of undulating to rolling uplands. Slopes are short and convex. The native vegetation is mainly grasses and forbs.

This unit is 30 percent Samday clay loam, 25 percent Shingle clay loam, and 25 percent Worf fine sandy loam. The components of this unit are so intricately intermingled that it was not practical to map them separately at the scale used.

Included in this unit are small areas of Worfka fine sandy loam, Renohill clay loam, and Theedle loam. Also included are small areas of Rock outcrop. Included areas make up about 20 percent of the total acreage. The percentage varies from one area to another.

The Samday soil is shallow and well drained. It formed in clayey residuum derived dominantly from calcareous shale. Typically, the surface layer is light brownish gray clay loam about 2 inches thick. The underlying material to a depth of 18 inches is light brownish gray clay. Soft shale is at a depth of 18 inches.

Permeability of the Samday soil is slow. Available water capacity is very low. Effective rooting depth is 6 to

20 inches. Runoff is rapid, and the hazard of water erosion is severe. The hazard of wind erosion is slight.

The Shingle soil is shallow and well drained. It formed in loamy residuum derived dominantly from calcareous shale. Typically, the surface layer is light brownish gray clay loam about 4 inches thick. The underlying material to a depth of 18 inches is light brownish gray clay loam. Soft shale is at a depth of 18 inches.

Permeability of the Shingle soil is moderate. Available water capacity is low. Effective rooting depth is 4 to 20 inches. Runoff is rapid, and the hazard of water erosion is severe. The hazard of wind erosion is slight.

The Worf soil is shallow and well drained. It formed in loamy residuum derived dominantly from interbedded shale and sandstone. Typically, the surface layer is grayish brown fine sandy loam about 2 inches thick. The subsoil is brown and light yellowish brown sandy clay loam about 16 inches thick. Soft shale is at a depth of 18 inches.

Permeability of the Worf soil is moderate. Available water capacity is low. Effective rooting depth is 8 to 20 inches. Runoff is medium, and the hazard of water erosion is moderate. The hazard of wind erosion is moderate.

This unit is used for livestock grazing and wildlife habitat.

The potential plant community on the Samday and Worf soils is mainly western wheatgrass, green needlegrass, and bluebunch wheatgrass. As the range condition deteriorates, birdfoot sagebrush and big sagebrush increase. As the range condition further deteriorates, broom snakeweed and annuals invade. The potential plant community produces about 900 pounds of air-dry vegetation in normal years. Production varies from 1,200 pounds in favorable years to 450 pounds in unfavorable years.

with undesirable plants can be improved by chemical or mechanical treatment. This unit is limited for livestock watering ponds and other water impoundments because of the seepage potential.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

This unit is poorly suited to homesite development. The main limitations are high shrink-swell potential, depth, and texture. Backfilling excavations with coarser textured material helps to overcome the hazard of shrink-swell potential. Absorption fields should be constructed using selected material.

This map unit is in capability subclass VIIc. The Samday and Worf soils are in the Shallow Clayey, 10- to 14-inch ppt., Northern Plains range site. The Shingle soil is in the Shallow Loamy, 10- to 14-inch ppt., Northern Plains range site.

30—Sear-Wibaux complex, 0 to 15 percent slopes.

This map unit is in nearly level areas on the summit of buttes and in undulating to rolling areas on the uplands. Slopes are short and are plane to convex. The native vegetation is mainly grasses and forbs.

This unit is 45 percent Sear loam and 35 percent Wibaux channery loam. The components of this unit are intricately intermingled that it was not practical to map them separately at the scale used.

Included in this unit are small areas of Shingle loam, Samday clay loam, and Rock outcrop. Included areas make up about 20 percent of the total acreage. The percentage varies from one area to another.

The Sear soil is very shallow and well drained. It is formed in channery loamy residuum derived dominantly from fragmented porcellanite. Typically, the surface layer is pinkish gray loam about 2 inches thick. The subsoil is brown channery loam about 7 inches thick. Fragmented cellanite with soil material partially filling voids in it is seen in depths of 9 and 60 inches or more.

Permeability of the Sear soil is moderate to a depth of 11 inches and very rapid below this depth. Available water capacity is low. Effective rooting depth is 5 to 10 inches. Runoff is medium, and the hazard of water erosion is moderate. The hazard of wind erosion is slight.

The Wibaux soil is shallow and somewhat excessively eroded. It formed in channery loamy residuum derived dominantly from fragmented porcellanite. Typically, the surface layer is pinkish gray channery loam about 4 inches thick. The underlying material to a depth of 11 inches is light brown very channery loam. Fragmented cellanite with soil material partially filling voids in it is seen in depths of 11 and 60 inches or more.

Permeability of the Wibaux soil is moderate to a depth of 11 inches and very rapid below this depth. Available water capacity is low. Effective rooting depth is 10 to 20 inches. Runoff is medium, and the hazard of water erosion is moderate. The hazard of wind erosion is slight.

This unit is used for livestock grazing and wildlife habitat.

The potential plant community on the Sear soil is mainly bluebunch wheatgrass, little bluestem, western wheatgrass, and needleandthread. As the range condition deteriorates, woody plants increase. As the range condition further deteriorates, annuals invade. The potential plant community produces about 600 pounds of air-dry vegetation in normal years. Production varies from 600 pounds in favorable years to 400 pounds in unfavorable years.

The potential plant community on the Wibaux soil is mainly western wheatgrass, bluebunch wheatgrass, needleandthread, and little bluestem. As the range condition deteriorates, blue grama and threadleaf sedge increase. As the range condition further deteriorates, broom snakeweed and cacti invade. The potential plant community produces about 900 pounds of air-dry vegetation in normal years. Production varies from 1,200 pounds in favorable years to 450 pounds in unfavorable years.

The production of forage on this unit is limited by restricted rooting depth and droughtiness. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of this unit for rangeland seeding is poor. The main limitations are limited rooting depth and the hazard of water erosion. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

This unit is limited for livestock watering ponds and other water impoundments because of the seepage potential.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

This unit is poorly suited to homesite development. The main limitation is depth to porcellanite fragments or soft bedrock. Absorption fields should be constructed using selected material.

This map unit is in capability subclass VIIc. The Sear soil is in the Very Shallow, 10- to 14-inch ppt., Northern Plains range site. The Wibaux soil is in the Shallow Loamy, 10- to 14-inch ppt., Northern Plains range site.

131—Shingle-Rock outcrop-Samday complex, 10 to 30 percent slopes.

This map unit is on ridgetops, shoulders, and back slopes of rolling to steep uplands and on actively eroding escarpments. Slopes are medium in length and are convex. The native vegetation is mainly grasses and forbs.

This unit is 40 percent Shingle clay loam, 25 percent Rock outcrop, and 20 percent Samday clay loam. The components of this unit are so intricately intermingled

LAND QUALITY DIVISION

Addendum D7 B3

that it was not practical to map them separately at the scale used.

Included in this unit are small areas of Theedle loam and Tassel sandy loam. Also included are small areas of Shingle, thin solum, soils and Tassel, thin solum, soils that formed in neutral, interbedded shale and sandstone. Included areas make up about 15 percent of the total acreage. The percentage varies from one area to another.

The Shingle soil is shallow and well drained. It formed in loamy residuum derived dominantly from calcareous shale. Typically, the surface layer is pale brown clay loam about 4 inches thick. The underlying material to a depth of 13 inches is light brownish gray clay loam. Interbedded shale and sandstone are at a depth of 13 inches.

Permeability of the Shingle soil is moderate. Available water capacity is very low. Effective rooting depth is 4 to 20 inches. Runoff is rapid, and the hazard of water erosion is severe. The hazard of wind erosion is slight.

Rock outcrop is exposures of multicolored, calcareous and noncalcareous, soft to moderately hard shale and siltstone.

The Samday soil is shallow and well drained. It formed in clayey residuum derived dominantly from calcareous shale. Typically, the surface layer is light brownish gray clay loam about 2 inches thick. The underlying material to a depth of 18 inches is light brownish gray clay. Interbedded shale and sandstone are at a depth of 18 inches.

Permeability of the Samday soil is slow. Available water capacity is very low. Effective rooting depth is 6 to 20 inches. Runoff is rapid, and the hazard of water erosion is severe. The hazard of wind erosion is slight.

This unit is used for livestock grazing and wildlife habitat.

The potential plant community on the Shingle soil is mainly western wheatgrass, bluebunch wheatgrass, needleandthread, and little bluestem. As the range condition deteriorates, blue grama and threadleaf sedge increase. As the range condition further deteriorates, broom snakeweed and cacti invade. The potential plant community produces about 900 pounds of air-dry vegetation in normal years. Production varies from 1,200 pounds in favorable years to 450 pounds in unfavorable years.

The potential plant community on the Samday soil is mainly western wheatgrass, green needlegrass, and bluebunch wheatgrass. As the range condition deteriorates, birdfoot sagebrush and big sagebrush increase. As the range condition further deteriorates, broom snakeweed and annuals invade. The potential plant community produces about 900 pounds of air-dry vegetation in normal years. Production varies from 1,200 pounds in favorable years to 450 pounds in unfavorable years.

The production of forage on these soils is limited by restricted rooting depth and droughtiness. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community. The suitability of these soils for rangeland seeding is poor. The main limitations are limited rooting depth and the hazard of water erosion. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment. The soils are limited for livestock watering ponds and other water impoundments because of the seepage potential.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

This unit is poorly suited to homesite development. The main limitations are high shrink-swell potential, slope, and depth to soft bedrock. Backfilling excavations with coarser textured material reduces the shrink-swell potential. Absorption fields should be constructed using selected material.

This map unit is in capability subclass VIIe. The Shingle soil is in the Shallow Loamy, 10- to 14-inch ppt., Northern Plains range site. The Samday soil is in the Shallow Clayey, 10- to 14-inch ppt., Northern Plains range site. The included Tassel, thin solum, soil is a woodland soil.

132—Shingle, thin solum-Rock outcrop-Tassel, thin solum complex, cool, 6 to 45 percent slopes. This map unit is in rolling to steep areas on upland ridges, escarpments, and badlands along the eastern edge of the survey area. Slopes are medium in length and are convex. The native vegetation is mainly ponderosa pine and grasses with scattered junipers.

This unit is 35 percent Shingle loam, thin solum; 25 percent Rock outcrop; and 20 percent Tassel loamy fine sand, thin solum. The components of this unit are so intricately intermingled that it was not practical to map them separately at the scale used.

Included in this unit are small areas of Samday clay loam, Tullock loamy sand, and Vonalee loamy sand. Also included are small areas of Samday soils that are less than 10 inches thick. Included areas make up about 20 percent of the total acreage. The percentage varies from one area to another.

The Shingle soil is very shallow and well drained. It formed in loamy residuum derived from interbedded, noncalcareous shale and sandstone. Typically, the surface layer is light gray loam about 2 inches thick. The underlying material to a depth of 9 inches is grayish brown clay loam.

Permeability of the Shingle soil is moderate. Available water capacity is very low. Effective rooting depth is 4 to 10 inches. Runoff is rapid, and the hazard of water

LANDQUALITY DIVISION

Addendum D7 B3

MAR 11 1991

Page 39

4 1/143 PERMIT

ion is severe. The hazard of wind erosion is moderate.

Rock outcrop is soft, mostly noncalcareous shale and sandstone with seams of coal and ironstone.

The Tassel soil is very shallow and well drained. It formed in loamy residuum derived dominantly from noncalcareous sandstone. Typically, the surface layer is pale brown loamy fine sand about 2 inches thick. The underlying material to a depth of 8 inches is light yellowish brown and light olive brown sandy loam. Depth to noncalcareous sandstone ranges from 5 to 10 inches.

Permeability of the Tassel soil is moderately rapid. Available water capacity is very low. Effective rooting depth is 5 to 10 inches. Runoff is medium, and the hazard of water erosion is moderate. The hazard of wind erosion is severe.

This unit is used for livestock grazing and wildlife habitat.

The Shingle and Tassel soils are poorly suited to the production of timber. The site index for ponderosa pine ranges from 20 to 30. These soils can produce 6 cords per acre in a stand of trees that average 5 inches in diameter at a height of 1 foot. The main concerns in producing and harvesting timber are the low density of the stands, the very shallow depth of the soils, slow regeneration, the hazard of erosion, and difficulty of harvesting. Plant competition delays natural regeneration but does not prevent the eventual development of a fully stocked, normal stand of trees. Minimizing the risk of erosion is essential in harvesting timber. The very low available water capacity generally influences seedling survival in areas where understory plants are numerous. Conventional methods of harvesting timber are difficult to use because of slope.

The potential understory plant community on the Shingle and Tassel soils is mainly needleandthread, prairie sandreed, little bluestem, and bluebunch wheatgrass. As the range condition deteriorates, threadleaf sedge and fringed sagewort increase. As the range condition further deteriorates, annuals invade. The potential understory plant community produces about 600 pounds of air-dry vegetation in normal years. Production varies from 800 pounds in favorable years to 400 pounds in unfavorable years.

About 20 percent of this unit is scattered 5- to 10-acre clearings that support mainly range vegetation. The potential plant community in these clearings is mainly prairie sandreed, bluebunch wheatgrass, little bluestem, and western wheatgrass.

If the plant communities are overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community. Brush management improves deteriorated areas that are producing more woody shrubs than were present in the potential plant community. Livestock

grazing should be managed to protect the soil from excessive erosion.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

This unit is poorly suited to homesite development. The main limitations are slope and depth to soft bedrock. Mounded absorption fields should be constructed.

This map unit is in capability subclass VIIe. It is in woodland suitability group 2D1.

133—Shingle-Theedle-Cambria association, 6 to 30 percent slopes. This map unit is on ridge crests, back slopes, and pediment slopes of rolling to steep uplands. Slopes are medium in length and are convex. The native vegetation is mainly grasses and forbs.

This unit is 40 percent Shingle clay loam, 25 percent Theedle loam, and 25 percent Cambria sandy loam. The Shingle soil is in the more convex, moderately steep and steep areas. The Theedle and Cambria soils are in the less convex, moderately sloping areas.

Included in this unit are small areas of Samday clay loam and Rock outcrop. Included areas make up about 10 percent of the total acreage. The percentage varies from one area to another.

The Shingle soil is shallow and well drained. It formed in loamy residuum derived dominantly from calcareous shale. Typically, the surface layer is light brownish gray clay loam about 4 inches thick. The underlying material to a depth of 18 inches is light brownish gray clay loam. Soft shale is at a depth of 18 inches.

Permeability of the Shingle soil is moderate. Available water capacity is low. Effective rooting depth is 4 to 20 inches. Runoff is rapid, and the hazard of water erosion is severe. The hazard of wind erosion is slight.

The Theedle soil is moderately deep and well drained. It formed in loamy residuum derived dominantly from calcareous shale. Typically, the surface layer is pale brown loam about 5 inches thick. The underlying material to a depth of 23 inches is light gray loam and light brownish gray clay loam. Soft shale is at a depth of 28 inches. In some areas shale is at a depth of 40 to 60 inches or more.

Permeability of the Theedle soil is moderate. Available water capacity is moderate. Effective rooting depth is 20 to 40 inches. Runoff is rapid, and the hazard of water erosion is severe. The hazard of wind erosion is moderate.

The Cambria soil is deep and well drained. It formed in loamy local alluvium and residuum derived dominantly from shale and sandstone. Typically, the surface layer is brown sandy loam about 4 inches thick. The upper 4 inches of the subsoil is yellowish brown loam, and the lower part to a depth of 60 inches or more is pale brown and brown loam. In a few areas, bedrock is at a depth of 40 to 60 inches.

Permeability of the Cambria soil is moderate. Available water capacity is high. Effective rooting depth is 60

Page 40

2 1/17

inches or more. Runoff is medium, and the hazard of water erosion is moderate. The hazard of wind erosion is moderate.

This unit is used for livestock grazing and wildlife habitat.

The potential plant community on the Shingle soil is mainly western wheatgrass, bluebunch wheatgrass, needleandthread, and little bluestem. As the range condition deteriorates, blue grama and threadleaf sedge increase. As the range condition further deteriorates, broom snakeweed and cacti invade. The potential plant community produces about 900 pounds of air-dry vegetation in normal years. Production varies from 1,200 pounds in favorable years to 450 pounds in unfavorable years.

The production of forage on the Shingle soil is limited by restricted rooting depth and droughtiness. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of this soil for rangeland seeding is poor. The main limitations are restricted rooting depth and the hazard of water erosion. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

This soil is limited for livestock watering ponds and other water impoundments because of the seepage potential.

The potential plant community on the Theedle and Cambria soils is mainly western wheatgrass, thickspike wheatgrass, and needleandthread. As the range condition deteriorates, big sagebrush and blue grama increase. As the range condition further deteriorates, cacti, annuals, and broom snakeweed invade. The potential plant community produces about 1,500 pounds of air-dry vegetation in normal years. Production varies from 2,000 pounds in favorable years to 850 pounds in unfavorable years.

The production of forage on Theedle and Cambria soils is limited by low annual precipitation. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of these soils for rangeland seeding is fair. The main limitation is the hazard of water erosion. Chiseling or other such practices can be used to improve areas of deteriorated rangeland. Such practices increase water infiltration, reduce plant competition, and allow the desirable native plants to increase. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

The Shingle soil is poorly suited to homesite development. The main limitations are moderate shrink-swell potential, slope, and depth to soft bedrock. If the Theedle soil is used for homesite development, the main limitations are moderate shrink-swell potential, slope, and depth to soft bedrock. If the Cambria soil is used for homesite development, the main limitations are slope and moderate shrink-swell potential. Backfilling excavations with coarser textured material helps to overcome the limitation of shrink-swell potential. Septic tank absorption lines in the Cambria soil operate best if placed deep in the subsoil. Areas of the Shingle and Theedle soils are not suitable for use as absorption fields.

The Shingle soil is in capability subclass VIIe, and the Theedle and Cambria soils are in capability subclass VIe, nonirrigated. The Shingle soil is in the Shallow Loamy, 10- to 14-inch ppt., Northern Plains range site. The Theedle and Cambria soils are in the Loamy, 10- to 14-inch ppt., Northern Plains range site.

134—Silhouette-Heldt association, 0 to 6 percent slopes. This map unit is in nearly level to undulating areas on alluvial flats, toe slopes, and foot slopes. Slopes are long and are plane to slightly concave. The Silhouette soils are on foot slopes and the outer margins of alluvial flats, and the Heldt soils are on toe slopes and at the center of alluvial flats. The native vegetation is mainly grasses.

This unit is 50 percent Silhouette clay loam and 35 percent Heldt clay loam.

Included in this unit are small areas of Bidman sandy loam, Ulm loam, and Zigweid loam. Included areas make up about 15 percent of the total acreage. The percentage varies from one area to another.

The Silhouette soil is deep and well drained. It formed in clayey local alluvium derived dominantly from calcareous shale. Typically, the surface layer is light brownish gray clay loam about 2 inches thick. The upper part of the subsoil is pale brown clay about 20 inches thick, and the lower part to a depth of 48 inches or more is very pale brown clay and light gray clay loam. In a few areas, soft shale is at a depth of 20 to 40 inches.

Permeability of the Silhouette soil is slow. Available water capacity is high. Effective rooting depth is 40 to 60 inches or more. Runoff is medium, and the hazard of water erosion is moderate. The hazard of wind erosion is slight.

The Heldt soil is deep and well drained. It formed in clayey local alluvium derived dominantly from calcareous shale. Typically, the surface layer is light gray clay loam about 1 inch thick. The subsoil is light brownish gray clay about 18 inches thick. The substratum to a depth of 60 inches or more is pale brown and very pale brown clay. Cracks as much as 0.5 inch wide extend to a depth of 20 inches when the soil is dry.

LANDQUALITY DIVISION

Addendum D7 B3 VED MAR 11, 1991

Permeability of the Heldt soil is slow. Available water capacity is high. Effective rooting depth is 60 inches or more. Runoff is medium, and the hazard of water erosion is moderate. The hazard of wind erosion is moderate.

This unit is used for livestock grazing and wildlife habitat.

The potential plant community on this unit is mainly western wheatgrass, green needlegrass, and thickspike wheatgrass. As the range condition deteriorates, big sagebrush and blue grama increase. As the range condition further deteriorates, cacti and broom snakeweed invade. The potential plant community produces about 1,300 pounds of air-dry vegetation in normal years. Production varies from 1,800 pounds in favorable years to 750 pounds in unfavorable years.

The production of forage is limited by low annual precipitation. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of this unit for rangeland seeding is good. Chiseling or other such practices can be used to improve areas of deteriorated rangeland. Such practices increase water infiltration, reduce plant competition, and allow the desirable native plants to increase. Areas that are heavily infested with undesirable plants can be removed by chemical or mechanical treatment.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

If this unit is used for homesite development, the main limitations are high shrink-swell potential and slow permeability. Backfilling excavations with coarser textured material reduces the shrink-swell potential. Constructing a larger absorption field helps to compensate for the slow permeability.

This unit is in capability subclass IVe. It is in the Clayey, 10- to 14-inch ppt., Northern Plains range site.

135—Tassel-Shingle complex, 6 to 30 percent slopes. This map unit is on ridgetops and shoulder slopes in undulating to steep areas on uplands and on partially stabilized escarpments. Slopes are medium in length and are convex. The native vegetation is mainly grasses and shrubs.

This unit is 50 percent Tassel fine sandy loam and 30 percent Shingle clay loam. The components of this unit are so intricately intermingled that it was not practical to map them separately at the scale used.

Included in this unit are small areas of Samday clay loam, Rock outcrop, Worf loamy sand, Worfka fine sandy loam, and Theedle loam. Also included are small areas of Gateson Variant and Tassel Variant soils along Pine Ridge and small areas of Shingle soils, thin solum, and Tassel soils, thin solum, along the eastern county line.

Wooded areas make up about 20 percent of the total

acreage. The percentage varies from one area to another.

The Tassel soil is shallow and well drained. It formed in loamy residuum derived dominantly from calcareous sandstone. Typically, the surface layer is pale brown fine sandy loam about 3 inches thick. The underlying material to a depth of 14 inches is pale brown and light yellowish brown fine sandy loam. Soft sandstone is at a depth of 14 inches.

Permeability of the Tassel soil is moderately rapid. Available water capacity is very low. Effective rooting depth is 6 to 20 inches. Runoff is medium, and the hazard of water erosion is moderate. The hazard of wind erosion is moderate.

The Shingle soil is shallow and well drained. It formed in loamy residuum derived dominantly from calcareous shale. Typically, the surface layer is light brownish gray clay loam about 4 inches thick. The underlying material to a depth of 18 inches is light brownish gray clay loam. Soft shale is at a depth of 18 inches.

Permeability of the Shingle soil is moderate. Available water capacity is low. Effective rooting depth is 4 to 20 inches. Runoff is rapid, and the hazard of water erosion is severe. The hazard of wind erosion is slight.

This unit is used for livestock grazing and wildlife habitat.

The potential plant community on the Tassel soil is mainly needleandthread, prairie sandreed, Indian ricegrass, and little bluestem. As the range condition deteriorates, threadleaf sedge and fringed sagewort increase. As the range condition further deteriorates, broom snakeweed and annuals invade. The potential plant community produces about 1,000 pounds of air-dry vegetation in normal years. Production varies from 1,400 pounds in favorable years to 600 pounds in unfavorable years.

The potential plant community on the Shingle soil is mainly western wheatgrass, bluebunch wheatgrass, needleandthread, and little bluestem. As the range condition deteriorates, blue grama and threadleaf sedge increase. As the range condition further deteriorates, broom snakeweed and cacti invade. The potential plant community produces about 900 pounds of air-dry vegetation in normal years. Production varies from 1,200 pounds in favorable years to 450 pounds in unfavorable years.

The production of forage on this unit is limited by restricted rooting depth and droughtiness. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of this unit for rangeland seeding is poor. The main limitations are limited rooting depth and the hazards of wind and water erosion. Areas that are

heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

This unit is limited for livestock watering ponds and other water impoundments because of the seepage potential.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

This unit is poorly suited to homesite development. The main limitations are depth to soft bedrock and slope. Absorption fields should be constructed using selected material.

This map unit is in capability subclass VIIe. The Tassel soil is in the Shallow Sandy, 10- to 14-inch ppt., Northern Plains range site. The Shingle soil is in the Shallow Loamy, 10- to 14-inch ppt., Northern Plains range site.

136—Tassel-Terro-Rock outcrop complex, 15 to 30 percent slopes. This map unit is in hilly to steep areas on upland ridgetops, shoulder slopes, and back slopes. Slopes are convex and are medium in length. The native vegetation is mainly grasses and shrubs.

This unit is 40 percent Tassel loamy fine sand, 20 percent Terro sandy loam, and 20 percent Rock outcrop. The components of this unit are so intricately intermingled that it was not practical to map them separately at the scale used.

Included in this unit are small areas of Tullock loamy sand and Turnback loamy fine sand on the upper part of hill slopes and Keeline sandy loam on the lower part of hill slopes. Included areas make up about 20 percent of the total acreage. The percentage varies from one area to another.

The Tassel soil is shallow and well drained. It formed in loamy residuum derived dominantly from calcareous sandstone. Typically, the surface layer is grayish brown loamy fine sand about 2 inches thick. The underlying material to a depth of 16 inches is pale brown fine sandy loam. Soft calcareous sandstone is at a depth of 16 inches.

Permeability of the Tassel soil is moderately rapid. Available water capacity is very low. Effective rooting depth is 6 to 20 inches. Runoff is medium, and the hazard of water erosion is moderate. The hazard of wind erosion is severe.

The Terro soil is moderately deep and somewhat excessively drained. It formed in loamy residuum derived dominantly from calcareous sandstone. Typically, the surface layer is brown sandy loam about 4 inches thick. The upper 6 inches of the subsoil is brown sandy loam, and the lower 24 inches is pale brown and light gray sandy loam. Soft sandstone is at a depth of 34 inches. A few areas have soft bedrock at a depth of 40 to 60 inches or more.

Permeability of the Terro soil is moderately rapid. Available water capacity is low. Effective rooting depth is 20 to 40 inches. Runoff is slow, and the hazard of water

erosion is moderate. The hazard of wind erosion is moderate.

Rock outcrop is exposures of mostly soft, calcareous sandstone on knolls and narrow ridges.

This unit is used for livestock grazing and wildlife habitat.

The potential plant community on the Tassel soil is mainly needleandthread, prairie sandreed, Indian ricegrass, and little bluestem. As the range condition deteriorates, threadleaf sedge and fringed sagewort increase. As the range condition further deteriorates, broom snakeweed and annuals invade. The potential plant community produces about 1,000 pounds of air-dry vegetation in normal years. Production varies from 1,400 pounds in favorable years to 600 pounds in unfavorable years.

The potential plant community on the Terro soil is mainly needleandthread, prairie sandreed, Indian ricegrass, and little bluestem. As the range condition deteriorates, sageworts and needleleaf sedge increase. As the range condition further deteriorates, annuals and broom snakeweed invade. The potential plant community produces about 1,600 pounds of air-dry vegetation in normal years. Production varies from 2,100 pounds in favorable years to 1,000 pounds in unfavorable years.

The production of forage on this unit is limited by low annual precipitation and limited rooting depth. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of this unit for rangeland seeding is poor. The main limitations are the hazards of wind and water erosion. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

This unit is limited for livestock watering ponds and other water impoundments because of the seepage potential.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

This unit is poorly suited to homesite development. The main limitations are slope and depth to soft bedrock. Mounded septic tank absorption fields should be installed in the less sloping areas, and selected material should be used.

This map unit is in capability subclass VIIe. The Tassel soil is in the Shallow Sandy, 10- to 14-inch ppt., Northern Plains range site. The Terro soil is in the Sandy, 10- to 14-inch ppt., Northern Plains range site. Rock outcrop is not placed in a range site.

137—Tassel-Tullock-Vonalee association, 6 to 30 percent slopes. This map unit is on ridges and hill slopes in an area of rolling to steep uplands. Slopes are

1 m in length and are convex. The native vegetation is mainly grasses and shrubs.

This unit is 40 percent Tassel loamy fine sand, 20 percent Tullock loamy sand, and 20 percent Vonalee loamy sand. The Tassel soil has slopes of 6 to 30 percent, the Tullock soil has slopes of 6 to 20 percent, and the Vonalee soil has slopes of 6 to 15 percent.

Included in this unit are small areas of Bowbac sandy loam, Turnback sandy loam, and Keeline sandy loam and small areas of sandstone Rock outcrop. Included areas make up about 20 percent of the total acreage. The percentage varies from one area to another.

The Tassel soil is shallow and well drained. It formed in loamy residuum derived dominantly from calcareous sandstone. Typically, the surface layer is grayish brown loamy fine sand about 2 inches thick. The underlying material to a depth of 16 inches is pale brown fine sandy loam. Soft calcareous sandstone is at a depth of 16 inches.

Permeability of the Tassel soil is moderately rapid. Available water capacity is very low. Effective rooting depth is 6 to 20 inches. Runoff is medium, and the hazard of water erosion is moderate. The hazard of wind erosion is severe.

The Tullock soil is moderately deep and excessively drained. It formed in sandy residuum derived dominantly from calcareous sandstone. Typically, the surface layer is brown loamy sand about 5 inches thick. The upper 15 inches of the underlying material is brown sand, and the remainder to a depth of 31 inches is pale brown loamy sand. Soft sandstone is at a depth of 31 inches. In a few areas, bedrock is at a depth of 40 to 60 inches or more.

Permeability of the Tullock soil is rapid. Available water capacity is very low to low. Effective rooting depth is 20 to 40 inches. Runoff is medium, and the hazard of water erosion is moderate. The hazard of wind erosion is severe.

The Vonalee soil is deep and somewhat excessively drained. It formed in loamy, wind-worked residuum derived dominantly from calcareous sandstone. Typically, the surface layer is dark grayish brown loamy sand about 3 inches thick. The upper 16 inches of the subsoil is light yellowish brown sandy loam, and the lower 5 inches is pale brown sandy loam. The substratum to a depth of 60 inches or more is pale brown loamy sand. In a few areas, soft bedrock is at a depth of 20 to 60 inches.

Permeability of the Vonalee soil is moderately rapid. Available water capacity is low. Effective rooting depth is 60 inches or more. Runoff is medium, and the hazard of water erosion is moderate. The hazard of wind erosion is severe.

This unit is used for livestock grazing and wildlife habitat.

The potential plant community on the Tassel soil is mainly needleandthread, prairie sandreed, Indian grass, and little bluestem. As the range condition deteriorates, threadleaf sedge and fringed sagewort

increase. As the range condition further deteriorates, broom snakeweed and annuals invade. The potential plant community produces about 1,000 pounds of air-dry vegetation in normal years. Production varies from 1,400 pounds in favorable years to 600 pounds in unfavorable years.

The production of forage on the Tassel soil is limited by restricted rooting depth and droughtiness. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of the Tassel soil for rangeland seeding is poor. The main limitations are limited rooting depth and the hazards of erosion by wind and water. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

The Tassel soil is limited for livestock watering ponds and other water impoundments because of the seepage potential.

The potential plant community on the Tullock soil is mainly prairie sandreed, sand bluestem, needleandthread, and Indian ricegrass. As the range condition deteriorates, sageworts increase. As the range condition further deteriorates, annuals and broom snakeweed invade. The potential plant community produces about 2,000 pounds of air-dry vegetation in normal years. Production varies from 2,500 pounds in favorable years to 1,400 pounds in unfavorable years.

The production of forage on the Tullock soil is limited by droughtiness. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of the Tullock soil for rangeland seeding is poor. The main limitations are the hazard of wind erosion, droughtiness, and slope. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

The Tullock soil is limited for livestock watering ponds and other water impoundments because of the seepage potential.

The potential plant community on the Vonalee soil is mainly needleandthread, prairie sandreed, Indian ricegrass, and little bluestem. The production of forage on the Vonalee soil is limited by low annual precipitation. If the range is overgrazed, the proportion of preferred forage plants decreases and

LAND QUALITY DIVISION

the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of the Vonalee soil for rangeland seeding is fair. The main limitations are the hazards of wind and water erosion. Chiseling or other such practices can be used to improve areas of deteriorated rangeland. Such practices increase water infiltration, reduce plant competition, and allow the desirable native plants to increase. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

The Vonalee soil is limited for livestock watering ponds and other water impoundments because of the seepage potential.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

The Tassel and Tullock soils are poorly suited to homesite development. The main limitations are slope, depth to soft bedrock, and the hazard of sand blowing. If the Vonalee soil is used for homesite development, the main limitation is slope. Areas of the Vonalee soil are most suitable for use as septic tank absorption fields.

The Tassel soil is in capability subclass VIIIe. The Tullock and Vonalee soils are in capability subclass VIe. The Tassel soil is in the Shallow Sandy, 10- to 14-inch ppt., Northern Plains range site. The Tullock soil is in the Sands, 10- to 14-inch ppt., Northern Plains range site. The Vonalee soil is in the Sandy, 10- to 14-inch ppt., Northern Plains range site.

138—Terro-Tullock-Orpha complex, 0 to 6 percent slopes. This map unit is in nearly level to undulating areas on upland summits and superimposed dunes. Slopes are short and convex. The native vegetation is mainly grasses and shrubs.

This unit is 35 percent Terro sandy loam, 30 percent Tullock loamy sand, and 20 percent Orpha loamy sand. The components of this unit are so intricately intermingled that it was not practical to map them separately at the scale used.

Included in this unit are small areas of Turnback sandy loam, Keeline sandy loam, and Bowbac sandy loam. Included areas make up about 15 percent of the total acreage. The percentage varies from one area to another.

The Terro soil is moderately deep and somewhat excessively drained. It formed in loamy residuum derived dominantly from calcareous sandstone. Typically, the surface layer is brown sandy loam about 4 inches thick. The upper 6 inches of the subsoil is brown sandy loam, and the lower 24 inches is pale brown and light gray sandy loam. Soft sandstone is at a depth of 34 inches. In a few areas, soft bedrock is at a depth of 40 to 60 inches or more.

Permeability of the Terro soil is moderately rapid. Available water capacity is low. Effective rooting depth is 20 to 40 inches. Runoff is slow, and the hazard of water erosion is moderate. The hazard of wind erosion is moderate.

The Tullock soil is moderately deep and excessively drained. It formed in sandy residuum derived dominantly from calcareous sandstone. Typically, the surface layer is brown loamy sand about 5 inches thick. The upper 15 inches of the underlying material is brown sand, and the lower part to a depth of 31 inches is pale brown loamy sand. Soft sandstone is at a depth of 31 inches.

Permeability of the Tullock soil is rapid. Available water capacity is very low. Effective rooting depth is 20 to 40 inches. Runoff is slow, and the hazard of water erosion is slight. The hazard of wind erosion is severe.

The Orpha soil is deep and excessively drained. It formed in eolian sand derived from mixed sources. Typically, the surface layer is pale brown loamy sand about 5 inches thick. The underlying material to a depth of 60 inches or more is light yellowish brown loamy sand. In some areas carbonates are above a depth of 40 inches.

Permeability of the Orpha soil is very rapid. Available water capacity is low. Effective rooting depth is 60 inches or more. Runoff is slow, and the hazard of water erosion is slight. The hazard of wind erosion is severe.

This unit is used for livestock grazing and wildlife habitat.

The potential plant community on the Terro soil is mainly needleandthread, prairie sandreed, Indian ricegrass, and little bluestem. As the range condition deteriorates, sageworts and needleleaf sedge increase. As the range condition further deteriorates, annuals and broom snakeweed invade. The Terro soil is limited for livestock watering ponds and other water impoundments because of the seepage

LAND QUALITY POTENTIAL

potential plant community on the Tullock and Orpha soils is mainly prairie sandreed, sand bluestem, needleandthread, and Indian ricegrass. As the range condition deteriorates, sageworts increase. As the range condition further deteriorates, annuals and broom snakeweed invade. The potential plant community produces about 2,000 pounds of air-dry vegetation in normal years. Production varies from 2,500 pounds in favorable years to 1,400 pounds in unfavorable years.

The production of forage on the Tullock and Orpha soils is limited by droughtiness. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of the Tullock and Orpha soils for rangeland seeding is poor. The main limitations are the hazard of wind erosion and droughtiness. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

The Tullock and Orpha soils are limited for livestock watering ponds and other water impoundments because of the seepage potential.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

If this unit is used for homesite development, the main limitations are depth to soft bedrock, the hazard of sand caving, and the hazard of excavations caving in. Areas of Orpha soil are most suitable for use as septic tank absorption fields.

This map unit is in capability subclass VIe. The Terro soil is in the Sandy, 10- to 14-inch ppt., Northern Plains range site. The Tullock and Orpha soils are in the Sands, 10- to 14-inch ppt., Northern Plains range site.

139—Terro-Tullock-Orpha complex, 6 to 15 percent slopes. This map unit is on ridgetops, shoulders, and back slopes of rolling uplands and on superimposed dunes. Slopes are short and convex. The native vegetation is mainly grasses and shrubs.

This unit is 35 percent Terro sandy loam, 30 percent Tullock loamy sand, and 20 percent Orpha loamy sand. The components of this unit are so intricately intermingled that it was not practical to map them separately at the scale used.

Included in this unit are small areas of Turnback sandy loam and Keeline sandy loam on ridges and shoulder slopes. Also included are small areas of Tassel loamy fine sand on ridgetops and Vonalee loamy sand on the lower part of hill slopes. Included areas make up about 15 percent of the total acreage. The percentage varies from one area to another.

The Terro soil is moderately deep and somewhat excessively drained. It formed in loamy residuum derived primarily from calcareous sandstone. Typically, the surface layer is brown sandy loam about 4 inches thick.

The upper 6 inches of the subsoil is brown sandy loam, and the lower 24 inches is pale brown and light gray sandy loam. Soft sandstone is at a depth of 34 inches.

Permeability of the Terro soil is moderately rapid. Available water capacity is low. Effective rooting depth is 20 to 40 inches. Runoff is medium, and the hazard of water erosion is moderate. The hazard of wind erosion is moderate.

The Tullock soil is moderately deep and excessively drained. It formed in sandy residuum derived dominantly from calcareous sandstone. Typically, the surface layer is brown loamy sand about 5 inches thick. The upper 15 inches of the underlying material is brown sand, and the lower part to a depth of 31 inches is pale brown loamy sand. Soft sandstone is at a depth of 31 inches.

Permeability of the Tullock soil is rapid. Available water capacity is very low. Effective rooting depth is 20 to 40 inches. Runoff is slow, and the hazard of water erosion is slight. The hazard of wind erosion is severe.

The Orpha soil is deep and excessively drained. It formed in eolian sand derived from mixed sources. Typically, the surface layer is pale brown loamy sand about 5 inches thick. The underlying material to a depth of 60 inches or more is light yellowish brown loamy sand. In a few areas, carbonates are above a depth of 40 inches.

Permeability of the Orpha soil is very rapid. Available water capacity is low. Effective rooting depth is 60 inches or more. Runoff is slow, and the hazard of water erosion is slight. The hazard of wind erosion is severe.

This unit is used for livestock grazing and wildlife habitat.

The potential plant community on the Terro soil is mainly needleandthread, prairie sandreed, Indian ricegrass, and little bluestem. As the range condition deteriorates, sageworts and needleleaf sedge increase. As the range condition further deteriorates, annuals and broom snakeweed invade. The potential plant community produces about 1,600 pounds of air-dry vegetation in normal years. Production varies from 2,100 pounds in favorable years to 1,000 pounds in unfavorable years.

The production of forage on the Terro soil is limited by low annual precipitation. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of the Terro soil for rangeland seeding is fair. The main limitations are the hazards of wind and water erosion. Chiseling or other such practices can be used to improve areas of deteriorated rangeland. Such practices increase water infiltration, reduce plant competition, and allow the desirable native plants to increase. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

RANGELAND QUALITY DIVISION

R

Addendum D7 B3

001

The Terro soil is limited for livestock watering ponds and other water impoundments because of the seepage potential.

The potential plant community on the Tullock and Orpha soils is mainly prairie sandreed, sand bluestem, needleandthread, and Indian ricegrass. As the range condition deteriorates, sageworts increase. As the range condition further deteriorates, annuals and broom snakeweed invade. The potential plant community produces about 2,000 pounds of air-dry vegetation in normal years. Production varies from 2,500 pounds in favorable years to 1,400 pounds in unfavorable years.

The production of forage on the Tullock and Orpha soils is limited by droughtiness. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of these soils for rangeland seeding is poor. The main limitations are the hazard of wind erosion and droughtiness. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

These soils are limited for livestock watering ponds and other water impoundments because of the seepage potential.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

If this unit is used for homesite development, the main limitations are depth to soft bedrock and the hazard of excavations caving in. Areas of the Terro and Tullock soils are not suitable for use as septic tank absorption fields.

This map unit is in capability subclass VIe. The Terro soil is in the Sandy, 10- to 14-inch ppt., Northern Plains range site. The Tullock and Orpha soils are in the Sands, 10- to 14-inch ppt., Northern Plains range site.

140—Theedle-Kishona association, 0 to 6 percent slopes. This map unit is in nearly level to undulating areas on alluvial flats, foot slopes, and toe slopes adjacent to rolling uplands. Slopes are medium to long in length and are slightly convex. The native vegetation is mainly grasses.

This unit is 45 percent Theedle loam and 35 percent Kishona loam. The Theedle soil is in the more convex areas, and the Kishona soil is in the more nearly plane areas.

Included in this unit are small areas of Cambria fine sandy loam, Bahl clay, and Cushman loam. Included areas make up about 20 percent of the total acreage. The percentage varies from one area to another.

The Theedle soil is moderately deep and well drained. It formed in loamy residuum derived dominantly from calcareous shale. Typically, the surface layer is pale brown loam about 5 inches thick. The underlying material

to a depth of 28 inches is light gray loam and light brownish gray clay loam. Soft shale is at a depth of 28 inches.

Permeability of the Theedle soil is moderate. Available water capacity is low. Effective rooting depth is 20 to 40 inches. Runoff is medium, and the hazard of water erosion is moderate. The hazard of wind erosion is moderate.

The Kishona soil is deep and well drained. It formed in loamy local residuum derived dominantly from calcareous shale. Typically, the surface layer is brown loam about 3 inches thick. The underlying material to a depth of 60 inches or more is light yellowish brown and light gray clay loam.

Permeability of the Kishona soil is moderate. Available water capacity is high. Effective rooting depth is 60 inches or more. Runoff is medium, and the hazard of water erosion is moderate. The hazard of wind erosion is moderate.

This unit is used for livestock grazing and wildlife habitat.

The potential plant community on this unit is mainly western wheatgrass, thickspike wheatgrass, and needleandthread. As the range condition deteriorates, big sagebrush and blue grama increase. As the range condition further deteriorates, cacti, annuals, and broom snakeweed invade. The potential plant community produces about 1,500 pounds of air-dry vegetation in normal years. Production varies from 2,000 pounds in favorable years to 850 pounds in unfavorable years.

The production of forage on this unit is limited by low annual precipitation. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of this unit for rangeland seeding is good. Chiseling or other such practices can be used to improve areas of deteriorated rangeland. Such practices increase water infiltration, reduce plant competition, and allow the desirable native plants to increase. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

If this unit is used for homesite development, the main limitations are depth of the Theedle soil to soft bedrock and moderate shrink-swell potential. Backfilling excavations with coarser textured material helps to overcome the limitation of shrink-swell potential. Areas of the Kishona soil are most suitable for use as septic tank absorption fields.

This map unit is in capability subclass IVe. It is in the Loamy, 10- to 14-inch ppt., Northern Plains range site.

LANDQUALITY DIVISION

41—Theedle-Kishona association, 6 to 15 percent slopes. This map unit is on pediment slopes in areas of rolling uplands and on alluvial fans adjacent to upland escarpments. Slopes are short and convex. The native vegetation is mainly grasses.

This unit is 55 percent Theedle loam and 25 percent Kishona loam. The Theedle soil is in the more convex areas, and the Kishona soil is in the more nearly level areas.

Included in this unit are small areas of Cambria sandy loam, Savageton clay loam, and Shingle clay loam. Included areas make up about 20 percent of the total acreage. The percentage varies from one area to another.

The Theedle soil is moderately deep and well drained. It formed in loamy residuum derived dominantly from calcareous shale. Typically, the surface layer is pale brown loam about 5 inches thick. The underlying material to a depth of 28 inches is light gray loam and light brownish gray clay loam. Soft shale is at a depth of 28 inches.

Permeability of the Theedle soil is moderate. Available water capacity is low. Effective rooting depth is 20 to 40 inches. Runoff is medium, and the hazard of water erosion is severe. The hazard of wind erosion is moderate.

The Kishona soil is deep and well drained. It formed in loamy local alluvium derived dominantly from calcareous shale. Typically, the surface layer is brown loam about 3 inches thick. The underlying material to a depth of 60 inches or more is light yellowish brown and light gray clay loam.

Permeability of the Kishona soil is moderate. Available water capacity is high. Effective rooting depth is 60 inches or more. Runoff is medium, and the hazard of water erosion is severe. The hazard of wind erosion is moderate.

This unit is used for livestock grazing and wildlife habitat.

The potential plant community on this unit is mainly western wheatgrass, thickspike wheatgrass, and needleandthread. As the range condition deteriorates, big sagebrush and blue grama increase. As the range condition further deteriorates, cacti, annuals, and broom snakeweed invade. The potential plant community produces about 1,500 pounds of air-dry vegetation in normal years. Production varies from 2,000 pounds in favorable years to 850 pounds in unfavorable years.

The production of forage on this unit is limited by low annual precipitation. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of this unit for rangeland seeding is fair. The main limitation is the hazard of water erosion.

Chiseling or other such practices can be used to improve areas of deteriorated rangeland. Such practices increase water infiltration, reduce plant competition, and allow the desirable native plants to increase. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

If this unit is used for homesite development, the main limitations are slope, depth of the Theedle soil to soft bedrock, and moderate shrink-swell potential. Backfilling excavations with coarser textured material reduces the limitation of shrink-swell potential. Areas of the Kishona soil are more suitable for use as septic tank absorption fields.

This map unit is in capability subclass VIe. It is in the Loamy, 10- to 14-inch ppt., Northern Plains range site.

142—Ulm-Bidman complex, 0 to 6 percent slopes. This map unit is on alluvial flats and in level to undulating areas on foot slopes and toe slopes. Slopes are long and are plane to concave. The native vegetation is mainly grasses and shrubs.

This unit is 45 percent Ulm clay loam and 40 percent Bidman sandy loam. The components of this unit are so intricately intermingled that it was not practical to map them separately at the scale used.

Included in this unit are small areas of Forkwood fine sandy loam, Bahl clay, and Absted fine sandy loam. Included areas make up about 15 percent of the total acreage. The percentage varies from one area to another.

The Ulm soil is deep and well drained. It formed in clayey local alluvium derived dominantly from calcareous shale. Typically, the surface layer is pale brown clay loam about 4 inches thick. The upper 13 inches of the subsoil is pale brown clay and pale brown clay loam, and the lower part to a depth of 60 inches or more is light yellowish brown clay loam.

Permeability of the Ulm soil is slow. Available water capacity is high. Effective rooting depth is 60 inches or more. Runoff is slow, and the hazard of water erosion is moderate. The hazard of wind erosion is slight.

The Bidman soil is deep and well drained. It formed in clayey local alluvium derived dominantly from calcareous shale. Typically, the surface layer is light brownish gray sandy loam about 3 inches thick. The subsurface layer is pale brown sandy loam about 4 inches thick. The upper 13 inches of the subsoil is light brownish gray clay, and the lower 28 inches is light brownish gray clay loam. The substratum to a depth of 60 inches or more is light brownish gray clay loam.

Permeability of the Bidman soil is slow. Available water capacity is high. Effective rooting depth is 60 inches or more. Runoff is medium, and the hazard of water erosion is moderate. The hazard of wind erosion is moderate.

LANDQUALITY DIVISION

This unit is used for livestock grazing and wildlife habitat.

The potential plant community on the Ulm soil is mainly western wheatgrass, green needlegrass, and thickspike wheatgrass. As the range condition deteriorates, big sagebrush and blue grama increase. As the range condition further deteriorates, cacti and broom snakeweed invade. The potential plant community produces about 1,300 pounds of air-dry vegetation in normal years. Production varies from 1,800 pounds in favorable years to 750 pounds in unfavorable years.

The potential plant community on the Bidman soil is mainly western wheatgrass, thickspike wheatgrass, and needleandthread. As the range condition deteriorates, big sagebrush and blue grama increase. As the range condition further deteriorates, cacti, annuals, and broom snakeweed invade. The potential plant community produces about 1,500 pounds of air-dry vegetation in normal years. Production varies from 2,000 pounds in favorable years to 850 pounds in unfavorable years.

The production of forage on this unit is limited by low annual precipitation. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of this unit for rangeland seeding is good. Chiseling or other such practices can be used to improve areas of deteriorated rangeland. Such practices increase water infiltration, reduce plant competition, and allow the desirable native plants to increase. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

This unit is poorly suited to homesite development. The main limitations are high shrink-swell potential and slow permeability. Backfilling excavations with coarser textured material reduces the limitation of shrink-swell potential. Constructing a larger absorption field helps to compensate for the slow permeability.

This map unit is in capability subclass IVe. The Ulm soil is in the Clayey, 10- to 14-inch ppt., Northern Plains range site. The Bidman soil is in the Loamy, 10- to 14-inch ppt., Northern Plains range site.

143—Ulm-Renohill complex, 0 to 6 percent slopes.

This map unit is in nearly level to undulating areas on foot slopes and toe slopes. Slopes are medium to long in length and are plane to concave. The native vegetation is mainly grasses and shrubs.

This unit is 50 percent Ulm loam and 40 percent Renohill fine sandy loam. The components of this unit are so intricately intermingled that it was not practical to map them separately at the scale used.

Included in this unit are small areas of Forkwood fine sandy loam, Zigweid clay loam, and Cambria fine sandy loam. Included areas make up about 10 percent of the total acreage. The percentage varies from one area to another.

The Ulm soil is deep and well drained. It formed in clayey local alluvium derived dominantly from calcareous shale. Typically, the surface layer is brown loam about 5 inches thick. The upper 16 inches of the subsoil is brown clay loam and clay, and the lower part to a depth of 60 inches or more is pale brown clay loam and light yellowish brown sandy clay loam. In some areas the surface layer is sandy loam.

Permeability of the Ulm soil is slow. Available water capacity is high. Effective rooting depth is 60 inches or more. Runoff is slow, and the hazard of water erosion is moderate. The hazard of wind erosion is slight.

The Renohill soil is moderately deep and well drained. It formed in clayey residuum derived dominantly from calcareous shale. Typically, the surface layer is pale brown fine sandy loam about 5 inches thick. The upper 15 inches of the subsoil is brown clay, and the lower 16 inches is pale brown clay loam. Calcareous shale is at a depth of 36 inches. In some areas the surface layer is thinner than is typical and has an abrupt boundary with the subsoil.

Permeability of the Renohill soil is slow. Available water capacity is moderate. Effective rooting depth is 20 to 40 inches. Runoff is medium, and the hazard of water erosion is moderate. The hazard of wind erosion is moderate.

This unit is used for livestock grazing and wildlife habitat.

The potential plant community on the Ulm soil is mainly western wheatgrass, green needlegrass, and thickspike wheatgrass. As the range condition deteriorates, big sagebrush and blue grama increase. As the range condition further deteriorates, cacti and broom snakeweed invade. The potential plant community produces about 1,300 pounds of air-dry vegetation in normal years. Production varies from 1,800 pounds in favorable years to 750 pounds in unfavorable years.

The potential plant community on the Renohill soil is mainly western wheatgrass, thickspike wheatgrass, and needleandthread. As the range condition deteriorates, big sagebrush and blue grama increase. As the range condition further deteriorates, cacti, annuals, and broom snakeweed invade. The potential plant community produces about 1,500 pounds of air-dry vegetation in normal years. Production varies from 2,000 pounds in favorable years to 850 pounds in unfavorable years.

The production of forage on this unit is limited by low annual precipitation. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that

LANDQUALITY DIVISION

a desired balance of preferred species is maintained in the plant community.

The suitability of this unit for rangeland seeding is good. Chiseling or other such practices can be used to improve areas of deteriorated rangeland. Such practices increase water infiltration, reduce plant competition, and allow the desirable native plants to increase. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

If this unit is used for homesite development, the main limitations are high shrink-swell potential, slow permeability, and the depth of the Renohill soil to soft bedrock. Backfilling excavations with coarser textured material helps to overcome the limitation of shrink-swell potential. Constructing a larger septic tank absorption field helps to compensate for the slow permeability. Areas of the Renohill soil are not suitable for use as septic tank absorption fields.

This map unit is in capability subclass IVe. The Ulm soil is in the Clayey, 10- to 14-inch ppt., Northern Plains range site. The Renohill soil is in the Loamy, 10- to 14-inch ppt., Northern Plains range site.

144—Ulm-Renohill clay loams, 6 to 15 percent slopes. This map unit is on ridges and hill slopes in areas of rolling uplands and on adjacent foot slopes. Slopes are short and convex. The native vegetation is mainly grasses and shrubs.

This unit is 45 percent Ulm clay loam and 45 percent Renohill clay loam. The components of this unit are so intricately intermingled that it was not practical to map them separately at the scale used.

Included in this unit are small areas of Shingle clay loam and Workka fine sandy loam. Included areas make up about 10 percent of the total acreage. The percentage varies from one area to another.

The Ulm soil is deep and well drained. It formed in clayey local alluvium derived dominantly from calcareous shale. Typically, the surface layer is light brownish gray clay loam about 4 inches thick. The upper 12 inches of the subsoil is brown clay loam, and the lower part to a depth of 60 inches or more is light gray clay loam. In some areas the surface layer is sandy loam, and in some areas the subsoil is sandy clay.

Permeability of the Ulm soil is slow. Available water capacity is high. Effective rooting depth is 60 inches or more. Runoff is medium, and the hazard of water erosion is severe. The hazard of wind erosion is slight.

The Renohill soil is moderately deep and well drained. It formed in clayey residuum derived dominantly from calcareous shale. Typically, the surface layer is light brownish gray clay loam about 5 inches thick. The subsoil is light brownish gray clay loam about 20 inches thick. Calcareous, gritty shale is at a depth of 25 inches. In some areas the surface layer is sandy loam.

Permeability of the Renohill soil is moderately slow. Available water capacity is low. Effective rooting depth is 20 to 40 inches. Runoff is medium, and the hazard of water erosion is severe. The hazard of wind erosion is slight.

This unit is used for livestock grazing and wildlife habitat.

The potential plant community on this unit is mainly western wheatgrass, green needlegrass, and thickspike wheatgrass. As the range condition deteriorates, big sagebrush and blue grama increase. rapid, and the hazard of water erosion is severe. The hazard of wind erosion is slight to severe.

This unit is used for livestock grazing and wildlife habitat.

A common plant community on this unit is mainly western wheatgrass, thickspike wheatgrass, big sagebrush, and fourwing saltbush. As the range condition deteriorates, Russian-thistle, cheatgrass, buffalobur, kochia, and Japanese brome increase.

This unit responds well to fertilizer, range seeding, and proper grazing use. The main limitation for seeding is the reaction of the soil, which ranges from 3.8 to 8.4 in various layers. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment. Management practices suitable for use on this unit include proper range use, deferred grazing, mowing, rotation grazing, and aerial spraying for brush management. Livestock grazing should be managed to protect the soil from excessive erosion.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

This map unit is in capability subclass VIe. It is not placed in a range site.

146—Vonalee-Terro complex, 0 to 6 percent slopes. This map unit is in nearly level to gently sloping areas on pediment slopes adjacent to rolling uplands and on stream terraces. Slopes are medium to long in length and are plane to slightly convex. The native vegetation is mainly grasses and shrubs.

This unit is 50 percent Vonalee loamy sand and 35 percent Terro sandy loam. The components of this unit are so intricately intermingled that it was not practical to map them separately at the scale used.

Included in this unit are small areas of Hiland sandy loam, Turnback sandy loam, and Keeline sandy loam. Included areas make up about 15 percent of the total acreage. The percentage varies from one area to another.

The Vonalee soil is deep and somewhat excessively drained. It formed in loamy, wind-worked residuum and local alluvium derived from mixed sources. Typically, the surface layer is yellowish brown loamy sand about 4 inches thick. The upper 20 inches of the subsoil is yellowish brown and grayish brown sandy loam. The subsoil to a depth of 60 inches or more is brown loamy sand and light brownish gray sandy clay loam. In some areas soft sandstone is at a depth of 40 to 60 inches.

Permeability of the Vonalee soil is moderately rapid. Available water capacity is moderate. Effective rooting depth is 60 inches or more. Runoff is slow, and the hazard of water erosion is slight. The hazard of wind erosion is severe.

The Terro soil is moderately deep and somewhat excessively drained. It formed in loamy residuum derived dominantly from calcareous sandstone. Typically, the surface layer is brown sandy loam about 4 inches thick.

The upper 6 inches of the subsoil is brown sandy loam, and the lower 24 inches is pale brown and light gray sandy loam. Soft, calcareous sandstone is at a depth of 34 inches.

Permeability of the Terro soil is moderately rapid. Available water capacity is low. Effective rooting depth is 20 to 40 inches. Runoff is slow, and the hazard of water erosion is moderate. The hazard of wind erosion is moderate.

This unit is used for livestock grazing and wildlife habitat.

The potential plant community on this unit is mainly needleandthread, prairie sandreed, Indian ricegrass, and little bluestem. As the range condition deteriorates, sageworts and needleleaf sedge increase. As the range condition further deteriorates, annuals and broom snakeweed invade. The potential plant community produces about 1,600 pounds of air-dry vegetation in normal years. Production varies from 2,100 pounds in favorable years to 1,000 pounds in unfavorable years.

The production of forage is limited by low annual precipitation. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of this unit for rangeland seeding is fair. The main limitation is the hazard of wind erosion. Chiseling or other such practices can be used to improve areas of deteriorated rangeland. Such practices increase water infiltration, reduce plant competition, and allow the desirable native plants to increase. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

If this unit is used for homesite development, the main limitations are the depth of the Terro soil to soft bedrock and the hazard of excavations caving in. Areas of the Vonalee soil are more suitable for use as septic tank absorption fields.

This map unit is in capability subclass IVe. It is in the Sandy, 10- to 14-inch ppt., Northern Plains range site.

147—Vonalee-Terro complex, 6 to 15 percent slopes. This map unit is on ridges and back slopes of rolling uplands. Slopes are short and convex. The native vegetation is mainly grasses and shrubs.

This unit is 45 percent Vonalee loamy sand and 40 percent Terro sandy loam. The components of this unit are so intricately intermingled that it was not practical to map them separately at the scale used.

Included in this unit are small areas of Bowbac sandy loam, Turnback sandy loam, and Keeline sandy loam. Included areas make up about 15 percent of the total

acreage. The percentage varies from one area to another.

The Vonalee soil is deep and somewhat excessively drained. It formed in loamy wind-worked residuum derived dominantly from calcareous sandstone. Typically, the surface layer is dark grayish brown loamy sand about 3 inches thick. The upper 16 inches of the subsoil is light yellowish brown sandy loam, and the lower 5 inches is pale brown sandy loam. The substratum to a depth of 60 inches or more is pale brown sandy loam.

Permeability of the Vonalee soil is moderately rapid. Available water capacity is moderate. Effective rooting depth is 60 inches or more. Runoff is slow, and the hazard of water erosion is moderate. The hazard of wind erosion is severe.

The Terro soil is moderately deep and somewhat excessively drained. It formed in loamy residuum derived dominantly from calcareous sandstone. Typically, the surface layer is brown sandy loam about 4 inches thick. The upper 6 inches of the subsoil is brown sandy loam, and the lower 24 inches is pale brown and light gray sandy loam and loamy sand. Soft, calcareous sandstone is at a depth of 34 inches.

Permeability of the Terro soil is moderately rapid. Available water capacity is low. Effective rooting depth is 20 to 40 inches. Runoff is slow, and the hazard of water erosion is moderate. The hazard of wind erosion is moderate.

This unit is used for livestock grazing and wildlife habitat.

The potential plant community on this unit is mainly needleandthread, prairie sandreed, Indian ricegrass, and little bluestem. As the range condition deteriorates, sageworts and needleleaf sedge increase. As the range condition further deteriorates, annuals and broom snakeweed invade. The potential plant community produces about 1,600 pounds of air-dry vegetation in normal years. Production varies from 2,100 pounds in favorable years to 1,000 pounds in unfavorable years.

The production of forage is limited by low annual precipitation. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of this unit for rangeland seeding is fair. The main limitations are the hazards of wind and water erosion. Chiseling or other such practices can be used to improve areas of deteriorated rangeland. Such practices increase water infiltration, reduce plant competition, and allow the desirable native plants to increase. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

This unit is limited for livestock watering ponds and other water impoundments because of the seepage potential.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

If this unit is used for homesite development, the main limitations are slope, depth of the Terro soil to soft bedrock, and the hazard of excavations caving in. Areas of the Vonalee soil are more suitable for use as septic tank absorption fields.

This map unit is in capability subclass VIe. It is in the Sandy, 10- to 14-inch ppt., Northern Plains range site.

148—Wibaux-Rock outcrop-Shingle complex, 6 to 45 percent slopes. This map unit is on steep porcellanite-capped buttes and rolling shale uplands. Slopes are short to medium in length and are plane to convex. The native vegetation is mainly grasses and forbs.

This unit is 35 percent Wibaux channery loam, 30 percent Rock outcrop, and 20 percent Shingle clay loam. The components of this unit are so intricately intermingled that it was not practical to map them separately at the scale used.

Included in this unit are small areas of Renohill clay loam and Sear loam. Included areas make up about 15 percent of the total acreage. The percentage varies from one area to another.

The Wibaux soil is shallow and somewhat excessively drained. It formed in channery residuum derived dominantly from fragmented porcellanite. Typically, the surface layer is pinkish gray channery loam about 4 inches thick. The underlying material to a depth of 11 inches is light brown very channery loam. Fragmented porcellanite in which soil partially fills voids is at a depth of 11 to 60 inches or more.

Permeability of the Wibaux soil is moderate to a depth of 11 inches and very rapid below this depth. Available water capacity is very low. Effective rooting depth is 10 to 20 inches. Runoff is medium, and the hazard of water erosion is moderate. The hazard of wind erosion is slight.

Rock outcrop is exposures of shale and siltstone on scarp slopes.

The Shingle soil is shallow and well drained. It formed in loamy residuum derived dominantly from shale. Typically, the surface layer is pale brown clay loam about 4 inches thick. The underlying material to a depth of 13 inches is light brownish gray clay loam. Soft, interbedded shale and sandstone are at a depth of 13 inches.

Permeability of the Shingle soil is moderate. Available water capacity is very low. Effective rooting depth is 4 to 20 inches. Runoff is rapid, and the hazard of water erosion is severe. The hazard of wind erosion is slight.

This unit is used for livestock grazing and wildlife habitat.

The potential plant community on the Wibaux and Shingle soils is mainly western wheatgrass, bluebunch wheatgrass, needleandthread, and little bluestem. As the range condition deteriorates, blue grama and threadleaf sedge increase. As the range condition further

QUALITY DIVISION

RECEIVED M

Addendum D7 B3

Page 52

deteriorates, broom snakeweed and cacti invade. The potential plant community produces about 900 pounds of air-dry vegetation in normal years. Production varies from 1,200 pounds in favorable years to 450 pounds in unfavorable years.

The production of forage is limited by restricted rooting depth and droughtiness. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of these soils for rangeland seeding is poor. The main limitations are restricted rooting depth and the hazard of water erosion. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

These soils are limited for livestock watering ponds and other water impoundments because of the seepage potential.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

This unit is poorly suited to homesite development. The main limitation is the depth to soft bedrock or fragmented porcellanite. Septic tank absorption fields should be constructed using selected material.

This map unit is in capability subclass VIIe. The Wibaux soil is in the Shallow Loamy, 10- to 14-inch ppt., Northern Plains range site. Rock outcrop is not assigned a range site. The Shingle soil is in the Shallow Loamy, 10- to 14-inch ppt., Northern Plains range site.

149—Worf-Shingle-Tassel complex, 3 to 30 percent slopes. This map unit is on ridgetops and shoulder slopes of undulating to steep uplands and on partially stabilized escarpments. Slopes are medium in length and are convex. The native vegetation is mainly grasses and shrubs.

This unit is 35 percent Worf loamy sand, 30 percent Shingle clay loam, and 20 percent Tassel fine sandy loam. The components of this unit are so intricately intermingled that it was not practical to map them separately at the scale used.

Included in this unit are small areas of Theedle loam, Cushman loam, Samday clay loam, and Worfka fine sandy loam. Included areas make up about 15 percent of the total acreage. The percentage varies from one area to another.

The Worf soil is shallow and well drained. It formed in loamy residuum derived dominantly from interbedded shale and sandstone. Typically, the surface layer is light brownish gray loamy sand about 5 inches thick. The subsoil is brown and yellowish brown clay loam about 10 inches thick. Calcareous shale and sandstone are at a depth of 15 inches.

Permeability of the Worf soil is moderate. Available water capacity is very low. Effective rooting depth is 8 to

20 inches. Runoff is medium, and the hazard of water erosion is moderate. The hazard of wind erosion is severe.

The Shingle soil is shallow and well drained. It formed in loamy residuum derived dominantly from calcareous shale. Typically, the surface layer is light brownish gray clay loam about 4 inches thick. The underlying material to a depth of 18 inches is light brownish gray clay loam. Soft shale is at a depth of 18 inches.

Permeability of the Shingle soil is moderate. Available water capacity is low. Effective rooting depth is 4 to 20 inches. Runoff is rapid, and the hazard of water erosion is severe. The hazard of wind erosion is slight.

The Tassel soil is shallow and well drained. It formed in loamy residuum derived dominantly from calcareous sandstone. Typically, the surface layer is pale brown fine sandy loam about 3 inches thick. The underlying material to a depth of 14 inches is pale brown and light yellowish brown fine sandy loam. Soft sandstone is at a depth of 14 inches.

Permeability of the Tassel soil is moderately rapid. Available water capacity is very low. Effective rooting depth is 6 to 20 inches. Runoff is medium, and the hazard of water erosion is moderate. The hazard of wind erosion is moderate.

This unit is used for livestock grazing and wildlife habitat.

The potential plant community on the Worf and Shingle soils is mainly western wheatgrass, bluebunch wheatgrass, needleandthread, and little bluestem. As the range condition deteriorates, blue grama and threadleaf sedge increase. As the range condition further deteriorates, broom snakeweed and cacti invade. The potential plant community produces about 900 pounds of air-dry vegetation in normal years. Production varies from 1,200 pounds in favorable years to 450 pounds in unfavorable years.

The potential plant community on the Tassel soil is mainly needleandthread, prairie sandreed, Indian ricegrass, and little bluestem. As the range condition deteriorates, threadleaf sedge and fringed sagewort increase. As the range condition further deteriorates, broom snakeweed and annuals invade. The potential plant community produces about 1,000 pounds of air-dry vegetation in normal years. Production varies from 1,400 pounds in favorable years to 600 pounds in unfavorable years.

The production of forage on this unit is limited by restricted rooting depth and droughtiness. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of this unit for rangeland seeding is poor. The main limitations are restricted rooting depth and the hazards of erosion by wind and water. Areas

LA QUALITY DIVISION

REIVED MAR 11 1991

Page 53

2 1/173 PERMIT

that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

This unit is limited for livestock watering ponds and other water impoundments because of the seepage potential.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

This unit is poorly suited to homesite development. The main limitations are slope and depth to soft bedrock. Septic tank absorption fields should be installed in the less sloping areas, and selected material should be used.

This map unit is in capability subclass VIIe. The Worf and Shingle soils are in the Shallow Loamy, 10- to 14-inch ppt., Northern Plains range site. The Tassel soil is in the Shallow Sandy, 10- to 14-inch ppt., Northern Plains range site.

150—Zigweid-Bahl association, 0 to 6 percent slopes. This map unit is in nearly level to undulating areas on alluvial flats and toe slopes adjacent to rolling uplands. Slopes are long and plane. The native vegetation is mainly grasses and shrubs.

This unit is 55 percent Zigweid loam and 30 percent Bahl clay. The Zigweid soil is on toe slopes, and the Bahl soil is on alluvial flats.

Included in this unit are small areas of Cambria fine sandy loam, Ulm clay loam, Theedle loam, and Haverdad fine sandy loam. Included areas make up about 15 percent of the total acreage. The percentage varies from one area to another.

The Zigweid soil is deep and well drained. It formed in loamy local alluvium derived dominantly from calcareous shale. Typically, the surface layer is grayish brown loam about 2 inches thick. The subsoil is grayish brown and light brownish gray clay loam about 33 inches thick. The substratum to a depth of 60 inches or more is light brownish gray clay loam. In a few areas soft shale is at a depth of 40 to 60 inches.

Permeability of the Zigweid soil is moderate. Available water capacity is high. Effective rooting depth is 60 inches or more. Runoff is medium, and the hazard of water erosion is moderate. The hazard of wind erosion is slight.

The Bahl soil is deep and well drained. It formed in clayey local alluvium derived dominantly from calcareous shale. Typically, the surface layer is pale olive clay about 4 inches thick. The underlying material to a depth of 60 inches or more is pale olive clay.

Permeability of the Bahl soil is slow. Available water capacity is high. Effective rooting depth is 60 inches or more. Runoff is medium, and the hazard of water erosion is moderate. The hazard of wind erosion is slight.

This unit is used for livestock grazing and wildlife habitat.

The potential plant community on the Zigweid soil is mainly western wheatgrass, thickspike wheatgrass, and

needleandthread. As the range condition deteriorates, big sagebrush and blue grama increase. As the range condition further deteriorates, cacti, annuals, and broom snakeweed invade. The potential plant community produces about 1,500 pounds of air-dry vegetation in normal years. Production varies from 2,000 pounds in favorable years to 850 pounds in unfavorable years.

The potential plant community on the Bahl soil is mainly western wheatgrass, thickspike wheatgrass, and green needlegrass. As the range condition deteriorates, big sagebrush and blue grama increase. As the range condition further deteriorates, cacti and broom snakeweed invade. The potential plant community produces about 1,300 pounds of air-dry vegetation in normal years. Production varies from 1,800 pounds in favorable years to 750 pounds in unfavorable years.

The production of forage on this unit is limited by low annual precipitation. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of this unit for rangeland seeding is good. Chiseling or other such practices can be used to improve areas of deteriorated rangeland. Such practices increase water infiltration, reduce plant competition, and allow the desirable native plants to increase. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

If this unit is used for homesite development, the main limitations are the slow permeability of the Bahl soil and shrink-swell potential. Constructing a larger absorption field helps to compensate for the slow permeability. Backfilling excavations with coarser textured material helps to overcome the limitation of shrink-swell potential.

This map unit is in capability subclass IVe. The Zigweid soil is in the Loamy, 10- to 14-inch ppt., Northern Plains range site. The Bahl soil is in the Clayey, 10- to 14-inch ppt., Northern Plains range site.

151—Zigweid-Cambria association, 0 to 6 percent slopes. This map unit is in nearly level to undulating areas on foot slopes and toe slopes adjacent to rolling uplands. Slopes are medium to long in length and are plane to slightly convex. The native vegetation is mainly grasses and shrubs.

This unit is 55 percent Zigweid clay loam and 30 percent Cambria fine sandy loam. The Zigweid soil is in the plane areas, and the Cambria soil is in the convex areas.

Included in this unit are small areas of Theedle loam and Bahl clay. Included areas make up about 15 percent of the total acreage. The percentage varies from one area to another.

The Zigweid soil is deep and well drained. It formed in loamy local alluvium derived dominantly from calcareous shale. Typically, the surface layer is brown clay loam about 3 inches thick. The subsoil is pale brown and light brownish gray clay loam to a depth of 60 inches or more. In a few areas, soft bedrock is at a depth of 40 to 60 inches.

Permeability of the Zigweid soil is moderate. Available water capacity is high. Effective rooting depth is 60 inches or more. Runoff is medium, and the hazard of water erosion is moderate. The hazard of wind erosion is slight.

The Cambria soil is deep and well drained. It formed in loamy local alluvium and residuum derived dominantly from shale and sandstone. Typically, the surface layer is grayish brown fine sandy loam about 2 inches thick. The upper 8 inches of the subsoil is brown sandy clay loam, and the lower 19 inches is pale brown sandy clay loam and loam. The substratum to a depth of 60 inches or more is pale brown sandy clay loam.

Permeability of the Cambria soil capacity is low. Effective rooting depth is 60 inches or more. Runoff is medium, and the hazard of water erosion is moderate. The hazard of wind erosion is slight.

This unit is used for livestock grazing and wildlife habitat.

The potential plant community on this unit is mainly western wheatgrass, thickspike wheatgrass, and needleandthread. As the range condition deteriorates, big sagebrush and blue grama increase. As the range condition further deteriorates, cacti, annuals, and broom snakeweed invade. The potential plant community produces about 1,500 pounds of air-dry vegetation in normal years. Production varies from 2,000 pounds in favorable years to 850 pounds in unfavorable years.

The production of forage is limited by low annual precipitation. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of this unit for rangeland seeding is good. Chiseling or other such practices can be used to improve areas of deteriorated rangeland. Such practices increase water infiltration, reduce plant competition, and allow the desirable native plants to increase. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

If this unit is used for homesite development, the main limitation is moderate shrink-swell potential. Backfilling excavations with coarser textured material helps to overcome this limitation. Septic tank absorption fields operative more effectively if they are placed deep in the subsoil.

This map unit is in capability subclass IVe. It is in the Loamy, 10- to 14-inch ppt., Northern Plains range site.

152—Zigweid-Cambria-Theedle association, 6 to 15 percent slopes. This map unit is on pediment slopes of rolling uplands and on adjacent foot slopes. Slopes are short and are mostly convex. The native vegetation is mostly grasses and shrubs.

This unit is 35 percent Zigweid loam, 25 percent Cambria sandy loam, and 25 percent Theedle loam. The Zigweid soil is on the longer, more nearly plane slopes, the Cambria soil is on the intermediate slopes, and the Theedle soil is on the shorter, more convex slopes.

Included in this unit are small areas of Shingle clay loam, Bahl clay, and Renohill clay loam. Included areas make up about 15 percent of the total acreage. The percentage varies from one area to another.

The Zigweid soil is deep and well drained. It formed in loamy local alluvium derived dominantly from calcareous shale. Typically, the surface layer is pale brown loam about 4 inches thick. The subsoil to a depth of 60 inches or more is pale brown and very pale brown clay loam. In a few areas, soft bedrock is at a depth of 40 to 60 inches.

Permeability of the Zigweid soil is moderate. Available water capacity is high. Effective rooting depth is 60 inches or more. Runoff is medium, and the hazard of water erosion is severe. The hazard of wind erosion is slight.

The Cambria soil is deep and well drained. It formed in loamy local alluvium and residuum derived dominantly from shale and sandstone. Typically, the surface layer is brown sandy loam about 4 inches thick. The upper 4 inches of the subsoil is yellowish brown loam, and the lower 22 inches is pale brown loam. The substratum to a depth of 60 inches or more is brown loam.

Permeability of the Cambria soil is moderate. Available water capacity is high. Effective rooting depth is 60 inches or more. Runoff is medium, and the hazard of water erosion is severe. The hazard of wind erosion is moderate.

The Theedle soil is moderately deep and well drained. It formed in loamy residuum derived dominantly from calcareous shale. Typically, the surface layer is pale brown loam about 5 inches thick. The underlying material to a depth of 28 inches is light gray loam and light brownish gray clay loam. Soft shale is at a depth of 28 inches.

Permeability of the Theedle soil is moderate. Available water capacity is moderate. Effective rooting depth is 20 to 40 inches. Runoff is rapid, and the hazard of water erosion is severe. The hazard of wind erosion is moderate.

This unit is used for livestock grazing and wildlife habitat.

The potential plant community on this unit is mainly western wheatgrass, thickspike wheatgrass, and

LAND QUALITY DIVISION

Page 55

73 PERMIT

needleandthread. As the range condition deteriorates, big sagebrush and blue grama increase. As the range condition further deteriorates, cacti, annuals, and broom snakeweed invade. The potential plant community produces about 1,500 pounds of air-dry vegetation in normal years. Production varies from 2,000 pounds in favorable years to 850 pounds in unfavorable years.

The production of forage is limited by low annual precipitation. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of this unit for rangeland seeding is fair. The main limitation is the hazard of water erosion. Chiseling or other such practices can be used to improve

areas of deteriorated rangeland. Such practices increase water infiltration, reduce plant competition, and allow the desirable native plants to increase. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

If this unit is used for homesite development, the main limitations are shrink-swell potential, slope, and the depth of the Theedle soil to soft bedrock. Backfilling excavations with coarser textured material helps to overcome the limitation of shrink-swell potential. Septic tank absorption fields in the Zigweid and Cambria soils operate most effectively if placed deep in the subsoil; areas of the Theedle soil are not suitable for this use.

This map unit is in capability subclass VIe. It is in the Loamy, 10- to 14-inch ppt., Northern Plains range site.

Classification of the Soils

The system of soil classification used by the National Cooperative Soil Survey has six categories (7). Beginning with the broadest, these categories are the order, suborder, great group, subgroup, family, and series. Classification is based on soil properties observed in the field or inferred from those observations or from laboratory measurements. Table 14 shows the classification of the soils in the survey area. The categories are defined in the following paragraphs.

ORDER. Ten soil orders are recognized. The differences among orders reflect the dominant soil-forming processes and the degree of soil formation. Each order is identified by a word ending in *sol*. An example is Aridisol.

SUBORDER. Each order is divided into suborders primarily on the basis of properties that influence soil genesis and are important to plant growth or properties that reflect the most important variables within the orders. The last syllable in the name of a suborder indicates the order. An example is Argid (*Arg*, meaning clay-rich horizon, plus *id*, from Aridisol).

GREAT GROUP. Each suborder is divided into great groups on the basis of close similarities in kind, arrangement, and degree of development of pedogenic horizons; soil moisture and temperature regimes; and base status. Each great group is identified by the name of a suborder and by a prefix that indicates a property of the soil. An example is Haplargids (*Hapl*, meaning minimal horizonation, plus *argid*, the suborder of the Aridisols that have a layer of clay accumulation).

SUBGROUP. Each great group has a typic subgroup. Other subgroups are intergrades or extragrades. The typic is the central concept of the great group; it is not necessarily the most extensive. Intergrades are transitions to other orders, suborders, or great groups. Extragrades have some properties that are not representative of the great group but do not indicate transitions to any other known kind of soil. Each subgroup is identified by one or more adjectives preceding the name of the great group. The adjective *Ustollic* identifies the subgroup that has more organic matter and receives more precipitation than the one that typifies the great group. An example is Ustollic Haplargids.

FAMILY. Families are established within a subgroup on the basis of physical and chemical properties and other characteristics that affect management. Mostly the

properties are those of horizons below plow depth where there is much biological activity. Among the properties and characteristics considered are particle-size class, mineral content, temperature regime, depth of the root zone, and permanent cracks. A family name consists of the name of a subgroup preceded by terms that indicate soil properties. An example is fine-loamy, mixed, mesic Ustollic Haplargids.

SERIES. The series consists of soils that have similar horizons in their profile. The horizons are similar in color, texture, structure, reaction, consistence, mineral and chemical composition, and arrangement in the profile. The texture of the surface layer or of the substratum can differ within a series.

Taxonomic Units and Their Morphology

In this section, each taxonomic unit recognized in the survey area is described. The descriptions are arranged in alphabetic order.

Characteristics of the soil and the material in which it formed are identified for each taxonomic unit. A pedon, a small three-dimensional area of soil, that is typical or representative of the taxonomic unit in the survey area is described. The detailed description of each soil horizon follows standards in the *Soil Survey Manual* (5). Many of the technical terms used in the descriptions are defined in *Soil Taxonomy* (7). Unless otherwise stated, colors in the descriptions are for dry soil. Following the pedon description is the range of important characteristics of the soils in the taxonomic unit.

The map units of each taxonomic unit are described in the section "Detailed Soil Map Units."

Absted Series

The Absted series consists of deep, well drained, slowly permeable soils on alluvial flats, toe slopes, and dissected terraces adjacent to major and minor drainageways. These soils formed in alluvial sediment derived from sedimentary rock. Slope is 0 to 6 percent.

Typical pedon of Absted fine sandy loam in an area of Absted-Arvada-Bone complex, 0 to 6 percent slopes, 1,250 feet east and 950 feet north of the southwest corner of sec. 30, T. 40 N., R. 68 W.

LAND QUALITY DIVISION

Addendum D7 B3

Page 58

11-1991

PERMIT

- E—0 to 3 inches; pale brown (10YR 6/3) fine sandy loam, brown (10YR 5/3) moist; weak medium and coarse granular structure; slightly hard, very friable, slightly sticky and slightly plastic; mildly alkaline; abrupt smooth boundary.
- Bt—3 to 14 inches; brown (10YR 5/3) clay, brown (10YR 4/3) moist; strong medium and fine subangular blocky structure; continuous thick clay films on faces of peds; very hard, very firm, sticky and plastic; moderately alkaline; gradual smooth boundary.
- Btnk—14 to 26 inches; grayish brown (10YR 5/2) clay, dark grayish brown (10YR 4/2) moist; strong medium and fine subangular blocky structure; continuous thick clay films on faces of peds; very hard, very firm, sticky and plastic; violently effervescent; many medium soft masses of calcium carbonate; strongly alkaline; gradual wavy boundary.
- Bnk—26 to 36 inches; light brownish gray (10YR 6/2) clay, grayish brown (10YR 5/2) moist; massive; very hard, very firm, sticky and plastic; violently effervescent; many medium soft masses of calcium carbonate; strongly alkaline; gradual wavy boundary.
- Bck—36 to 60 inches; light brownish gray (10YR 6/2) clay, grayish brown (10YR 5/2) moist; massive; very hard, very firm, sticky and plastic; slightly effervescent; few fine soft masses of calcium carbonate; moderately alkaline.

The depth to calcium carbonate ranges from 12 to 28 inches.

The E horizon and the A horizon, where present, have hue of 2.5Y or 10YR, value of 6 or 7 when dry and 5 or 6 when moist, and chroma of 2 or 3. Reaction is neutral or mildly alkaline.

The Btnk horizon has hue of 10YR, value of 5 or 6 when dry and 4 or 5 when moist, and chroma of 2 or 3. It is clay or clay loam that is 15 to 40 percent sand. The Btnk and Bnk horizons are moderately alkaline or strongly alkaline.

Aeric Haplaquepts

Aeric Haplaquepts are deep, poorly drained, very slowly permeable soils on playa lakebeds in areas characterized by centripetal drainage. These soils formed in clayey local alluvium derived from calcareous sedimentary rock. Slope is 0 to 3 percent.

Reference pedon of Aeric Haplaquepts clay loam in an area of Aeric Haplaquepts, 0 to 3 percent slopes, 800 feet south and 450 feet east of the northwest corner of sec. 15, T. 34 N., R. 71 W.

- A—0 to 3 inches; light gray (10YR 6/1) clay loam, grayish brown (10YR 5/2) moist; weak fine granular structure; very hard, firm, sticky and plastic; common fine mottles; mildly alkaline; abrupt smooth boundary.

- AC—3 to 8 inches; light brownish gray (10YR 6/2) clay loam, grayish brown (10YR 5/2) moist; weak fine subangular blocky structure; very hard, firm, sticky and plastic; few fine mottles; neutral; clear wavy boundary.

- C1—8 to 20 inches; light gray (10YR 6/1) clay, grayish brown (10YR 5/2) moist; massive; very hard, firm, sticky and plastic; few fine mottles; mildly alkaline; gradual irregular boundary.

- C2—20 to 30 inches; light gray (10YR 7/2) clay, pale brown (10YR 6/3) moist; massive; very hard, firm, very sticky and very plastic; few fine mottles and few medium iron and manganese concretions; strongly effervescent; few fine calcium carbonate concretions; mildly alkaline; gradual irregular boundary.

- C3—30 to 48 inches; very pale brown (10YR 7/3) clay, grayish brown (10YR 5/2) moist; massive; very hard, very firm, very sticky and plastic; few fine mottles and few fine iron and manganese concretions; mildly alkaline.

Depth to bedrock typically is more than 60 inches, but it is as little as 20 inches in the smaller playas. Accumulation of carbonates and depth to them vary with the parent material. The control section is fine or fine-loamy.

The A horizon has hue of 10YR or 2.5Y, value of 6 or 7 when dry and 4 or 5 when moist, and chroma of 1 or 2. Texture is clay loam or clay. Reaction is neutral or mildly alkaline.

The C horizon has hue of 10YR or 2.5Y, value of 6 or 7 when dry and 4 to 6 when moist, and chroma of 1 to 3. Reaction is mildly alkaline to strongly alkaline.

Arvada Series

The Arvada series consists of deep, well drained, slowly permeable soils on alluvial flats, toe slopes, and dissected terraces adjacent to major and minor drainageways. These soils formed in alluvial sediment derived from sedimentary rock. Slope is 0 to 6 percent.

Typical pedon of an Arvada loam in an area of Absted-Arvada-Bone complex, 0 to 6 percent slopes, 1,100 feet south and 1,000 feet east of the northwest corner of sec. 35, T. 41 N., R. 70 W.

- A—0 to 3 inches; light brownish gray (10YR 6/2) loam, brown (10YR 5/3) moist; moderate fine platy structure parting to moderate very fine granular; soft, friable, slightly sticky and slightly plastic; slightly effervescent; moderately alkaline; abrupt smooth boundary.

- Btn1—3 to 7 inches; pale brown (10YR 6/3) clay, brown (10YR 5/3) moist; weak medium and coarse prismatic structure parting to strong fine angular blocky; continuous thick clay films on faces of peds;

QUALITY DIVISION

RECEIVED MAR 11 1981

1/173 PERMIT

hard, friable, sticky and plastic; strongly alkaline; slightly effervescent; clear smooth boundary.

Btn2—7 to 15 inches; light brownish gray (10YR 6/2) clay, grayish brown (10YR 5/2) moist; strong fine angular blocky structure; continuous thick clay films on faces of peds; hard, friable, sticky and plastic; very strongly alkaline; slightly effervescent; clear wavy boundary.

Bk—15 to 22 inches; light brownish gray (10YR 6/2) clay, grayish brown (10YR 5/2) moist; weak fine subangular blocky structure; hard, friable, sticky and plastic; slightly effervescent; moderately alkaline; clear wavy boundary.

C—22 to 48 inches; pale brown (10YR 6/3) clay, grayish brown (10YR 5/2) moist; massive; hard, friable, sticky and plastic; slightly effervescent; strongly alkaline.

The depth to calcium carbonate ranges from 0 to 12 inches.

The A horizon has hue of 10YR, value of 5 or 6 when dry and 4 or 5 when moist, and chroma of 2 or 3. Reaction is mildly alkaline to strongly alkaline.

The Btn horizons have hue of 2.5Y or 10YR, value of 5 or 6 when dry and 4 or 5 when moist, and chroma of 2 to 4. They are typically clay or clay loam and are 10 to 40 percent sand. They are strongly alkaline or very strongly alkaline.

The C horizon is strongly alkaline or very strongly alkaline.

Bahl Series

The Bahl series consists of deep, well drained, slowly permeable soils on alluvial flats and toe slopes. These soils formed in local alluvium derived from calcareous shale. Slopes range from 0 to 6 percent.

Typical pedon of a Bahl clay in an area of Zigweid-Bahl association, 0 to 6 percent slopes, in the NE1/4NE1/4 of sec. 24, T. 40 N., R. 72 W.

A—0 to 4 inches; pale olive (5Y 6/3) clay, olive (5Y 5/3) moist; weak thick platy structure parting to weak medium and fine subangular blocky; hard, friable, sticky and plastic; strongly effervescent; moderately alkaline; gradual wavy boundary.

AC—4 to 9 inches; pale olive (5Y 6/3) clay, olive (5Y 5/3) moist; massive; hard, firm, sticky and plastic; strongly effervescent; strongly alkaline; gradual wavy boundary.

CK—9 to 40 inches; pale olive (5Y 6/3) clay, olive (5Y 5/3) moist; massive; hard, firm, sticky and plastic; strongly effervescent; few fine soft masses and filaments of calcium carbonate; strongly alkaline.

These soils typically are leached in the upper few inches, but in some areas they are calcareous throughout.

The A horizon has chroma of 2 or 3. Reaction is neutral to moderately alkaline.

The C horizon is mildly alkaline to strongly alkaline. The control section typically is about 45 percent clay and 15 to 25 percent sand.

Bidman Series

The Bidman series consists of deep, well drained, slowly permeable soils on alluvial flats, toe slopes, and foot slopes of upland hills. These soils formed in local alluvium derived from soft calcareous shale. Slope is 0 to 6 percent.

Typical pedon of a Bidman sandy loam in an area of Ulm-Bidman complex, 0 to 6 percent slopes, 2,500 feet east and 300 feet north of the southwest corner of sec. 1, T. 37 N., R. 68 W.

A—0 to 3 inches; light brownish gray (10YR 6/2) sandy loam, dark grayish brown (10YR 4/2) moist; weak fine granular structure; soft, very friable, nonsticky and nonplastic; neutral; abrupt smooth boundary.

E—3 to 7 inches; pale brown (10YR 6/3) sandy loam, brown (10YR 5/3) moist; weak medium subangular blocky structure; slightly hard, very friable, slightly sticky and slightly plastic; neutral; clear smooth boundary.

Bt—7 to 20 inches; light brownish gray (10YR 6/2) clay, grayish brown (10YR 5/2) moist and crushed; weak medium prismatic structure parting to strong medium and coarse angular blocky; very hard, firm, sticky and plastic; continuous thick clay films on faces of peds; neutral; clear wavy boundary.

Bk1—20 to 35 inches; light brownish gray (2.5Y 6/2) clay loam, grayish brown (2.5Y 5/2) moist; moderate medium and coarse angular blocky structure; very hard, firm, sticky and plastic; few medium hard iron concretions; strongly effervescent; common medium and fine filaments and seams of calcium carbonate; moderately alkaline; gradual wavy boundary.

Bk2—35 to 52 inches; light brownish gray (2.5Y 6/2) clay loam, grayish brown (2.5Y 5/2) moist; massive; hard, friable, slightly sticky and slightly plastic; few medium iron concretions; strongly effervescent; moderately alkaline; diffuse wavy boundary.

C—52 to 67 inches; light brownish gray (2.5Y 6/2) clay loam, grayish brown (2.5Y 5/2) moist; massive; hard, friable; slightly effervescent; moderately alkaline.

The depth to calcium carbonate ranges from 12 to 24 inches.

The A horizon has hue of 10YR or 2.5Y, value of 5 or 6 when dry and 3 to 5 when moist, and chroma of 2 or 3. It is sandy loam or loam.

The Bt horizon has value of 5 or 6 when dry and 4 or 5 when moist, and it has chroma of 2 to 4. It is

LABORATORY DIVISION

RECEIVED MAR 19 1961

dominantly clay, but the range includes clay loam and sandy clay. It averages 37 to 47 percent clay. Reaction is neutral to moderately alkaline.

The Bk horizon has hue of 10YR or 2.5Y, value of 5 or 6 when dry and 4 or 5 when moist, and chroma of 2 to 4. Texture is clay loam, sandy clay loam, or clay. Reaction is mildly alkaline to strongly alkaline.

Bigwinder Series

The Bigwinder series consists of deep, poorly drained, moderately permeable soils on flood plains and low stream terraces. These soils formed in recent stratified alluvium derived dominantly from sedimentary rock. Slope is 0 to 3 percent.

Typical pedon of a Bigwinder fine sandy loam in an area of Clarkelen-Haverdad-Bigwinder complex, 0 to 3 percent slopes; 1,250 feet north and 1,400 feet west of the southeast corner of sec. 24, T. 39 N., R. 75 W.

- A—0 to 3 inches; light brownish gray (10YR 6/2) fine sandy loam, grayish brown (10YR 5/2) moist; common fine strong brown (7.5YR 5/8) mottles along root channels; moderate thick platy structure; slightly hard, very friable, nonsticky and nonplastic; strongly effervescent; mildly alkaline; clear smooth boundary.
- AC—3 to 8 inches; light gray (10YR 7/2), stratified sandy loam and loam, grayish brown (10YR 5/2) moist; common fine strong brown (7.5YR 5/8) mottles along root channels; weak thick platy structure; hard, friable, slightly sticky and plastic; strongly effervescent; moderately alkaline; clear smooth boundary.
- C1—8 to 17 inches; light gray (10YR 7/2), stratified loamy sand, loam, and sandy loam, pale brown (10YR 6/3) moist; common medium strong brown (7.5YR 5/8) mottles and faint organic stains on faces of fragments; massive; slightly hard, very friable, nonsticky and nonplastic; violently effervescent; moderately alkaline; clear wavy boundary.
- C2—17 to 24 inches; light gray (10YR 7/2), stratified sandy loam and loamy sand, light brownish gray (10YR 6/2) moist; single grain; slightly hard, very friable, nonsticky and nonplastic; slightly effervescent; mildly alkaline; gradual smooth boundary.
- C3—24 to 60 inches; mottled, light gray (10YR 7/2) and reddish yellow (7.5YR 6/8), stratified loamy sand, sandy loam, and sand, light brownish gray (10YR 6/2) and reddish yellow (5YR 6/8) moist; single grain; loose, nonsticky and nonplastic; slightly effervescent; mildly alkaline.

Depth to sand strata ranges from 30 to 40 inches.

The A horizon is fine sandy loam or sandy clay loam. Reaction is neutral to moderately alkaline. It has weak or moderate grades of platy structure.

The C horizon has value of 5 or 6 when moist. Matrix chroma is 2 or 3. Reaction is on mildly alkaline or moderately alkaline. Texture of the strata ranges from loam to sand.

Bone Series

The Bone series consists of deep, well drained, very slowly permeable soils on alluvial flats and toe slopes of dissected terraces adjacent to major and minor drainageways. These soils formed in alluvial sediment derived from sedimentary rock. Slope is 0 to 6 percent.

Typical pedon of a Bone clay loam in an area of Absted-Arvada-Bone complex, 0 to 6 percent slopes, 1,100 feet south and 500 feet west of the northeast corner of sec. 8, T. 36 N., R. 68 W.

- E—0 to 2 inches; pale brown (10YR 6/3) light clay loam, brown (10YR 5/3) moist; weak thin platy structure; slightly hard, very friable, slightly sticky and slightly plastic; mildly alkaline; abrupt smooth boundary.
- Bt—2 to 5 inches; light brownish gray (10YR 6/2) clay loam, brown (10YR 5/3) moist; moderate fine subangular blocky structure; few thin clay films on faces of peds; hard, friable, slightly sticky and slightly plastic; moderately alkaline; clear smooth boundary.
- Bk—5 to 10 inches; light gray (10YR 7/2) clay loam, pale brown (10YR 6/3) moist; moderate fine subangular blocky structure; very hard, friable, sticky and plastic; strongly effervescent; calcium carbonate segregated in common fine soft masses; moderately alkaline; gradual smooth boundary.
- C1—10 to 20 inches; very pale brown (10YR 7/3) heavy clay loam, pale brown (10YR 6/3) moist; massive; very hard, firm, sticky and plastic; strongly effervescent; calcium carbonate disseminated throughout matrix; very strongly alkaline; gradual smooth boundary.
- C2—20 to 60 inches; very pale brown (10YR 7/3) clay, pale brown (10YR 6/3) moist; massive; very hard, friable, sticky and plastic; strongly effervescent; calcium carbonate disseminated throughout matrix; moderately alkaline.

The profile commonly is leached to a depth of 2 to 5 inches, or to the base of the Bt horizon, but many pedons are calcareous throughout. The solum has hue of 2.5Y or 10YR.

The E horizon has value of 6 or 7 when dry and 4 to 6 when moist. The Bt horizon has value of 5 or 6 when dry and 4 or 5 when moist, and it has chroma of 2 to 4. The Bk and C horizons are heavy clay loam or clay.

SOIL QUALITY DIVISION

Bowbac Series

The Bowbac series consists of moderately deep, well drained, moderately permeable soils on shoulder slopes, back slopes, and pediment slopes of rolling uplands. These soils formed in residuum derived from soft sandstone. Slope is 0 to 15 percent.

Typical pedon of a Bowbac sandy loam (fig. 3) in an area of Hiland-Bowbac complex, 6 to 15 percent slopes, 2,450 feet north and 500 feet east of the southwest corner of sec. 27, T. 36 N., R. 70 W.

- A—0 to 3 inches; brown (10YR 5/3) sandy loam, dark brown (10YR 4/3) moist; weak fine granular structure parting to single grain; soft, loose, slightly sticky and slightly plastic; neutral; abrupt smooth boundary.
- Bt1—3 to 6 inches; brown (7.5YR 5/4) sandy clay loam, dark brown (7.5YR 4/4) moist; strong coarse subangular blocky structure parting to strong fine angular blocky; slightly hard, friable, sticky and plastic; few thin clay bridges between mineral grains; neutral; clear smooth boundary.
- Bt2—6 to 18 inches; brown (7.5YR 5/4) sandy clay loam, dark brown (7.5YR 4/4) moist; strong coarse prismatic structure parting to strong fine subangular blocky; hard, friable, sticky and plastic; common moderately thick clay bridges between mineral grains; neutral; clear smooth boundary.
- Btk—18 to 26 inches; brown (10YR 5/3) sandy loam, dark brown (10YR 4/3) moist; moderate coarse subangular blocky structure parting to weak fine subangular blocky; slightly hard, very friable, slightly sticky and slightly plastic; thin clay bridges between mineral grains; slightly effervescent; disseminated calcium carbonate; mildly alkaline; gradual wavy boundary.
- Bk—26 to 36 inches; light yellowish brown (2.5Y 6/4) loam, light olive brown (2.5Y 5/4) moist; weak coarse subangular blocky structure parting to weak very fine granular; soft, loose, slightly sticky and slightly plastic; strongly effervescent; disseminated calcium carbonate; moderately alkaline; gradual wavy boundary.
- Cr—36 inches; soft calcareous sandstone.

The depth to calcium carbonate ranges from 14 to 26 inches. The depth to bedrock ranges from 24 to 37 inches.

The Bt horizon has chroma of 3 or 4. Texture is dominantly sandy clay loam that is 20 to 35 percent clay and more than 35 percent sand that is fine or coarser. The Bk horizon has hue of 2.5Y to 10YR, value of 6 or 7 when dry, and chroma of 2 to 4.

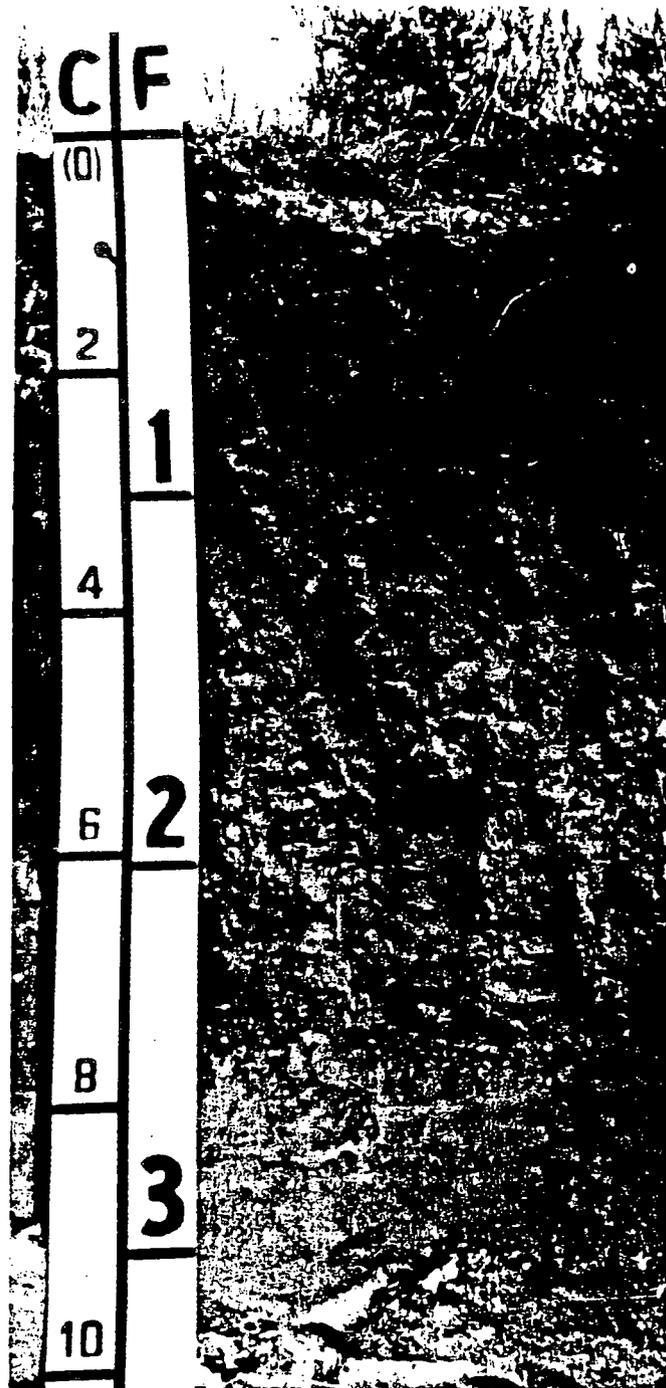

Figure 3.—Profile of Bowbac sandy loam. Soft sandstone is at depth of about 2.5 feet.

LAND QUALITY DIVISION
RECEIVED MAP 11 1981

Cambria Series

The Cambria series consists of deep, well drained, moderately permeable soils on ridge crests, back slopes, foot slopes, and toe slopes of nearly level to rolling uplands. These soils formed in mixed residuum and local alluvium derived from shale and sandstone. Slope is 0 to 15 percent.

Typical pedon of a Cambria fine sandy loam in an area of Forkwood-Cambria fine sandy loams, 0 to 6 percent slopes, 2,000 feet south and 500 feet east of the northwest corner of sec. 10, T. 36 N., R. 70 W.

- A—0 to 2 inches; grayish brown (10YR 5/2) fine sandy loam, dark grayish brown (10YR 4/3) moist; weak moderate subangular blocky structure parting to weak very fine granular; soft, very friable, slightly sticky and slightly plastic; neutral; clear wavy boundary.
- Bt1—2 to 4 inches; brown (10YR 5/3) sandy clay loam, dark brown (10YR 4/3) moist; moderate coarse subangular structure parting to weak fine granular; soft, very friable, slightly sticky and slightly plastic; few thin clay films on faces of peds; neutral; clear wavy boundary.
- Bt2—4 to 10 inches; brown (10YR 5/3) sandy clay loam, dark brown (10YR 4/3) moist; strong coarse prismatic structure parting to moderate medium subangular blocky; slightly hard, friable, sticky and plastic; many moderately thick clay films on faces of peds; mildly alkaline; clear wavy boundary.
- Btk—10 to 14 inches; pale brown (10YR 6/3) loam, brown (10YR 5/3) moist; moderate coarse subangular blocky structure parting to moderate fine subangular blocky; slightly hard, friable, sticky and plastic; few thin clay films on faces of peds; strongly effervescent; common fine irregularly shaped calcium carbonate masses in the form of filaments and threads; moderately alkaline; gradual wavy boundary.
- Bk1—14 to 29 inches; pale brown (10YR 6/3) loam, brown (10YR 5/3) moist; massive; soft, very friable, slightly sticky and slightly plastic; violently effervescent; few fine soft masses of calcium carbonate; moderately alkaline; gradual wavy boundary.
- Bk2—29 to 60 inches; pale brown (10YR 6/3) loam, brown (10YR 5/3) moist; massive; soft, very friable, slightly sticky and slightly plastic; strongly effervescent; moderately alkaline.

The A horizon has value of 5 or 6 when dry and 4 or 5 when moist. It is fine sandy loam, sandy loam, loam, or clay loam.

The Bt horizon has hue of 2.5Y to 10YR, value of 5 or 6 when dry, and and chroma of 3 or 4. Texture is loam or clay loam. The Bt horizon is 24 to 34 percent clay.

The Bk horizon has hue of 2.5Y to 10YR, value of 5 to 7 when dry and 4 or 5 when moist, and chroma of 2 or 3.

Cambria Variant

The Cambria Variant consists of deep, well drained, moderately permeable soils in nearly level to undulating areas on toe slopes and alluvial flats. These soils formed in alluvium derived from interbedded shale and sandstone. Slope is 0 to 6 percent.

Typical pedon of a Cambria Variant fine sandy loam in an area of Cambria Variant-Forkwood Variant complex, 0 to 6 percent slopes; 1,150 feet west and 400 feet south of the northeast corner of sec. 27, T. 39 N., R. 71 W.

- A—0 to 2 inches; light gray (10YR 7/2) fine sandy loam, grayish brown (10YR 5/2) moist; weak fine subangular blocky and granular structure; soft, very friable, nonsticky and nonplastic; neutral; abrupt smooth boundary.
- Bw—2 to 5 inches; light brownish gray (2.5Y 6/2) clay loam, grayish brown (2.5Y 5/2) moist; moderate fine subangular blocky structure; slightly hard, friable, slightly sticky and slightly plastic; neutral; clear smooth boundary.
- Bt—5 to 9 inches; light brownish gray (2.5Y 6/2) clay loam, grayish brown (2.5Y 5/2) moist; moderate medium and fine subangular blocky structure; hard, friable, sticky and plastic; common moderately thick clay films on faces of peds; neutral; clear smooth boundary.
- Bt—9 to 16 inches; light brownish gray (2.5Y 6/2) loam, grayish brown (2.5Y 5/2) moist; fine medium subangular blocky structure; hard, friable, slightly sticky and slightly plastic; slightly effervescent; few fine soft masses of calcium carbonate; moderately alkaline; clear smooth boundary.
- 2Bk1—16 to 30 inches; light brownish gray (2.5Y 6/2), stratified clay loam, loam, and fine sandy loam, grayish brown (2.5Y 5/2) moist; massive; hard, friable, slightly sticky and slightly plastic; strongly effervescent; few fine soft masses of calcium carbonate; moderately alkaline; gradual smooth boundary.
- 2Bk2—30 to 60 inches; light brownish gray (2.5Y 6/2), stratified loam, sandy clay loam, and sandy loam, grayish brown (2.5Y 5/2) moist; massive; slightly hard, friable, slightly sticky and slightly plastic; strongly effervescent; few fine soft masses of calcium carbonate; moderately alkaline.

Depth to carbonates ranges from 8 to 12 inches.

Depth to stratified textures ranges from 12 to 24 inches. The profile is 0 to 5 percent coarse fragments.

The A horizon has hue of 10YR or 2.5Y, value of 6 or 7 when dry and 4 or 5 when moist, and chroma of 2 or

LAND QUALITY DIVISION

RECEIVED MAR 11 1991

3. Texture is fine sandy loam or sandy loam. Reaction is neutral or mildly alkaline.

The Bt horizon has hue of 10YR or 2.5Y, value of 6 or 7 when dry and 4 or 5 when moist, and chroma of 2 or 3. Texture is fine sandy loam or sandy loam. Reaction is neutral or mildly alkaline.

The 2Bk horizon and the C horizon, where present, have hue of 10YR or 2.5Y, value of 6 or 7 when dry and 5 or 6 when moist, and chroma of 2 or 3. Texture varies, but centers on loam or clay loam with thin coarser textured strata. Reaction is mildly alkaline or moderately alkaline.

Clarkelen Series

The Clarkelen series consists of deep, somewhat excessively drained, moderately rapidly permeable soils on flood plains and low stream terraces. These soils formed in stratified Recent alluvium derived from sedimentary rock. Slope is 0 to 3 percent.

Typical pedon of a Clarkelen sandy loam in an area of Clarkelen-Draknab complex, 0 to 3 percent slopes, 2,130 feet north and 285 feet east of the southwest corner of sec. 31., T. 41 N., R. 69 W.

A—0 to 1 inch; pale brown (10YR 6/3) sandy loam, grayish brown (10YR 5/2) moist; weak thin platy structure parting to moderate very fine granular; soft, very friable; slightly effervescent; mildly alkaline; clear smooth boundary.

AC—1 to 3 inches; grayish brown (10YR 5/2) sandy loam, dark grayish brown (10YR 4/2) moist; moderate medium subangular blocky structure; soft, very friable; slightly effervescent; mildly alkaline; clear smooth boundary.

C1—3 to 37 inches; light brownish gray (10YR 6/2) and pale brown (10YR 6/3), stratified sandy loam, loamy sand, sandy clay loam, and silt loam, grayish brown (10YR 5/2) and brown (10YR 5/3) moist; massive; soft, very friable; slightly effervescent; mildly alkaline; clear smooth boundary.

C2—37 to 60 inches; light brownish gray (10YR 6/2) sand, grayish brown (10YR 5/2) moist; single grain; loose; slightly effervescent; mildly alkaline.

The A horizon has value of 5 or 6 when dry and 4 or 5 when moist. It is sandy loam, loamy sand, or loam.

Cushman Series

The Cushman series consists of moderately deep, well drained, moderately permeable soils on upland ridges, back slopes, and pediment slopes. These soils formed in residuum derived dominantly from calcareous shale and sandstone. Slope is 0 to 15 percent.

Typical pedon of a Cushman loam in an area of Cambria-Cushman complex, 6 to 15 percent slopes, in the SW1/4 of sec. 15, T. 38 N., R. 72 W.

A—0 to 3 inches; pale brown (10YR 6/3) loam, dark brown (10YR 4/3) moist; moderate medium subangular blocky structure parting to weak fine granular; slightly hard, friable, slightly sticky and slightly plastic; neutral; clear smooth boundary.

Bt—3 to 9 inches; pale brown (10YR 6/3) clay loam, dark brown (10YR 4/3) moist; strong medium prismatic structure parting to coarse angular blocky; hard, firm, slightly sticky and slightly plastic; common moderately thick clay films on faces of peds and in pores; neutral; clear smooth boundary.

Btk—9 to 17 inches; light gray (2.5Y 7/2) clay loam, grayish brown (2.5Y 5/2) moist; moderate coarse angular blocky structure parting to moderate medium angular blocky; hard, firm, slightly sticky and slightly plastic; common thin clay films on faces of peds; effervescent; mildly alkaline; gradual wavy boundary.

Bk—17 to 25 inches; pale yellow (2.5Y 7/4) loam, light yellowish brown (2.5Y 6/4) moist; hard, friable, sticky and slightly plastic; strongly effervescent; moderately alkaline, clear smooth boundary.

Crk—25 to 35 inches; calcareous shale; common fine soft masses of calcium carbonate, abrupt smooth boundary.

2Cr—35 inches; calcareous sandstone.

The depth to bedrock ranges from 24 to 35 inches. The depth to calcium carbonate ranges from 9 to 18 inches.

The A horizon has chroma of 2 or 3.

The Bt and Btk horizons have value of 5 or 6 when dry and 4 or 5 when moist. Reaction is neutral to moderately alkaline. The Bk horizon has value of 5 to 7 when dry and 4 to 6 when moist.

Draknab Series

The Draknab series consists of deep, excessively drained, rapidly permeable soils on flood plains. These formed in Recent alluvium derived dominantly from calcareous sedimentary rock. Slope is 0 to 3 percent.

Typical pedon of a Draknab loamy sand in an area of Clarkelen-Draknab complex, 0 to 3 percent slopes, 1,900 feet north and 400 feet east of the southwest corner of sec. 5, T. 40 N., R. 74 W.

A1—0 to 2 inches; yellowish brown (10YR 5/4) loamy sand, brown (10YR 4/3) moist; weak medium and fine granular structure; soft, very friable, nonsticky and nonplastic; strongly effervescent; moderately alkaline; abrupt smooth boundary.

AC—2 to 8 inches; yellowish brown (10YR 5/4) sandy loam, brown (10YR 4/3) moist; weak medium subangular blocky structure parting to weak medium granular; soft, very friable, nonsticky and nonplastic; slightly effervescent; moderately alkaline; clear smooth boundary.

A QUALITY DIVISION

- C1—8 to 18 inches; very pale brown (10YR 7/3) sand, yellowish brown (10YR 5/4) moist; single grain; loose; strongly effervescent; moderately alkaline (pH 8.0); clear wavy boundary.
- C2—18 to 26 inches; pale brown (10YR 6/3) loamy coarse sand, dark yellowish brown (10YR 4/4) moist; massive; soft, very friable; strongly effervescent; moderately alkaline; gradual smooth boundary.
- C3—26 to 60 inches; very pale brown (10YR 7/3), stratified coarse sand and loamy sand, pale brown (10YR 6/3) moist; single grain; loose; strongly effervescent; moderately alkaline.

The profile typically is calcareous throughout, but depth to calcium carbonate is as much as 10 inches. Coarse fragment content ranges from 0 to 15 percent.

The A horizon has hue of 10YR or 2.5Y, value of 5 to 7 when dry and 4 to 6 when moist, and chroma of 2 to 4. Texture is loam, sandy loam, or loamy sand. Reaction is mildly alkaline or moderately alkaline.

The C horizon has hue of 2.5Y to 7.5YR. Most pedons are highly stratified. Texture is loamy sand, loamy coarse sand, or sand. Thickness and texture of the strata are highly variable. Reaction is mildly alkaline to strongly alkaline.

Dwyer Series

The Dwyer series consists of deep, excessively drained, rapidly permeable soils on dunes. These soils formed in eolian sand. Slope is 0 to 15 percent.

Typical pedon of a Dwyer loamy sand in an area of Dwyer-Orpha loamy sands, 3 to 15 percent slopes, 50 feet west and 1,050 feet north of the southeast corner of sec. 29, T. 35 N., R. 73 W.

- A—0 to 5 inches; brown (10YR 5/3) loamy sand, dark brown (10YR 4/3) moist; weak coarse granular structure parting to single grain; soft, loose; strongly effervescent; moderately alkaline; gradual wavy boundary.
- AC—5 to 21 inches; pale brown (10YR 6/3) loamy sand, brown (10YR 5/3) moist; single grain; soft, loose; strongly effervescent; moderately alkaline; gradual wavy boundary.
- C—21 to 60 inches; pale brown (10YR 6/3) loamy sand, brown (10YR 5/3) moist; single grain; soft, loose; strongly effervescent; moderately alkaline.

Carbonates commonly are throughout the profile, but in some pedons the carbonates are leached from the A and AC horizons.

The A horizon has value of 5 or 6 when dry and 4 or 5 when moist, and it has chroma of 3 or 4. It is loamy sand to fine sand. The C horizon has value of 5 or 6 when dry and 4 or 5 when moist, and it has chroma of 2 to 4. It is mildly alkaline or moderately alkaline. In some pedons a

layer of sandy clay loam, clay loam, loam, or clay is below a depth of 40 inches.

Forkwood Series

The Forkwood series consists of deep, well drained, moderately permeable soils on foot slopes and toe slopes of rolling uplands. These soils formed in local alluvium that is derived from calcareous shale and in some places has a thin mantle of eolian deposits. Slope is 0 to 15 percent.

Typical pedon of a Forkwood fine sandy loam in an area of Forkwood-Cambria fine sandy loams, 0 to 6 percent slopes, 1,050 feet west and 1,600 feet north of the southeast corner of sec. 35, T. 36 N., R. 68 W.

- A—0 to 4 inches; pale brown (10YR 6/3) fine sandy loam, brown (10YR 5/3) moist; weak medium and fine granular structure; slightly hard, very friable, slightly sticky and slightly plastic; neutral; abrupt smooth boundary.
- BA—4 to 7 inches; pale brown (10YR 6/3) fine sandy loam, brown (10YR 5/3) moist; moderate medium subangular blocky structure; slightly hard, friable, slightly sticky and slightly plastic; neutral; clear smooth boundary.
- Bt—7 to 14 inches; pale brown (10YR 6/3) clay loam, brown (10YR 5/3) moist; strong medium and coarse subangular blocky structure; thin continuous clay films on faces of peds; very hard, firm, sticky and plastic; neutral; clear smooth boundary.
- Bk1—14 to 20 inches; light brownish gray (10YR 6/2) clay loam, grayish brown (10YR 5/2) moist; moderate medium and coarse subangular blocky structure; very hard, firm, sticky and plastic; strongly effervescent; few fine calcium carbonate concretions; mildly alkaline; gradual wavy boundary.
- Bk2—20 to 27 inches; light gray (10YR 7/2) clay loam, grayish brown (10YR 5/2) moist; weak coarse subangular blocky structure; very hard, friable, sticky and plastic; strongly effervescent; common fine soft masses and filaments of calcium carbonate; mildly alkaline; diffuse wavy boundary.
- Bk3—27 to 60 inches; light gray (10YR 7/2) clay loam, grayish brown (10YR 5/2) moist; massive; very hard, friable, sticky and plastic; strongly effervescent; many medium soft masses of calcium carbonate; mildly alkaline.

The depth to calcium carbonate typically is 12 to 20 inches, but it is as much as 30 inches in some pedons.

The A horizon has hue of 10YR or less; it typically is 2.5Y. It has value of 3 to 5 when moist. Reaction is neutral or mildly alkaline.

The Bt horizon has hue of 10YR or 2.5Y, and it has value of 5 or 6 when dry.

LANDQUALITY DIVISION

RECEIVED MAR 11 1991

The Bk horizon has hue of 10YR or 2.5Y. It is not present in some pedons that are deeply leached.

Forkwood Variant

The Forkwood Variant consists of deep, well drained, moderately slowly permeable soils in nearly level to undulating areas on toe slopes and alluvial flats. These soils formed in alluvium derived from shale with some interbedded sandstone. Slope is 0 to 6 percent.

Typical pedon of a Forkwood Variant clay loam in an area of Cambria Variant-Forkwood Variant complex, 0 to 6 percent slopes, 1,400 feet north and 1,100 feet west of the southeast corner of sec. 21, T. 39 N., R. 71 W.

- A—0 to 3 inches; light gray (10YR 7/2) clay loam, grayish brown (10YR 5/2) moist; weak medium and fine subangular blocky structure; slightly hard, friable, slightly sticky and plastic; neutral; abrupt smooth boundary.
- Bt1—3 to 9 inches; pale brown (10YR 6/3) clay loam, brown (10YR 5/3) moist; moderate medium subangular blocky structure; hard, firm, sticky and plastic; common thin clay films on faces of peds; neutral; clear smooth boundary.
- Bt2—9 to 16 inches; pale brown (10YR 6/3) clay loam, brown (10YR 5/3) moist; weak coarse prismatic structure parting to moderate medium subangular blocky; very hard, firm, sticky and plastic; common thin clay films on faces of peds; neutral; clear smooth boundary.
- 2Bk1—16 to 30 inches; light gray (2.5Y 7/2), stratified loam, clay loam, and fine sandy loam, grayish brown (2.5Y 5/2) moist; massive; hard, friable, slightly sticky and plastic; few fine soft masses of calcium carbonate and concretions of calcium carbonate in a noncalcareous matrix; mildly alkaline; gradual smooth boundary.
- 2Bk2—30 to 60 inches; light gray (10YR 7/2), stratified clay loam and loam, grayish brown (10YR 5/2) moist; massive; hard, firm, sticky and plastic; slightly effervescent; few fine soft masses of calcium carbonate and concretions of calcium carbonate; moderately alkaline.

Depth to carbonates and stratified material ranges from 12 to 24 inches. Coarse fragments typically are absent, but where present they make up as much as 5 percent of the profile.

The A horizon has hue of 10YR or 2.5Y, value of 6 or 7 when dry and 4 to 6 when moist, and chroma of 2 or 3. Texture is loam or clay loam. Reaction is neutral or mildly alkaline.

The Bt horizon has hue of 10YR or 2.5Y, value of 5 or 6 when dry and 4 or 5 when moist, and chroma of 2 or 3. Texture is clay loam or heavy loam. Reaction is neutral or mildly alkaline.

The 2Bk horizon has hue of 10YR or 2.5Y, value of 6 or 7 when dry and 5 or 6 when moist, and chroma of 2 or 3. Texture is stratified clay loam to fine sandy loam. Reaction is mildly alkaline or moderately alkaline.

Gateson Variant

The Gateson Variant consists of shallow, well drained, moderately permeable soils on upland shoulder slopes and back slopes. These soils formed in residuum derived dominantly from noncalcareous sandstone. Slope is 10 to 45 percent.

Typical pedon of a Gateson Variant loamy sand in an area of Gateson Variant-Tassel Variant association, 10 to 45 percent slopes, in the NE1/4NE1/4SW1/4 of sec. 12, T. 40 N., R. 77 W.

- Oi—1 inch to 0; forest litter consisting largely of undecomposed pine needles.
- E—0 to 4 inches; pinkish gray (7.5YR 7/2) loamy sand, pinkish gray (7.5YR 6/2) moist; weak medium platy structure; soft, very friable, nonsticky and nonplastic; neutral; clear smooth boundary.
- Bt—4 to 11 inches; reddish yellow (7.5YR 6/6) sandy clay loam, strong brown (7.5YR 5/6) moist; moderate medium and coarse subangular blocky structure; hard, friable, slightly sticky and plastic; common thin yellowish red (5YR 5/6) clay films on faces of peds; mildly alkaline; clear smooth boundary.
- 2C—11 to 16 inches; pinkish gray (5YR 7/2) clay, reddish brown (5YR 5/3) moist; massive; hard, firm, sticky and plastic; about 15 percent shale chips and sandstone channery fragments; mildly alkaline; gradual smooth boundary.
- 3Cr—16 inches; soft interbedded noncalcareous fractured sandstone and shale flagstones.

Depth to rock and thickness of the solium range from 15 to 24 inches. Coarse fragment content typically is less than 15 percent.

The Bt horizon typically is 18 to 35 percent clay, but in a few pedons it is as little as 15 percent clay. In some pedons there is a BK or CK horizon.

Haverdad Series

The Haverdad series consists of deep, well drained, moderately permeable soils on flood plains and low terraces. These soils formed in stratified Recent alluvium derived from sedimentary rock. Slope is 0 to 6 percent.

Typical pedon of a Haverdad fine sandy loam in an area of Haverdad-Lohmiller complex, 0 to 6 percent slopes, 1,300 feet east and 130 feet south of the northwest corner of sec. 31., T. 40 N., R. 68 W.

- A—0 to 6 inches; grayish brown (10YR 5/2) fine sandy loam, dark grayish brown (10YR 4/2) moist;

LANDQUALITY DIVISION

RECEIVED MAR 11 1991

moderate medium and fine granular structure; soft, very friable, slightly sticky and slightly plastic; mildly alkaline; abrupt smooth boundary.

C1—6 to 10 inches; light brownish gray (10YR 6/2) clay loam, grayish brown (10YR 5/2) moist; weak medium and fine subangular blocky structure; slightly hard, friable, sticky and plastic; slightly effervescent; moderately alkaline; abrupt smooth boundary.

C2—10 to 60 inches; light brownish gray (10YR 6/2) loam stratified with sandy loam, clay loam, and loamy sand, grayish brown (10YR 5/2) moist; massive; soft, very friable, slightly sticky and slightly plastic; slightly effervescent; moderately alkaline.

The profile typically is leached in the A horizon, but some pedons are calcareous throughout.

The A horizon has chroma of 2 or 3. It is fine sandy loam, loam, silt loam, or sandy loam. Reaction is mildly alkaline or moderately alkaline.

The control section is clay loam, loam, or very fine sandy loam.

Heldt Series

The Heldt series consists of deep, well drained, slowly permeable soils on toe slopes and alluvial flats. These soils formed in local alluvium derived dominantly from calcareous shale. Slope is 0 to 6 percent.

Typical pedon of a Heldt clay loam in an area of Silhouette-Heldt association, 0 to 6 percent slopes; 1,200 feet east and 75 feet south of the northwest corner of sec. 15, T. 38 N., R. 71 W.

E—0 to 1 inch; light gray (10YR 7/2) clay loam, brown (10YR 5/3) moist; vesicular crust; massive; slightly hard, friable, sticky and plastic; slightly effervescent; neutral; abrupt smooth boundary.

AB—1 to 8 inches; light brownish gray (10YR 6/2) clay, grayish brown (10YR 5/2) moist; weak fine subangular blocky and granular structure; hard, firm, sticky and plastic; slightly effervescent; mildly alkaline; clear smooth boundary.

Bw1—8 to 15 inches; light brownish gray (10YR 6/2) clay, grayish brown (10YR 5/2) moist; weak medium and fine subangular blocky structure; very hard, very firm, sticky and plastic; slightly effervescent; mildly alkaline; gradual smooth boundary.

Bw2—15 to 26 inches; light gray (10YR 7/2) clay, pale brown (10YR 6/3) moist; weak medium angular blocky structure; very hard, very firm, sticky and plastic; slightly effervescent; mildly alkaline; gradual smooth boundary.

C—26 to 35 inches; pale brown (10YR 6/3) clay, brown (10YR 5/3) moist; massive; very hard, very firm, sticky and plastic; common distinct pressure faces at an angle of about 20 degrees from vertical;

slightly effervescent; mildly alkaline; gradual smooth boundary.

Ck—35 to 60 inches; very pale brown (10YR 7/3) clay, yellowish brown (10YR 5/4) moist; massive; very hard, very firm, sticky and plastic; slightly effervescent; common medium seams and filaments of calcium carbonate; mildly alkaline.

Electrical conductivity typically is less than 4 millimhos per centimeter, and cation exchange capacity per 100 grams of clay ranges from 90 to 100.

The E horizon has hue of 10YR or 2.5Y and chroma of 2 or 3.

The Bw horizon has hue of 10YR or 2.5Y and chroma of 2 or 3.

The Ck horizon has hue of 10YR or 2.5Y. It is mildly alkaline or moderately alkaline.

Hiland Series

The Hiland series consists of deep, well drained, moderately permeable soils on back slopes of rolling uplands and adjacent foot slopes. These soils formed in residuum and local alluvium derived from soft calcareous sandstone and in eolian material. Slope is 0 to 15 percent.

Typical pedon of a Hiland sandy clay loam in an area of Hiland-Bowbac complex, 6 to 15 percent slopes, 3,000 feet west and 600 feet south of the northeast corner of sec. 26, T. 35 N., R. 75 W.

A—0 to 3 inches; brown (10YR 5/3) sandy clay loam, dark brown (10YR 4/3) moist; weak medium granular structure; soft, very friable, nonsticky and nonplastic; neutral; clear wavy boundary.

BA—3 to 10 inches; brown (10YR 5/3) sandy loam, dark brown (10YR 4/3) moist; moderate coarse subangular blocky structure parting to weak fine granular; slightly hard, very friable, slightly sticky and slightly plastic; neutral; clear wavy boundary.

Bt—10 to 19 inches; brown (10YR 5/3) sandy clay loam, dark brown (10YR 4/3) moist; strong very coarse prismatic structure parting to moderate coarse subangular blocky; hard, friable, sticky and plastic; many moderately thick clay bridges between sand grains; mildly alkaline; clear smooth boundary.

Btk—19 to 24 inches; grayish brown (10YR 5/2) sandy loam, dark grayish brown (10YR 4/2) moist; moderate coarse subangular blocky structure; hard, friable, sticky and plastic; many moderately thick clay bridges between sand grains; strongly effervescent; common fine irregularly shaped calcium carbonate filaments and threads; moderately alkaline; gradual wavy boundary.

Bk1—24 to 36 inches; grayish brown (10YR 5/2) sandy clay loam, dark grayish brown (10YR 4/2) moist; moderate coarse subangular blocky structure; hard,

LANDQUALITY DIVISION

RECEIVED MAR 11 1991

TFN 2 1/173 PERMIT

friable, sticky and plastic; strongly effervescent; common fine calcium carbonate filaments; moderately alkaline; gradual wavy boundary.

Bk2—36 to 60 inches; light brownish gray (10YR 6/2) sandy clay loam, grayish brown (10YR 5/2) moist; massive; slightly hard, friable, sticky and plastic; strongly effervescent; common fine irregularly shaped calcium carbonate filaments and threads; moderately alkaline.

The depth to calcium carbonate ranges from 15 to 30 inches.

The A horizon is sandy loam or sandy clay loam.

The Bt horizon has hue of 2.5Y to 10YR, and it has value of 5 or 6 when dry and 4 or 5 when moist. Clay content averages 24 to 34 percent. Reaction is neutral to moderately alkaline. The Bk horizon has hue of 2.5Y to 10YR, and it has value of 4 or 5 when moist. Reaction is mildly alkaline or moderately alkaline.

Keeline Series

The Keeline series consists of deep, somewhat excessively drained, moderately rapidly permeable soils on ridges and sides slopes of rolling uplands. These soils formed in wind-worked residuum derived dominantly from calcareous sandstone. Slope is 6 to 15 percent.

Typical pedon of a Keeline sandy loam in an area of Keeline-Tassel-Turnback complex, 6 to 15 percent slopes; 2,100 feet north and 400 feet west of the southeast corner of sec. 29, T. 40 N., R. 75 W.

A—0 to 3 inches; yellowish brown (10YR 5/4) sandy loam, brown (10YR 4/3) moist; weak fine subangular blocky and granular structure; soft, very friable, nonsticky and nonplastic; slightly effervescent; mildly alkaline; abrupt smooth boundary.

Bw—3 to 8 inches; pale brown (10YR 6/3) sandy loam, brown (10YR 5/3) moist; weak medium subangular blocky structure; slightly hard, friable, slightly sticky and slightly plastic; strongly effervescent; calcium carbonate disseminated throughout matrix; mildly alkaline; clear smooth boundary.

C1—8 to 17 inches; very pale brown (10YR 7/3) sandy loam, light yellowish brown (10YR 6/4) moist; massive; soft, very friable, nonsticky and nonplastic; strongly effervescent; calcium carbonate disseminated throughout matrix; moderately alkaline; gradual smooth boundary.

C2—17 to 30 inches; very pale brown (10YR 7/3) sandy loam, pale brown (10YR 6/3) moist; massive; soft, very friable, nonsticky and nonplastic; strongly effervescent; calcium carbonate disseminated throughout matrix; moderately alkaline; gradual smooth boundary.

C3—30 to 60 inches; very pale brown (10YR 7/3) sandy loam, light yellowish brown (10YR 6/4) moist; massive; soft, very friable, nonsticky and nonplastic;

strongly effervescent; calcium carbonate disseminated throughout matrix; moderately alkaline.

The profile is calcareous throughout in most pedons, but in some pedons the upper few inches is leached.

The A horizon has hue of 7.5YR or 10YR and chroma of 3 or 4. Reaction is mildly alkaline or neutral.

The C horizon has hue of 7.5YR to 2.5Y. Reaction is moderately alkaline or strongly alkaline.

Kishona Series

Kishona series consists of deep, well drained, moderately permeable soils on upland hill slopes and on adjacent toe slopes, foot slopes, and alluvial flats and fans. These soils formed in calcareous local alluvium derived dominantly from sedimentary rock. Slope is 0 to 15 percent.

Typical pedon of a Kishona loam in an area of Theedle-Kishona association, 6 to 15 percent slopes; 2,600 feet east and 50 feet north of the southwest corner of sec. 35, T. 38 N., R. 75 W.

A—0 to 3 inches; brown (10YR 5/3) loam, brown (10YR 4/3) moist; weak fine and medium granular structure; soft, friable, slightly sticky and slightly plastic; violently effervescent; moderately alkaline; abrupt smooth boundary.

AC—3 to 12 inches; pale brown (10YR 6/3) clay loam, brown (10YR 5/3) moist; moderate fine and medium subangular blocky structure; hard, firm, sticky and plastic; violently effervescent; moderately alkaline; clear smooth boundary.

C1—12 to 36 inches; light yellowish brown (2.5Y 6/4) clay loam, light olive brown (2.5Y 5/4) moist; massive; hard, friable, slightly sticky and slightly plastic; violently effervescent; few fine soft masses of calcium carbonate; moderately alkaline; gradual smooth boundary.

C2—36 to 60 inches; light gray (2.5Y 7/2) clay loam, light yellowish brown (2.5Y 6/4) moist; massive; slightly hard, friable, slightly sticky and slightly plastic; violently effervescent; few fine soft masses of calcium carbonate; moderately alkaline.

The A horizon is loam or light clay loam.

The C horizon has hue of 10YR or 2.5Y. Reaction is moderately alkaline or strongly alkaline.

Lohmiller Series

The Lohmiller series consists of deep, well drained, moderately slowly permeable soils on narrow flood plains. These soils formed in stratified Recent alluvium derived from sedimentary rock. Slope is 0 to 6 percent.

Typical pedon of a Lohmiller clay loam in an area of Haverdad-Lohmiller complex, 0 to 6 percent slopes,

Page 68

1,980 feet south and 1,580 feet west of the northeast corner of sec. 35, T. 37 N., R. 73 W.

A—0 to 3 inches; grayish brown (2.5Y 5/2) clay loam, dark grayish brown (2.5Y 4/2) moist; moderate fine subangular blocky structure; slightly hard, friable, sticky and plastic; slightly effervescent; mildly alkaline; clear smooth boundary.

AC—3 to 16 inches; brown (10YR 5/3) clay, brown (10YR 4/3) moist; moderate medium and fine subangular blocky structure; hard, very firm, sticky and plastic; slightly effervescent; mildly alkaline; clear smooth boundary.

C1—16 to 19 inches; light yellowish brown (2.5Y 6/4) clay loam, light olive brown (2.5Y 5/4) moist; massive; hard, friable, slightly sticky and nonplastic; slightly effervescent; moderately alkaline; clear wavy boundary.

C2—19 to 60 inches; light yellowish brown (2.5Y 6/4) and brown (10YR 5/3), stratified sandy clay loam, sandy loam, and sandy clay, light olive brown (2.5Y 5/4) and brown (10YR 4/3) moist; massive; hard, friable, slightly sticky and plastic; slightly effervescent; moderately alkaline.

The profile commonly is calcareous throughout, but in some pedons the upper few inches is leached.

The A horizon has hue of 2.5Y or 10YR, value of 5 or 6 when dry and 4 or 5 when moist, and chroma of 2 or 3. Reaction is mildly alkaline to strongly alkaline.

The C horizon has hue of 2.5Y or 10YR. Reaction is moderately alkaline or strongly alkaline. The control section is heavy clay loam or silty clay.

Orella Series

The Orella series consists of shallow, well drained, slowly permeable soils on back slopes and ridgetops of uplands. These soils formed in residuum derived from sodic shale. Slope is 3 to 25 percent.

Typical pedon of an Orella clay loam in an area of Orella-Rock outcrop-Samday complex, 3 to 30 percent slopes, 1,800 feet north and 1,200 feet west of the southeast corner of sec. 2, T. 40 N., R. 71 W.

A—0 to 4 inches; light gray (2.5Y 7/2) clay loam, light brownish gray (2.5Y 6/2) moist; weak fine subangular blocky structure; slightly hard, friable, sticky and plastic; few medium and fine roots; slightly effervescent; moderately alkaline; clear smooth boundary.

ACk—4 to 13 inches; light gray (2.5Y 7/2) light clay, light brownish gray (2.5Y 6/2) moist; moderate fine angular blocky structure; hard, firm, sticky and plastic; few fine roots; content of shale fragments increases with increasing depth; strongly effervescent; common medium seams of calcium

carbonate; moderately alkaline; gradual smooth boundary.

Ck—13 to 20 inches; light brownish gray (2.5Y 6/2) clay between weathered shale fragments, grayish brown (2.5Y 5.2) moist; common medium yellowish red (5YR 5/6) oxide stains on shale fragments; massive; hard, firm, very sticky and very plastic; few fine and very fine roots; noneffervescent; few medium and fine calcium carbonate concretions; moderately alkaline; gradual smooth boundary.

Cr—20 to 60 inches; light gray (2.5Y 7/2) shale, grayish brown (2.5Y 5.2) moist; common medium and fine olive yellow (2.5Y 6/8) and brownish yellow (10YR 6/8) oxides and oxide stains; noneffervescent.

The depth to shale ranges from 10 to 20 inches. The profile commonly is calcareous throughout, but in some pedons it is leached to a depth of as much as 10 inches.

The A horizon has hue of 10YR or 2.5Y, value of 6 or 7 when dry and 5 or 6 when moist, and chroma of 2 or 3. It is typically clay loam or clay.

The Ck horizon has hue of 2.5Y or 10YR, value of 6 or 7 when dry and 5 or 6 when moist, and chroma of 2 or 3. It is clay or heavy clay loam.

Orpha Series

The Orpha series consists of deep, excessively drained, very rapidly permeable soils on dunes. These soils formed in eolian sand. Slope is 0 to 15 percent.

Typical pedon of an Orpha loamy sand in an area of Dwyer-Orpha loamy sands, 3 to 15 percent slopes, 200 feet west and 1,250 feet south of the northeast corner of sec. 31, T. 41 N., R. 67 W.

A—0 to 6 inches; grayish brown (10YR 5/2) loamy sand, dark grayish brown (10YR 4/2) moist; weak moderate and coarse granular structure parting to single grain; loose; mildly alkaline; gradual wavy boundary.

C—6 to 60 inches; light brownish gray (10YR 6/2) sand, grayish brown (10YR 5/2) moist; single grain; loose; mildly alkaline.

Depth to calcium carbonate ranges from 40 to 60 inches or more.

The A horizon has value of 5 or 6 when dry and 4 or 5 when moist, and it has chroma of 2 or 3. It is loamy sand or sand.

The C horizon has value of 6 or 7 when dry and 5 or 6 when moist, and it has chroma of 2 to 4. Clay content ranges from 3 to 10 percent. Reaction is neutral or mildly alkaline.

Renohill Series

The Renohill series consists of moderately deep, well drained, slowly permeable soils on upland ridgetops,

LAND QUALITY DIVISION

RECEIVED MAR 11 1991

TFN 2 1/173 PERMIT

back slopes, and foot slopes. These soils formed in residuum derived from soft shale. Slope is 0 to 15 percent.

Typical pedon of a Renohill fine sandy loam in an area of Ulm-Renohill complex, 0 to 6 percent slopes, 2,640 feet south of the northeast corner of sec. 31, T. 38 N., R. 68 W.

A—0 to 5 inches; pale brown (10YR 6/3) fine sandy loam, brown (10YR 5/3) moist; weak fine and medium granular structure; soft, very friable, slightly sticky and slightly plastic; neutral; clear smooth boundary.

Bt—5 to 20 inches; brown (10YR 5/3) clay, dark brown (10YR 4/3) moist; strong coarse prismatic structure parting to coarse subangular blocky; very hard, very firm, sticky and plastic; common moderately thick clay films on faces of peds; mildly alkaline; gradual wavy boundary.

Bk—20 to 36 inches; pale brown (10YR 6/3) clay loam, brown (10YR 5/3) moist; moderate medium and coarse subangular blocky structure; hard, firm, sticky and plastic; slightly effervescent; few fine soft white filaments and threads of carbonates; moderately alkaline.

Cr—36 inches; calcareous shale.

The depth to bedrock ranges from 20 to 40 inches. The depth to calcium carbonate ranges from 10 to 20 inches.

The A horizon has value of 5 or 6 when dry and 4 or 5 when moist, and it has chroma of 2 or 3. It is fine sandy loam or clay loam.

The Bt horizon has hue of 10YR or 2.5Y, value of 4 to 7 when dry and 4 or 5 when moist, and chroma of 2 to 4. It is clay or clay loam and averages 37 to 46 percent clay. Reaction is neutral to moderately alkaline.

The Bk horizon has value of 6 or 7 when dry and chroma of 2 to 4. It is moderately alkaline or strongly alkaline.

The Cr horizon is calcareous shale or sandstone.

Samday Series

The Samday series consists of shallow, well drained, very slowly permeable soils on summits, shoulder slopes, and ridges of upland hills and on scarps where the shale beds have been exposed by geologic erosion. These soils formed in residuum derived from soft calcareous shale. Slope is 3 to 30 percent.

Typical pedon of a Samday clay loam in an area of Samday-Shingle-Worf complex, 3 to 15 percent slopes, 2,500 feet north and 1,600 feet west of the southeast corner of sec. 36, T. 37 N., R. 69 W.

A—0 to 2 inches; light brownish gray (10YR 6/2) clay loam, grayish brown (10YR 5/2) moist; moderate coarse platy structure parting to weak fine granular;

slightly hard, friable, sticky and plastic; effervescent; disseminated carbonates; moderately alkaline; gradual wavy boundary.

C—2 to 10 inches; light brownish gray (10YR 6/2) clay, grayish brown (10YR 5/2) moist; strong coarse subangular blocky structure parting to moderate fine subangular blocky; hard, firm, sticky and plastic; strongly effervescent; disseminated carbonates; moderately alkaline; gradual wavy boundary.

Cky—10 to 18 inches; light brownish gray (10YR 6/2) clay, grayish brown (10YR 5/2) moist; massive; hard, firm, sticky and plastic; strongly effervescent; gypsum crystals and many fine soft filaments and threads of carbonates and gypsum crystals; about 20 percent soft weathered shale chips; moderately alkaline, clear wavy boundary.

Cr—18 inches; calcareous shale and sandstone.

The A horizon has value of 6 or 7 when dry and 5 or 6 when moist. It is clay loam or clay.

The AC horizon has value of 6 or 7 when dry and 5 or 6 when moist, and it has chroma of 2 or 3. Reaction is moderately alkaline or strongly alkaline.

The Cky horizon has value of 5 or 6 when moist. Reaction is neutral to moderately alkaline.

The Cr horizon is calcareous shale or sandstone.

Savageton Series

The Savageton series consists of moderately deep, well drained, slowly permeable soils on toe slopes and alluvial flats. These soils formed in residuum or local alluvium derived from calcareous shale. Slope is 0 to 6 percent.

Typical pedon of a Savageton clay loam in an area of Bahl-Savageton complex, 0 to 6 percent slopes, 400 feet north and 750 feet west of the southeast corner of sec. 31, T. 37 N., R. 68 W.

A—0 to 2 inches; gray (10YR 5/1) clay loam, dark gray (10YR 4/1) moist; moderate medium platy structure and moderate medium granular; slightly hard, friable, sticky and plastic, mildly alkaline; clear wavy boundary.

Bw—2 to 22 inches; light brownish gray (2.5Y 6/2) clay, grayish brown (2.5Y 5/2) moist; moderate coarse prismatic structure that parts to moderate medium subangular blocky; hard, firm, sticky and plastic; slightly effervescent; moderately alkaline; abrupt wavy boundary.

Bk1—22 to 28 inches; light brownish gray (10YR 6/2) clay, grayish brown (10YR 5/2) moist; moderate coarse subangular blocky structure parting to fine subangular blocky; hard, firm, sticky and plastic; many moderately thick clay films on faces of peds; strongly effervescent; common fine irregularly

shaped filaments or threads of calcium carbonate; moderately alkaline; clear smooth boundary.

Bk2—28 to 32 inches; grayish brown (10YR 5/2) clay, dark brown (10YR 4/2) moist; massive; hard, firm, sticky and plastic; strongly effervescent; common fine irregularly shaped filaments or threads of calcium carbonate; moderately alkaline; abrupt wavy boundary.

Cr—32 inches; calcareous platy shale.

The depth to calcium carbonate ranges from 10 to 22 inches. Depth to bedrock ranges from 32 to 39 inches.

The A horizon has value of 4 to 6 when dry and chroma of 1 or 2.

The Bw horizon has value of 5 or 6 when dry. It averages 35 to 40 percent clay.

Sear Series

The Sear series consists of very shallow, well drained, moderately permeable soils on hill slopes and on the summit of buttes. These soils formed in residuum derived from porcellanite. Slope is 0 to 15 percent.

Typical pedon of a Sear loam in an area of Sear-Wibaux complex, 0 to 15 percent slopes, 1,825 feet north and 1,650 feet west of the southeast corner of sec. 2, T. 40 N., R. 71 W.

A—0 to 2 inches; pinkish gray (7.5YR 6/2) loam, brown (7.5YR 4/2) moist; weak fine granular structure; soft, very friable, slightly sticky and slightly plastic; common fine and very fine roots and few medium roots; about 15 percent reddish yellow (5YR 6/8) and red (2.5YR 6/8) porcellanite fragments 0.25 to 1.0 inch in diameter; neutral; clear smooth boundary.

Bt—2 to 9 inches; brown (7.5YR 5/4) channery loam, dark brown (7.5YR 4/4) moist; weak medium prismatic structure parting to moderate medium subangular blocky; slightly hard, friable, sticky and slightly plastic; few thin clay films on faces of peds; common fine and very fine roots; about 30 percent red (2.5YR 6/8) and brown (7.5YR 5/4) porcellanite fragments 0.25 inch to 2.0 inches in diameter; neutral; clear irregular boundary.

Bk1—9 to 35 inches; red (2.5YR 6/8) and reddish yellow (5YR 6/8) porcellanite fragments 0.5 inch to 4.0 inches in diameter; light brown (7.5YR 6/4) loam fills voids in upper part of horizon and decreases to a trace in lower part; calcium carbonate coating on undersides of larger fragments; diffuse wavy boundary.

Bk2—35 to 60 inches; red (2.5YR 5/6 and 5/8) porcellanite fragments 1 inch to 4 inches in diameter; traces of red (2.5YR 5/6) sandy loam in vertical and horizontal fractures in upper part.

Depth to calcium carbonate ranges mainly from 5 to 10 inches, but it is as much as 20 inches in some

pedons. Fragmented porcellanite makes up 90 percent or more of all horizons below a depth of 10 inches.

The A horizon has hue of 7.5YR or 10YR, value of 5 or 6 when dry and 4 or 5 when moist, and chroma of 2 or 3. Reaction is neutral or mildly alkaline.

The Bt horizon has hue of 5YR to 10YR, value of 5 or 6 when dry and 4 or 5 when moist, and chroma of 2 to 4. It is clay loam or loam and is 10 to 35 percent porcellanite fragments. Reaction is neutral to moderately alkaline.

The Bk horizon has traces of soil material between porcellanite fragments.

Shingle Series

The Shingle series consists of shallow, well drained, moderately permeable soils on ridgetops, shoulder slopes, and back slopes of uplands and on scarps in areas where the shale beds have been exposed by geologic erosion. These soils formed in residuum derived from soft calcareous shale. Slope is 3 to 45 percent.

Typical pedon of a Shingle clay loam in an area of Wolf-Shingle-Tassel complex, 3 to 30 percent slopes, 1,320 feet west and 550 feet north of the southeast corner of sec. 30, T. 40 N., R. 68 W.

A—0 to 4 inches; light brownish gray (2.5Y 6/2) clay loam, grayish brown (2.5Y 5/2) moist; moderate very thin and thin platy structure parting to moderate very fine and fine granular; slightly hard, friable, slightly sticky and slightly plastic; slightly effervescent; disseminated carbonates; moderately alkaline; clear wavy boundary.

C—4 to 18 inches; light brownish gray (2.5Y 6/2) clay loam, grayish brown (2.5Y 5/2) moist; massive; hard, firm, sticky and plastic; strongly effervescent; disseminated carbonates; about 15 percent shale fragments; strongly alkaline, clear wavy boundary.

Cr—18 inches; calcareous shale.

The A horizon has hue of 10YR or 2.5Y, value of 5 to 7 when dry and 4 or 5 when moist, and chroma of 2 to 4. It is clay loam, very fine sandy loam, loam, or sandy clay loam.

The C horizon has hue of 10YR or 2.5Y, value of 5 to 7 when dry and 4 to 6 when moist, and chroma of 2 to 4. It is mildly alkaline to strongly alkaline.

Silhouette Series

The Silhouette series consists of deep, well drained, slowly permeable soils on foot slopes and alluvial flats. These soils formed in local alluvium derived dominantly from calcareous shale. Slope is 0 to 6 percent.

Typical pedon of a Silhouette clay loam in an area of Silhouette-Heldt association, 0 to 6 percent slopes, 150

LA IDQUALITY DIVISION

feet west and 600 feet south of the northeast corner of sec. 20, T. 39 N., R. 71 W.

- A—0 to 2 inches; light brownish gray (10YR 6/2) clay loam, brown (10YR 5/3) moist; weak medium and fine granular structure; slightly hard, very friable, slightly sticky and slightly plastic; slightly effervescent; mildly alkaline; abrupt smooth boundary.
- BA—2 to 6 inches; pale brown (10YR 6/3) clay, brown (10YR 5/3) moist; weak medium subangular blocky structure; hard, friable, sticky and plastic; slightly effervescent; moderately alkaline; clear smooth boundary.
- Bw1—6 to 14 inches; pale brown (10YR 6/3) clay, grayish brown (10YR 5/2) moist; weak fine prismatic structure; hard, friable, sticky and plastic; slightly effervescent; moderately alkaline; clear smooth boundary.
- Bw2—14 to 22 inches; pale brown (10YR 6/3) clay, grayish brown (10YR 5/2) moist; weak fine angular blocky structure; very hard, firm, slightly sticky and slightly plastic; slightly effervescent; moderately alkaline; gradual smooth boundary.
- Bk1—22 to 34 inches; very pale brown (10YR 7/3) clay, light brownish gray (10YR 6/2) moist; massive; very hard, firm, slightly sticky and slightly plastic; slightly effervescent; common medium seams and filaments of calcium carbonate; moderately alkaline; gradual smooth boundary.
- Bk2—34 to 60 inches; light gray (10YR 7/2) clay loam, light brownish gray (10YR 6/2) moist; massive; very hard, very firm, slightly sticky and slightly plastic; slightly effervescent; few medium soft calcium carbonate masses and iron concretions; mildly alkaline.

Electrical conductivity typically is less than 4 millimhos per centimeter, and cation exchange capacity per 100 grams of clay ranges from 80 to 90.

Tassel Series

The Tassel series consists of shallow, well drained, moderately rapidly permeable soils on shoulder slopes and ridgetops of uplands. These soils formed in residuum derived from soft calcareous sandstone. Slope is 3 to 30 percent.

Typical pedon of a Tassel loamy fine sand in an area of Tassel-Tulloch-Vonalee association, 6 to 30 percent slopes, 1,950 feet east and 375 feet south of the northwest corner of sec. 8, T. 40 N., R. 68 W.

- A—0 to 2 inches; light brownish gray (10YR 5/2) loamy fine sand, dark grayish brown (10YR 4/2) moist; weak medium and coarse granular structure; soft, very friable, nonsticky and nonplastic; slightly effervescent; disseminated carbonates; mildly alkaline; gradual wavy boundary.

- AC—2 to 5 inches; light brownish gray (10YR 6/2) fine sandy loam, grayish brown (10YR 5/2) moist; weak medium and coarse granular structure; soft, very friable, nonsticky and nonplastic; slightly effervescent; disseminated carbonates; mildly alkaline; gradual wavy boundary.
- C—5 to 16 inches; pale brown (10YR 6/3) fine sandy loam, brown (10YR 5/3) moist; weak very fine and fine subangular blocky structure; soft, very friable, slightly sticky and nonplastic; common very fine pores; slightly effervescent; disseminated carbonates; mildly alkaline, clear wavy boundary.
- Cr—16 inches; soft, calcareous, light gray (5Y 7/1) sandstone.

The profile is neutral to moderately alkaline. It commonly has calcium carbonate throughout, but in a few areas it is noncalcareous.

The A horizon is loamy fine sand, loamy sand, sandy loam, or fine sandy loam.

The C horizon has chroma of 3 or 4. The control section is fine sandy loam or sandy loam.

Tassel Variant

The Tassel Variant consists of very shallow, well drained, moderately rapidly permeable soils on ridges of rolling and hilly uplands. These soils formed in residuum derived from calcareous sandstone interbedded with shale. Slope is 10 to 30 percent.

Typical pedon of a Tassel Variant very fine sandy loam in an area of Gateson Variant-Tassel Variant association, 10 to 45 percent slopes, in the S1/4 of sec. 11, T. 40 N., R. 77 W.

- A—0 to 4 inches; light yellowish brown (10YR 6/4) very fine sandy loam, dark yellowish brown (10YR 4/4) moist; weak fine subangular blocky structure; soft, very friable, nonsticky and nonplastic; strongly effervescent; mildly alkaline; clear smooth boundary.
- Ck—4 to 9 inches; gray (5YR 5/1) loam, dark gray (5YR 4/1) moist; massive; slightly hard, friable, slightly sticky and slightly plastic; strongly effervescent; few fine soft masses and filaments of calcium carbonate; moderately alkaline; gradual wavy boundary.
- Cr—9 inches; interbedded sedimentary rock, dominantly shale.

Depth to soft sedimentary rock ranges from 5 to 10 inches. Content of coarse fragments does not normally exceed 5 percent, but in some areas as much as 10 percent of the surface is covered with ironstone flagstones.

The A horizon has hue of 10YR or 2.5Y, value of 6 or 7 when dry and 4 or 5 when moist, and chroma of 2 to 4. Texture is fine sandy loam or very fine sandy loam. Reaction is neutral or mildly alkaline.

LAND REFORM DIVISION

MAR 11 1991

The Ck horizon has hue of 5YR to 10YR, value of 5 or 6 when dry and 4 or 5 when moist, and chroma of 1 to 3. Texture is loam or sandy loam. Reaction is mildly alkaline or moderately alkaline.

Terro Series

The Terro series consists of moderately deep, somewhat excessively drained, moderately rapidly permeable soils on ridges, hill slopes, and pediment slopes of uplands. These soils formed in residuum derived from soft calcareous sandstone. Slope is 0 to 30 percent.

Typical pedon of a Terro sandy loam (fig. 4) in an area of Vonalee-Terro complex, 0 to 15 percent slopes, 1,000 feet west and 1,250 feet south of the northeast corner of sec. 17, T. 31 N., R. 74 W.

- A—0 to 4 inches; brown (10YR 5/3) sandy loam, dark brown (10YR 4/3) moist; weak medium and fine granular structure; loose, slightly sticky and slightly plastic; neutral; clear smooth boundary.
- Bt1—4 to 10 inches; brown (10YR 5/3) sandy loam, dark brown (10YR 4/3) moist; moderate coarse subangular blocky structure; slightly hard, very friable, slightly sticky and slightly plastic, clear smooth boundary.
- Bt2—10 to 23 inches; pale brown (10YR 6/3) sandy loam, brown (10YR 5/3) moist; weak coarse subangular blocky structure; slightly hard, very friable, slightly sticky and slightly plastic; common thin clay bridges between sand grains; mildly alkaline; clear smooth boundary.
- Bk—23 to 34 inches; light gray (10YR 7/2) sandy loam, light brownish gray (10YR 6/2) moist; weak medium and coarse subangular blocky structure; slightly hard, very friable, slightly sticky and slightly plastic; violently effervescent; many fine irregularly shaped soft masses of calcium carbonate; moderately alkaline; clear irregular boundary.
- Cr—34 inches; white (10YR 8/2) calcareous coarse-grained soft sandstone.

The depth to continuous carbonates ranges from 15 to 30 inches. Depth to bedrock ranges from 26 to 39 inches.

The A horizon has value of 5 or 6 when dry and chroma of 2 or 3. It is sandy loam or fine sandy loam.

The Bt horizon has value of 5 or 6 when dry and chroma of 3 or 4. Reaction is neutral to moderately alkaline.

The Bk horizon has value of 6 or 7 when dry and 5 or 6 when moist, and it has chroma of 2 to 4. It is neutral to moderately alkaline.

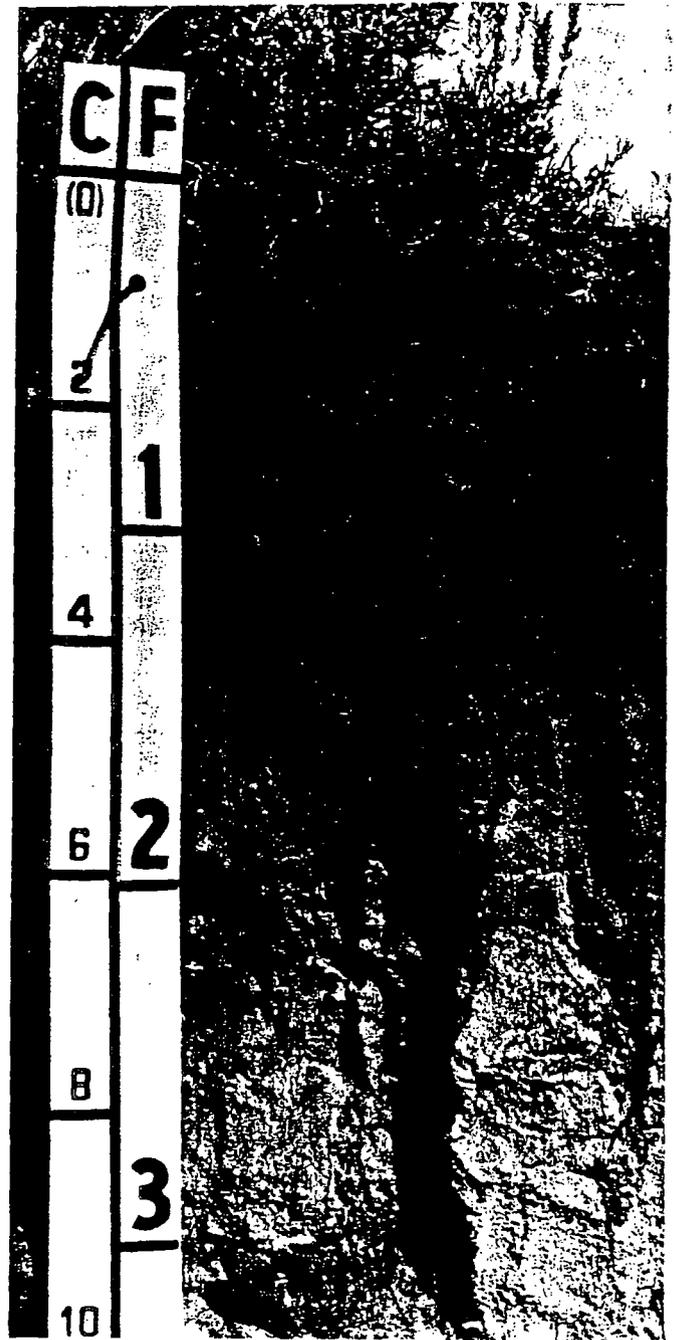

Figure 4.—Profile of Terro sandy loam. Soft sandstone is at depth of 2 feet; some roots have penetrated to depths of 3 feet in softer soils.

FY 2 1/173 PERMIT

Theedle Series

The Theedle series consists of moderately deep, well drained, moderately permeable soils on ridges, hill slopes, and pediment slopes of uplands and on alluvial fans and foot slopes adjacent to major and minor drainageways. These soils formed in residuum derived from calcareous shale. Slope is 0 to 30 percent.

Typical pedon of a Theedle loam in an area of Zigweid-Cambria-Theedle association, 6 to 15 percent slopes, 1,580 feet south and 10 feet west of the northeast corner of sec. 19, T. 35 N., R. 67 W.

A—0 to 2 inches; pale brown (10YR 6/3) loam, brown (10YR 5/3) moist; weak fine granular structure; slightly hard, very friable, slightly sticky and slightly plastic; strongly effervescent; calcium carbonate disseminated throughout matrix; mildly alkaline; clear wavy boundary.

AC—2 to 5 inches; pale brown (10YR 6/3) loam, brown (10YR 5/3) moist; weak medium and fine subangular blocky structure; hard, friable, slightly sticky and slightly plastic; strongly effervescent; calcium carbonate disseminated throughout matrix; mildly alkaline; gradual wavy boundary.

Ck—5 to 20 inches; light gray (10YR 7/2) loam, very pale brown (10YR 7/4) moist; massive; hard, friable, slightly sticky and slightly plastic; strongly effervescent; common fine masses and seams of calcium carbonate; moderately alkaline; gradual wavy boundary.

Ck2—20 to 28 inches; light brownish gray (10YR 6/2) clay loam, grayish brown (10YR 5/2) moist; massive; very hard, friable, sticky and plastic; strongly effervescent; few fine soft masses and seams of calcium carbonate; strongly alkaline; clear wavy boundary.

Crk—28 to 48 inches; gray (10YR 5/1) clay shale changing with depth to light gray (10YR 6/1) noncalcareous; common medium seams and filaments of calcium carbonate that decrease in number and size as depth increases.

The C horizon has hue of 10YR to 5Y and value of 5 or 6 when moist. Reaction is moderately alkaline or strongly alkaline. Texture is loam or light clay loam.

Tullock Series

The Tullock series consists of moderately deep, excessively drained, rapidly permeable soils on shoulder slopes, back slopes, and ridges of upland hills. These soils formed in residuum derived from calcareous sandstone. Slope is 0 to 30 percent.

Typical pedon of a Tullock loamy sand in an area of Tassel-Tullock-Vonalee association, 6 to 30 percent slopes, 1,200 feet west and 1,000 feet north of the southeast corner of sec. 29, T. 35 N., R. 73 W.

A—0 to 5 inches; brown (10YR 5/3) loamy sand, dark brown (10YR 4/3) moist; weak medium and fine crumb structure; soft, loose; slightly effervescent; disseminated calcium carbonate; mildly alkaline; clear wavy boundary.

AC—5 to 20 inches; brown (10YR 5/3) sand, dark brown (10YR 4/3) moist; massive; soft, loose; strongly effervescent; disseminated calcium carbonate; mildly alkaline; clear wavy boundary.

C—20 to 31 inches; pale brown (10YR 6/3) loamy sand, brown (10YR 5/3) moist; massive; soft, loose; strongly effervescent; disseminated calcium carbonate; mildly alkaline; clear wavy boundary.

Cr—31 inches; soft calcareous sandstone.

The depth to bedrock ranges from 24 to 36 inches.

The A horizon has hue of 10YR or 2.5Y, value of 5 or 6 when dry and 4 or 5 when moist, and chroma of 2 to 4. Reaction is mildly alkaline or moderately alkaline.

The AC horizon has hue of 10YR or 2.5Y, value of 5 or 6 when dry and 4 or 5 when moist, and chroma of 2 to 4. It is loamy sand, fine sand, loamy fine sand, or fine sandy loam. Reaction is mildly alkaline or moderately alkaline.

The C horizon has hue of 10YR or 2.5Y, value of 6 or 7 when dry and 5 or 6 when moist, and chroma of 2 to 4. Reaction is mildly alkaline or moderately alkaline.

The Cr horizon is dominantly soft calcareous sandstone, but in some pedons it is interbedded with seams of calcareous shale.

Turnback Series

The Turnback series consists of moderately deep, well drained, moderately rapidly permeable soils on upland ridgetops and shoulders. These soils formed in wind-worked residuum derived from calcareous sandstone. Slope is 6 to 15 percent.

Typical pedon of a Turnback loamy fine sand in an area of Keeline-Tassel-Turnback complex, 6 to 15 percent slopes, 2,500 feet east and 1,900 feet north of the southwest corner of sec. 19, T. 39 N., R. 74 W.

A—0 to 4 inches; pale brown (10YR 6/3) loamy fine sand, brown (10YR 5/3) moist; weak fine granular structure; loose, nonsticky and nonplastic; few fine calcium carbonate seams; moderately alkaline; clear smooth boundary.

Bw1—4 to 8 inches; pale brown (10YR 6/3) sandy loam, yellowish brown (10YR 5/4) moist; weak medium and fine subangular blocky structure; loose, nonsticky and nonplastic; violently effervescent; few fine calcium carbonate seams; moderately alkaline; clear smooth boundary.

Bw2—8 to 20 inches; light yellowish brown (2.5Y 6/4) sandy loam, light olive brown (2.5Y 5/4) moist; weak medium subangular blocky structure; soft, very

LANDQUILTY DIVISION

RECEIVE

Addendum D7 B3

FEB 2 11

Page 74

friable, slightly sticky and slightly plastic; strongly effervescent; common medium and fine calcium carbonate seams; moderately alkaline; clear wavy boundary.

Bk1—20 to 30 inches; pale yellow (2.5Y 7/4) sandy loam, light olive brown (2.5Y 5/4) moist; massive with some inherited rock structural planes; soft, very friable, slightly sticky and slightly plastic; strongly effervescent; few medium and coarse soft masses of calcium carbonate and few fine calcium carbonate seams; moderately alkaline; gradual wavy boundary.

Cr—30 inches; yellow (10YR 7/8) soft calcareous sandstone; moderately alkaline; very slightly effervescent.

The profile commonly is leached in the upper few inches, but in some pedons it is calcareous throughout. Coarse fragment content is typically less than 5 percent.

Ulm Series

The Ulm series consists of deep, well drained, moderately permeable to slowly permeable soils on alluvial flats and toe slopes and on foot slopes of rolling uplands. These soils formed in local alluvium derived from soft calcareous shale. Slope is 0 to 15 percent.

Typical pedon of an Ulm loam in an area of Ulm-Bidman complex, 0 to 6 percent slopes, 751 feet west and 203 feet north of the southeast corner of sec. 32, T. 35 N., R. 70 W.

A—0 to 5 inches; brown (10YR 5/3) loam, dark brown (10YR 4/3) moist; weak fine and medium subangular blocky structure parting to moderate medium granular; slightly hard, very friable, slightly sticky and slightly plastic; neutral; gradual wavy boundary.

Bt1—5 to 9 inches; brown (10YR 5/3) clay loam, dark brown (10YR 4/3) moist; moderate fine and medium prismatic structure parting to moderate fine and medium subangular blocky; hard, friable, sticky and plastic; few thin clay bridges between mineral grains; neutral; clear wavy boundary.

Bt2—9 to 21 inches; brown (10YR 5/3) clay, dark brown (10YR 4/3) moist; strong fine and medium prismatic structure parting to strong fine and medium subangular blocky; very hard, very firm, very sticky and very plastic; many moderately thick clay films on faces of peds; mildly alkaline; gradual wavy boundary.

Bk1—21 to 36 inches; pale brown (10YR 6/3) clay loam, brown (10YR 5/3) moist; moderate fine and medium prismatic structure parting to moderate fine and medium subangular blocky; very hard, very firm, sticky and plastic; strongly effervescent; common medium masses of carbonates; moderately alkaline; clear wavy boundary.

Bk2—36 to 60 inches; light yellowish brown (10YR 6/4) sandy clay loam, yellowish brown (10YR 5/4) moist; massive; hard, friable, sticky and plastic; violently effervescent; common fine masses of carbonates; moderately alkaline.

The depth to calcium carbonate ranges from 15 to 28 inches.

The A horizon has value of 4 to 7 when dry and 4 or 5 when moist, and it has chroma of 2 or 3. It is loam or clay loam.

The Bt horizon has value of 5 or 6 when dry and 4 or 5 when moist, and it has chroma of 2 to 4. Texture is clay, clay loam, or sandy clay that averages 37 to 45 percent clay. Reaction is neutral or mildly alkaline.

The Bk horizon has hue of 10YR or 2.5Y, value of 5 to 7 when dry and 4 to 6 when moist, and chroma of 1 to 4. Texture is clay loam, fine sandy loam, sandy loam, loam, or sandy clay loam. Reaction is moderately alkaline or strongly alkaline.

Ustic Torriorthents

Ustic Torriorthents are mainly deep, well drained soils of variable permeability around coal and uranium strip mines and porcellanite borrow areas. These soils formed in recently reclaimed overburden from mining operations. Slope is 3 to 30 percent.

Reference pedon of Ustic Torriorthents, reclaimed, 3 to 30 percent slopes, 800 feet south and 250 feet west of the northeast corner of sec. 10, T. 35 N., R. 75 W.

A—0 to 5 inches; brown (10YR 5/3) sandy loam, brown (10YR 4/3) moist; massive; slightly hard, friable, slightly sticky and slightly plastic; moderately acid; clear wavy boundary.

C1—5 to 9 inches; light gray (10YR 7/2) loamy sand, light brownish gray (10YR 6/2) moist; massive; loose, very friable, nonsticky and nonplastic; extremely acid; gradual broken boundary.

C2—9 to 15 inches; reddish yellow (7.5YR 6/8) loamy sand, strong brown (7.5YR 6.8) moist; massive; loose, very friable, nonsticky and nonplastic; extremely acid; gradual broken boundary.

C3—15 to 20 inches; light brownish gray (10YR 6/2) loamy sand, grayish brown (10YR 5/2) moist; massive; loose, very friable, nonsticky and nonplastic; about 10 percent fine coal fragments; extremely acid; gradual broken boundary.

C4—20 to 60 inches; light gray (10YR 7/2) loamy sand, light brownish gray (10YR 6/2) moist; massive; loose, very friable, nonsticky and nonplastic; very strongly acid.

Reaction ranges from extremely acid to moderately alkaline. The control section is loamy sand to clay loam.

RECEIVED MAR 11 1961

Thin seams of mostly shale or coal fragments are present in some pedons.

Vonalee Series

The Vonalee series consists of deep, somewhat excessively drained, rapidly permeable soils in undulating to rolling areas on uplands and high terraces. These soils formed in eolian sand and wind-reworked sandstone residuum. Slope is 0 to 15 percent.

Typical pedon of a Vonalee loamy sand in an area of Vonalee-Terro complex, 6 to 15 percent slopes, 100 feet west and 1,600 feet north of southeast corner of sec. 29, T. 35 N., R. 73 W.

- A—0 to 4 inches; yellowish brown (10YR 5/4) loamy sand, dark yellowish brown (10YR 4/4) moist; moderate thin platy structure parting to weak fine granular; soft, loose, nonsticky and nonplastic; neutral; gradual wavy boundary.
- BA—4 to 10 inches; yellowish brown (10YR 5/4) sandy loam, dark yellowish brown (10YR 4/4) moist; moderate coarse subangular blocky structure; soft, very friable, nonsticky and nonplastic; neutral; gradual wavy boundary.
- Bt1—10 to 17 inches; grayish brown (10YR 5/2) sandy loam, dark grayish brown (10YR 4/2) moist; moderate coarse subangular blocky structure; soft, very friable, slightly sticky and slightly plastic; few thin clay bridges between sand grains; mildly alkaline; gradual wavy boundary.
- Bt2—17 to 24 inches; yellowish brown (10YR 5/4) sandy loam, dark yellowish brown (10YR 4/4) moist; moderate coarse subangular blocky structure; slightly hard, very friable, slightly sticky and slightly plastic; few thin clay bridges between sand grains; moderately alkaline; clear wavy boundary.
- Bk1—24 to 44 inches; brown (10YR 5/3) loamy sand, dark brown (10YR 4/3) moist; moderate coarse prismatic structure; soft, loose, nonsticky and nonplastic; slightly effervescent; mildly alkaline; clear wavy boundary.
- Bk2—44 to 60 inches; light brownish gray (10YR 6/2) loam, grayish brown (10YR 5/2) moist; massive; slightly hard, friable, sticky and plastic; violently effervescent; many fine and medium irregularly shaped threads and filaments of calcium carbonate; moderately alkaline.

Wibaux Series

The Wibaux series consists of shallow, somewhat excessively drained, moderately permeable soils on hill slopes, buttes, and ridge crests of uplands. These soils formed in residuum derived from porcellanite. Slope is 0 to 45 percent.

Typical pedon of a Wibaux channery loam in an area of Sear-Wibaux complex, 0 to 15 percent slopes, 1,450

feet west and 1,300 feet south of the northeast corner of sec. 2, T. 40 N., R. 71 W.

- A—0 to 4 inches; pinkish gray (7.5YR 6/2) channery loam, brown (7.5YR 5/4) moist; weak fine granular structure; soft, friable; about 35 percent red (2.5YR 4/8) porcellanite fragments 0.5 inch to 1.5 inches in diameter; mildly alkaline; clear smooth boundary.
- AC—4 to 11 inches; light brown (7.5YR 6/4) very channery loam, brown (7.5YR 4/4) moist; very weak fine granular structure; soft, very friable; about 75 percent brown (7.5YR 4/4) porcellanite fragments 0.5 inch to 2.0 inches in diameter; neutral; clear smooth boundary.
- C—11 to 28 inches; dark yellowish brown (10YR 4/6) fragmented porcellanite grading to strong brown (7.5YR 5/6) in the lower part; single grain; yellowish brown (10YR 5/6) sandy loam occupies narrow voids between 1- to 3-inch fragments; neutral; gradual wavy boundary.
- Ck—28 to 60 inches; red (2.5YR 5/6) porcellanite flagstones underlain by red (2.5YR 5/6) fractured porcellanite; traces of light reddish brown (2.5YR 6/3) sandy loam, mostly along vertical fractures, extend to a depth of about 45 inches; calcium carbonate coatings on underside of larger flagstones.

Depth to calcium carbonate and porcellanite ranges from 10 to 20 inches.

The A horizon has hue of 2.5YR to 7.5YR, value of 5 or 6 when dry and 4 or 5 when moist, and chroma of 2 to 4. Reaction is neutral or mildly alkaline. Texture is commonly loam that has 20 to 60 percent porcellanite fragments.

The C horizon has hue of 10R to 5YR, value of 5 or 6 when dry and 4 or 5 when moist, and chroma of 3 to 6. Reaction is neutral to moderately alkaline. The horizon commonly is fractured porcellanite with loam or sandy loam in the voids in the upper part grading to largely in place fractured porcellanite with traces of soil in voids in the lower part.

Worf Series

The Worf series consists of shallow, well drained, moderately permeable soils on shoulder slopes, back slopes, and ridges and other summits of rolling uplands. These soils formed in residuum derived from interbedded shale and sandstone. Slope is 3 to 30 percent.

Typical pedon of a Worf fine sandy loam in an area of Worf-Shingle-Tassel complex, 3 to 30 percent slopes, in the NW1/4NW1/4NW1/4 of sec. 29, T. 35 N., R. 73 W.

- A—0 to 2 inches; grayish brown (10YR 5/2) fine sandy loam, dark grayish brown (10YR 4/2) moist; weak thin platy structure parting to weak fine granular;

LANDQUALITY DIVISION

soft, loose, slightly sticky and slightly plastic; neutral; clear wavy boundary.

- Bt1—2 to 8 inches; brown (10YR 5/3) sandy clay loam, dark brown (10YR 4/3) moist; moderate coarse subangular blocky structure; slightly hard, friable, sticky and plastic; few thin clay films on ped faces; mildly alkaline; clear wavy boundary.
- Bt2—8 to 14 inches; brown (10YR 5/3) sandy clay loam, dark brown (10YR 4/3) moist; strong coarse prismatic structure parting to moderate fine and medium subangular blocky; hard, firm, sticky and plastic; common moderately thick clay films on ped faces; mildly alkaline; clear wavy boundary.
- Bk—14 to 18 inches; light yellowish brown (2.5Y 5/3) sandy clay loam, light olive brown (2.5Y 5/4) moist; massive; hard, firm, sticky and plastic; strongly effervescent; disseminated calcium carbonates and few fine calcium carbonate filaments; moderately alkaline; abrupt wavy boundary.
- Cr—18 inches; soft calcareous shale.

Depth to calcium carbonate ranges from 7 to 18 inches, and depth to bedrock ranges from 14 to 19 inches. Rock fragment content is 0 to 18 percent but typically is less than 3 percent. In some areas gravel covers 15 percent of surface.

The A horizon has value 5 or 6 when dry and 3 to 5 when moist, and it has chroma of 2 or 3. It is fine sandy loam, sandy loam, or loam.

The Bt horizon has hue of 2.5Y to 7.5YR, value of 5 to 7 when dry and 4 or 5 when moist, and chroma of 2 to 4. It is sandy clay loam, clay loam, or loam and is 22 to 34 percent clay. Reaction is neutral to moderately alkaline.

The Bk horizon has hue of 2.5Y or 10YR, value of 5 to 7 when dry and 4 to 6 when moist, and chroma of 2 to 4.

The Cr horizon is soft, interbedded shale and sandstone.

Worfka Series

The Worfka series consists of shallow, well drained, slowly permeable soils on summits and back slopes of undulating to rolling uplands. These soils formed in residuum derived from interbedded shale and sandstone. Slope is 0 to 15 percent.

Typical pedon of a Worfka fine sandy loam in an area of Renohill-Worfka-Shingle complex, 6 to 15 percent slopes, 2,640 feet south and 300 feet east of the northwest corner of sec. 21., T. 36 N., R. 70 W.

- A—0 to 3 inches; grayish brown (10YR 5/2) fine sandy loam, dark grayish brown (10YR 4/2) moist; weak coarse subangular blocky structure parting to moderate very fine granular; soft, very friable, slightly sticky and slightly plastic; neutral; abrupt smooth boundary.

- Bt—3 to 8 inches; pale brown (10YR 6/3) clay, brown (10YR 5/3) moist; strong coarse subangular blocky structure parting to moderately fine subangular blocky; slightly hard, friable, sticky and plastic; many moderately thick clay films on faces of peds; mildly alkaline; gradual wavy boundary.

- Btk—8 to 14 inches; light yellowish brown (10YR 6/4) clay loam, pale brown (10YR 6/3) moist; strong coarse subangular blocky structure parting to weak fine subangular blocky; slightly hard, friable, sticky and plastic; many moderately thick clay films on faces of peds; strongly effervescent; common fine irregularly shaped calcium carbonate in seams; moderately alkaline; gradual wavy boundary.

- Cr—14 inches; soft calcareous shale.

Depth to bedrock ranges from 10 to 20 inches.

The A horizon has value of 5 or 6 when dry and 4 or 5 when moist, and it has chroma of 2 to 4. Texture is fine sandy loam, sandy loam, loam, or clay loam.

The Bt horizon has value 5 or 6 when dry and 4 or 5 when moist, and it has chroma of 2 to 4. It is clay or clay loam. Reaction is neutral to moderately alkaline.

The Btk horizon has hue of 2.5Y to 10YR, value of 5 to 7 when dry and 5 or 6 when moist, and chroma of 2 to 4. It is mildly alkaline to strongly alkaline.

The Cr horizon is soft interbedded shale and sandstone.

Zigweid Series

The Zigweid series consists of deep, well drained, moderately permeable soils on foot slopes, toe slopes, and alluvial flats. These soils formed in local alluvium derived dominantly from calcareous shale. Slope is 0 to 15 percent.

Typical pedon of a Zigweid clay loam in an area of Zigweid-Cambria-Theedle association, 6 to 15 percent slopes, 300 feet east and 1,800 feet north of the southwest corner of sec. 4, T. 38 N., R. 74 W.

- A—0 to 3 inches; brown (10YR 5/3) clay loam, dark grayish brown (10YR 4/2) moist; weak medium platy structure parting to weak fine subangular blocky; hard, friable, sticky and plastic; neutral; abrupt smooth boundary.

- Bw—3 to 9 inches; pale brown (10YR 6/3) clay loam, grayish brown (10YR 5/2) moist; moderate medium and fine subangular blocky structure; hard, friable, sticky and plastic; strongly effervescent; neutral; clear smooth boundary.

- Bk1—9 to 28 inches; light brownish gray (2.5Y 6/2) clay loam, grayish brown (2.5Y 5/2) moist; weak fine subangular blocky structure; hard, friable, sticky and plastic; violently effervescent; common fine soft masses and filaments of calcium carbonate; moderately alkaline; gradual smooth boundary.

EQUQUALITY DIVISION

RECEIVED MAR 11 1991

Bk2—28 to 60 inches; light brownish gray (2.5Y 6/2) clay loam, grayish brown (2.5Y 5/2) moist; massive; slightly hard, friable, sticky and plastic; violently effervescent; few fine soft masses and filaments of calcium carbonate; moderately alkaline.

The A horizon has hue of 10YR or 2.5YR. Some pedons have weak platy structure in the surface layer.

Texture is loam or clay loam. Reaction is neutral to moderately alkaline.

The Bw horizon has hue of 10YR or 2.5Y and chroma of 2 to 4. Reaction is neutral to moderately alkaline.

The Bk horizon has hue of 2.5YR or 10YR. Reaction centers on moderately alkaline. A Ck horizon is present in some pedons.

APPENDIX D-7

SOILS

PROPOSED REYNOLDS RANCH AMENDMENT AREA CONVERSE COUNTY WYOMING

1.0 General

The impact to the topsoil resource at the Reynolds Ranch amendment area will be relatively minor when compared to typical surface mining operations as the in-situ recovery process results in very limited topsoil disturbance. Accordingly, most of the required topsoil salvage is restricted to constructed access roads and building sites.

2.0 Soil Baseline Studies

Baseline soil studies performed for the amendment area include an Order 3 soil survey conducted by the U.S. Soil Conservation Service (SCS) in 1982 and an Order 1-2 soil assessment conducted by BKS Environmental Associates, Inc. (BKS) in 1997 for Rio Algom Mining Corporation (RAMC).

The soil survey conducted by the SCS included all of Converse County, including the Reynolds Ranch amendment area. Applicable portions of this survey are contained in Addendum D7-C1 and includes detailed SCS map unit descriptions, typical SCS soil profile descriptions of each series, engineering index properties, and physical and chemical properties. Plate D7-1 shows the delineation of the SCS soil unit boundaries for the Reynolds Ranch amendment area.

The 1997 soil assessment is contained in Addendum D7-C2. This assessment was a higher intensity Order 1-2 survey and includes mechanical and chemical analysis of several sampling locations throughout the amendment area, additional soil unit descriptions, and reclamation suitability analysis. An area soils map was also developed during this survey utilizing previous mapping and soil unit information and information gained during the 1997 survey.

SOIL SURVEY OF CONVERSE COUNTY, WYOMING,
NORTHERN PART
U.S. SOIL CONSERVATION SERVICE

Detailed Soil Map Units

The map units delineated on the detailed maps at the end of this survey represent the soils or miscellaneous areas in the survey area. The map unit descriptions in this section, along with the maps, can be used to determine the suitability and potential of a unit for specific uses. They also can be used to plan the management needed for those uses. More information for each map unit is given under "Use and Management of Soils."

Map unit delineation on a map represents an area delineated by one or more major kinds of soil or miscellaneous areas. A map unit is identified and named according to the taxonomic classification of the dominant soil or miscellaneous areas. Within a taxonomic class there are precisely defined limits for the properties of the soil or miscellaneous areas, however, the soils and miscellaneous areas are natural phenomena, and they have a characteristic variability of all natural phenomena. Thus, the range of some observed phenomena may extend beyond the limits defined for a taxonomic class. Areas of soils of a single taxonomic class, if ever, can be mapped without including soils of other taxonomic classes. Consequently, every map unit is made up of the soils or miscellaneous areas in which it is named and some "included" areas that belong to other taxonomic classes.

Most included soils have properties similar to those of the dominant soil or soils in the map unit, and thus they do not affect use and management. These are called contrasting, or similar, inclusions. They may or may not be mentioned in the map unit description. Other included soils and miscellaneous areas, however, have properties and behavior divergent enough to affect use and management. These are called contrasting, or dissimilar, inclusions. They generally are small areas and could not be mapped separately at the scale used. Some small areas of strongly contrasting soils or miscellaneous areas are identified by a special symbol on the maps. The included areas of contrasting soils or miscellaneous areas are mentioned in the map unit descriptions. A few included areas may have been observed, and consequently they are not mentioned in the descriptions, especially where the pattern was so complex that it was impractical to make observations to identify all the soils and miscellaneous areas on the landscape.

The presence of included areas in a map unit in no way diminishes the usefulness or accuracy of the data. The objective of mapping is not to delineate pure taxonomic classes but rather to separate the landscape into segments that have similar use and management requirements. The delineation of such landscape segments on the map provides sufficient information for the development of resource plans, but if intensive use of small areas is planned, onsite investigation to precisely define and locate the soils and miscellaneous areas is needed.

An identifying symbol precedes the map unit name in the map unit descriptions. Each description includes general facts about the unit and gives the principal hazards and limitations to be considered in planning for specific uses.

Soils that have profiles that are almost alike make up a *soil series*. Except for differences in texture of the surface layer or of the underlying layers, all the soils of a series have major horizons that are similar in composition, thickness, and arrangement.

Soils of one series can differ in texture of the surface layer or of the underlying layers. They also can differ in characteristics that affect their use. On the basis of such differences, a soil series is divided into *soil phases*. Most of the areas shown on the detailed soil maps are phases of soil series. The name of a soil phase commonly indicates a feature that affects use or management. For example, Shingle loam, thin solum, is one of several phases in the Shingle series.

Most map units are made up of two or more major soils or miscellaneous areas. These map units are complexes or associations.

A *complex* consists of two or more soils or miscellaneous areas in such an intricate pattern or in such small areas that they cannot be shown separately on the maps. The pattern and proportion of the soils or miscellaneous areas are somewhat similar in all areas. Ulm-Renonill complex, 0 to 5 percent slopes, is an example.

An *association* is made up of two or more geographically associated soils or miscellaneous areas that are shown as one unit on the maps. Because of present or anticipated uses of the map units in the survey area, it was not considered practical or necessary to map the soils or miscellaneous areas separately. The pattern and relative proportion of the soils or

miscellaneous areas are somewhat similar. Zigweid-imbria association, 0 to 6 percent slopes, is an example.

This survey includes *miscellaneous areas*. Such areas have little or no soil material and support little or no vegetation. Rock outcrop is an example.

Table 3 gives the acreage and proportionate extent of each map unit. Other tables (see "Summary of tables") give properties of the soils and the limitations, capabilities, and potentials for many uses. The Glossary defines many of the terms used in describing the soils or miscellaneous areas.

Map Unit Descriptions

101—Absted-Arvada-Bone complex, 0 to 6 percent slopes. This map unit is in nearly level to undulating areas on toe slopes, alluvial flats, and stream terraces. Slopes are medium in length and are plane. The native vegetation is mainly salt tolerant grasses, shrubs, and woody plants.

This unit is 40 percent Absted fine sandy loam, 25 percent Arvada loam, and 20 percent Bone clay loam. The components of this unit are so intricately intermingled that it was not practical to map them separately at the scale used.

Included in this unit are small areas of Ulm loam, Lohmiller clay loam, Haverdad fine sandy loam, and Bahl clay. Included areas make up about 15 percent of the total acreage. The percentage varies from one area to another.

The Absted soil is deep and well drained. It formed in clayey alluvium derived dominantly from sedimentary rock. Typically, the surface layer is pale brown fine sandy loam about 3 inches thick. The upper 23 inches of the subsoil is brown and grayish brown clay, and the lower 34 inches or more is light brownish gray clay. In a few areas soft bedrock is at a depth of 20 to 60 inches.

Permeability of the Absted soil is slow. Available water capacity is moderate. Effective rooting depth is 60 inches or more. Runoff is slow, and the hazard of water erosion is moderate. The hazard of wind erosion is moderate. Excess sodium or soluble salts are at an average depth of 15 inches.

The Arvada soil is deep and well drained. It formed in clayey alluvium derived dominantly from sedimentary rock. Typically, the surface layer is light brownish gray loam about 3 inches thick. The subsoil is pale brown and light brownish gray clay about 19 inches thick. The substratum to a depth of 60 inches or more is pale brown clay.

Permeability of the Arvada soil is very slow. Available water capacity is low. Effective rooting depth is 60 inches or more. Runoff is slow, and the hazard of water erosion is moderate. The hazard of wind erosion is moderate. Excess sodium or soluble salts are in the upper part of the subsoil.

The Bone soil is deep and well drained. It formed in clayey alluvium derived dominantly from sedimentary rock. Typically, the surface layer is pale brown clay loam about 2 inches thick. The upper 3 inches of the subsoil is light brownish gray clay loam, and the lower 5 inches is light gray clay loam. The substratum to a depth of 60 inches or more is very pale brown clay loam and clay.

Permeability of the Bone soil is very slow. Available water capacity is low. Effective rooting depth is 60 inches or more. Runoff is slow, and the hazard of water erosion is moderate. The hazard of wind erosion is moderate. Excess sodium or soluble salts occur throughout the profile.

Most areas of this unit are used for livestock grazing and wildlife habitat. A few areas are used for hay production.

The potential plant community on this unit is mainly inland saltgrass, western wheatgrass, Indian ricegrass, and Gardner saltbush. The Bone soil commonly does not support any significant amount of vegetation. As the range condition deteriorates, greasewood increases. As the range condition further deteriorates, annuals invade. The potential plant community produces about 500 pounds of air-dry vegetation in normal years. Production varies from 650 pounds in favorable years to 250 pounds in unfavorable years.

Some areas of this unit east of Wyoming Highway 59, immediately adjacent to the Cheyenne River, support different species and significantly higher levels of plant production than is typical for this unit. Alkali sacaton and western wheatgrass dominate these areas, and yields may range from 1,200 to 2,000 pounds of air-dry vegetation per year. These sites are on the lower parts of stream terraces and receive runoff from river tributaries.

The production of forage in most areas is limited by salinity or alkalinity and low annual precipitation. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

Range seeding is suitable if the range is in poor condition. The main limitations are salinity or alkalinity and lack of suitable adapted species for use in reclamation. The areas of this unit on the lower parts of stream terraces have fair suitability for seeding. These areas also can be improved by mechanical or chemical treatment if heavily infested with undesirable plants.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

This unit is poorly suited to homesite development. The main limitations are high shrink-swell potential, slow and very slow permeability, and slow runoff. Backfilling excavations with coarser textured material reduces the shrink-swell potential. Constructing a larger absorption

field or using selected material will help compensate for the slow and very slow permeability.

This map unit is in capability subclass VI_s. Most of the unit is in the Saline Upland, 10- to 14-inch ppt., Northern Plains range site. The areas on the lower parts of stream terraces adjacent to the Cheyenne River are in Saline Lowland, 10- to 14-inch ppt., Northern Plains range site.

102—Aeric Haplaquepts, 0 to 3 percent slopes.

These deep, poorly drained soils are in areas of centripetal drainage in playas. The soils formed in clayey local alluvium derived dominantly from sedimentary rock. Slopes are concave and are short or medium in length. Areas are generally oval in shape and are 1 to 100 acres in size. The native vegetation is mainly grasses.

Included in this unit are small areas of Silhouette clay loam, Savageton clay loam, and Bahl clay. Also included are small intermittent ponds. Included areas make up about 25 percent of the total acreage. The percentage varies from one area to another.

No single profile of Aeric Haplaquepts is typical, but one commonly observed in the survey area has a surface layer of light gray and light brownish gray clay loam about 8 inches thick. The underlying material to a depth of 48 inches or more is light gray and pale brown clay with yellow and yellowish red mottles. In some of the smaller areas of these soils, soft sedimentary bedrock is at a depth of 20 to 60 inches.

Permeability of the Aeric Haplaquepts is very slow. Available water capacity is high. Effective rooting depth is 30 inches for water-tolerant plants but is limited to depths between 0 and 12 inches for non-water-tolerant plants. Runoff is very slow, and the hazard of water erosion is slight. The hazard of wind erosion is slight. A seasonal high water table fluctuates between depths of 0 and 24 inches from March through July. Some areas of this unit are covered by water from snowmelt, intense rain showers, and runoff from adjacent areas.

This unit is used for livestock grazing and wildlife habitat.

The potential plant community on this unit is mainly basin wildrye, green needlegrass, western wheatgrass, and Canada wildrye. As the range condition deteriorates, needleleaf sedge and Sandberg bluegrass increase. As the range condition further deteriorates, annual forbs invade. The potential plant community produces about 2,300 pounds of air-dry vegetation in normal years. Production varies from 2,800 pounds in favorable years to 1,900 pounds in unfavorable years. The types of vegetation in the larger playas also include those of wetland and subirrigated range sites in the lower positions and no vegetation in the lowest positions because of intermittent ponding.

The production of forage is limited by low annual precipitation. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore,

livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of this unit for rangeland seeding is good. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds. Larger areas of this unit are used temporarily by migratory shore birds.

This unit is not suited to homesite development because of ponding.

This map unit is in capability subclass VI_w. *Most of this unit is in the Clayey Overflow, 10- to 14-inch ppt., Northern Plains range site.

103—Bahl-Savageton complex, 0 to 6 percent slopes. This map unit is in nearly level to undulating areas on toe slopes and alluvial flats. Slopes are medium in length and are plane to slightly concave. The native vegetation is mainly grasses.

This unit is 40 percent Bahl clay and 35 percent Savageton clay loam. The components of this unit are so intricately intermingled that it was not practical to map them separately at the scale used.

Included in this unit are small areas of Ulm loam and Zigweid clay loam. Included areas make up about 25 percent of the total acreage. The percentage varies from one area to another.

The Bahl soil is deep and well drained. It formed in clayey local alluvium derived dominantly from calcareous shale. Typically, the surface layer is pale olive clay at 4 inches thick. The underlying material to a depth of 60 inches or more is pale olive clay.

Permeability of the Bahl soil is slow. Available water capacity is high. Effective rooting depth is 60 inches or more. Runoff is medium, and the hazard of water erosion is moderate. The hazard of wind erosion is slight.

The Savageton soil is moderately deep and well drained. It formed in clayey local alluvium and residuum derived dominantly from calcareous shale. Typically, the surface layer is gray clay loam about 2 inches thick. The subsoil is light brownish gray and grayish brown clay about 30 inches thick. Platy shale is at a depth of 32 inches.

Permeability of the Savageton soil is very slow. Available water capacity is low. Effective rooting depth is 20 to 40 inches. Runoff is medium, and the hazard of water erosion is moderate. The hazard of wind erosion is slight.

This unit is used for livestock grazing and wildlife habitat.

The potential plant community on this unit is mainly western wheatgrass, green needlegrass, and thickspike wheatgrass. As the range condition deteriorates, big sagebrush and blue grama increase. As the range condition further deteriorates, cactus and broom

snakeweed invade. The potential plant community produces about 1,300 pounds of air-dry vegetation in normal years. Production varies from 1,800 pounds in favorable years to 750 pounds in unfavorable years.

The production of forage is limited by low annual precipitation. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of this unit for rangeland seeding is good. Chiseling or other such practices can be used to improve areas of deteriorated rangeland. Such practices increase water infiltration, reduce plant competition, and allow the desirable native plants to increase. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

This unit is poorly suited to homesite development. The main limitations are high shrink-swell potential, slow and very slow permeability, and the depth of the the Savageton soil to soft bedrock. Backfilling excavations with coarser textured material reduces the limitation of shrink-swell potential. Constructing a larger absorption field or using selected material helps to overcome the slow permeability of the Bahl soil. Areas of the Savageton soil are not suitable for use as septic tank absorption fields.

This map unit is in capability subclass IVe. It is in the Clayey, 10- to 14-inch ppt., Northern Plains range site.

104—Cambria-Cushman complex, 0 to 6 percent slopes. This map unit is on toe slopes and ridge crests of rolling uplands. Slopes are medium in length and are slightly convex to plane. The native vegetation is mainly grasses and shrubs.

This unit is 60 percent Cambria fine sandy loam and 30 percent Cushman loam. The components of this unit are so intricately intermingled that it was not practical to map them separately at the scale used.

Included in this unit are small areas of Ulm loam and Renohill sandy loam. Included areas make up about 10 percent of the total acreage. The percentage varies from one area to another.

The Cambria soil is deep and well drained. It formed in loamy local alluvium and residuum derived dominantly from sedimentary rock. Typically, the surface layer is grayish brown fine sandy loam about 2 inches thick. The upper 8 inches of the subsoil is brown sandy clay loam, and the lower part to a depth of 60 inches or more is pale brown loam. In some areas soft bedrock is at a depth of 40 to 60 inches.

Permeability of the Cambria soil is moderate. Available water capacity is high. Effective rooting depth is 60 inches or more. Runoff is medium, and the hazard of water erosion is moderate. The hazard of wind erosion is moderate.

The Cushman soil is moderately deep and well drained. It formed in loamy residuum derived dominantly from calcareous shale and sandstone. Typically, the surface layer is brown loam about 4 inches thick. The upper 11 inches of the subsoil is yellowish brown and light yellowish brown clay loam, and the lower 18 inches is pale brown clay loam and very pale brown sandy clay loam. Interbedded shale and sandstone are at a depth 33 inches.

Permeability of the Cushman soil is moderate. Available water capacity is moderate. Effective rooting depth is 20 to 40 inches. Runoff is medium, and the hazard of water erosion is moderate. The hazard of wind erosion is moderate.

This unit is used for livestock grazing and wildlife habitat.

The potential plant community on this unit is mainly western wheatgrass, thickspike wheatgrass, and needleandthread. As the range condition deteriorates, big sagebrush and blue grama increase. As the range condition further deteriorates, cacti, annuals, and broom snakeweed invade. The potential plant community produces about 1,500 pounds of air-dry vegetation in normal years. Production varies from 2,000 pounds in favorable years to 850 pounds in unfavorable years.

The production of forage is limited by low annual precipitation. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of this unit for rangeland seeding is good. Chiseling or other such practices can be used to improve areas of deteriorated rangeland. Such practices increase water infiltration, reduce plant competition, and allow the desirable native plants to increase.

This unit is limited for livestock watering ponds and other water impoundments because of the seepage potential.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

If this unit is used for homesite development, the main limitations are moderate shrink-swell potential and the depth of the Cushman soil to soft bedrock. Backfilling excavations with coarser textured material reduces the limitation of shrink-swell potential. Areas of the Cushman soil are not suitable for use as septic tank absorption fields.

This map unit is in capability subclass IVe. It is in the Loamy, 10- to 14-inch ppt., Northern Plains range site.

105—Cambria-Cushman complex, 6 to 15 percent slopes. This map unit is on back slopes of rolling uplands and on adjacent foot slopes. Slopes are short and are mostly convex. The native vegetation is mainly grasses and shrubs.

This unit is 50 percent Cambria sandy loam and 30 percent Cushman loam. The components of this unit are intricately intermingled that it was not practical to map them separately at the scale used.

Included in this unit are small areas of Renohill clay loam and Worf fine sandy loam. Included areas make up about 20 percent of the total acreage. The percentage varies from one area to another.

The Cambria soil is deep and well drained. It formed in loamy local alluvium and residuum derived dominantly from sedimentary rock. Typically, the surface layer is brown sandy loam about 4 inches thick. The upper 4 inches of the subsoil is yellowish brown loam, and the lower part to a depth of 60 inches or more is pale brown loam. In some areas soft bedrock is between depths of 40 and 60 inches.

Permeability of the Cambria soil is moderate. Available water capacity is high. Effective rooting depth is 60 inches or more. Runoff is medium, and the hazard of water erosion is severe. The hazard of wind erosion is moderate.

The Cushman soil is moderately deep and well drained. It formed in loamy residuum derived dominantly from calcareous shale and sandstone. Typically, the surface layer is pale brown loam about 3 inches thick. The upper 14 inches of the subsoil is pale brown and light gray clay loam, and the lower 8 inches is pale yellow loam. Interbedded shale and sandstone are at a depth of 25 inches.

Permeability of the Cushman soil is moderate.

Available water capacity is low. Effective rooting depth is 40 to 40 inches. Runoff is medium, and the hazard of water erosion is severe. The hazard of wind erosion is moderate.

This unit is used for livestock grazing and wildlife habitat.

The potential plant community on this unit is mainly western wheatgrass, thickspike wheatgrass, and needleandthread. As the range condition deteriorates, big sagebrush and blue grama increase. As the range condition further deteriorates, cacti, annuals, and broom snakeweed invade. The potential plant community produces about 1,500 pounds of air-dry vegetation in normal years. Production varies from 2,000 pounds in favorable years to 850 pounds in unfavorable years.

The production of forage is limited by low annual precipitation. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of this unit for rangeland seeding is fair. The main limitation is the hazard of water erosion. Chiseling or other such practices can be used to improve areas of deteriorated rangeland. Such practices increase water infiltration, reduce plant competition, and allow the

desirable native plants to increase. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

If this unit is used for homesite development, the main limitations are moderate shrink-swell potential, slope, and the depth of the Cushman soil to soft bedrock. Backfilling with coarser textured material reduces the limitation of shrink-swell potential. Areas of the Cushman soil are not suitable for use as septic tank absorption fields.

This map unit is in capability subclass VIe. It is in the Loamy, 10- to 14-inch ppt., Northern Plains range site.

106—Cambria Variant-Forkwood Variant complex, 0 to 6 percent slopes. This map unit is in nearly level to undulating areas on toe slopes and alluvial flats. Slopes are long and plane. The native vegetation is mainly grasses and shrubs.

This unit is 45 percent Cambria Variant fine sandy loam and 35 percent Forkwood Variant clay loam. The components of this unit are so intricately intermingled that it was not practical to map them separately at the scale used.

Included in this unit are small areas of Hiland sandy loam and Ulm loam. Also included are small areas of soils that have a stratified substratum. Included areas make up about 20 percent of the total acreage. The percentage varies from one area to another.

The Cambria Variant soil is deep and well drained. It formed in loamy alluvium derived dominantly from interbedded sandstone and shale. Typically, the surface layer is light gray fine sandy loam about 2 inches thick. The upper 14 inches of the subsoil is light brownish gray clay loam and loam, and the lower 32 inches is light brownish gray stratified loam, clay loam, and sandy clay loam to a depth of 60 inches or more.

Permeability of the Cambria Variant soil is moderate. Available water capacity is high. Effective rooting depth is 60 inches or more. Runoff is slow, and the hazard of water erosion is moderate. The hazard of wind erosion is moderate.

The Forkwood Variant soil is deep and well drained. It formed in loamy alluvium derived dominantly from interbedded sandstone and shale. Typically, the surface layer is light gray clay loam about 3 inches thick. The upper 13 inches of the subsoil is pale brown clay loam, and the lower part to a depth of 60 inches or more is light gray stratified loam, clay loam, and fine sandy loam.

Permeability of the Forkwood Variant soil is moderate. Available water capacity is high. Effective rooting depth is 60 inches or more. Runoff is medium, and the hazard of water erosion is moderate. The hazard of wind erosion is slight.

This unit is used for livestock grazing and wildlife habitat.

The potential plant community on this unit is mainly stern wheatgrass, thickspike wheatgrass, and needleandthread. As the range condition deteriorates, big sagebrush and blue grama increase. As the range condition further deteriorates, cacti, annuals, and broom snakeweed invade. The potential plant community produces about 1,500 pounds of air-dry vegetation in normal years. Production varies from 2,000 pounds in favorable years to 850 pounds in unfavorable years.

The production of forage is limited by low annual precipitation. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of this unit for rangeland seeding is good. Chiseling or other such practices can be used to improve areas of deteriorated rangeland. Such practices increase water infiltration, reduce plant competition, and allow the desirable native plants to increase.

This unit is limited for livestock watering ponds and other water impoundments because of the seepage potential.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

If this unit is used for homesite development, the main limitation is moderate shrink-swell potential. Backfilling excavations with coarser textured material helps to overcome this limitation.

This map unit is in capability subclass IVe. It is in the Loamy, 10- to 14-inch ppt., Northern Plains range site. There are inclusions of Clayey Overflow, 10- to 14-inch ppt., Northern Plains range site in areas where runoff water collects.

107—Clarkelen-Draknab complex, 0 to 3 percent slopes. This map unit is on flood plains. Slopes are long and plane. The native vegetation is mainly grasses and woody plants.

This unit is 50 percent Clarkelen sandy loam and 35 percent Draknab loamy sand. The components of this unit are so intricately intermingled that it was not practical to map them separately at the scale used.

Included in this unit are small areas of Keeline sandy loam, Haverdad fine sandy loam, and Bigwin fine sandy loam. Included areas make up about 15 percent of the total acreage. The percentage varies from one area to another.

The Clarkelen soil is deep and somewhat excessively drained. It formed in loamy recently deposited alluvium derived dominantly from sedimentary rock. Typically, the surface layer is pale brown and grayish brown sandy loam about 3 inches thick. The underlying material to a depth of 60 inches or more is highly stratified light brownish gray sand, sandy loam, sandy clay loam, and silt loam.

Permeability of the Clarkelen soil is moderately rapid. Available water capacity is moderate. Effective rooting depth is 60 inches or more. Runoff is slow, and the hazard of water erosion is moderate. The hazard of wind erosion is moderate. This soil is subject to flooding during prolonged, high-intensity storms. Channeling and deposition occur along streambanks.

The Draknab soil is deep and excessively drained. It formed in sandy recently deposited alluvium derived dominantly from sandstone. Typically, the surface layer is yellowish brown loamy sand about 2 inches thick. The underlying material to a depth of 60 inches or more is pale brown and very pale brown, stratified sand, coarse sand, loamy sand, and loamy coarse sand.

Permeability of the Draknab soil is rapid. Available water capacity is low. Effective rooting depth is 60 inches or more. Runoff is very slow, and the hazard of water erosion is slight. The hazard of wind erosion is severe. This soil is subject to flooding during prolonged, high-intensity storms. Channeling and deposition occur along streambanks.

This unit is used for livestock grazing and wildlife habitat.

The potential plant community on this unit is mainly western wheatgrass, slender wheatgrass, needleandthread, and cottonwood trees. As the range condition deteriorates, silver sagebrush, rubber rabbitbrush, and snowberry increase. As the range condition further deteriorates, annual forbs and cheatgrass invade. The potential plant community produces about 2,500 pounds of air-dry vegetation in normal years. Production varies from 3,000 pounds in favorable years to 2,000 pounds in unfavorable years.

The production of forage is limited by low annual precipitation and the hazard of flooding. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of this unit for rangeland seeding is good. Chiseling or other such practices can be used to improve areas of deteriorated rangeland. Such practices increase water infiltration, reduce plant competition, and allow the desirable native plants to increase.

This unit is limited for livestock watering ponds and other water impoundments because of the seepage potential.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds. Cottonwood trees commonly provide important riparian habitat for birds and small mammals.

This unit is poorly suited to homesite development. The main limitations are the hazard of excavations caving in and the hazard of flooding. Constructing dikes reduces the risk of flooding. Use of septic tank

absorption fields could create a hazard of polluting ground water.

This map unit is in capability subclass IVe. It is in the Lowland, 10- to 14-inch ppt., Northern Plains range site.

108—Clarkelen-Dwyer-Orpha association, 0 to 10 percent slopes. This map unit is in gently sloping areas on flood plains and in undulating to gently rolling areas on dunes that are superimposed on stream terraces. The Clarkelen soil is on flood plains, and the Dwyer and Orpha soils are on terrace dunes. Slopes are medium in length and are plane, or they are short and convex. The native vegetation is mainly grasses and woody plants.

This unit is 40 percent Clarkelen sandy loam, 25 percent Dwyer loamy sand, and 20 percent Orpha loamy sand.

Included in this unit are small areas of Haverdad fine sandy loam, Draknab loamy sand, Keeline sandy loam, and Kishona loam. Included areas make up about 15 percent of the total acreage. The percentage varies from one area to another.

The Clarkelen soil is deep and somewhat excessively drained. It formed in loamy recently deposited alluvium derived dominantly from sedimentary rock. Typically, the surface layer is pale brown and grayish brown sandy loam about 3 inches thick. The underlying material to a depth of 60 inches or more is highly stratified, light brownish gray sand, sandy loam, sandy clay loam, and silt loam that contain carbonates.

Permeability of the Clarkelen soil is moderately rapid. Available water capacity is moderate. Effective rooting depth is 60 inches or more. Runoff is slow, and the hazard of water erosion is severe. The hazard of wind erosion is moderate. This soil is subject to flooding during prolonged, high-intensity storms. Channeling and deposition are common along streambanks.

The Dwyer soil is deep and excessively drained. It formed in eolian sand derived from mixed sources. Typically, the surface layer is brown loamy sand about 5 inches thick. The underlying material to a depth of 60 inches or more is pale brown loamy sand that contains carbonates within a depth of 40 inches.

Permeability of the Dwyer soil is rapid. Available water capacity is low. Effective rooting depth is 60 inches or more. Runoff is slow, and the hazard of water erosion is moderate. The hazard of wind erosion is severe.

The Orpha soil is deep and excessively drained. It formed in eolian sand derived from mixed sources. Typically, the surface layer is pale brown loamy sand about 5 inches thick. The underlying material to a depth of 60 inches or more is light yellowish brown loamy sand.

Permeability of the Orpha soil is very rapid. Available water capacity is low. Effective rooting depth is 60 inches or more. Runoff is slow, and the hazard of water erosion is slight. The hazard of wind erosion is severe.

This unit is used for livestock grazing and wildlife habitat.

The potential plant community on the Clarkelen soil mainly needleandthread, slender wheatgrass, western wheatgrass, and cottonwood trees. As the range condition deteriorates, silver sagebrush, rubber rabbitbrush, and snowberry increase. As the range condition further deteriorates, annual forbs and cheatgrass invade. The potential plant community produces about 2,500 pounds of air-dry vegetation in normal years. Production varies from 3,000 pounds in favorable years to 2,000 pounds in unfavorable years.

The production of forage on the Clarkelen soil is limited by low annual precipitation and the hazard of flooding. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community. The suitability of this soil for rangeland seeding is good. Chiseling or other such practices can be used to improve areas of deteriorated rangeland. Such practices increase water infiltration, reduce plant competition, and allow the desirable native plants to increase. This soil is limited for livestock watering ponds and other water impoundments because of the seepage potential.

The potential plant community on the Dwyer and Orpha soils is mainly prairie sandreed, sand bluestem, needleandthread, and Indian ricegrass. As the range condition deteriorates, sageworts increase. As the range condition further deteriorates, annuals and broom snakeweed invade. The potential plant community produces about 2,000 pounds of air-dry vegetation in normal years. Production varies from 2,500 pounds in favorable years to 1,400 pounds in unfavorable years.

The production of forage on the Dwyer and Orpha soils is limited by droughtiness. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community. The suitability of these soils for rangeland seeding is poor. The main limitations are the hazard of wind erosion and droughtiness. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment. These soils are limited for livestock watering ponds and other water impoundments because of the seepage potential.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds. Cottonwood trees commonly provide important riparian habitat for birds and small mammals.

The Clarkelen soil is poorly suited to homesite development. The main limitation is the hazard of flooding. Use of septic tank absorption fields could

create a hazard of polluting ground water. If the Dwyer and Orpha soils are used for homesite development, the main limitations are slope, the hazard of excavations caving in, and sand blowing.

The Clarkelen soil is in capability subclass IVe. The Dwyer and Orpha soils are in capability subclass VIe. The Clarkelen soil is in the Lowland, 10- to 14-inch ppt., Northern Plains range site. The Dwyer and Orpha soils are in the Sands, 10- to 14-inch ppt., Northern Plains range site.

109—Clarkelen-Haverdad-Bigwinder complex, 0 to 3 percent slopes. This map unit is on flood plains and low terraces of major streams. Slopes are medium in length and are plane. The native vegetation is mainly grasses, sedges, and woody plants.

This unit is 35 percent Clarkelen sandy loam, 25 percent Haverdad fine sandy loam, and 25 percent Bigwinder fine sandy loam. The components of this unit are so intricately intermingled that it was not practical to map them separately at the scale used.

Included in this unit are small areas of Draknab loamy sand, Keeline sandy loam, and Dwyer loamy sand. Included areas make up about 15 percent of the total acreage. The percentage varies from one area to another.

The Clarkelen soil is deep and somewhat excessively drained. It formed in loamy recently deposited alluvium derived dominantly from sedimentary rock. Typically, the surface layer is pale brown and grayish brown sandy loam about 3 inches thick. The underlying material to a depth of 60 inches or more is highly stratified, light brownish gray sand, sandy loam, sandy clay loam, and silt loam.

Permeability of the Clarkelen soil is moderately rapid. Available water capacity is moderate. Effective rooting depth is 60 inches or more. Runoff is slow, and the hazard of water erosion is moderate. The hazard of wind erosion is moderate. This soil is subject to flooding during prolonged, high-intensity storms. Channeling and deposition are common along streambanks.

The Haverdad soil is deep and well drained. It formed in loamy recently deposited alluvium derived dominantly from sedimentary rock. Typically, the surface layer is grayish brown fine sandy loam about 6 inches thick. The underlying material to a depth of 60 inches or more is light brownish gray loam with lenses of clay loam and fine sandy loam.

Permeability of the Haverdad soil is moderate. Available water capacity is moderate. Effective rooting depth is 60 inches or more. Runoff is slow, and the hazard of water erosion is moderate. The hazard of wind erosion is moderate. This soil is subject to flooding during prolonged, high-intensity storms. Channeling and deposition occur along streambanks.

The Bigwinder soil is deep and poorly drained. It formed in loamy alluvium derived dominantly from

sedimentary rock. Typically, the surface layer is light brownish gray fine sandy loam about 3 inches thick. It has strong brown mottles. The upper 21 inches of the underlying material is stratified, light gray loam, sandy loam, and loamy sand, and the lower part to a depth of 60 inches or more is stratified, light gray and reddish yellow loamy sand and sand.

Permeability of the Bigwinder soil is moderate to moderately rapid to a depth of 24 inches and is rapid below this depth. Available water capacity is high. Effective rooting depth is 60 inches or more. Runoff is slow, and the hazard of water erosion is moderate. The hazard of wind erosion is moderate. This soil is subject to flooding during prolonged, high-intensity storms. Channeling and deposition occur along streambanks.

This unit is used mainly for livestock grazing and wildlife habitat. It is also used as hayland.

The potential plant community on the Clarkelen and Haverdad soils is mainly needleandthread, slender wheatgrass, green needlegrass, and cottonwood trees (fig. 2). As the range condition deteriorates, silver sagebrush, rubber rabbitbrush, and snowberry increase. As the range condition further deteriorates, annual forbs and cheatgrass invade. The potential plant community produces about 2,500 pounds of air-dry vegetation in normal years. Production varies from 3,000 pounds in favorable years to 2,000 pounds in unfavorable years.

The production of forage on these soils is limited by low annual precipitation and the hazard of flooding. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of these soils for rangeland seeding is good. Chiseling or other such practices can be used to improve areas of deteriorated rangeland. Such practices increase water infiltration, reduce plant competition, and allow the desirable native plants to increase.

The potential plant community on the Bigwinder soil is mainly Nebraska sedge, basin wildrye, slender wheatgrass, and willows. As the range condition deteriorates, western wheatgrass, mat muhly, and spike sedge increase. As the range condition further deteriorates, annual forbs invade. The potential plant community produces about 4,000 pounds of air-dry vegetation in normal years. Production varies from 4,500 pounds in favorable years to 3,500 pounds in unfavorable years.

The production of forage on this soil is limited by wetness and the hazard of flooding. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

Figure 2.—Area of Clarkelen-Haverdad-Bigwinder complex, 0 to 3 percent slope, along Box Creek. This area supports scattered cottonwood trees.

The suitability of this soil for rangeland seeding is good. The main limitations are wetness and the hazard of flooding.

This unit is limited for livestock watering ponds and other water impoundments because of the seepage potential.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds. Cottonwood trees commonly provide important riparian habitat for birds and small mammals.

This unit is poorly suited to homesite development. The main limitations are the hazard of flooding and wetness. Construction of dikes reduces the risk of flooding. Use of septic tank absorption fields could create a hazard of polluting ground water.

This map unit is in capability subclass IVe. The Clarkelen and Haverdad soils are in the Lowland, 10- to 14-inch ppt., Northern Plains range site. The Bigwinder soil is in the Subirrigated, 10- to 14-inch ppt., Northern Plains range site.

110—Cushman-Terro complex, 0 to 6 percent slopes. This map unit is on pediment slopes of nearly level to undulating dissected uplands. Slopes are medium in length and are convex. The native vegetation is mainly grasses and shrubs.

This unit is 45 percent Cushman loam and 40 percent Terro sandy loam. The components of this unit are so intricately intermingled that it was not practical to map them separately at the scale used.

Included in this unit are small areas of Shingle clay loam in the more highly dissected areas. Also included are small areas of Hiland sandy loam. Included areas make up about 15 percent of the total acreage. The percentage varies from one area to another.

The Cushman soil is moderately deep and well drained. It formed in loamy residuum derived dominantly from calcareous shale and sandstone. Typically, the surface layer is brown loam about 4 inches thick. The upper 11 inches of the subsoil is yellowish brown and light yellowish brown clay loam, and the lower 18 inches

pale brown clay loam and very pale brown loam.
bedded sandstone and shale are at a depth of 33

Permeability of the Cushman soil is moderate. Available water capacity is moderate. Effective rooting depth is 20 to 40 inches. Runoff is medium, and the hazard of water erosion is moderate. The hazard of wind erosion is moderate.

The Terro soil is moderately deep and somewhat excessively drained. It formed in loamy residuum derived dominantly from calcareous sandstone. Typically, the surface layer is brown sandy loam about 4 inches thick. The upper 19 inches of the subsoil is brown and pale brown sandy loam, and the lower 11 inches is light gray sandy loam. Soft sandstone is at a depth of 34 inches. In some areas soft bedrock is at a depth of 40 to 60 inches or more.

Permeability of the Terro soil is moderately rapid. Available water capacity is low. Effective rooting depth is 20 to 40 inches. Runoff is slow, and the hazard of water erosion is moderate. The hazard of wind erosion is moderate.

This unit is used for livestock grazing and wildlife habitat.

The potential plant community on the Cushman soil is mainly western wheatgrass, thickspike wheatgrass, and needleandthread. As the range condition deteriorates, big sagebrush and blue grama increase. As the range condition further deteriorates, cacti, annuals, and broom sedge invade. The potential plant community produces about 1,500 pounds of air-dry vegetation in normal years. Production varies from 2,000 pounds in favorable years to 850 pounds in unfavorable years.

The potential plant community on the Terro soil is mainly needleandthread, prairie sandreed, Indian ricegrass, and little bluestem. As the range condition deteriorates, sageworts and needleleaf sedge increase. As the range condition further deteriorates, annuals and broom snakeweed invade. The potential plant community produces about 1,600 pounds of air-dry vegetation in normal years. Production varies from 2,100 pounds in favorable years to 1,000 pounds in unfavorable years.

The production of forage on this unit is limited by low annual precipitation. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of this unit for rangeland seeding is good. The main limitation is the hazard of wind erosion. Chiseling or other such practices can be used to improve areas of deteriorated rangeland. Such practices increase water infiltration, reduce plant competition, and allow the desirable native plants to increase. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

This unit is limited for livestock watering ponds and other water impoundments because of the seepage potential.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

If this unit is used for homesite development, the main limitations are depth to soft bedrock and shrink-swell potential. Backfilling excavations with coarser textured material helps to overcome the problem of shrink-swell potential. It may be necessary to construct a mounded absorption field to compensate for the restricted depth to bedrock.

This map unit is in capability subclass IVe. The Cushman soil is in the Loamy, 10- to 14-inch ppt., Northern Plains range site. The Terro soil is in the Sandy, 10- to 14-inch ppt., Northern Plains range site.

111—Cushman-Terro complex, 6 to 15 percent slopes. This map unit is on shoulder slopes and back slopes of rolling uplands. Slopes are short and convex. The native vegetation is mainly grasses and shrubs.

This unit is 55 percent Cushman loam and 30 percent Terro sandy loam. The components of this unit are so intricately intermingled that it was not practical to map them separately at the scale used.

Included in this unit are small areas of Shingle clay loam and Worf fine sandy loam on shoulder slopes. Also included are small areas of Hiland sandy loam on back slopes. Included areas make up about 15 percent of the total acreage. The percentage varies from one area to another.

The Cushman soil is moderately deep and well drained. It formed in loamy residuum derived dominantly from calcareous shale and sandstone. Typically, the surface layer is pale brown loam about 3 inches thick. The upper 14 inches of the subsoil is pale brown and light gray clay loam, and the lower 8 inches is pale yellow loam. Interbedded sandstone and shale are at a depth of 25 inches. In some areas soft bedrock is at a depth of 40 to 60 inches or more.

Permeability of the Cushman soil is moderate. Available water capacity is low. Effective rooting depth is 20 to 40 inches. Runoff is medium, and the hazard of water erosion is severe. The hazard of wind erosion is moderate.

The Terro soil is somewhat excessively drained. It formed in loamy residuum derived dominantly from calcareous sandstone. Typically, the surface layer is brown sandy loam about 4 inches thick. The upper 19 inches of the subsoil is brown and pale brown sandy loam, and the lower 11 inches is light gray sandy loam. Soft sandstone is at a depth of 34 inches. In some areas soft bedrock is at a depth of 40 to 60 inches or more.

Permeability of the Terro soil is moderately rapid. Available water capacity is low. Effective rooting depth is 20 to 40 inches. Runoff is slow, and the hazard of water

erosion is moderate. The hazard of wind erosion is moderate.

This unit is used for livestock grazing and wildlife habitat.

The potential plant community on the Cushman soil is mainly western wheatgrass, thickspike wheatgrass, and needleandthread. As the range condition deteriorates, big sagebrush and blue grama increase. As the range condition further deteriorates, cacti, annuals, and broom snakeweed invade. The potential plant community produces about 1,500 pounds of air-dry vegetation in normal years. Production varies from 2,000 pounds in favorable years to 850 pounds in unfavorable years.

The potential plant community on the Terro soil is mainly needleandthread, prairie sandreed, Indian ricegrass, and little bluestem. As the range condition deteriorates, sageworts and needleleaf sedge increase. As the range condition further deteriorates, annuals and broom snakeweed invade. The potential plant community produces about 1,600 pounds of air-dry vegetation in normal years. Production varies from 2,100 pounds in favorable years to 1,000 pounds in unfavorable years.

The production of forage on this unit is limited by low annual precipitation. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of this unit for rangeland seeding is fair. The main limitations are the hazards of wind and water erosion. Chiseling or other such practices can be used to improve areas of deteriorated rangeland. Such practices increase water infiltration, reduce plant competition, and allow the desirable native plants to increase. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

If this unit is used for homesite development, the main limitations are depth to soft bedrock, slope, and the moderate shrink-swell potential of the Cushman soil, which can be overcome by backfilling with coarser textured material. It may be necessary to construct a mounded absorption field to compensate for the limited depth to bedrock.

This map unit is in capability subclass VIe. The Cushman soil is in the Loamy, 10- to 14-inch ppt., Northern Plains range site. The Terro soil is in the Sandy, 10- to 14-inch ppt., Northern Plains range site.

112—Cushman-Worf association, 6 to 15 percent slopes. This map unit is on ridges, shoulder slopes, and back slopes of rolling uplands. Slopes are convex and are medium in length. The native vegetation is mainly grasses and shrubs.

This unit is 50 percent Cushman loam, 6 to 10 percent slopes, and 35 percent Worf fine sandy loam, 10 to 15 percent slopes. The Cushman soil is on back slopes, and the Worf soil is on ridges and shoulder slopes.

Included in this unit are small areas of Worfka fine sandy loam and Shingle loam intermingled with areas of the Worf soil. Also included are small areas of Forkwood sandy loam on concave slopes bordering areas of the Cushman soil. Included areas make up about 15 percent of the total acreage. The percentage varies from one area to another.

The Cushman soil is moderately deep and well drained. It formed in loamy residuum derived dominantly from interbedded sandstone and shale. Typically, the surface layer is pale brown loam about 3 inches thick. The upper 14 inches of the subsoil is pale brown and light gray clay loam, and the lower 8 inches is pale yellow loam. Interbedded shale and sandstone are at a depth of 25 inches.

Permeability of the Cushman soil is moderate. Available water capacity is low. Effective rooting depth is 20 to 40 inches. Runoff is medium to rapid, and the hazard of water erosion is severe. The hazard of wind erosion is moderate.

The Worf soil is shallow and well drained. It formed in residuum derived dominantly from calcareous shale. Typically, the surface layer is grayish brown fine sandy loam about 2 inches thick. The subsoil is brown and light yellowish brown sandy clay loam about 16 inches thick. Soft, calcareous shale is at a depth of 18 inches.

Permeability of the Worf soil is moderate. Available water capacity is low. Effective rooting depth is 8 to 20 inches. Runoff is medium to rapid, and the hazard of water erosion is severe. The hazard of wind erosion is moderate.

This unit is used for livestock grazing and wildlife habitat.

The potential plant community on the Cushman soil is mainly western wheatgrass, thickspike wheatgrass, and needleandthread. As the range condition deteriorates, big sagebrush and blue grama increase. As the range condition further deteriorates, cacti, annuals, and broom snakeweed invade. The potential plant community produces about 1,500 pounds of air-dry vegetation in normal years. Production varies from 2,000 pounds in favorable years to 850 pounds in unfavorable years. The production of forage is limited by low annual precipitation. The suitability of this soil for rangeland seeding is good.

The potential plant community on the Worf soil is mainly western wheatgrass, green needlegrass, and bluebunch wheatgrass. As the range condition deteriorates, birdfoot sagebrush and big sagebrush increase. As the range condition further deteriorates, broom snakeweed and annuals invade. The potential plant community produces about 900 pounds of air-dry vegetation in normal years. Production varies from 1,200

ground in favorable years to 450 pounds in unfavorable years.

The production of forage on this unit is limited by restricted rooting depth and droughtiness. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of this unit for rangeland seeding is poor. The main limitations are the limited rooting depth and the hazard of water erosion. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

This unit is limited for livestock watering ponds and other water impoundments because of the seepage potential.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

If this unit is used for homesite development, the main limitations are slope, depth to soft bedrock, and moderate shrink-swell potential. Backfilling excavations with coarser textured material helps to overcome the limitation of moderate shrink-swell potential. Construction of a mounded absorption field may be needed to compensate for the depth to rock.

This map unit is in capability subclass VIe. The Cushman soil is in the Loamy, 10- to 14-inch ppt., Northern Plains range site. The Worf soil is in the Shallow Clayey, 10- to 14-inch ppt., Northern Plains range site.

113—Dwyer-Orpha loamy sands, 3 to 15 percent slopes. This map unit is on undulating to rolling dunes superimposed on stream terraces and alluvial flats. Slopes are short and convex. The native vegetation is mainly grasses and shrubs.

This unit is 50 percent Dwyer loamy sand and 30 percent Orpha loamy sand. The components of this unit are so intricately intermingled that it was not practical to map them separately at the scale used.

Included in this unit are small areas of Keeline sandy loam, Vonalee loamy sand, and Hiland sandy loam in swales and other depressional areas. Included areas make up about 20 percent of the total acreage. The percentage varies from one area to another.

The Dwyer soil is deep and excessively drained. It is formed in sandy eolian material derived from mixed sources. Typically, the surface layer is brown loamy sand about 5 inches thick. The underlying material to a depth of 60 inches or more is pale brown loamy sand. Carbonates are within 40 inches of the surface. In some areas buried loamy strata are at a depth of 40 inches or more. In a few areas calcareous sandstone is at a depth of 20 to 60 inches.

Permeability of the Dwyer soil is rapid. Available water capacity is low. Effective rooting depth is 60 inches or

more. Runoff is slow, and the hazard of water erosion is moderate. The hazard of wind erosion is severe.

The Orpha soil is deep and excessively drained. It is formed in sandy eolian material derived from mixed sources. Typically, the surface layer is grayish brown loamy sand about 6 inches thick. The underlying material to a depth of 60 inches or more is light brownish gray sand. Carbonates are below a depth of 40 inches. In some areas buried loamy strata are at a depth of 40 inches or more.

Permeability of the Orpha soil is very rapid. Available water capacity is low. Effective rooting depth is 60 inches or more. Runoff is slow, and the hazard of water erosion is slight. The hazard of wind erosion is severe.

This unit is used for livestock grazing and wildlife habitat.

The potential plant community on this unit is mainly prairie sandreed, Indian ricegrass, needleandthread, and little bluestem. As the range condition deteriorates, sageworts and needleleaf sedge increase. If the vegetation further deteriorates, annuals and snakeweed invade. The potential plant community produces about 1,600 pounds of air-dry vegetation in normal years. Production varies from 2,100 pounds in favorable years to 1,000 pounds in unfavorable years.

The production of forage is limited by low annual precipitation. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of this unit for rangeland seeding is fair. The main limitations are the hazards of erosion by wind and water. Chiseling or other such practices can be used to improve areas of deteriorated rangeland. Such practices increase water infiltration, reduce plant competition, and allow the desirable native plants to increase. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment. This unit is limited for livestock watering ponds and other water impoundments because of the seepage potential.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

If this unit is used for homesite development, the main limitations are the hazard of excavations caving in, slope, and sand blowing.

This map unit is in capability subclass VIIe. It is in the Sandy, 10- to 14-inch ppt., Northern Plains range site. In some of the steeper areas are inclusions of Sands, 10- to 14-inch ppt., Northern Plains range site.

114—Forkwood-Cambria fine sandy loams, 0 to 6 percent slopes. This map unit is in nearly level to undulating areas of foot slopes and toe slopes of rolling

uplands. Slopes are long and plane. The native vegetation is mainly grasses and shrubs.

This unit is 55 percent Forkwood fine sandy loam and 30 percent Cambria fine sandy loam. The components of this unit are so intricately intermingled that it was not practical to map them separately at the scale used.

Included in this unit are small areas of Ulm loam and Zigweid clay loam. Included areas make up about 15 percent of the total acreage. The percentage varies from one area to another.

The Forkwood soil is deep and well drained. It formed in loamy local alluvium derived dominantly from calcareous shale. Typically, the surface layer is pale brown fine sandy loam about 7 inches thick. The upper 7 inches of the subsoil is pale brown clay loam, and the lower part to a depth of 60 inches or more is light brownish gray and light gray clay loam. In some areas bedrock is at a depth of 20 to 60 inches.

Permeability of the Forkwood soil is moderate. Available water capacity is high. Effective rooting depth is 60 inches or more. Runoff is slow, and the hazard of water erosion is slight. The hazard of wind erosion is moderate.

The Cambria soil is deep and well drained. It formed in loamy local alluvium and residuum derived dominantly from sedimentary rock. Typically, the surface layer is grayish brown fine sandy loam about 2 inches thick. The upper 8 inches of the subsoil is brown sandy clay loam, and the lower part to a depth of 60 inches or more is pale brown loam.

Permeability of the Cambria soil is moderate. Available water capacity is high. Effective rooting depth is 60 inches or more. Runoff is medium, and the hazard of water erosion is moderate. The hazard of wind erosion is moderate.

This unit is used for livestock grazing and wildlife habitat.

The potential plant community on this unit is mainly western wheatgrass, thickspike wheatgrass, and needleandthread. As the range condition deteriorates, big sagebrush and blue grama increase. As the range condition further deteriorates, cacti, annuals, and broom snakeweed invade. The potential plant community produces about 1,500 pounds of air-dry vegetation in normal years. Production varies from 2,000 pounds in favorable years to 850 pounds in unfavorable years.

The production of forage is limited by low annual precipitation. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of this unit for rangeland seeding is good. Chiseling or other such practices can be used to improve areas of deteriorated rangeland. Such practices increase water infiltration, reduce plant competition, and

allow the desirable native plants to increase. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

This unit is well suited to homesite development. It has few limitations. Backfilling excavations with coarser textured material helps to overcome the limitation of shrink-swell potential. Septic tank absorption fields operate most effectively if placed deep in the subsoil.

This map unit is in capability subclass IVe. It is in the Loamy, 10- to 14-inch ppt., Northern Plains range site.

115--Forkwood-Cambria-Cushman complex, 6 to 15 percent slopes. This map unit is on ridge crests, back slopes, and foot slopes of rolling uplands. Slopes are short and are mostly convex. The native vegetation is mainly grasses and shrubs.

This unit is 30 percent Forkwood fine sandy loam, 30 percent Cambria sandy loam, and 30 percent Cushman loam. The components of this unit are so intricately intermingled that it was not practical to map them separately at the scale used.

Included in this unit are small areas of Ulm loam and Worf fine sandy loam. Included areas make up about 10 percent of the total acreage. The percentage varies from one area to another.

The Forkwood soil is deep and well drained. It formed in loamy local alluvium derived dominantly from calcareous shale. Typically, the surface layer is pale brown fine sandy loam about 5 inches thick. The upper 13 inches of the subsoil is light yellowish brown clay loam, and the lower part to a depth of 60 inches or more is pale yellow and light gray loam.

Permeability of the Forkwood soil is moderate. Available water capacity is high. Effective rooting depth is 60 inches or more. Runoff is medium, and the hazard of water erosion is moderate. The hazard of wind erosion is moderate.

The Cambria soil is deep and well drained. It formed in loamy local alluvium and residuum derived dominantly from sedimentary rock. Typically, the surface layer is brown sandy loam about 4 inches thick. The upper 4 inches of the subsoil is yellowish brown loam, and the lower part to a depth of 60 inches or more is pale brown loam.

Permeability of the Cambria soil is moderate. Available water capacity is high. Effective rooting depth is 60 inches or more. Runoff is medium, and the hazard of water erosion is severe. The hazard of wind erosion is moderate.

The Cushman soil is moderately deep and well drained. It formed in loamy residuum derived dominantly from calcareous shale. Typically, the surface layer is pale brown loam about 3 inches thick. The upper 14 inches of the subsoil is pale brown and light gray clay loam, and the lower 8 inches is pale yellow loam over

interbedded shale and sandstone. Soft bedrock is at a depth of 25 inches.

Permeability of the Cushman soil is moderate. Available water capacity is moderate. Effective rooting depth is 20 to 40 inches. Runoff is medium, and the hazard of water erosion is severe. The hazard of wind erosion is moderate.

This unit is used for livestock grazing and wildlife habitat.

The potential plant community on this unit is mainly western wheatgrass, thickspike wheatgrass, and needleandthread. As the range condition deteriorates, big sagebrush and blue grama increase. As the range condition further deteriorates, cacti, annuals, and broom snakeweed invade. The potential plant community produces about 1,500 pounds of air-dry vegetation in normal years. Production varies from 2,000 pounds in favorable years to 850 pounds in unfavorable years.

The production of forage is limited by low annual precipitation. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of this unit for rangeland seeding is fair. The main limitation is the hazard of water erosion. Chiseling or other such practices can be used to improve areas of deteriorated rangeland. Such practices increase water infiltration, reduce plant competition, and allow the desirable native plants to increase. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

If this unit is used for homesite development, the main limitations are moderate shrink-swell potential and the depth of the Cushman soil to soft bedrock. Backfilling excavations with coarser textured material helps to overcome the limitation of moderate shrink-swell potential. Septic tank absorption fields operate most effectively if placed deep in the subsoil of the Cambria and Forkwood soils; areas of the Cushman soil are not suitable for this use.

This map unit is in capability subclass VIe. It is in the Loamy, 10- to 14-inch ppt., Northern Plains range site.

116—Forkwood-Ulm complex, 0 to 6 percent slopes. This map unit is on foot slopes and toe slopes. Slopes are plane and are medium to long. The native vegetation is mainly grasses and shrubs.

This unit is 50 percent Forkwood fine sandy loam and 40 percent Ulm loam. The components of this unit are so intricately intermingled that it was not practical to map them separately at the scale used.

Included in this unit are small areas of Bidman sandy loam. Included areas make up about 10 percent of the

total acreage. The percentage varies from one area to another.

The Forkwood soil is deep and well drained. It formed in loamy local alluvium derived dominantly from calcareous shale. Typically, the surface layer is pale brown fine sandy loam about 7 inches thick. The upper inches of the subsoil is pale brown clay loam, and the lower part to a depth of 60 inches or more is light brownish gray and light gray clay loam. In some areas the subsoil is sandy clay loam.

Permeability of the Forkwood soil is moderate. Available water capacity is high. Effective rooting depth is 60 inches or more. Runoff is slow, and the hazard of water erosion is slight. The hazard of wind erosion is moderate.

The Ulm soil is deep and well drained. It formed in clayey local alluvium derived dominantly from calcareous shale. Typically, the surface layer is brown loam about 5 inches thick. The upper 16 inches of the subsoil is brown clay loam and clay, and the lower part to a depth of 60 inches or more is pale brown clay loam and light yellowish brown sandy clay loam.

Permeability of the Ulm soil is slow. Available water capacity is high. Effective rooting depth is 60 inches or more. Runoff is slow, and the hazard of water erosion is moderate. The hazard of wind erosion is slight.

This unit is used for livestock grazing and wildlife habitat.

The potential plant community on this unit is mainly western wheatgrass, thickspike wheatgrass, and needleandthread. As the range condition deteriorates, big sagebrush and blue grama increase. As the range condition further deteriorates, cacti, annuals, and broom snakeweed invade. The potential plant community produces about 1,500 pounds of air-dry vegetation in normal years. Production varies from 2,000 pounds in favorable years to 850 pounds in unfavorable years.

The production of forage is limited by low annual precipitation. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of this unit for rangeland seeding is good. Chiseling or other such practices can be used to improve areas of deteriorated rangeland. Such practices increase water infiltration, reduce plant competition, and allow the desirable native plants to increase. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

If this unit is used for homesite development, the main limitations are high shrink-swell potential and the slow permeability of the Ulm soil. Backfilling excavations with coarser textured material helps to overcome the

limitation of shrink-swell potential. Constructing a larger septic tank absorption field helps to compensate for the slow permeability of the Ulm soil. Absorption lines operate most effectively if they are placed deep in the subsoil.

This map unit is in capability subclass IVe. It is in the Loamy, 10- to 14-inch ppt., Northern Plains range site.

117—Forkwood-Ulm-Renohill complex, 6 to 15 percent slopes. This map unit is on foot slopes, back slopes, and ridges of rolling uplands. Slopes are short and are convex to plane. The native vegetation is mainly grasses and shrubs.

This unit is 35 percent Forkwood fine sandy loam, 30 percent Ulm clay loam, and 20 percent Renohill clay loam. The components of this unit are so intricately intermingled that it was not practical to map them separately at the scale used.

Included in this unit are small areas of Cushman loam, Bidman sandy loam, and Worfka fine sandy loam. Included areas make up about 15 percent of the total acreage. The percentage varies from one area to another.

The Forkwood soil is deep and well drained. It formed in loamy local alluvium derived dominantly from calcareous shale. Typically, the surface layer is pale brown fine sandy loam about 7 inches thick. The upper 7 inches of the subsoil is pale brown clay loam, and the lower part to a depth of 60 inches or more is light brownish gray and light gray clay loam.

Permeability of the Forkwood soil is moderate. Available water capacity is high. Runoff is medium, and the hazard of water erosion is moderate. Effective rooting depth is 60 inches or more. The hazard of wind erosion is moderate.

The Ulm soil is deep and well drained. It formed in clayey local alluvium derived dominantly from calcareous shale. Typically, the surface layer is light brownish gray clay loam about 4 inches thick. The upper 12 inches of the subsoil is brown clay loam, and the lower part to a depth of 60 inches or more is light gray clay loam.

Permeability of the Ulm soil is slow. Available water capacity is high to very high. Effective rooting depth is 60 inches or more. Runoff is medium, and the hazard of water erosion is severe. The hazard of wind erosion is slight.

The Renohill soil is moderately deep and well drained. It formed in clayey residuum derived dominantly from calcareous shale. Typically, the surface layer is light brownish gray clay loam about 5 inches thick. The subsoil is light brownish gray clay loam about 20 inches thick. Calcareous gritty shale is at a depth of 25 inches.

Permeability of the Renohill soil is slow. Available water capacity is low. Effective rooting depth is 20 to 40 inches. Runoff is medium, and the hazard of water erosion is severe. The hazard of wind erosion is slight.

This unit is used for livestock grazing and wildlife habitat.

The potential plant community on the Forkwood is mainly western wheatgrass, thickspike wheatgrass, a needleandthread. As the range condition deteriorates, big sagebrush and blue grama increase. As the range condition further deteriorates, cacti, annuals, and broom snakeweed invade. The potential plant community produces about 1,500 pounds of air-dry vegetation in normal years. Production varies from 2,000 pounds in favorable years to 850 pounds in unfavorable years.

The potential plant community on the Ulm and Renohill soils is mainly western wheatgrass, thickspike wheatgrass, and green needlegrass. As the range condition deteriorates, big sagebrush and blue grama increase. As the range condition further deteriorates, broom snakeweed and cacti invade. The potential plant community produces about 1,300 pounds of air-dry vegetation in normal years. Production varies from 1,800 pounds in favorable years to 750 pounds in unfavorable years.

The production of forage on this unit is limited by low annual precipitation. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of this unit for rangeland seeding is fair. The main limitation is the hazard of water erosion. Chiseling or other such practices can be used to improve areas of deteriorated rangeland. Such practices increase water infiltration, reduce plant competition, and allow the desirable native plants to increase. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

This unit is poorly suited to homesite development. The main limitations are high shrink-swell potential, slope, slow permeability of the Ulm and Renohill soils, and the depth of the Renohill soil to soft bedrock. Backfilling excavations with coarser textured material helps to overcome the limitation of shrink-swell potential. Constructing a larger absorption field helps to compensate for the slow permeability of the Ulm and Renohill soils. Absorption fields are most effective if they are placed deep in the subsoil of the Forkwood soil; the Renohill soil is not suitable for use as absorption fields.

This map unit is in capability subclass VIe. The Forkwood soil is in the Loamy, 10- to 14-inch ppt., Northern Plains range site. The Ulm and Renohill soils are in the Clayey, 10- to 14-inch ppt., Northern Plains range site.

118—Gateson Variant-Tassel Variant association, 10 to 45 percent slopes. This map unit is on upland

ges, shoulder slopes, and back slopes on the northern end of Pine Ridge. Slopes are convex and are medium in length. The native vegetation in the steeper areas is mainly conifers with an understory of grasses, and in the less sloping areas it is mainly grasses with scattered conifers. Sandstone and ironstone channery fragments and flagstones cover as much as 50 percent of the surface in some areas.

This unit is 45 percent Gateson Variant loamy sand and 35 percent Tassel Variant very fine sandy loam. The Gateson Variant soil is on steep back slopes, and the Tassel Variant soil is on ridges.

Included in this unit are small areas of Worf fine sandy loam, Tullock loamy sand, and Terro loamy fine sand. Included areas make up about 20 percent of the total acreage. The percentage varies from one area to another.

The Gateson Variant soil is shallow and well drained. It formed in loamy residuum derived dominantly from noncalcareous sandstone. Typically, the surface is covered with a mat of pine needles and other forest litter about 2 inches thick. The surface layer is pinkish gray loamy sand about 4 inches thick. The subsoil is reddish yellow sandy clay loam about 7 inches thick. The substratum is pinkish gray clay about 5 inches thick over soft, noncalcareous, interbedded sandstone and shale. Soft bedrock is at a depth of 15 to 24 inches.

Permeability of the Gateson Variant soil is moderate. Available water capacity is very low. Effective rooting depth is 10 to 20 inches. Runoff is rapid, and the hazard of water erosion is moderate. The hazard of wind erosion is severe.

The Tassel Variant soil is very shallow and well drained. It formed in loamy residuum derived dominantly from calcareous sandstone. Typically, the surface layer is light yellowish brown very fine sandy loam about 4 inches thick. The underlying material to a depth of 9 inches is gray loam. Soft, calcareous sandstone is at a depth of 9 inches.

Permeability of the Tassel Variant soil is moderate. Available water capacity is very low. Effective rooting depth is 5 to 10 inches. Runoff is rapid, and the hazard of water erosion is severe. The hazard of wind erosion is moderate.

Most areas of this unit are used for livestock grazing and wildlife habitat. A few areas are used as a source of wood products.

The Gateson Variant soil is poorly suited to the production of ponderosa pine. The site index for ponderosa pine ranges from 35 to 50. This soil can produce 12 cords per acre in a stand of trees that average 5 inches in diameter at a height of 1 foot. The main concerns in producing and harvesting timber are shallow soil depth, slow regeneration of trees, the hazard of erosion, and difficulty of harvesting on the steeper slopes. Plant competition delays natural regeneration but does not prevent the eventual development of a fully

stocked, normal stand of trees. The very low available water capacity generally influences seedling survival in areas where understory plants are numerous. Conventional methods of harvesting timber are difficult to use because of slope.

The potential understory plant community on the Gateson Variant soil is mainly Idaho fescue and yarrow. The woodland understory produces about 650 pounds of air-dry vegetation in normal years. Production varies from 800 pounds in favorable years to 400 pounds in unfavorable years.

The potential plant community on the Tassel Variant soil is mainly needleandthread, prairie sandreed, little bluestem, and bluebunch wheatgrass. As the range condition deteriorates, threadleaf sedge and fringed sagewort increase. As the range condition further deteriorates, broom snakeweed and annuals invade. The potential plant community produces about 1,300 pounds of air-dry vegetation in normal years. Production varies from 1,600 pounds in favorable years to 1,000 pounds in unfavorable years.

The production of forage on this soil is limited by restricted rooting depth and droughtiness. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of the Tassel Variant soil for rangeland seeding is poor. The main limitations are limited rooting depth and the hazards of erosion by wind and water. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

This unit is limited for livestock watering ponds and other water impoundments because of the seepage potential.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

This unit is poorly suited to homesite development. The main limitations are slope, shrink-swell potential, and depth to soft bedrock. Backfilling excavations with coarser textured material reduces the limitation of shrink-swell potential. Absorption fields should be constructed of selected material.

This map unit is in capability subclass VIIe. The Gateson Variant soil is not placed in a range site. The Tassel Variant soil is in the Shallow Sandy, 15- to 17-inch ppt., Northern Plains range site.

119—Gullied land. This map unit is in rolling to steep areas where gullies have downcut into friable soil material. The remaining soil material is shallow to deep and is well drained. It was derived from sedimentary residuum and local alluvium. Slopes are short and convex. This unit is essentially barren.

Typically, the original surface layer and subsoil have been lost through erosion. The remaining soil material is

10 to 60 inches thick or more over bedrock. Texture ranges from sandy loam to clay loam.

Included in this unit are small areas of Shingle clay loam, Theedle loam, Samday clay loam, and Savageton clay loam. Also included are small areas of exposed sandstone and shale. Included areas make up about 15 percent of the total acreage. The percentage varies from one area to another.

Permeability of the soil material in this unit is slow to moderate. Available water capacity is low to moderate. Effective rooting depth is 10 to 60 inches. Runoff is rapid, and the hazard of water erosion is severe. The hazard of wind erosion is moderate.

This unit is used mainly for wildlife habitat. The included areas are also used for livestock grazing.

The vegetation on the included areas in this unit provides some food for antelope, deer, small mammals, and birds.

This map unit is in capability subclass VIIIe. It is not placed in a range site.

120—Haverdad-Lohmiller complex, 0 to 6 percent slopes. This map unit is on flood plains. Slopes are short and plane. The native vegetation is mainly grasses, woody shrubs, and scattered cottonwood trees. This unit is subject to flooding during prolonged, high-intensity storms. Channeling and deposition are common along streambanks.

This unit is 50 percent Haverdad fine sandy loam and 50 percent Lohmiller clay loam. The components of this unit are so intricately intermingled that it was not practical to map them separately at the scale used.

Included in this unit are small areas of Draknab loamy sand on flood plains and small areas of Kishona loam and Bahl clay on alluvial flat remnants. Included areas make up about 20 percent of the total acreage. The percentage varies from one area to another.

The Haverdad soil is deep and well drained. It formed in loamy recently deposited alluvium derived dominantly from sedimentary rock. Typically, the surface layer is grayish brown fine sandy loam about 6 inches thick. The underlying material to a depth of 60 inches or more is light brownish gray loam with lenses of clay loam and fine sandy loam.

Permeability of the Haverdad soil is moderate. Available water capacity is high. Effective rooting depth is 60 inches or more. Runoff is slow, and the hazard of water erosion is slight. The hazard of wind erosion is moderate. A slight accumulation of soluble salts is in the surface layer and the upper part of the subsoil in some areas.

The Lohmiller soil is deep and well drained. It formed in stratified, clayey, recently deposited alluvium derived dominantly from shale. Typically, the surface layer is grayish brown clay loam about 3 inches thick. The next layer is brown clay 13 inches thick. Below this to a depth

of 60 inches or more is stratified, light yellowish brown and brown sandy clay loam, sandy loam, and sandy clay.

Permeability of the Lohmiller soil is slow to moderate. Available water capacity is moderate. Effective rooting depth is 60 inches or more. Runoff is medium, and the hazard of water erosion is moderate. The hazard of wind erosion is moderate.

This unit is used for livestock grazing and wildlife habitat.

The potential plant community on this unit is mainly green needlegrass, slender wheatgrass, needleandthread, and cottonwood trees. As the range condition deteriorates, woody plants such as snowberry, silver sagebrush, and rubber rabbitbrush increase. As the range condition further deteriorates, annual forbs and cheatgrass invade. The potential plant community produces about 2,500 pounds of air-dry vegetation in normal years. Production varies from 3,000 pounds in favorable years to 2,000 pounds in unfavorable years.

The production of forage is limited by low annual precipitation and the hazard of flooding. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of this unit for rangeland seeding is good. Chiseling or other such practices can be used to improve areas of deteriorated rangeland. Such practices increase water infiltration, reduce plant competition, or allow the desirable native plants to increase. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds. Cottonwood trees commonly provide important riparian habitat for birds and small mammals.

This unit is poorly suited to homesite development. The main limitations are the hazard of flooding and shrink-swell potential. Construction of dikes reduces the risk of flooding. Backfilling excavations with coarser textured material helps to overcome the limitation of shrink-swell potential.

This map unit is in capability subclass IVw. It is in the Lowland, 10- to 14-inch ppt., Northern Plains range site. In some areas are inclusions of Clayey Overflow, 10- to 14-inch ppt., Northern Plains range site.

121—Hiland-Bowbac sandy loams, 0 to 6 percent slopes. This map unit is on foot slopes and pediment slopes. Slopes are convex and are medium in length. The native vegetation is mainly grasses and shrubs.

This unit is 70 percent Hiland sandy loam and 30 percent Bowbac sandy loam. The components of this unit are so intricately intermingled that it was not practical to map them separately at the scale used.

Included in this unit are small areas of Ulm loam, Vonalee loamy sand, and Terro sandy loam. Included areas make up about 10 percent of the total acreage. The percentage varies from one area to another.

The Hiland soil is deep and well drained. It formed in loamy residuum, local alluvium, and eolian material derived dominantly from calcareous sandstone. Typically, the surface layer is pale brown sandy loam about 5 inches thick. The upper 25 inches of the subsoil is pale brown and light yellowish brown sandy clay loam, and the lower part to a depth of 60 inches or more is very pale brown sandy loam. In some areas the subsoil is loam or light clay loam.

Permeability of the Hiland soil is moderate. Available water capacity is moderate. Effective rooting depth is 60 inches or more. Runoff is slow, and the hazard of water erosion is slight. The hazard of wind erosion is moderate.

The Bowbac soil is moderately deep and well drained. It formed in loamy residuum derived dominantly from calcareous sandstone. Typically, the surface layer is brown sandy loam about 3 inches thick. The upper 15 inches of the subsoil is brown sandy clay loam, and the lower 18 inches is brown and light yellowish brown sandy loam. Soft, calcareous sandstone is at a depth of 36 inches. In some areas the subsoil is loam or light clay loam.

Permeability of the Bowbac soil is moderate. Available water capacity is low. Effective rooting depth is 20 to 40 inches. Runoff is medium, and the hazard of water erosion is moderate. The hazard of wind erosion is moderate.

Most areas of this unit are used for livestock grazing and wildlife habitat. A few areas where water is available from small reservoirs are used for irrigated alfalfa.

The potential plant community on this unit is mainly western wheatgrass, thickspike wheatgrass, and needleandthread. As the range condition deteriorates, big sagebrush and blue grama increase. As the range condition further deteriorates, cacti, annuals, and broom snakeweed invade. The potential plant community produces about 1,500 pounds of air-dry vegetation in normal years. Production varies from 2,000 pounds in favorable years to 850 pounds in unfavorable years.

The production of forage is limited by low annual precipitation. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of this unit for rangeland seeding is good. Chiseling or other such practices can be used to improve areas of deteriorated rangeland. Such practices increase water infiltration, reduce plant competition, and allow the desirable native plants to increase. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment. Alfalfa

yields average about 2.0 to 2.5 tons per acre with a moderate level of management.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

If this unit is used for homesite development, the limitation is depth to soft bedrock in the Bowbac soil. Areas of Hiland soil should be selected for absorption fields.

This map unit is in capability subclass IVe, irrigated and nonirrigated. It is in the Loamy, 10- to 14-inch ppt., Northern Plains range site.

122—Hiland-Bowbac complex, 6 to 15 percent slopes. This map unit is on ridges and back slopes of rolling uplands. Slopes are short and convex. The native vegetation is mainly grasses and shrubs.

This unit is 60 percent Hiland sandy clay loam and 30 percent Bowbac sandy loam. The components of this unit are so intricately intermingled that it was not practical to map them separately at the scale used.

Included in this unit are small areas of Vonalee loamy sand, Renohill clay loam, Terro sandy loam, and Worf fine sandy loam. Included areas make up about 10 percent of the total acreage. The percentage varies from one area to another.

The Hiland soil is deep and well drained. It formed in loamy residuum and eolian material derived dominantly from calcareous sandstone. Typically, the surface layer is brown sandy clay loam about 3 inches thick. The upper 21 inches of the subsoil is brown sandy loam and sandy clay loam, and the lower part to a depth of 60 inches or more is grayish brown and light brownish gray sandy loam and sandy clay loam. In some areas the subsoil is loam or light clay loam.

Permeability of the Hiland soil is moderate to moderately rapid. Available water capacity is moderate. Effective rooting depth is 60 inches or more. Runoff is medium, and the hazard of water erosion is moderate. The hazard of wind erosion is moderate.

The Bowbac soil is moderately deep and well drained. It formed in loamy residuum derived dominantly from calcareous sandstone. Typically, the surface layer is brown sandy loam about 4 inches thick. The upper 11 inches of the subsoil is brown and dark yellowish brown sandy clay loam, and the lower 13 inches is light yellowish brown fine sandy loam. Soft calcareous sandstone is at a depth of 28 inches. In some areas the subsoil is loam or light clay loam.

Permeability of the Bowbac soil is moderate. Available water capacity is low. Effective rooting depth is 20 to 40 inches. Runoff is medium, and the hazard of water erosion is moderate. The hazard of wind erosion is moderate.

This unit is used for livestock grazing and wildlife habitat.

The potential plant community on this unit is mainly western wheatgrass, thickspike wheatgrass, and

needleandthread. As the range condition deteriorates, big sagebrush and blue grama increase. As the range condition further deteriorates, cacti, annuals, and broom snakeweed invade. The potential plant community produces about 1,500 pounds of air-dry vegetation in normal years. Production varies from 2,000 pounds in favorable years to 850 pounds in unfavorable years.

The production of forage is limited by low annual precipitation. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of this unit for rangeland seeding is fair. The main limitation is the hazard of water erosion. Chiseling or other such practices can be used to improve areas of deteriorated rangeland. Such practices increase water infiltration, reduce plant competition, and allow the desirable native plants to increase. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

If this unit is used for homesite development, the main limitations are slope and the depth of the Bowbac soil to soft bedrock. Areas of the Bowbac soil are not suitable for absorption fields.

This map unit is in capability subclass VIe. It is in the Loamy, 10- to 14-inch ppt., Northern Plains range site.

123—Keeline-Tassel-Turnback complex, 6 to 15 percent slopes. This map unit is on rolling uplands. Slopes are short to medium in length and are mostly convex. The native vegetation is mainly grasses.

This unit is 35 percent Keeline sandy loam, 25 percent Tassel loamy fine sand, and 20 percent Turnback loamy fine sand. The components of this unit are so intricately intermingled that it was not practical to map them separately at the scale used.

Included in this unit are small areas of Tullock loamy sand, Orpha loamy sand, and Dwyer loamy sand on ridge crests and on lee slopes where windblown sand collects. Included areas make up about 20 percent of the total acreage. The percentage varies from one area to another.

The Keeline soil is deep and somewhat excessively drained. It formed in loamy, wind-worked residuum derived dominantly from calcareous sandstone. Typically, the surface layer is yellowish brown sandy loam about 3 inches thick. The subsoil is pale brown sandy loam about 5 inches thick. The underlying material to a depth of 60 inches or more is very pale brown sandy loam.

Permeability of the Keeline soil is moderately rapid. Available water capacity is moderate. Effective rooting depth is 60 inches or more. Runoff is slow, and the

hazard of water erosion is slight. The hazard of v erosion is moderate.

The Tassel soil is shallow and well drained. It is in loamy residuum derived dominantly from calcareous sandstone. Typically, the surface layer is light brownish gray loamy fine sand 2 inches thick. The underlying material to a depth of 16 inches is pale brown fine sandy loam. Soft sandstone is at a depth of 16 inches.

Permeability of the Tassel soil is moderately rapid. Available water capacity is very low. Effective rooting depth is 6 to 20 inches. Runoff is medium, and the hazard of water erosion is moderate. The hazard of wind erosion is severe.

The Turnback soil is moderately deep and well drained. It formed in loamy, wind-worked residuum derived dominantly from calcareous sandstone. Typically, the surface layer is pale brown loamy fine sand about 4 inches thick. The subsoil is light yellowish brown and pale yellow sandy loam about 26 inches thick. Soft sandstone is at a depth of 30 inches.

Permeability of the Turnback soil is moderately rapid. Available water capacity is very low to low. Effective rooting depth is 20 to 40 inches. Runoff is slow, and the hazard of water erosion is moderate. The hazard of wind erosion is severe.

This unit is used for livestock grazing and wildlife habitat.

The potential plant community on the Keeline and Turnback soils is mainly needleandthread, prairie sandreed, Indian ricegrass, and little bluestem. As range condition deteriorates, sageworts and need sedge increase. As the range condition further deteriorates, annuals and broom snakeweed invade. The potential plant community produces about 1,600 pounds of air-dry vegetation in normal years. Production varies from 2,100 pounds in favorable years to 1,000 pounds in unfavorable years.

The production of forage is limited by low annual precipitation. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of these soils for rangeland seeding is fair. The main limitation is the hazard of wind erosion. Chiseling or other such practices can be used to improve areas of deteriorated rangeland. Such practices increase water infiltration, reduce plant competition, and allow the desirable native plants to increase. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

These soils are limited for livestock watering ponds and other water impoundments because of the seepage potential.

The potential plant community on the Tassel soil is mainly needleandthread, prairie sandreed, Indian

ricegrass, and little bluestem. As the range condition deteriorates, threadleaf sedge and fringed sagewort increase. As the range condition further deteriorates, broom snakeweed and annuals invade. The potential plant community produces about 1,000 pounds of air-dry vegetation in normal years. Production varies from 1,400 pounds in favorable years to 600 pounds in unfavorable years.

The production of forage on this soil is limited by restricted rooting depth and droughtiness. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of this soil for rangeland seeding is poor. The main limitations are limited rooting depth and the hazards of wind and water erosion. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

This soil is limited for livestock watering ponds and other water impoundments because of the seepage potential.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

If the Keeline soil is used for homesite development, the main limitation is slope. The Tassel and Turnback soils are limited by depth to soft bedrock. They are not suitable for absorption fields.

This map unit is in capability subclass VIe. The Keeline and Turnback soils are in the Sandy, 10- to 14-inch ppt., Northern Plains range site. The Tassel soil is in the Shallow Sandy, 10- to 14-inch ppt., Northern Plains range site.

124—Kishona-Dwyer-Orpha association, 0 to 10 percent slopes. This map unit is on nearly level to undulating alluvial flats and gently rolling dunes superimposed on stream terraces. Slopes are long and plane or short and convex. The Kishona soils are on alluvial flats, and the Dwyer and Orpha soils are on terrace dunes. The native vegetation is mainly grasses.

This unit is 35 percent Kishona loam, 25 percent Dwyer loamy sand, and 15 percent Orpha loamy sand.

Included in this unit are small areas of Draknab loamy sand and Haverdad fine sandy loam on flood plains and Bahl clay on alluvial flats. Included areas make up about 25 percent of the total acreage. The percentage varies from one area to another.

The Kishona soil is deep and well drained. It formed in loamy local alluvium derived dominantly from calcareous shale. Typically, the surface layer is brown loam about 3 inches thick. The underlying material to a depth of 60 inches or more is light yellowish brown and light gray clay loam. Carbonates are disseminated throughout the soil.

Permeability of the Kishona soil is moderate. Available water capacity is high. Effective rooting depth is 60 inches or more. Runoff is medium, and the hazard of water erosion is moderate. The hazard of wind erosion is moderate.

The Dwyer soil is deep and excessively drained. It formed in eolian sand derived dominantly from mixed sources. Typically, the surface layer is brown loamy sand about 5 inches thick. The underlying material to a depth of 60 inches or more is pale brown loamy sand. Carbonates are at a depth of less than 40 inches.

Permeability of the Dwyer soil is rapid. Available water capacity is low. Effective rooting depth is 60 inches or more. Runoff is slow, and the hazard of water erosion is moderate. The hazard of wind erosion is severe.

The Orpha soil is deep and excessively drained. It formed in eolian sand derived from mixed sources. Typically, the surface layer is pale brown loamy sand about 5 inches thick. The underlying material to a depth of 60 inches or more is light yellowish brown loamy sand. Depth to carbonates is less than 40 inches.

Permeability of the Orpha soil is very rapid. Available water capacity is low. Effective rooting depth is 60 inches or more. Runoff is slow, and the hazard of water erosion is slight. The hazard of wind erosion is severe.

This unit is used for livestock grazing and wildlife habitat.

The potential plant community on the Kishona soil is mainly western wheatgrass, thickspike wheatgrass, and needleandthread. As the range condition deteriorates, big sagebrush and blue grama increase. As the range condition further deteriorates, cacti, annuals, and broom snakeweed invade. The potential plant community produces about 1,500 pounds of air-dry vegetation in normal years. Production varies from 2,000 pounds in favorable years to 850 pounds in unfavorable years.

The production of forage on the Kishona soil is limited by low annual precipitation. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of this soil for rangeland seeding is good. Chiseling or other such practices can be used to improve areas of deteriorated rangeland. Such practices increase water infiltration, reduce plant competition, and allow the desirable native plants to increase. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

The potential plant community on the Dwyer and Orpha soils is mainly prairie sandreed, sand bluestem, needleandthread, and Indian ricegrass. As the range condition deteriorates, sageworts increase. As the range condition further deteriorates, annuals and broom snakeweed invade. The potential plant community produces about 2,000 pounds of air-dry vegetation in

normal years. Production varies from 2,500 pounds in favorable years to 1,400 pounds in unfavorable years. The production of forage is limited by droughtiness. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of these soils for rangeland seeding is poor. The main limitations are the hazard of wind erosion and droughtiness. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

These soils are limited for livestock watering ponds and other water impoundments because of the seepage potential.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

If the Kishona soil is used for homesite development, the main limitation is moderate shrink-swell potential. If the Dwyer and Orpha soils are used for homesite development, the main limitations are the hazard of cutbanks caving in, sand blowing, and slope. Backfilling excavations with coarser textured material helps to overcome the limitation of shrink-swell potential in the Kishona soil.

The Kishona soil is in capability subclass IVe, and the Dwyer and Orpha soils are in capability subclass VIe.

The Kishona soil is in the Loamy, 10- to 14-inch ppt., Northern Plains range site. The Dwyer and Orpha soils are in the Sands, 10- to 14-inch ppt., Northern Plains range site.

125—Orella-Rock outcrop-Samday complex, 3 to 30 percent slopes. This map unit is on ridgetops, shoulders, and back slopes of undulating to steep uplands. Slopes are medium in length and are convex. The native vegetation is mainly grasses and forbs.

This unit is 35 percent Orella clay loam, 25 percent Rock outcrop, and 25 percent Samday clay loam. The components of this unit are so intricately intermingled that it was not practical to map them separately at the scale used.

Included in this unit are small areas of Shingle clay loam, Tassel sandy loam, and Theedle loam. Included areas make up about 15 percent of the total acreage. The percentage varies from one area to another.

The Orella soil is shallow and well drained. It formed in clayey residuum derived dominantly from sodic shale. The surface layer is light gray clay loam about 4 inches thick. The underlying material to a depth of 20 inches is light gray and light brownish gray clay. Fragmented shale is at a depth of 20 inches.

Permeability of the Orella soil is very slow. Available water capacity is very low. Effective rooting depth is 10 to 20 inches. Runoff is rapid, and the hazard of water

erosion is severe. The hazard of wind erosion is moderate.

Rock outcrop is exposures of multicolored, calcareous and noncalcareous, soft and moderately hard shale and siltstone.

The Samday soil is shallow and well drained. It formed in clayey residuum derived dominantly from calcareous shale. Typically, the surface layer is light brownish gray clay loam about 2 inches thick. The underlying material to a depth of 18 inches is light brownish gray clay. Soft shale is at a depth of 18 inches.

Permeability of the Samday soil is slow. Available water capacity is very low. Effective rooting depth is 6 to 20 inches. Runoff is rapid, and the hazard of water erosion is severe. The hazard of wind erosion is slight.

This unit is used for livestock grazing and wildlife habitat.

The potential plant community on this unit is mainly western wheatgrass, green needlegrass, and bluebunch wheatgrass. As the range condition deteriorates, birdfoot sagebrush and big sagebrush increase. As the range condition further deteriorates, broom snakeweed and annuals invade. The potential plant community produces about 900 pounds of air-dry vegetation in normal years. Production varies from 1,200 pounds in favorable years to 450 pounds in unfavorable years.

The production of forage is limited by restricted rooting depth and droughtiness. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of this unit for rangeland seeding is poor. The main limitations are limited rooting depth and the hazard of water erosion. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

This unit is limited for livestock watering ponds and other water impoundments because of the seepage potential.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

This unit is poorly suited to homesite development. The main limitations are high shrink-swell potential, slope, and depth to shale. Backfilling excavations with coarser textured material helps to overcome the limitation of shrink-swell potential.

This map unit is in capability subclass VIIe. The Orella and Samday soils are in the Shallow Clayey, 10- to 14-inch ppt., Northern Plains range site.

126—Pits, mine. This map unit consists of open pits and spoil material from small- and moderate-sized uranium operations. None of these areas are currently being mined, and reclamation plans have not been developed. These areas support little if any vegetation.

Open pits are vertical or very steep excavations into sedimentary rock consisting of rippable sandstone with some interbedded shale and coal seams. Physical and chemical properties of the pit wall and displaced spoil banks are highly variable. The spoil material is mixed, and it is extremely acid to moderately alkaline. The material commonly is sandy, but some layers are loamy and clayey.

Onsite investigation of individual areas is necessary to determine reclamation potential. Backfilling excavations and reshaping cut slopes reduce the risk of erosion. Backfilling with suitable topsoil aids revegetation.

127--Renohill-Worfka-Shingle complex, 0 to 6 percent slopes. This map unit is on upland summits and back slopes. Slopes are medium in length and are convex. The native vegetation is mainly grasses and shrubs.

This unit is 35 percent Renohill fine sandy loam, 30 percent Worfka fine sandy loam, and 20 percent Shingle clay loam. The components of this unit are so intricately intermingled that it was not practical to map them separately at the scale used.

Included in this unit are small areas of Samday clay loam, Worf fine sandy loam, and Bidman sandy loam. Included areas make up about 15 percent of the total acreage. The percentage varies from one area to another.

The Renohill soil is moderately deep and well drained. It formed in clayey residuum derived dominantly from soft shale. Typically, the surface layer is pale brown fine sandy loam about 5 inches thick. The upper 15 inches of the subsoil is brown clay, and the lower 16 inches is pale brown clay loam. Calcareous shale is at a depth of 36 inches. In some areas depth to soft bedrock ranges from 40 to 60 inches or more.

Permeability of the Renohill soil is slow. Available water capacity is moderate. Effective rooting depth is 20 to 40 inches. Runoff is medium, and the hazard of water erosion is moderate. The hazard of wind erosion is moderate.

The Worfka soil is shallow and well drained. It formed in clayey residuum derived dominantly from calcareous shale and sandstone. Typically, the surface layer is pale brown fine sandy loam about 6 inches thick. The upper 6 inches of the subsoil is light brownish gray clay, and the lower 6 inches is light yellowish brown clay loam. Soft interbedded shale and sandstone are at a depth of 18 inches.

Permeability of the Worfka soil is slow. Available water capacity is very low to low. Effective rooting depth is 7 to 20 inches. Runoff is medium, and the hazard of water erosion is moderate. The hazard of wind erosion is moderate.

The Shingle soil is shallow and well drained. It formed in loamy residuum derived dominantly from calcareous shale. Typically, the surface layer is light brownish gray

clay loam about 4 inches thick. The underlying material to a depth of 18 inches is light brownish gray clay loam. Soft shale is at a depth of 18 inches.

Permeability of the Shingle soil is moderate. Available water capacity is low. Effective rooting depth is 4 to 20 inches. Runoff is medium, and the hazard of water erosion is moderate. The hazard of wind erosion is slight.

This unit is used for livestock grazing, nonirrigated crops, and wildlife habitat.

The potential plant community on the Renohill soil is mainly western wheatgrass, thickspike wheatgrass, and needleandthread. As the range condition deteriorates, big sagebrush and blue grama increase. As the range condition further deteriorates, cacti, annuals, and brown snakeweed invade. The potential plant community produces about 1,500 pounds of air-dry vegetation in normal years. Production varies from 2,000 pounds in favorable years to 850 pounds in unfavorable years.

The production of forage on the Renohill soil is limited by low annual precipitation. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of this soil for rangeland seeding is good. Chiseling or other such practices can be used to improve areas of deteriorated rangeland. Such practices increase water infiltration, reduce plant competition, and allow the desirable native plants to increase. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

The potential plant community on the Worfka and Shingle soils is mainly western wheatgrass, bluebunch wheatgrass, needleandthread, and little bluestem. As the range condition deteriorates, blue grama and threadleaf sedge increase. As the range condition further deteriorates, broom snakeweed and cacti invade. The potential plant community produces about 900 pounds of air-dry vegetation in normal years. Production varies from 1,200 pounds in favorable years to 450 pounds in unfavorable years.

The production of forage is limited by restricted rooting depth and droughtiness. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of these soils for rangeland seeding is poor. The main limitations are limited rooting depth and the hazard of water erosion. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment. This unit is limited by livestock watering ponds and other water impoundments because of the seepage potential.

A few small, nearly level areas of this unit have a higher percentage of Renohill soil than is typical; these areas are used for nonirrigated wheat. Yield averages about 15 to 20 bushels per acre every other year with a moderate level of management. Because precipitation is not sufficient for annual cropping, a cropping system that includes small grain and summer fallow is most suitable. Crop residue left on or near the surface helps to conserve moisture, maintain tilth, and control erosion.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

This unit is poorly suited to homesite development. The main limitations are high shrink-swell potential and depth to soft bedrock. Backfilling excavations with coarser textured material helps to overcome the limitation of shrink-swell potential.

This map unit is in capability subclass VIe. The Renohill soil is in the Loamy, 10- to 14-inch ppt., Northern Plains range site. The Worfka and Shingle soils are in the Shallow Loamy, 10- to 14-inch ppt., Northern Plains range site.

128—Renohill-Worfka-Shingle complex, 6 to 15 percent slopes. This map unit is on back slopes of rolling uplands. Slopes are short to medium in length and are convex. The native vegetation is mainly grasses and shrubs.

This unit is 35 percent Renohill clay loam, 30 percent Worfka fine sandy loam, and 20 percent Shingle clay loam. The components of this unit are so intricately intermingled that it was not practical to map them separately at the scale used.

Included in this unit are small areas of Samday clay loam, Worf fine sandy loam, and Cushman loam. Included areas make up about 15 percent of the total acreage. The percentage varies from one area to another.

The Renohill soil is moderately deep and well drained. It formed in clayey residuum derived dominantly from soft shale. Typically, the surface layer is light brownish gray clay loam about 5 inches thick. The subsoil is light brownish gray clay loam 20 inches thick. Calcareous, gritty shale is at a depth of 25 inches. In some areas soft bedrock is at a depth of 40 to 60 inches or more.

Permeability of the Renohill soil is slow. Available water capacity is low. Effective rooting depth is 20 to 40 inches. Runoff is medium, and the hazard of water erosion is severe. The hazard of wind erosion is slight.

The Worfka soil is shallow and well drained. It formed in clayey residuum derived dominantly from calcareous shale and sandstone. Typically, the surface layer is grayish brown fine sandy loam about 3 inches thick. The upper 5 inches of the subsoil is pale brown clay, and the lower 6 inches is light yellowish brown clay loam. Interbedded shale and sandstone are at a depth of 14 inches.

Permeability of the Worfka soil is slow. Available water capacity is very low. Effective rooting depth is 7 to 20 inches. Runoff is medium, and the hazard of water erosion is moderate. The hazard of wind erosion is moderate.

The Shingle soil is shallow and well drained. It formed in loamy residuum derived dominantly from calcareous shale. Typically, the surface layer is light brownish gray clay loam about 4 inches thick. The underlying material to a depth of 18 inches is light brownish gray clay loam. Soft shale is at a depth of 18 inches.

Permeability of the Shingle soil is moderate. Available water capacity is low. Effective rooting depth is 4 to 20 inches. Runoff is medium, and the hazard of water erosion is severe. The hazard of wind erosion is slight.

This unit is used for livestock grazing and wildlife habitat.

The potential plant community on the Renohill soil is mainly western wheatgrass, green needlegrass, and thickspike wheatgrass. As the range condition deteriorates, big sagebrush and blue grama increase. As the range condition further deteriorates, cacti and broom snakeweed invade. The potential plant community produces about 1,300 pounds of air-dry vegetation in normal years. Production varies from 1,800 pounds in favorable years to 750 pounds in unfavorable years.

The production of forage on the Renohill soil is limited by low annual precipitation. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of this soil for rangeland seeding is fair. The main limitation is the hazard of water erosion. Chiseling or other such practices can be used to improve areas of deteriorated rangeland. Such practices increase water infiltration, reduce plant competition, and allow the desirable native plants to increase. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

The potential plant community on the Worfka soil is mainly western wheatgrass, green needlegrass, and bluebunch wheatgrass. As the range condition deteriorates, birdfoot sagebrush and big sagebrush increase. As the range condition further deteriorates, broom snakeweed and annuals invade. The potential plant community produces about 900 pounds of air-dry vegetation in normal years. Production varies from 1,200 pounds in favorable years to 450 pounds in unfavorable years.

The potential plant community on the Shingle soil is mainly western wheatgrass, bluebunch wheatgrass, needleandthread, and little bluestem. As the range condition deteriorates, blue grama and threadleaf sedge increase. As the range condition further deteriorates, broom snakeweed and cacti invade. The potential plant

community produces about 900 pounds of air-dry vegetation in normal years. Production varies from 1,200 pounds in favorable years to 450 pounds in unfavorable years.

The production of forage on the Worfka and Shingle soils is limited by restricted rooting depth and droughtiness. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of these soils for rangeland seeding is poor. The main limitations are limited rooting depth and the hazard of water erosion. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

This unit is limited for livestock watering ponds and other water impoundments because of the seepage potential.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

This unit is poorly suited to homesite development. The main limitations are high shrink-swell potential, slope, and depth to soft bedrock. Backfilling excavations with coarser textured material helps to overcome the limitation of shrink-swell potential.

This map unit is in capability subclass VIIe. The Renohill soil is in the Clayey, 10- to 14-inch ppt., Northern Plains range site. The Worfka soil is in the Shallow Clayey, 10- to 14-inch ppt., Northern Plains range site. The Shingle soil is in the Shallow Loamy, 10- to 14-inch ppt., Northern Plains range site.

129—Samday-Shingle-Worf complex, 3 to 15 percent slopes. This map unit is on summits and ridges of undulating to rolling uplands. Slopes are short and convex. The native vegetation is mainly grasses and forbs.

This unit is 30 percent Samday clay loam, 25 percent Shingle clay loam, and 25 percent Worf fine sandy loam. The components of this unit are so intricately intermingled that it was not practical to map them separately at the scale used.

Included in this unit are small areas of Worfka fine sandy loam, Renohill clay loam, and Theedle loam. Also included are small areas of Rock outcrop. Included areas make up about 20 percent of the total acreage. The percentage varies from one area to another.

The Samday soil is shallow and well drained. It formed in clayey residuum derived dominantly from calcareous shale. Typically, the surface layer is light brownish gray clay loam about 2 inches thick. The underlying material to a depth of 18 inches is light brownish gray clay. Soft shale is at a depth of 18 inches.

Permeability of the Samday soil is slow. Available water capacity is very low. Effective rooting depth is 6 to

20 inches. Runoff is rapid, and the hazard of water erosion is severe. The hazard of wind erosion is slight.

The Shingle soil is shallow and well drained. It formed in loamy residuum derived dominantly from calcareous shale. Typically, the surface layer is light brownish gray clay loam about 4 inches thick. The underlying material to a depth of 18 inches is light brownish gray clay loam. Soft shale is at a depth of 18 inches.

Permeability of the Shingle soil is moderate. Available water capacity is low. Effective rooting depth is 4 to 20 inches. Runoff is rapid, and the hazard of water erosion is severe. The hazard of wind erosion is slight.

The Worf soil is shallow and well drained. It formed in loamy residuum derived dominantly from interbedded shale and sandstone. Typically, the surface layer is grayish brown fine sandy loam about 2 inches thick. The subsoil is brown and light yellowish brown sandy clay loam about 16 inches thick. Soft shale is at a depth of 18 inches.

Permeability of the Worf soil is moderate. Available water capacity is low. Effective rooting depth is 8 to 20 inches. Runoff is medium, and the hazard of water erosion is moderate. The hazard of wind erosion is moderate.

This unit is used for livestock grazing and wildlife habitat.

The potential plant community on the Samday and Worf soils is mainly western wheatgrass, green needlegrass, and bluebunch wheatgrass. As the range condition deteriorates, birdfoot sagebrush and big sagebrush increase. As the range condition further deteriorates, broom snakeweed and annuals invade. The potential plant community produces about 900 pounds of air-dry vegetation in normal years. Production varies from 1,200 pounds in favorable years to 450 pounds in unfavorable years.

The potential plant community on the Shingle soil is mainly western wheatgrass, bluebunch wheatgrass, needleandthread, and little bluestem. As the range condition deteriorates, blue grama and threadleaf sedge increase. As the range condition further deteriorates, broom snakeweed and cacti invade. The potential plant community produces about 900 pounds of air-dry vegetation in normal years. Production varies from 1,200 pounds in favorable years to 450 pounds in unfavorable years.

The production of forage on this unit is limited by restricted rooting depth and droughtiness. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of this unit for rangeland seeding is poor. The main limitations are limited rooting depth and the hazard of water erosion. Areas that are heavily

infested with undesirable plants can be improved by chemical or mechanical treatment.

This unit is limited for livestock watering ponds and other water impoundments because of the seepage potential.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

This unit is poorly suited to homesite development. The main limitations are high shrink-swell potential, slope, and depth to shale. Backfilling excavations with coarser textured material helps to overcome the limitation of shrink-swell potential. Absorption fields should be constructed using selected material.

This map unit is in capability subclass VIIe. The Samday and Worf soils are in the Shallow Clayey, 10- to 14-inch ppt., Northern Plains range site. The Shingle soil is in the Shallow Loamy, 10- to 14-inch ppt., Northern Plains range site.

130—Sear-Wibaux complex, 0 to 15 percent slopes. This map unit is in nearly level areas on the summit of buttes and in undulating to rolling areas on shale uplands. Slopes are short and are plane to convex. The native vegetation is mainly grasses and forbs.

This unit is 45 percent Sear loam and 35 percent Wibaux channery loam. The components of this unit are so intricately intermingled that it was not practical to map them separately at the scale used.

Included in this unit are small areas of Shingle loam, Samday clay loam, and Rock outcrop. Included areas make up about 20 percent of the total acreage. The percentage varies from one area to another.

The Sear soil is very shallow and well drained. It formed in channery loamy residuum derived dominantly from fragmented porcellanite. Typically, the surface layer is pinkish gray loam about 2 inches thick. The subsoil is brown channery loam about 7 inches thick. Fragmented porcellanite with soil material partially filling voids in it is between depths of 9 and 60 inches or more.

Permeability of the Sear soil is moderate to a depth of 9 inches and very rapid below this depth. Available water capacity is low. Effective rooting depth is 5 to 10 inches. Runoff is medium, and the hazard of water erosion is moderate. The hazard of wind erosion is slight.

The Wibaux soil is shallow and somewhat excessively drained. It formed in channery loamy residuum derived dominantly from fragmented porcellanite. Typically, the surface layer is pinkish gray channery loam about 4 inches thick. The underlying material to a depth of 11 inches is light brown very channery loam. Fragmented porcellanite with soil material partially filling voids in it is between depths of 11 and 60 inches or more.

Permeability of the Wibaux soil is moderate to a depth of 11 inches and very rapid below this depth. Available water capacity is low. Effective rooting depth is 10 to 20 inches. Runoff is medium, and the hazard of water erosion is moderate. The hazard of wind erosion is slight.

This unit is used for livestock grazing and wildlife habitat.

The potential plant community on the Sear soil is mainly bluebunch wheatgrass, little bluestem, western wheatgrass, and needleandthread. As the range condition deteriorates, woody plants increase. As the range condition further deteriorates, annuals invade. The potential plant community produces about 600 pounds of air-dry vegetation in normal years. Production varies from 600 pounds in favorable years to 400 pounds in unfavorable years.

The potential plant community on the Wibaux soil is mainly western wheatgrass, bluebunch wheatgrass, needleandthread, and little bluestem. As the range condition deteriorates, blue grama and threadleaf sedge increase. As the range condition further deteriorates, broom snakeweed and cacti invade. The potential plant community produces about 900 pounds of air-dry vegetation in normal years. Production varies from 1,200 pounds in favorable years to 450 pounds in unfavorable years.

The production of forage on this unit is limited by restricted rooting depth and droughtiness. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of this unit for rangeland seeding is poor. The main limitations are limited rooting depth and the hazard of water erosion. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

This unit is limited for livestock watering ponds and other water impoundments because of the seepage potential.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

This unit is poorly suited to homesite development. The main limitation is depth to porcellanite fragments or soft bedrock. Absorption fields should be constructed using selected material.

This map unit is in capability subclass VIIe. The Sear soil is in the Very Shallow, 10- to 14-inch ppt., Northern Plains range site. The Wibaux soil is in the Shallow Loamy, 10- to 14-inch ppt., Northern Plains range site.

131—Shingle-Rock outcrop-Samday complex, 10 to 30 percent slopes. This map unit is on ridgetops, shoulders, and back slopes of rolling to steep uplands and on actively eroding escarpments. Slopes are medium in length and are convex. The native vegetation is mainly grasses and forbs.

This unit is 40 percent Shingle clay loam, 25 percent Rock outcrop, and 20 percent Samday clay loam. The components of this unit are so intricately intermingled

that it was not practical to map them separately at the scale used.

Included in this unit are small areas of Theedle loam and Tassel sandy loam. Also included are small areas of Shingle, thin solum, soils and Tassel, thin solum, soils that formed in neutral, interbedded shale and sandstone. Included areas make up about 15 percent of the total acreage. The percentage varies from one area to another.

The Shingle soil is shallow and well drained. It formed in loamy residuum derived dominantly from calcareous shale. Typically, the surface layer is pale brown clay loam about 4 inches thick. The underlying material to a depth of 13 inches is light brownish gray clay loam. Interbedded shale and sandstone are at a depth of 13 inches.

Permeability of the Shingle soil is moderate. Available water capacity is very low. Effective rooting depth is 4 to 20 inches. Runoff is rapid, and the hazard of water erosion is severe. The hazard of wind erosion is slight.

Rock outcrop is exposures of multicolored, calcareous and noncalcareous, soft to moderately hard shale and siltstone.

The Samday soil is shallow and well drained. It formed in clayey residuum derived dominantly from calcareous shale. Typically, the surface layer is light brownish gray clay loam about 2 inches thick. The underlying material to a depth of 18 inches is light brownish gray clay. Interbedded shale and sandstone are at a depth of 18 inches.

Permeability of the Samday soil is slow. Available water capacity is very low. Effective rooting depth is 6 to 20 inches. Runoff is rapid, and the hazard of water erosion is severe. The hazard of wind erosion is slight.

This unit is used for livestock grazing and wildlife habitat.

The potential plant community on the Shingle soil is mainly western wheatgrass, bluebunch wheatgrass, needleandthread, and little bluestem. As the range condition deteriorates, blue grama and threadleaf sedge increase. As the range condition further deteriorates, broom snakeweed and cacti invade. The potential plant community produces about 900 pounds of air-dry vegetation in normal years. Production varies from 1,200 pounds in favorable years to 450 pounds in unfavorable years.

The potential plant community on the Samday soil is mainly western wheatgrass, green needlegrass, and bluebunch wheatgrass. As the range condition deteriorates, birdfoot sagebrush and big sagebrush increase. As the range condition further deteriorates, broom snakeweed and annuals invade. The potential plant community produces about 900 pounds of air-dry vegetation in normal years. Production varies from 1,200 pounds in favorable years to 450 pounds in unfavorable years.

The production of forage on these soils is limited by restricted rooting depth and droughtiness. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community. The suitability of these soils for rangeland seeding is poor. The main limitations are limited rooting depth and the hazard of water erosion. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment. The soils are limited for livestock watering ponds and other water impoundments because of the seepage potential.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

This unit is poorly suited to homesite development. The main limitations are high shrink-swell potential, slope, and depth to soft bedrock. Backfilling excavations with coarser textured material reduces the shrink-swell potential. Absorption fields should be constructed using selected material.

This map unit is in capability subclass VIIe. The Shingle soil is in the Shallow Loamy, 10- to 14-inch ppt., Northern Plains range site. The Samday soil is in the Shallow Clayey, 10- to 14-inch ppt., Northern Plains range site. The included Tassel, thin solum, soil is a woodland soil.

132—Shingle, thin solum-Rock outcrop-Tassel, thin solum complex, cool, 6 to 45 percent slopes. This map unit is in rolling to steep areas on upland ridges, escarpments, and badlands along the eastern edge of the survey area. Slopes are medium in length and are convex. The native vegetation is mainly ponderosa pine and grasses with scattered junipers.

This unit is 35 percent Shingle loam, thin solum; 25 percent Rock outcrop; and 20 percent Tassel loamy fine sand, thin solum. The components of this unit are so intricately intermingled that it was not practical to map them separately at the scale used.

Included in this unit are small areas of Samday clay loam, Tullock loamy sand, and Vonalee loamy sand. Also included are small areas of Samday soils that are less than 10 inches thick. Included areas make up about 20 percent of the total acreage. The percentage varies from one area to another.

The Shingle soil is very shallow and well drained. It formed in loamy residuum derived from interbedded, noncalcareous shale and sandstone. Typically, the surface layer is light gray loam about 2 inches thick. The underlying material to a depth of 9 inches is grayish brown clay loam.

Permeability of the Shingle soil is moderate. Available water capacity is very low. Effective rooting depth is 4 to 10 inches. Runoff is rapid, and the hazard of water

erosion is severe. The hazard of wind erosion is moderate.

Rock outcrop is soft, mostly noncalcareous shale and sandstone with seams of coal and ironstone.

The Tassel soil is very shallow and well drained. It formed in loamy residuum derived dominantly from noncalcareous sandstone. Typically, the surface layer is pale brown loamy fine sand about 2 inches thick. The underlying material to a depth of 8 inches is light yellowish brown and light olive brown sandy loam. Depth to noncalcareous sandstone ranges from 5 to 10 inches.

Permeability of the Tassel soil is moderately rapid. Available water capacity is very low. Effective rooting depth is 5 to 10 inches. Runoff is medium, and the hazard of water erosion is moderate. The hazard of wind erosion is severe.

This unit is used for livestock grazing and wildlife habitat.

The Shingle and Tassel soils are poorly suited to the production of timber. The site index for ponderosa pine ranges from 20 to 30. These soils can produce 6 cords per acre in a stand of trees that average 5 inches in diameter at a height of 1 foot. The main concerns in producing and harvesting timber are the low density of the stands, the very shallow depth of the soils, slow regeneration, the hazard of erosion, and difficulty of harvesting. Plant competition delays natural regeneration but does not prevent the eventual development of a fully stocked, normal stand of trees. Minimizing the risk of erosion is essential in harvesting timber. The very low available water capacity generally influences seedling survival in areas where understory plants are numerous.

Conventional methods of harvesting timber are difficult because of slope.

The potential understory plant community on the Shingle and Tassel soils is mainly needleandthread, prairie sandreed, little bluestem, and bluebunch wheatgrass. As the range condition deteriorates, threadleaf sedge and fringed sagewort increase. As the range condition further deteriorates, annuals invade. The potential understory plant community produces about 600 pounds of air-dry vegetation in normal years. Production varies from 800 pounds in favorable years to 400 pounds in unfavorable years.

About 20 percent of this unit is scattered 5- to 10-acre clearings that support mainly range vegetation. The potential plant community in these clearings is mainly prairie sandreed, bluebunch wheatgrass, little bluestem, and western wheatgrass.

If the plant communities are overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community. Brush management improves deteriorated areas that are producing more woody shrubs than were present in the potential plant community. Livestock

grazing should be managed to protect the soil from excessive erosion.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

This unit is poorly suited to homesite development. The main limitations are slope and depth to soft bedrock. Mounded absorption fields should be constructed.

This map unit is in capability subclass VIIe. It is in woodland suitability group 2D1.

133—Shingle-Theedle-Cambria association, 6 to 30 percent slopes. This map unit is on ridge crests, back slopes, and pediment slopes of rolling to steep uplands. Slopes are medium in length and are convex. The native vegetation is mainly grasses and forbs.

This unit is 40 percent Shingle clay loam, 25 percent Theedle loam, and 25 percent Cambria sandy loam. The Shingle soil is in the more convex, moderately steep and steep areas. The Theedle and Cambria soils are in the less convex, moderately sloping areas.

Included in this unit are small areas of Samday clay loam and Rock outcrop. Included areas make up about 10 percent of the total acreage. The percentage varies from one area to another.

The Shingle soil is shallow and well drained. It formed in loamy residuum derived dominantly from calcareous shale. Typically, the surface layer is light brownish gray clay loam about 4 inches thick. The underlying material to a depth of 18 inches is light brownish gray clay loam. Soft shale is at a depth of 18 inches.

Permeability of the Shingle soil is moderate. Available water capacity is low. Effective rooting depth is 4 to 20 inches. Runoff is rapid, and the hazard of water erosion is severe. The hazard of wind erosion is slight.

The Theedle soil is moderately deep and well drained. It formed in loamy residuum derived dominantly from calcareous shale. Typically, the surface layer is pale brown loam about 5 inches thick. The underlying material to a depth of 23 inches is light gray loam and light brownish gray clay loam. Soft shale is at a depth of 28 inches. In some areas shale is at a depth of 40 to 60 inches or more.

Permeability of the Theedle soil is moderate. Available water capacity is moderate. Effective rooting depth is 20 to 40 inches. Runoff is rapid, and the hazard of water erosion is severe. The hazard of wind erosion is moderate.

The Cambria soil is deep and well drained. It formed in loamy local alluvium and residuum derived dominantly from shale and sandstone. Typically, the surface layer is brown sandy loam about 4 inches thick. The upper 4 inches of the subsoil is yellowish brown loam, and the lower part to a depth of 60 inches or more is pale brown and brown loam. In a few areas, bedrock is at a depth of 40 to 60 inches.

Permeability of the Cambria soil is moderate. Available water capacity is high. Effective rooting depth is 60

inches or more. Runoff is medium, and the hazard of water erosion is moderate. The hazard of wind erosion is moderate.

This unit is used for livestock grazing and wildlife habitat.

The potential plant community on the Shingle soil is mainly western wheatgrass, bluebunch wheatgrass, needleandthread, and little bluestem. As the range condition deteriorates, blue grama and threadleaf sedge increase. As the range condition further deteriorates, broom snakeweed and cacti invade. The potential plant community produces about 900 pounds of air-dry vegetation in normal years. Production varies from 1,200 pounds in favorable years to 450 pounds in unfavorable years.

The production of forage on the Shingle soil is limited by restricted rooting depth and droughtiness. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of this soil for rangeland seeding is poor. The main limitations are restricted rooting depth and the hazard of water erosion. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

This soil is limited for livestock watering ponds and other water impoundments because of the seepage potential.

The potential plant community on the Theedle and Cambria soils is mainly western wheatgrass, thickspike wheatgrass, and needleandthread. As the range condition deteriorates, big sagebrush and blue grama increase. As the range condition further deteriorates, cacti, annuals, and broom snakeweed invade. The potential plant community produces about 1,500 pounds of air-dry vegetation in normal years. Production varies from 2,000 pounds in favorable years to 850 pounds in unfavorable years.

The production of forage on Theedle and Cambria soils is limited by low annual precipitation. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of these soils for rangeland seeding is fair. The main limitation is the hazard of water erosion. Chiseling or other such practices can be used to improve areas of deteriorated rangeland. Such practices increase water infiltration, reduce plant competition, and allow the desirable native plants to increase. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

The Shingle soil is poorly suited to homesite development. The main limitations are moderate shrink-swell potential, slope, and depth to soft bedrock. If the Theedle soil is used for homesite development, the main limitations are moderate shrink-swell potential, slope, and depth to soft bedrock. If the Cambria soil is used for homesite development, the main limitations are slope and moderate shrink-swell potential. Backfilling excavations with coarser textured material helps to overcome the limitation of shrink-swell potential. Septic tank absorption lines in the Cambria soil operate best if placed deep in the subsoil. Areas of the Shingle and Theedle soils are not suitable for use as absorption fields.

The Shingle soil is in capability subclass VIIe, and the Theedle and Cambria soils are in capability subclass VIe, nonirrigated. The Shingle soil is in the Shallow Loamy, 10- to 14-inch ppt., Northern Plains range site. The Theedle and Cambria soils are in the Loamy, 10- to 14-inch ppt., Northern Plains range site.

134—Silhouette-Heldt association, 0 to 6 percent slopes. This map unit is in nearly level to undulating areas on alluvial flats, toe slopes, and foot slopes.

Slopes are long and are plane to slightly concave. The Silhouette soils are on foot slopes and the outer margins of alluvial flats, and the Heldt soils are on toe slopes and at the center of alluvial flats. The native vegetation is mainly grasses.

This unit is 50 percent Silhouette clay loam and 35 percent Heldt clay loam.

Included in this unit are small areas of Bidman sandy loam, Ulm loam, and Zigweid loam. Included areas make up about 15 percent of the total acreage. The percentage varies from one area to another.

The Silhouette soil is deep and well drained. It formed in clayey local alluvium derived dominantly from calcareous shale. Typically, the surface layer is light brownish gray clay loam about 2 inches thick. The upper part of the subsoil is pale brown clay about 20 inches thick, and the lower part to a depth of 48 inches or more is very pale brown clay and light gray clay loam. In a few areas, soft shale is at a depth of 20 to 40 inches.

Permeability of the Silhouette soil is slow. Available water capacity is high. Effective rooting depth is 40 to 60 inches or more. Runoff is medium, and the hazard of water erosion is moderate. The hazard of wind erosion is slight.

The Heldt soil is deep and well drained. It formed in clayey local alluvium derived dominantly from calcareous shale. Typically, the surface layer is light gray clay loam about 1 inch thick. The subsoil is light brownish gray clay about 18 inches thick. The substratum to a depth of 60 inches or more is pale brown and very pale brown clay. Cracks as much as 0.5 inch wide extend to a depth of 20 inches when the soil is dry.

Permeability of the Heldt soil is slow. Available water capacity is high. Effective rooting depth is 60 inches or more. Runoff is medium, and the hazard of water erosion is moderate. The hazard of wind erosion is moderate. This unit is used for livestock grazing and wildlife habitat.

The potential plant community on this unit is mainly western wheatgrass, green needlegrass, and thickspike wheatgrass. As the range condition deteriorates, big sagebrush and blue grama increase. As the range condition further deteriorates, cacti and broom snakeweed invade. The potential plant community produces about 1,300 pounds of air-dry vegetation in normal years. Production varies from 1,800 pounds in favorable years to 750 pounds in unfavorable years.

The production of forage is limited by low annual precipitation. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of this unit for rangeland seeding is good. Chisel plowing or other such practices can be used to improve areas of deteriorated rangeland. Such practices increase water infiltration, reduce plant competition, and allow the desirable native plants to increase. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

If this unit is used for homesite development, the main limitations are high shrink-swell potential and slow permeability. Backfilling excavations with coarser textured material reduces the shrink-swell potential. Constructing a larger absorption field helps to compensate for the slow permeability.

This unit is in capability subclass IVe. It is in the Clayey, 10- to 14-inch ppt., Northern Plains range site.

135—Tassel-Shingle complex, 6 to 30 percent slopes. This map unit is on ridgetops and shoulder slopes in undulating to steep areas on uplands and on partially stabilized escarpments. Slopes are medium in length and are convex. The native vegetation is mainly grasses and shrubs.

This unit is 50 percent Tassel fine sandy loam and 30 percent Shingle clay loam. The components of this unit are so intricately intermingled that it was not practical to map them separately at the scale used.

Included in this unit are small areas of Samday clay loam, Rock outcrop, Worf loamy sand, Worfka fine sandy loam, and Theedle loam. Also included are small areas of Gateson Variant and Tassel Variant soils along Pine Ridge and small areas of Shingle soils, thin solum, and Tassel soils, thin solum, along the eastern county line. Included areas make up about 20 percent of the total

acreage. The percentage varies from one area to another.

The Tassel soil is shallow and well drained. It forms in loamy residuum derived dominantly from calcareous sandstone. Typically, the surface layer is pale brown fine sandy loam about 3 inches thick. The underlying material to a depth of 14 inches is pale brown and light yellowish brown fine sandy loam. Soft sandstone is at a depth of 14 inches.

Permeability of the Tassel soil is moderately rapid. Available water capacity is very low. Effective rooting depth is 6 to 20 inches. Runoff is medium, and the hazard of water erosion is moderate. The hazard of wind erosion is moderate.

The Shingle soil is shallow and well drained. It formed in loamy residuum derived dominantly from calcareous shale. Typically, the surface layer is light brownish gray clay loam about 4 inches thick. The underlying material to a depth of 18 inches is light brownish gray clay loam. Soft shale is at a depth of 18 inches.

Permeability of the Shingle soil is moderate. Available water capacity is low. Effective rooting depth is 4 to 20 inches. Runoff is rapid, and the hazard of water erosion is severe. The hazard of wind erosion is slight.

This unit is used for livestock grazing and wildlife habitat.

The potential plant community on the Tassel soil is mainly needleandthread, prairie sandreed, Indian ricegrass, and little bluestem. As the range condition deteriorates, threadleaf sedge and fringed sagewort increase. As the range condition further deteriorates, broom snakeweed and annuals invade. The potential plant community produces about 1,000 pounds of air-dry vegetation in normal years. Production varies from 1,400 pounds in favorable years to 600 pounds in unfavorable years.

The potential plant community on the Shingle soil is mainly western wheatgrass, bluebunch wheatgrass, needleandthread, and little bluestem. As the range condition deteriorates, blue grama and threadleaf sedge increase. As the range condition further deteriorates, broom snakeweed and cacti invade. The potential plant community produces about 900 pounds of air-dry vegetation in normal years. Production varies from 1,200 pounds in favorable years to 450 pounds in unfavorable years.

The production of forage on this unit is limited by restricted rooting depth and droughtiness. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of this unit for rangeland seeding is poor. The main limitations are limited rooting depth and the hazards of wind and water erosion. Areas that are

heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

This unit is limited for livestock watering ponds and other water impoundments because of the seepage potential.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

This unit is poorly suited to homesite development. The main limitations are depth to soft bedrock and slope. Absorption fields should be constructed using selected material.

This map unit is in capability subclass VIIe. The Tassel soil is in the Shallow Sandy, 10- to 14-inch ppt., Northern Plains range site. The Shingle soil is in the Shallow Loamy, 10- to 14-inch ppt., Northern Plains range site.

136—Tassel-Terro-Rock outcrop complex, 15 to 30 percent slopes. This map unit is in hilly to steep areas on upland ridgetops, shoulder slopes, and back slopes. Slopes are convex and are medium in length. The native vegetation is mainly grasses and shrubs.

This unit is 40 percent Tassel loamy fine sand, 20 percent Terro sandy loam, and 20 percent Rock outcrop. The components of this unit are so intricately intermingled that it was not practical to map them separately at the scale used.

Included in this unit are small areas of Tullock loamy sand and Turnback loamy fine sand on the upper part of hill slopes and Keeline sandy loam on the lower part of hill slopes. Included areas make up about 20 percent of the total acreage. The percentage varies from one area to another.

The Tassel soil is shallow and well drained. It formed in loamy residuum derived dominantly from calcareous sandstone. Typically, the surface layer is grayish brown loamy fine sand about 2 inches thick. The underlying material to a depth of 16 inches is pale brown fine sandy loam. Soft calcareous sandstone is at a depth of 16 inches.

Permeability of the Tassel soil is moderately rapid. Available water capacity is very low. Effective rooting depth is 6 to 20 inches. Runoff is medium, and the hazard of water erosion is moderate. The hazard of wind erosion is severe.

The Terro soil is moderately deep and somewhat excessively drained. It formed in loamy residuum derived dominantly from calcareous sandstone. Typically, the surface layer is brown sandy loam about 4 inches thick. The upper 6 inches of the subsoil is brown sandy loam, and the lower 24 inches is pale brown and light gray sandy loam. Soft sandstone is at a depth of 34 inches. A few areas have soft bedrock at a depth of 40 to 60 inches or more.

Permeability of the Terro soil is moderately rapid. Available water capacity is low. Effective rooting depth is 20 to 40 inches. Runoff is slow, and the hazard of water

erosion is moderate. The hazard of wind erosion is moderate.

Rock outcrop is exposures of mostly soft, calcareous sandstone on knolls and narrow ridges.

This unit is used for livestock grazing and wildlife habitat.

The potential plant community on the Tassel soil is mainly needleandthread, prairie sandreed, Indian ricegrass, and little bluestem. As the range condition deteriorates, threadleaf sedge and fringed sagewort increase. As the range condition further deteriorates, broom snakeweed and annuals invade. The potential plant community produces about 1,000 pounds of air-dry vegetation in normal years. Production varies from 1,400 pounds in favorable years to 600 pounds in unfavorable years.

The potential plant community on the Terro soil is mainly needleandthread, prairie sandreed, Indian ricegrass, and little bluestem. As the range condition deteriorates, sageworts and needleleaf sedge increase. As the range condition further deteriorates, annuals and broom snakeweed invade. The potential plant community produces about 1,600 pounds of air-dry vegetation in normal years. Production varies from 2,100 pounds in favorable years to 1,000 pounds in unfavorable years.

The production of forage on this unit is limited by low annual precipitation and limited rooting depth. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of this unit for rangeland seeding is poor. The main limitations are the hazards of wind and water erosion. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

This unit is limited for livestock watering ponds and other water impoundments because of the seepage potential.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

This unit is poorly suited to homesite development. The main limitations are slope and depth to soft bedrock. Mounded septic tank absorption fields should be installed in the less sloping areas, and selected material should be used.

This map unit is in capability subclass VIIe. The Tassel soil is in the Shallow Sandy, 10- to 14-inch ppt., Northern Plains range site. The Terro soil is in the Sandy, 10- to 14-inch ppt., Northern Plains range site. Rock outcrop is not placed in a range site.

137—Tassel-Tullock-Vonalee association, 6 to 30 percent slopes. This map unit is on ridges and hill slopes in an area of rolling to steep uplands. Slopes are

medium in length and are convex. The native vegetation is mainly grasses and shrubs.

This unit is 40 percent Tassel loamy fine sand, 20 percent Tullock loamy sand, and 20 percent Vonalee loamy sand. The Tassel soil has slopes of 6 to 30 percent, the Tullock soil has slopes of 6 to 20 percent, and the Vonalee soil has slopes of 6 to 15 percent.

Included in this unit are small areas of Bowbac sandy loam, Turnback sandy loam, and Keeline sandy loam and small areas of sandstone Rock outcrop. Included areas make up about 20 percent of the total acreage. The percentage varies from one area to another.

The Tassel soil is shallow and well drained. It formed in loamy residuum derived dominantly from calcareous sandstone. Typically, the surface layer is grayish brown loamy fine sand about 2 inches thick. The underlying material to a depth of 16 inches is pale brown fine sandy loam. Soft calcareous sandstone is at a depth of 16 inches.

Permeability of the Tassel soil is moderately rapid. Available water capacity is very low. Effective rooting depth is 6 to 20 inches. Runoff is medium, and the hazard of water erosion is moderate. The hazard of wind erosion is severe.

The Tullock soil is moderately deep and excessively drained. It formed in sandy residuum derived dominantly from calcareous sandstone. Typically, the surface layer is brown loamy sand about 5 inches thick. The upper 15 inches of the underlying material is brown sand, and the lower part to a depth of 31 inches is pale brown loamy sand. Soft sandstone is at a depth of 31 inches. In a few areas, bedrock is at a depth of 40 to 60 inches or more.

Permeability of the Tullock soil is rapid. Available water capacity is very low to low. Effective rooting depth is 20 to 40 inches. Runoff is medium, and the hazard of water erosion is moderate. The hazard of wind erosion is severe.

The Vonalee soil is deep and somewhat excessively drained. It formed in loamy, wind-worked residuum derived dominantly from calcareous sandstone. Typically, the surface layer is dark grayish brown loamy sand about 3 inches thick. The upper 16 inches of the subsoil is light yellowish brown sandy loam, and the lower 5 inches is pale brown sandy loam. The substratum to a depth of 60 inches or more is pale brown loamy sand. In a few areas, soft bedrock is at a depth of 20 to 60 inches.

Permeability of the Vonalee soil is moderately rapid. Available water capacity is low. Effective rooting depth is 60 inches or more. Runoff is medium, and the hazard of water erosion is moderate. The hazard of wind erosion is severe.

This unit is used for livestock grazing and wildlife habitat.

The potential plant community on the Tassel soil is mainly needleandthread, prairie sandreed, Indian ricegrass, and little bluestem. As the range condition deteriorates, threadleaf sedge and fringed sagewort

increase. As the range condition further deteriorates, broom snakeweed and annuals invade. The potential plant community produces about 1,000 pounds of air-dry vegetation in normal years. Production varies from 1,400 pounds in favorable years to 600 pounds in unfavorable years.

The production of forage on the Tassel soil is limited by restricted rooting depth and droughtiness. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of the Tassel soil for rangeland seeding is poor. The main limitations are limited rooting depth and the hazards of erosion by wind and water. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

The Tassel soil is limited for livestock watering ponds and other water impoundments because of the seepage potential.

The potential plant community on the Tullock soil is mainly prairie sandreed, sand bluestem, needleandthread, and Indian ricegrass. As the range condition deteriorates, sageworts increase. As the range condition further deteriorates, annuals and broom snakeweed invade. The potential plant community produces about 2,000 pounds of air-dry vegetation in normal years. Production varies from 2,500 pounds in favorable years to 1,400 pounds in unfavorable years.

The production of forage on the Tullock soil is limited by droughtiness. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of the Tullock soil for rangeland seeding is poor. The main limitations are the hazard of wind erosion, droughtiness, and slope. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

The Tullock soil is limited for livestock watering ponds and other water impoundments because of the seepage potential.

The potential plant community on the Vonalee soil is mainly needleandthread, prairie sandreed, Indian ricegrass, and little bluestem. As the range condition deteriorates, sageworts and needleleaf sedge increase. As the range condition further deteriorates, annuals and broom snakeweed invade. The potential plant community produces about 1,600 pounds of air-dry vegetation in normal years. Production varies from 2,100 pounds in favorable years to 1,000 pounds in unfavorable years.

The production of forage on the Vonalee soil is limited by low annual precipitation. If the range is overgrazed, the proportion of preferred forage plants decreases and

the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of the Vonalee soil for rangeland seeding is fair. The main limitations are the hazards of wind and water erosion. Chiseling or other such practices can be used to improve areas of deteriorated rangeland. Such practices increase water infiltration, reduce plant competition, and allow the desirable native plants to increase. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

The Vonalee soil is limited for livestock watering ponds and other water impoundments because of the seepage potential.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

The Tassel and Tullock soils are poorly suited to homesite development. The main limitations are slope, depth to soft bedrock, and the hazard of sand blowing. If the Vonalee soil is used for homesite development, the main limitation is slope. Areas of the Vonalee soil are most suitable for use as septic tank absorption fields.

The Tassel soil is in capability subclass VIIe. The Tullock and Vonalee soils are in capability subclass VIe. The Tassel soil is in the Shallow Sandy, 10- to 14-inch ppt., Northern Plains range site. The Tullock soil is in the Sands, 10- to 14-inch ppt., Northern Plains range site. The Vonalee soil is in the Sandy, 10- to 14-inch ppt., Northern Plains range site.

138—Terro-Tullock-Orpha complex, 0 to 6 percent slopes. This map unit is in nearly level to undulating areas on upland summits and superimposed dunes. Slopes are short and convex. The native vegetation is mainly grasses and shrubs.

This unit is 35 percent Terro sandy loam, 30 percent Tullock loamy sand, and 20 percent Orpha loamy sand. The components of this unit are so intricately intermingled that it was not practical to map them separately at the scale used.

Included in this unit are small areas of Turnback sandy loam, Keeline sandy loam, and Bowbac sandy loam. Included areas make up about 15 percent of the total acreage. The percentage varies from one area to another.

The Terro soil is moderately deep and somewhat excessively drained. It formed in loamy residuum derived dominantly from calcareous sandstone. Typically, the surface layer is brown sandy loam about 4 inches thick. The upper 6 inches of the subsoil is brown sandy loam, and the lower 24 inches is pale brown and light gray sandy loam. Soft sandstone is at a depth of 34 inches. In a few areas, soft bedrock is at a depth of 40 to 60 inches or more.

Permeability of the Terro soil is moderately rapid. Available water capacity is low. Effective rooting depth is 20 to 40 inches. Runoff is slow, and the hazard of water erosion is moderate. The hazard of wind erosion is moderate.

The Tullock soil is moderately deep and excessively drained. It formed in sandy residuum derived dominantly from calcareous sandstone. Typically, the surface layer is brown loamy sand about 5 inches thick. The upper 15 inches of the underlying material is brown sand, and the lower part to a depth of 31 inches is pale brown loamy sand. Soft sandstone is at a depth of 31 inches.

Permeability of the Tullock soil is rapid. Available water capacity is very low. Effective rooting depth is 20 to 40 inches. Runoff is slow, and the hazard of water erosion is slight. The hazard of wind erosion is severe.

The Orpha soil is deep and excessively drained. It formed in eolian sand derived from mixed sources. Typically, the surface layer is pale brown loamy sand about 5 inches thick. The underlying material to a depth of 60 inches or more is light yellowish brown loamy sand. In some areas carbonates are above a depth of 40 inches.

Permeability of the Orpha soil is very rapid. Available water capacity is low. Effective rooting depth is 60 inches or more. Runoff is slow, and the hazard of water erosion is slight. The hazard of wind erosion is severe.

This unit is used for livestock grazing and wildlife habitat.

The potential plant community on the Terro soil is mainly needleandthread, prairie sandreed, Indian ricegrass, and little bluestem. As the range condition deteriorates, sageworts and needleleaf sedge increase. As the range condition further deteriorates, annuals and broom snakeweed invade. The potential plant community produces about 1,600 pounds of air-dry vegetation in normal years. Production varies from 2,100 pounds in favorable years to 1,000 pounds in unfavorable years.

The production of forage on the Terro soil is limited by low annual precipitation. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of the Terro soil for rangeland seeding is good. The main limitation is the hazard of wind erosion. Chiseling or other such practices can be used to improve areas of deteriorated rangeland. Such practices increase water infiltration, reduce plant competition, and allow the desirable native plants to increase. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

The Terro soil is limited for livestock watering ponds and other water impoundments because of the seepage potential.

The potential plant community on the Tullock and Orpha soils is mainly prairie sandreed, sand bluestem, needleandthread, and Indian ricegrass. As the range condition deteriorates, sageworts increase. As the range condition further deteriorates, annuals and broom snakeweed invade. The potential plant community produces about 2,000 pounds of air-dry vegetation in normal years. Production varies from 2,500 pounds in favorable years to 1,400 pounds in unfavorable years.

The production of forage on the Tullock and Orpha soils is limited by droughtiness. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of the Tullock and Orpha soils for rangeland seeding is poor. The main limitations are the hazard of wind erosion and droughtiness. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

The Tullock and Orpha soils are limited for livestock watering ponds and other water impoundments because of the seepage potential.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

If this unit is used for homesite development, the main limitations are depth to soft bedrock, the hazard of sand blowing, and the hazard of excavations caving in. Areas of the Orpha soil are most suitable for use as septic tank absorption fields.

This map unit is in capability subclass VIe. The Terro soil is in the Sandy, 10- to 14-inch ppt., Northern Plains range site. The Tullock and Orpha soils are in the Sands, 10- to 14-inch ppt., Northern Plains range site.

139—Terro-Tullock-Orpha complex, 6 to 15 percent slopes. This map unit is on ridgetops, shoulders, and back slopes of rolling uplands and on superimposed dunes. Slopes are short and convex. The native vegetation is mainly grasses and shrubs.

This unit is 35 percent Terro sandy loam, 30 percent Tullock loamy sand, and 20 percent Orpha loamy sand. The components of this unit are so intricately intermingled that it was not practical to map them separately at the scale used.

Included in this unit are small areas of Turnback sandy loam and Keeline sandy loam on ridges and shoulder slopes. Also included are small areas of Tassel loamy fine sand on ridgetops and Vonalee loamy sand on the lower part of hill slopes. Included areas make up about 15 percent of the total acreage. The percentage varies from one area to another.

The Terro soil is moderately deep and somewhat excessively drained. It formed in loamy residuum derived dominantly from calcareous sandstone. Typically, the surface layer is brown sandy loam about 4 inches thick.

The upper 6 inches of the subsoil is brown sandy loam, and the lower 24 inches is pale brown and light gray sandy loam. Soft sandstone is at a depth of 34 inches.

Permeability of the Terro soil is moderately rapid. Available water capacity is low. Effective rooting depth is 20 to 40 inches. Runoff is medium, and the hazard of water erosion is moderate. The hazard of wind erosion is moderate.

The Tullock soil is moderately deep and excessively drained. It formed in sandy residuum derived dominantly from calcareous sandstone. Typically, the surface layer is brown loamy sand about 5 inches thick. The upper 15 inches of the underlying material is brown sand, and the lower part to a depth of 31 inches is pale brown loamy sand. Soft sandstone is at a depth of 31 inches.

Permeability of the Tullock soil is rapid. Available water capacity is very low. Effective rooting depth is 20 to 40 inches. Runoff is slow, and the hazard of water erosion is slight. The hazard of wind erosion is severe.

The Orpha soil is deep and excessively drained. It formed in eolian sand derived from mixed sources. Typically, the surface layer is pale brown loamy sand about 5 inches thick. The underlying material to a depth of 60 inches or more is light yellowish brown loamy sand. In a few areas, carbonates are above a depth of 40 inches.

Permeability of the Orpha soil is very rapid. Available water capacity is low. Effective rooting depth is 60 inches or more. Runoff is slow, and the hazard of water erosion is slight. The hazard of wind erosion is severe.

This unit is used for livestock grazing and wildlife habitat.

The potential plant community on the Terro soil is mainly needleandthread, prairie sandreed, Indian ricegrass, and little bluestem. As the range condition deteriorates, sageworts and needleleaf sedge increase. As the range condition further deteriorates, annuals and broom snakeweed invade. The potential plant community produces about 1,600 pounds of air-dry vegetation in normal years. Production varies from 2,100 pounds in favorable years to 1,000 pounds in unfavorable years.

The production of forage on the Terro soil is limited by low annual precipitation. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of the Terro soil for rangeland seeding is fair. The main limitations are the hazards of wind and water erosion. Chiseling or other such practices can be used to improve areas of deteriorated rangeland. Such practices increase water infiltration, reduce plant competition, and allow the desirable native plants to increase. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

The Terro soil is limited for livestock watering ponds and other water impoundments because of the seepage potential.

The potential plant community on the Tullock and Orpha soils is mainly prairie sandreed, sand bluestem, needleandthread, and Indian ricegrass. As the range condition deteriorates, sageworts increase. As the range condition further deteriorates, annuals and broom snakeweed invade. The potential plant community produces about 2,000 pounds of air-dry vegetation in normal years. Production varies from 2,500 pounds in favorable years to 1,400 pounds in unfavorable years.

The production of forage on the Tullock and Orpha soils is limited by droughtiness. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of these soils for rangeland seeding is poor. The main limitations are the hazard of wind erosion and droughtiness. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

These soils are limited for livestock watering ponds and other water impoundments because of the seepage potential.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

If this unit is used for homesite development, the main limitations are depth to soft bedrock and the hazard of excavations caving in. Areas of the Terro and Tullock soils are not suitable for use as septic tank absorption fields.

This map unit is in capability subclass VIe. The Terro soil is in the Sandy, 10- to 14-inch ppt., Northern Plains range site. The Tullock and Orpha soils are in the Sands, 10- to 14-inch ppt., Northern Plains range site.

140—Theedle-Kishona association, 0 to 6 percent slopes. This map unit is in nearly level to undulating areas on alluvial flats, foot slopes, and toe slopes adjacent to rolling uplands. Slopes are medium to long in length and are slightly convex. The native vegetation is mainly grasses.

This unit is 45 percent Theedle loam and 35 percent Kishona loam. The Theedle soil is in the more convex areas, and the Kishona soil is in the more nearly plane areas.

Included in this unit are small areas of Cambria fine sandy loam, Bahl clay, and Cushman loam. Included areas make up about 20 percent of the total acreage. The percentage varies from one area to another.

The Theedle soil is moderately deep and well drained. It formed in loamy residuum derived dominantly from calcareous shale. Typically, the surface layer is pale brown loam about 5 inches thick. The underlying material

to a depth of 28 inches is light gray loam and light brownish gray clay loam. Soft shale is at a depth of 28 inches.

Permeability of the Theedle soil is moderate. Available water capacity is low. Effective rooting depth is 20 inches. Runoff is medium, and the hazard of water erosion is moderate. The hazard of wind erosion is moderate.

The Kishona soil is deep and well drained. It formed in loamy local residuum derived dominantly from calcareous shale. Typically, the surface layer is brown loam about 3 inches thick. The underlying material to a depth of 60 inches or more is light yellowish brown and light gray clay loam.

Permeability of the Kishona soil is moderate. Available water capacity is high. Effective rooting depth is 60 inches or more. Runoff is medium, and the hazard of water erosion is moderate. The hazard of wind erosion is moderate.

This unit is used for livestock grazing and wildlife habitat.

The potential plant community on this unit is mainly western wheatgrass, thickspike wheatgrass, and needleandthread. As the range condition deteriorates, big sagebrush and blue grama increase. As the range condition further deteriorates, cacti, annuals, and broom snakeweed invade. The potential plant community produces about 1,500 pounds of air-dry vegetation in normal years. Production varies from 2,000 pounds in favorable years to 850 pounds in unfavorable years.

The production of forage on this unit is limited by low annual precipitation. If the range is overgrazed, the proportion of preferred forage plants decreases and proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of this unit for rangeland seeding is good. Chiseling or other such practices can be used to improve areas of deteriorated rangeland. Such practices increase water infiltration, reduce plant competition, and allow the desirable native plants to increase. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

If this unit is used for homesite development, the main limitations are depth of the Theedle soil to soft bedrock and moderate shrink-swell potential. Backfilling excavations with coarser textured material helps to overcome the limitation of shrink-swell potential. Areas of the Kishona soil are most suitable for use as septic tank absorption fields.

This map unit is in capability subclass IVe. It is in the Loamy, 10- to 14-inch ppt., Northern Plains range site.

141—Theedle-Kishona association, 6 to 15 percent slopes. This map unit is on pediment slopes in areas of rolling uplands and on alluvial fans adjacent to upland escarpments. Slopes are short and convex. The native vegetation is mainly grasses.

This unit is 55 percent Theedle loam and 25 percent Kishona loam. The Theedle soil is in the more convex areas, and the Kishona soil is in the more nearly level areas.

Included in this unit are small areas of Cambria sandy loam, Savageton clay loam, and Shingle clay loam. Included areas make up about 20 percent of the total acreage. The percentage varies from one area to another.

The Theedle soil is moderately deep and well drained. It formed in loamy residuum derived dominantly from calcareous shale. Typically, the surface layer is pale brown loam about 5 inches thick. The underlying material to a depth of 28 inches is light gray loam and light brownish gray clay loam. Soft shale is at a depth of 28 inches.

Permeability of the Theedle soil is moderate. Available water capacity is low. Effective rooting depth is 20 to 40 inches. Runoff is medium, and the hazard of water erosion is severe. The hazard of wind erosion is moderate.

The Kishona soil is deep and well drained. It formed in loamy local alluvium derived dominantly from calcareous shale. Typically, the surface layer is brown loam about 3 inches thick. The underlying material to a depth of 60 inches or more is light yellowish brown and light gray clay loam.

Permeability of the Kishona soil is moderate. Available water capacity is high. Effective rooting depth is 60 inches or more. Runoff is medium, and the hazard of water erosion is severe. The hazard of wind erosion is moderate.

This unit is used for livestock grazing and wildlife habitat.

The potential plant community on this unit is mainly western wheatgrass, thickspike wheatgrass, and needleandthread. As the range condition deteriorates, big sagebrush and blue grama increase. As the range condition further deteriorates, cacti, annuals, and broom snakeweed invade. The potential plant community produces about 1,500 pounds of air-dry vegetation in normal years. Production varies from 2,000 pounds in favorable years to 850 pounds in unfavorable years.

The production of forage on this unit is limited by low annual precipitation. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of this unit for rangeland seeding is fair. The main limitation is the hazard of water erosion.

Chiseling or other such practices can be used to improve areas of deteriorated rangeland. Such practices increase water infiltration, reduce plant competition, and allow desirable native plants to increase. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

If this unit is used for homesite development, the main limitations are slope, depth of the Theedle soil to soft bedrock, and moderate shrink-swell potential. Backfilling excavations with coarser textured material reduces the limitation of shrink-swell potential. Areas of the Kishona soil are more suitable for use as septic tank absorption fields.

This map unit is in capability subclass VIe. It is in the Loamy, 10- to 14-inch ppt., Northern Plains range site.

142—Ulm-Bidman complex, 0 to 6 percent slopes.

This map unit is on alluvial flats and in level to undulating areas on foot slopes and toe slopes. Slopes are long and are plane to concave. The native vegetation is mainly grasses and shrubs.

This unit is 45 percent Ulm clay loam and 40 percent Bidman sandy loam. The components of this unit are so intricately intermingled that it was not practical to map them separately at the scale used.

Included in this unit are small areas of Forkwood fine sandy loam, Bahi clay, and Absted fine sandy loam. Included areas make up about 15 percent of the total acreage. The percentage varies from one area to another.

The Ulm soil is deep and well drained. It formed in clayey local alluvium derived dominantly from calcareous shale. Typically, the surface layer is pale brown clay loam about 4 inches thick. The upper 13 inches of the subsoil is pale brown clay and pale brown clay loam, and the lower part to a depth of 60 inches or more is light yellowish brown clay loam.

Permeability of the Ulm soil is slow. Available water capacity is high. Effective rooting depth is 60 inches or more. Runoff is slow, and the hazard of water erosion is moderate. The hazard of wind erosion is slight.

The Bidman soil is deep and well drained. It formed in clayey local alluvium derived dominantly from calcareous shale. Typically, the surface layer is light brownish gray sandy loam about 3 inches thick. The subsurface layer is pale brown sandy loam about 4 inches thick. The upper 13 inches of the subsoil is light brownish gray clay, and the lower 28 inches is light brownish gray clay loam. The substratum to a depth of 60 inches or more is light brownish gray clay loam.

Permeability of the Bidman soil is slow. Available water capacity is high. Effective rooting depth is 60 inches or more. Runoff is medium, and the hazard of water erosion is moderate. The hazard of wind erosion is moderate.

This unit is used for livestock grazing and wildlife habitat.

The potential plant community on the Ulm soil is mainly western wheatgrass, green needlegrass, and thickspike wheatgrass. As the range condition deteriorates, big sagebrush and blue grama increase. As the range condition further deteriorates, cacti and broom snakeweed invade. The potential plant community produces about 1,300 pounds of air-dry vegetation in normal years. Production varies from 1,800 pounds in favorable years to 750 pounds in unfavorable years.

The potential plant community on the Bidman soil is mainly western wheatgrass, thickspike wheatgrass, and needleandthread. As the range condition deteriorates, big sagebrush and blue grama increase. As the range condition further deteriorates, cacti, annuals, and broom snakeweed invade. The potential plant community produces about 1,500 pounds of air-dry vegetation in normal years. Production varies from 2,000 pounds in favorable years to 850 pounds in unfavorable years.

The production of forage on this unit is limited by low annual precipitation. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of this unit for rangeland seeding is good. Chiseling or other such practices can be used to improve areas of deteriorated rangeland. Such practices increase water infiltration, reduce plant competition, and allow the desirable native plants to increase. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

This unit is poorly suited to homesite development. The main limitations are high shrink-swell potential and slow permeability. Backfilling excavations with coarser textured material reduces the limitation of shrink-swell potential. Constructing a larger absorption field helps to compensate for the slow permeability.

This map unit is in capability subclass IVe. The Ulm soil is in the Clayey, 10- to 14-inch ppt., Northern Plains range site. The Bidman soil is in the Loamy, 10- to 14-inch ppt., Northern Plains range site.

143—Ulm-Renohill complex, 0 to 6 percent slopes.

This map unit is in nearly level to undulating areas on foot slopes and toe slopes. Slopes are medium to long in length and are plane to concave. The native vegetation is mainly grasses and shrubs.

This unit is 50 percent Ulm loam and 40 percent Renohill fine sandy loam. The components of this unit are so intricately intermingled that it was not practical to map them separately at the scale used.

Included in this unit are small areas of Forkwood fine sandy loam, Zigweid clay loam, and Cambria fine sandy loam. Included areas make up about 10 percent of the total acreage. The percentage varies from one area to another.

The Ulm soil is deep and well drained. It formed clayey local alluvium derived dominantly from calcareous shale. Typically, the surface layer is brown loam about 5 inches thick. The upper 16 inches of the subsoil is brown clay loam and clay, and the lower part to a depth of 60 inches or more is pale brown clay loam and light yellowish brown sandy clay loam. In some areas the surface layer is sandy loam.

Permeability of the Ulm soil is slow. Available water capacity is high. Effective rooting depth is 60 inches or more. Runoff is slow, and the hazard of water erosion is moderate. The hazard of wind erosion is slight.

The Renohill soil is moderately deep and well drained. It formed in clayey residuum derived dominantly from calcareous shale. Typically, the surface layer is pale brown fine sandy loam about 5 inches thick. The upper 15 inches of the subsoil is brown clay, and the lower 16 inches is pale brown clay loam. Calcareous shale is at a depth of 36 inches. In some areas the surface layer is thinner than is typical and has an abrupt boundary with the subsoil.

Permeability of the Renohill soil is slow. Available water capacity is moderate. Effective rooting depth is 20 to 40 inches. Runoff is medium, and the hazard of water erosion is moderate. The hazard of wind erosion is moderate.

This unit is used for livestock grazing and wildlife habitat.

The potential plant community on the Ulm soil is mainly western wheatgrass, green needlegrass, and thickspike wheatgrass. As the range condition deteriorates, big sagebrush and blue grama increase. As the range condition further deteriorates, cacti and broom snakeweed invade. The potential plant community produces about 1,300 pounds of air-dry vegetation in normal years. Production varies from 1,800 pounds in favorable years to 750 pounds in unfavorable years.

The potential plant community on the Renohill soil is mainly western wheatgrass, thickspike wheatgrass, and needleandthread. As the range condition deteriorates, big sagebrush and blue grama increase. As the range condition further deteriorates, cacti, annuals, and broom snakeweed invade. The potential plant community produces about 1,500 pounds of air-dry vegetation in normal years. Production varies from 2,000 pounds in favorable years to 850 pounds in unfavorable years.

The production of forage on this unit is limited by low annual precipitation. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that

the desired balance of preferred species is maintained in a plant community.

The suitability of this unit for rangeland seeding is good. Chiseling or other such practices can be used to improve areas of deteriorated rangeland. Such practices increase water infiltration, reduce plant competition, and allow the desirable native plants to increase. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

If this unit is used for homesite development, the main limitations are high shrink-swell potential, slow permeability, and the depth of the Renohill soil to soft bedrock. Backfilling excavations with coarser textured material helps to overcome the limitation of shrink-swell potential. Constructing a larger septic tank absorption field helps to compensate for the slow permeability. Areas of the Renohill soil are not suitable for use as septic tank absorption fields.

This map unit is in capability subclass IVe. The Ulm soil is in the Clayey, 10- to 14-inch ppt., Northern Plains range site. The Renohill soil is in the Loamy, 10- to 14-inch ppt., Northern Plains range site.

144—Ulm-Renohill clay loams, 6 to 15 percent slopes. This map unit is on ridges and hill slopes in areas of rolling uplands and on adjacent foot slopes. Slopes are short and convex. The native vegetation is mainly grasses and shrubs.

This unit is 45 percent Ulm clay loam and 45 percent Renohill clay loam. The components of this unit are so intricately intermingled that it was not practical to map them separately at the scale used.

Included in this unit are small areas of Shingle clay loam and Worfka fine sandy loam. Included areas make up about 10 percent of the total acreage. The percentage varies from one area to another.

The Ulm soil is deep and well drained. It formed in clayey local alluvium derived dominantly from calcareous shale. Typically, the surface layer is light brownish gray clay loam about 4 inches thick. The upper 12 inches of the subsoil is brown clay loam, and the lower part to a depth of 60 inches or more is light gray clay loam. In some areas the surface layer is sandy loam, and in some areas the subsoil is sandy clay.

Permeability of the Ulm soil is slow. Available water capacity is high. Effective rooting depth is 60 inches or more. Runoff is medium, and the hazard of water erosion is severe. The hazard of wind erosion is slight.

The Renohill soil is moderately deep and well drained. It formed in clayey residuum derived dominantly from calcareous shale. Typically, the surface layer is light brownish gray clay loam about 5 inches thick. The subsoil is light brownish gray clay loam about 20 inches thick. Calcareous, gritty shale is at a depth of 25 inches. In some areas the surface layer is sandy loam.

Permeability of the Renohill soil is moderately slow. Available water capacity is low. Effective rooting depth is 20 to 40 inches. Runoff is medium, and the hazard of water erosion is severe. The hazard of wind erosion is slight.

This unit is used for livestock grazing and wildlife habitat.

The potential plant community on this unit is mainly western wheatgrass, green needlegrass, and thickspike wheatgrass. As the range condition deteriorates, big sagebrush and blue grama increase. As the range condition further deteriorates, cacti and broom snakeweed invade. The potential plant community produces about 1,300 pounds of air-dry vegetation in normal years. Production varies from 1,800 pounds in favorable years to 750 pounds in unfavorable years.

The production of forage is limited by low annual precipitation. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of this unit for rangeland seeding is fair. The main limitation is the hazard of water erosion. Chiseling or other such practices can be used to improve areas of deteriorated rangeland. Such practices increase water infiltration, reduce plant competition, and allow the desirable native plants to increase. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

If this unit is used for homesite development, the main limitations are high shrink-swell potential, slow permeability, slope, and the depth of the Renohill soil to soft bedrock. Backfilling excavations with coarser textured material reduces the limitation of shrink-swell potential. Constructing a larger absorption field helps to compensate for the slow permeability. Areas of the Renohill soil are not suitable for use as septic tank absorption fields.

This map unit is in capability subclass VIe. It is in the Clayey, 10- to 14-inch ppt., Northern Plains range site.

145—Ustic Torriorthents, reclaimed, 3 to 30 percent slopes. These deep, well drained soils consist of reclaimed areas around coal and uranium strip mines and porcellanite borrow areas. They formed in an overburden derived from mining operations.

Typically, the profile to a depth of 60 inches or more is strong brown to light gray loamy sand to clay loam. In some areas layers of rearranged coal and shale are at a depth of less than 60 inches.

Permeability of these soils is slow to moderately rapid. Available water capacity is low to moderate. Effective rooting depth is 60 inches or more. Runoff is medium to

rapid, and the hazard of water erosion is severe. The hazard of wind erosion is slight to severe.

This unit is used for livestock grazing and wildlife habitat.

A common plant community on this unit is mainly western wheatgrass, thickspike wheatgrass, big sagebrush, and fourwing saltbush. As the range condition deteriorates, Russian-thistle, cheatgrass, buffalobur, Kochia, and Japanese brome increase.

This unit responds well to fertilizer, range seeding, and proper grazing use. The main limitation for seeding is the reaction of the soil, which ranges from 3.8 to 8.4 in various layers. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment. Management practices suitable for use on this unit include proper range use, deferred grazing, mowing, rotation grazing, and aerial spraying for brush management. Livestock grazing should be managed to protect the soil from excessive erosion.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

This map unit is in capability subclass VIe. It is not placed in a range site.

146—Vonalee-Terro complex, 0 to 6 percent slopes. This map unit is in nearly level to gently sloping areas on pediment slopes adjacent to rolling uplands and on stream terraces. Slopes are medium to long in length and are plane to slightly convex. The native vegetation is mainly grasses and shrubs.

This unit is 50 percent Vonalee loamy sand and 35 percent Terro sandy loam. The components of this unit are so intricately intermingled that it was not practical to map them separately at the scale used.

Included in this unit are small areas of Hiland sandy loam, Turnback sandy loam, and Keeline sandy loam. Included areas make up about 15 percent of the total acreage. The percentage varies from one area to another.

The Vonalee soil is deep and somewhat excessively drained. It formed in loamy, wind-worked residuum and local alluvium derived from mixed sources. Typically, the surface layer is yellowish brown loamy sand about 4 inches thick. The upper 20 inches of the subsoil is yellowish brown and grayish brown sandy loam. The subsoil to a depth of 60 inches or more is brown loamy sand and light brownish gray sandy clay loam. In some areas soft sandstone is at a depth of 40 to 60 inches.

Permeability of the Vonalee soil is moderately rapid. Available water capacity is moderate. Effective rooting depth is 60 inches or more. Runoff is slow, and the hazard of water erosion is slight. The hazard of wind erosion is severe.

The Terro soil is moderately deep and somewhat excessively drained. It formed in loamy residuum derived dominantly from calcareous sandstone. Typically, the surface layer is brown sandy loam about 4 inches thick.

The upper 6 inches of the subsoil is brown sandy loam, and the lower 24 inches is pale brown and light gray sandy loam. Soft, calcareous sandstone is at a depth of 34 inches.

Permeability of the Terro soil is moderately rapid. Available water capacity is low. Effective rooting depth is 20 to 40 inches. Runoff is slow, and the hazard of water erosion is moderate. The hazard of wind erosion is moderate.

This unit is used for livestock grazing and wildlife habitat.

The potential plant community on this unit is mainly needleandthread, prairie sandreed, Indian ricegrass, and little bluestem. As the range condition deteriorates, sageworts and needleleaf sedge increase. As the range condition further deteriorates, annuals and broom snakeweed invade. The potential plant community produces about 1,600 pounds of air-dry vegetation in normal years. Production varies from 2,100 pounds in favorable years to 1,000 pounds in unfavorable years.

The production of forage is limited by low annual precipitation. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of this unit for rangeland seeding is fair. The main limitation is the hazard of wind erosion. Chiseling or other such practices can be used to improve areas of deteriorated rangeland. Such practices increase water infiltration, reduce plant competition, and allow the desirable native plants to increase. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

If this unit is used for homesite development, the main limitations are the depth of the Terro soil to soft bedrock and the hazard of excavations caving in. Areas of the Vonalee soil are more suitable for use as septic tank absorption fields.

This map unit is in capability subclass IVe. It is in the Sandy, 10- to 14-inch ppt., Northern Plains range site.

147—Vonalee-Terro complex, 6 to 15 percent slopes. This map unit is on ridges and back slopes of rolling uplands. Slopes are short and convex. The native vegetation is mainly grasses and shrubs.

This unit is 45 percent Vonalee loamy sand and 40 percent Terro sandy loam. The components of this unit are so intricately intermingled that it was not practical to map them separately at the scale used.

Included in this unit are small areas of Bowbac sandy loam, Turnback sandy loam, and Keeline sandy loam. Included areas make up about 15 percent of the total

crease. The percentage varies from one area to another.

The Vonalee soil is deep and somewhat excessively drained. It formed in loamy wind-worked residuum derived dominantly from calcareous sandstone. Typically, the surface layer is dark grayish brown loamy sand about 3 inches thick. The upper 16 inches of the subsoil is light yellowish brown sandy loam, and the lower 5 inches is pale brown sandy loam. The substratum to a depth of 60 inches or more is pale brown sandy loam.

Permeability of the Vonalee soil is moderately rapid. Available water capacity is moderate. Effective rooting depth is 60 inches or more. Runoff is slow, and the hazard of water erosion is moderate. The hazard of wind erosion is severe.

The Terro soil is moderately deep and somewhat excessively drained. It formed in loamy residuum derived dominantly from calcareous sandstone. Typically, the surface layer is brown sandy loam about 4 inches thick. The upper 6 inches of the subsoil is brown sandy loam, and the lower 24 inches is pale brown and light gray sandy loam and loamy sand. Soft, calcareous sandstone is at a depth of 34 inches.

Permeability of the Terro soil is moderately rapid. Available water capacity is low. Effective rooting depth is 20 to 40 inches. Runoff is slow, and the hazard of water erosion is moderate. The hazard of wind erosion is moderate.

This unit is used for livestock grazing and wildlife habitat.

The potential plant community on this unit is mainly needleandthread, prairie sandreed, Indian ricegrass, and little bluestem. As the range condition deteriorates, clover and needleleaf sedge increase. As the range condition further deteriorates, annuals and broom snakeweed invade. The potential plant community produces about 1,600 pounds of air-dry vegetation in normal years. Production varies from 2,100 pounds in favorable years to 1,000 pounds in unfavorable years.

The production of forage is limited by low annual precipitation. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of this unit for rangeland seeding is fair. The main limitations are the hazards of wind and water erosion. Chiseling or other such practices can be used to improve areas of deteriorated rangeland. Such practices increase water infiltration, reduce plant competition, and allow the desirable native plants to increase. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

This unit is limited for livestock watering ponds and other water impoundments because of the seepage potential.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

If this unit is used for homesite development, the main limitations are slope, depth of the Terro soil to soft bedrock, and the hazard of excavations caving in. Areas of the Vonalee soil are more suitable for use as septic tank absorption fields.

This map unit is in capability subclass VIe. It is in the Sandy, 10- to 14-inch ppt., Northern Plains range site.

148—Wibaux-Rock outcrop-Shingle complex, 6 to 45 percent slopes. This map unit is on steep porcellanite-capped buttes and rolling shale uplands. Slopes are short to medium in length and are plane to convex. The native vegetation is mainly grasses and forbs.

This unit is 35 percent Wibaux channery loam, 30 percent Rock outcrop, and 20 percent Shingle clay loam. The components of this unit are so intricately intermingled that it was not practical to map them separately at the scale used.

Included in this unit are small areas of Renohill clay loam and Sear loam. Included areas make up about 15 percent of the total acreage. The percentage varies from one area to another.

The Wibaux soil is shallow and somewhat excessively drained. It formed in channery residuum derived dominantly from fragmented porcellanite. Typically, the surface layer is pinkish gray channery loam about 4 inches thick. The underlying material to a depth of 11 inches is light brown very channery loam. Fragmented porcellanite in which soil partially fills voids is at a depth of 11 to 60 inches or more.

Permeability of the Wibaux soil is moderate to a depth of 11 inches and very rapid below this depth. Available water capacity is very low. Effective rooting depth is 10 to 20 inches. Runoff is medium, and the hazard of water erosion is moderate. The hazard of wind erosion is slight.

Rock outcrop is exposures of shale and siltstone on scarp slopes.

The Shingle soil is shallow and well drained. It formed in loamy residuum derived dominantly from shale. Typically, the surface layer is pale brown clay loam about 4 inches thick. The underlying material to a depth of 13 inches is light brownish gray clay loam. Soft, interbedded shale and sandstone are at a depth of 13 inches.

Permeability of the Shingle soil is moderate. Available water capacity is very low. Effective rooting depth is 4 to 20 inches. Runoff is rapid, and the hazard of water erosion is severe. The hazard of wind erosion is slight.

This unit is used for livestock grazing and wildlife habitat.

The potential plant community on the Wibaux and Shingle soils is mainly western wheatgrass, bluebunch wheatgrass, needleandthread, and little bluestem. As the range condition deteriorates, blue grama and threadleaf sedge increase. As the range condition further

deteriorates, broom snakeweed and cacti invade. The potential plant community produces about 900 pounds of air-dry vegetation in normal years. Production varies from 1,200 pounds in favorable years to 450 pounds in unfavorable years.

The production of forage is limited by restricted rooting depth and droughtiness. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of these soils for rangeland seeding is poor. The main limitations are restricted rooting depth and the hazard of water erosion. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

These soils are limited for livestock watering ponds and other water impoundments because of the seepage potential.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

This unit is poorly suited to homesite development. The main limitation is the depth to soft bedrock or fragmented porcellanite. Septic tank absorption fields should be constructed using selected material.

This map unit is in capability subclass VIII. The Wibaux soil is in the Shallow Loamy, 10- to 14-inch ppt., Northern Plains range site. Rock outcrop is not assigned a range site. The Shingle soil is in the Shallow Loamy, 10- to 14-inch ppt., Northern Plains range site.

149—Worf-Shingle-Tassel complex, 3 to 30 percent slopes. This map unit is on ridgetops and shoulder slopes of undulating to steep uplands and on partially stabilized escarpments. Slopes are medium in length and are convex. The native vegetation is mainly grasses and shrubs.

This unit is 35 percent Worf loamy sand, 30 percent Shingle clay loam, and 20 percent Tassel fine sandy loam. The components of this unit are so intricately intermingled that it was not practical to map them separately at the scale used.

Included in this unit are small areas of Theedle loam, Cushman loam, Samday clay loam, and Worfka fine sandy loam. Included areas make up about 15 percent of the total acreage. The percentage varies from one area to another.

The Worf soil is shallow and well drained. It formed in loamy residuum derived dominantly from interbedded shale and sandstone. Typically, the surface layer is light brownish gray loamy sand about 5 inches thick. The subsoil is brown and yellowish brown clay loam about 10 inches thick. Calcareous shale and sandstone are at a depth of 15 inches.

Permeability of the Worf soil is moderate. Available water capacity is very low. Effective rooting depth is 8 to

20 inches. Runoff is medium, and the hazard of water erosion is moderate. The hazard of wind erosion is severe.

The Shingle soil is shallow and well drained. It formed in loamy residuum derived dominantly from calcareous shale. Typically, the surface layer is light brownish gray clay loam about 4 inches thick. The underlying material to a depth of 18 inches is light brownish gray clay loam. Soft shale is at a depth of 18 inches.

Permeability of the Shingle soil is moderate. Available water capacity is low. Effective rooting depth is 4 to 20 inches. Runoff is rapid, and the hazard of water erosion is severe. The hazard of wind erosion is slight.

The Tassel soil is shallow and well drained. It formed in loamy residuum derived dominantly from calcareous sandstone. Typically, the surface layer is pale brown fine sandy loam about 3 inches thick. The underlying material to a depth of 14 inches is pale brown and light yellowish brown fine sandy loam. Soft sandstone is at a depth of 14 inches.

Permeability of the Tassel soil is moderately rapid. Available water capacity is very low. Effective rooting depth is 6 to 20 inches. Runoff is medium, and the hazard of water erosion is moderate. The hazard of wind erosion is moderate.

This unit is used for livestock grazing and wildlife habitat.

The potential plant community on the Worf and Shingle soils is mainly western wheatgrass, bluebunch wheatgrass, needleandthread, and little bluestem. As the range condition deteriorates, blue grama and threadleaf sedge increase. As the range condition further deteriorates, broom snakeweed and cacti invade. The potential plant community produces about 900 pounds of air-dry vegetation in normal years. Production varies from 1,200 pounds in favorable years to 450 pounds in unfavorable years.

The potential plant community on the Tassel soil is mainly needleandthread, prairie sandreed, Indian ricegrass, and little bluestem. As the range condition deteriorates, threadleaf sedge and fringed sagewort increase. As the range condition further deteriorates, broom snakeweed and annuals invade. The potential plant community produces about 1,000 pounds of air-dry vegetation in normal years. Production varies from 1,400 pounds in favorable years to 600 pounds in unfavorable years.

The production of forage on this unit is limited by restricted rooting depth and droughtiness. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of this unit for rangeland seeding is poor. The main limitations are restricted rooting depth and the hazards of erosion by wind and water. Areas

that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

This unit is limited for livestock watering ponds and other water impoundments because of the seepage potential.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

This unit is poorly suited to homesite development. The main limitations are slope and depth to soft bedrock. Septic tank absorption fields should be installed in the less sloping areas, and selected material should be used.

This map unit is in capability subclass VIIe. The Worf and Shingle soils are in the Shallow Loamy, 10- to 14-inch ppt., Northern Plains range site. The Tassel soil is in the Shallow Sandy, 10- to 14-inch ppt., Northern Plains range site.

150—Zigweid-Bahl association, 0 to 6 percent slopes. This map unit is in nearly level to undulating areas on alluvial flats and toe slopes adjacent to rolling uplands. Slopes are long and plane. The native vegetation is mainly grasses and shrubs.

This unit is 55 percent Zigweid loam and 30 percent Bahl clay. The Zigweid soil is on toe slopes, and the Bahl soil is on alluvial flats.

Included in this unit are small areas of Cambria fine sandy loam, Ulm clay loam, Theedle loam, and Haverdard fine sandy loam. Included areas make up about 15 percent of the total acreage. The percentage varies from one area to another.

The Zigweid soil is deep and well drained. It formed in loamy local alluvium derived dominantly from calcareous shale. Typically, the surface layer is grayish brown loam about 2 inches thick. The subsoil is grayish brown and light brownish gray clay loam about 33 inches thick. The substratum to a depth of 60 inches or more is light brownish gray clay loam. In a few areas soft shale is at a depth of 40 to 60 inches.

Permeability of the Zigweid soil is moderate. Available water capacity is high. Effective rooting depth is 60 inches or more. Runoff is medium, and the hazard of water erosion is moderate. The hazard of wind erosion is slight.

The Bahl soil is deep and well drained. It formed in clayey local alluvium derived dominantly from calcareous shale. Typically, the surface layer is pale olive clay about 4 inches thick. The underlying material to a depth of 60 inches or more is pale olive clay.

Permeability of the Bahl soil is slow. Available water capacity is high. Effective rooting depth is 60 inches or more. Runoff is medium, and the hazard of water erosion is moderate. The hazard of wind erosion is slight.

This unit is used for livestock grazing and wildlife habitat.

The potential plant community on the Zigweid soil is mainly western wheatgrass, thickspike wheatgrass, and

needleandthread. As the range condition deteriorates, big sagebrush and blue grama increase. As the range condition further deteriorates, cacti, annuals, and brs snakeweed invade. The potential plant community produces about 1,500 pounds of air-dry vegetation in normal years. Production varies from 2,000 pounds in favorable years to 850 pounds in unfavorable years.

The potential plant community on the Bahl soil is mainly western wheatgrass, thickspike wheatgrass, and green needlegrass. As the range condition deteriorates, big sagebrush and blue grama increase. As the range condition further deteriorates, cacti and broom snakeweed invade. The potential plant community produces about 1,300 pounds of air-dry vegetation in normal years. Production varies from 1,800 pounds in favorable years to 750 pounds in unfavorable years.

The production of forage on this unit is limited by low annual precipitation. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of this unit for rangeland seeding is good. Chiseling or other such practices can be used to improve areas of deteriorated rangeland. Such practices increase water infiltration, reduce plant competition, and allow the desirable native plants to increase. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

If this unit is used for homesite development, the main limitations are the slow permeability of the Bahl soil and shrink-swell potential. Constructing a larger absorption field helps to compensate for the slow permeability. Backfilling excavations with coarser textured material helps to overcome the limitation of shrink-swell potential.

This map unit is in capability subclass IVe. The Zigweid soil is in the Loamy, 10- to 14-inch ppt., Northern Plains range site. The Bahl soil is in the Clayey, 10- to 14-inch ppt., Northern Plains range site.

151—Zigweid-Cambria association, 0 to 6 percent slopes. This map unit is in nearly level to undulating areas on foot slopes and toe slopes adjacent to rolling uplands. Slopes are medium to long in length and are plane to slightly convex. The native vegetation is mainly grasses and shrubs.

This unit is 55 percent Zigweid clay loam and 30 percent Cambria fine sandy loam. The Zigweid soil is in the plane areas, and the Cambria soil is in the convex areas.

Included in this unit are small areas of Theedle loam and Bahl clay. Included areas make up about 15 percent of the total acreage. The percentage varies from one area to another.

The Zigweid soil is deep and well drained. It formed in loamy local alluvium derived dominantly from calcareous shale. Typically, the surface layer is brown clay loam about 3 inches thick. The subsoil is pale brown and light brownish gray clay loam to a depth of 60 inches or more. In a few areas, soft bedrock is at a depth of 40 to 60 inches.

Permeability of the Zigweid soil is moderate. Available water capacity is high. Effective rooting depth is 60 inches or more. Runoff is medium, and the hazard of water erosion is moderate. The hazard of wind erosion is slight.

The Cambria soil is deep and well drained. It formed in loamy local alluvium and residuum derived dominantly from shale and sandstone. Typically, the surface layer is grayish brown fine sandy loam about 2 inches thick. The upper 8 inches of the subsoil is brown sandy clay loam, and the lower 19 inches is pale brown sandy clay loam and loam. The substratum to a depth of 60 inches or more is pale brown sandy clay loam.

Permeability of the Cambria soil capacity is low. Effective rooting depth is 60 inches or more. Runoff is medium, and the hazard of water erosion is moderate. The hazard of wind erosion is slight.

This unit is used for livestock grazing and wildlife habitat.

The potential plant community on this unit is mainly western wheatgrass, thickspike wheatgrass, and needlandthread. As the range condition deteriorates, big sagebrush and blue grama increase. As the range condition further deteriorates, cacti, annuals, and broom snakeweed invade. The potential plant community produces about 1,500 pounds of air-dry vegetation in normal years. Production varies from 2,000 pounds in favorable years to 850 pounds in unfavorable years.

The production of forage is limited by low annual precipitation. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of this unit for rangeland seeding is good. Chiseling or other such practices can be used to improve areas of deteriorated rangeland. Such practices increase water infiltration, reduce plant competition, and allow the desirable native plants to increase. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

If this unit is used for homesite development, the main limitation is moderate shrink-swell potential. Backfilling excavations with coarser textured material helps to overcome this limitation. Septic tank absorption fields operate more effectively if they are placed deep in the subsoil.

This map unit is in capability subclass IVe. It is in the Loamy, 10- to 14-inch ppt., Northern Plains range site.

152—Zigweid-Cambria-Theedle association, 6 to 15 percent slopes. This map unit is on pediment slopes of rolling uplands and on adjacent foot slopes. Slopes are short and are mostly convex. The native vegetation is mostly grasses and shrubs.

This unit is 35 percent Zigweid loam, 25 percent Cambria sandy loam, and 25 percent Theedle loam. The Zigweid soil is on the longer, more nearly plane slopes, the Cambria soil is on the intermediate slopes, and the Theedle soil is on the shorter, more convex slopes.

Included in this unit are small areas of Shingle loam, Bahl clay, and Renohill clay loam. Included areas make up about 15 percent of the total acreage. The percentage varies from one area to another.

The Zigweid soil is deep and well drained. It formed in loamy local alluvium derived dominantly from calcareous shale. Typically, the surface layer is pale brown loam about 4 inches thick. The subsoil to a depth of 60 inches or more is pale brown and very pale brown clay loam. In a few areas, soft bedrock is at a depth of 40 to 60 inches.

Permeability of the Zigweid soil is moderate. Available water capacity is high. Effective rooting depth is 60 inches or more. Runoff is medium, and the hazard of water erosion is severe. The hazard of wind erosion is slight.

The Cambria soil is deep and well drained. It formed in loamy local alluvium and residuum derived dominantly from shale and sandstone. Typically, the surface layer is brown sandy loam about 4 inches thick. The upper 4 inches of the subsoil is yellowish brown loam, and the lower 22 inches is pale brown loam. The substratum to a depth of 60 inches or more is brown loam.

Permeability of the Cambria soil is moderate. Available water capacity is high. Effective rooting depth is 60 inches or more. Runoff is medium, and the hazard of water erosion is severe. The hazard of wind erosion is moderate.

The Theedle soil is moderately deep and well drained. It formed in loamy residuum derived dominantly from calcareous shale. Typically, the surface layer is pale brown loam about 5 inches thick. The underlying material to a depth of 28 inches is light gray loam and light brownish gray clay loam. Soft shale is at a depth of 28 inches.

Permeability of the Theedle soil is moderate. Available water capacity is moderate. Effective rooting depth is 20 to 40 inches. Runoff is rapid, and the hazard of water erosion is severe. The hazard of wind erosion is moderate.

This unit is used for livestock grazing and wildlife habitat.

The potential plant community on this unit is mainly western wheatgrass, thickspike wheatgrass, and

needleandthread. As the range condition deteriorates, sagebrush and blue grama increase. As the range condition further deteriorates, cacti, annuals, and broom snakeweed invade. The potential plant community produces about 1,500 pounds of air-dry vegetation in normal years. Production varies from 2,000 pounds in favorable years to 850 pounds in unfavorable years.

The production of forage is limited by low annual precipitation. If the range is overgrazed, the proportion of preferred forage plants decreases and the proportion of less preferred forage plants increases. Therefore, livestock grazing should be managed so that the desired balance of preferred species is maintained in the plant community.

The suitability of this unit for rangeland seeding is fair. The main limitation is the hazard of water erosion. Chiseling or other such practices can be used to improve

areas of deteriorated rangeland. Such practices increase water infiltration, reduce plant competition, and allow the desirable native plants to increase. Areas that are heavily infested with undesirable plants can be improved by chemical or mechanical treatment.

The vegetation on this unit provides some food for antelope, deer, small mammals, and birds.

If this unit is used for homesite development, the main limitations are shrink-swell potential, slope, and the depth of the Theedle soil to soft bedrock. Backfilling excavations with coarser textured material helps to overcome the limitation of shrink-swell potential. Septic tank absorption fields in the Zigweid and Cambria soils operate most effectively if placed deep in the subsoil; areas of the Theedle soil are not suitable for this use.

This map unit is in capability subclass VIe. It is in the Loamy, 10- to 14-inch ppt., Northern Plains range site.

Classification of the Soils

The system of soil classification used by the National Cooperative Soil Survey has six categories (7). Beginning with the broadest, these categories are the order, suborder, great group, subgroup, family, and series. Classification is based on soil properties observed in the field or inferred from those observations or from laboratory measurements. Table 14 shows the classification of the soils in the survey area. The categories are defined in the following paragraphs.

ORDER. Ten soil orders are recognized. The differences among orders reflect the dominant soil-forming processes and the degree of soil formation. Each order is identified by a word ending in *sol*. An example is *Aridisol*.

SUBORDER. Each order is divided into suborders primarily on the basis of properties that influence soil formation and are important to plant growth or properties that are the most important variables within the order. The last syllable in the name of a suborder indicates the order. An example is *Argid* (*Arg*, meaning clay-rich horizon, plus *id*, from *Aridisol*).

GREAT GROUP. Each suborder is divided into great groups on the basis of close similarities in kind, development, and degree of development of pedogenic zones; soil moisture and temperature regimes; and soil status. Each great group is identified by the name of a suborder and by a prefix that indicates a property of soil. An example is *Haplargids* (*Hapl*, meaning normal horizonation, plus *argid*, the suborder of the *argisols* that have a layer of clay accumulation).

SUBGROUP. Each great group has a typical subgroup. Other subgroups are intergrades or extragrades. The typical subgroup is the central concept of the great group; it is not necessarily the most extensive. Intergrades are combinations to other orders, suborders, or great groups. Extragrades have some properties that are not representative of the great group but do not indicate combinations to any other known kind of soil. Each subgroup is identified by one or more adjectives preceding the name of the great group. The adjective *ustollic* identifies the subgroup that has more organic matter and receives more precipitation than the one that is typical of the great group. An example is *Ustollic argids*.

FAMILY. Families are established within a subgroup on the basis of physical and chemical properties and other characteristics that affect management. Mostly the

properties are those of horizons below plow depth where there is much biological activity. Among the properties and characteristics considered are particle-size class, mineral content, temperature regime, depth of the root zone, and permanent cracks. A family name consists of the name of a subgroup preceded by terms that indicate soil properties. An example is *fine-loamy, mixed, mesic Ustollic Haplargids*.

SERIES. The series consists of soils that have similar horizons in their profile. The horizons are similar in color, texture, structure, reaction, consistence, mineral and chemical composition, and arrangement in the profile. The texture of the surface layer or of the substratum can differ within a series.

Taxonomic Units and Their Morphology

In this section, each taxonomic unit recognized in the survey area is described. The descriptions are arranged in alphabetic order.

Characteristics of the soil and the material in which it formed are identified for each taxonomic unit. A pedon, a small three-dimensional area of soil, that is typical or representative of the taxonomic unit in the survey area is described. The detailed description of each soil horizon follows standards in the *Soil Survey Manual* (5). Many of the technical terms used in the descriptions are defined in *Soil Taxonomy* (7). Unless otherwise stated, colors in the descriptions are for dry soil. Following the pedon description is the range of important characteristics of the soils in the taxonomic unit.

The map units of each taxonomic unit are described in the section "Detailed Soil Map Units."

Absted Series

The Absted series consists of deep, well drained, slowly permeable soils on alluvial flats, toe slopes, and dissected terraces adjacent to major and minor drainageways. These soils formed in alluvial sediment derived from sedimentary rock. Slope is 0 to 6 percent.

Typical pedon of Absted fine sandy loam in an area of Absted-Arvada-Bone complex, 0 to 6 percent slopes, 1,250 feet east and 950 feet north of the southwest corner of sec. 30, T. 40 N., R. 68 W.

E—0 to 3 inches; pale brown (10YR 6/3) fine sandy loam, brown (10YR 5/3) moist; weak medium and coarse granular structure; slightly hard, very friable, slightly sticky and slightly plastic; mildly alkaline; abrupt smooth boundary.

st—3 to 14 inches; brown (10YR 5/3) clay, brown (10YR 4/3) moist; strong medium and fine subangular blocky structure; continuous thick clay films on faces of peds; very hard, very firm, sticky and plastic; moderately alkaline; gradual smooth boundary.

Btnk—14 to 26 inches; grayish brown (10YR 5/2) clay, dark grayish brown (10YR 4/2) moist; strong medium and fine subangular blocky structure; continuous thick clay films on faces of peds; very hard, very firm, sticky and plastic; violently effervescent; many medium soft masses of calcium carbonate; strongly alkaline; gradual wavy boundary.

Bnk—26 to 36 inches; light brownish gray (10YR 6/2) clay, grayish brown (10YR 5/2) moist; massive; very hard, very firm, sticky and plastic; violently effervescent; many medium soft masses of calcium carbonate; strongly alkaline; gradual wavy boundary.

Bck—36 to 60 inches; light brownish gray (10YR 6/2) clay, grayish brown (10YR 5/2) moist; massive; very hard, very firm, sticky and plastic; slightly effervescent; few fine soft masses of calcium carbonate; moderately alkaline.

The depth to calcium carbonate ranges from 12 to 28 inches.

The E horizon and the A horizon, where present, have hue of 2.5Y or 10YR, value of 6 or 7 when dry and 5 or 6 when moist, and chroma of 2 or 3. Reaction is neutral mildly alkaline.

The Btnk horizon has hue of 10YR, value of 5 or 6 when dry and 4 or 5 when moist, and chroma of 2 or 3. It is clay or clay loam that is 15 to 40 percent sand. The Btnk and Bnk horizons are moderately alkaline or strongly alkaline.

Aeric Haplaquepts

Aeric Haplaquepts are deep, poorly drained, very slowly permeable soils on playa lakebeds in areas characterized by centripetal drainage. These soils formed in clayey local alluvium derived from calcareous sedimentary rock. Slope is 0 to 3 percent.

Reference pedon of Aeric Haplaquepts clay loam in an area of Aeric Haplaquepts, 0 to 3 percent slopes, 800 feet south and 450 feet east of the northwest corner of sec. 15, T. 34 N., R. 71 W.

A—0 to 3 inches; light gray (10YR 6/1) clay loam, grayish brown (10YR 5/2) moist; weak fine granular structure; very hard, firm, sticky and plastic; common fine mottles; mildly alkaline; abrupt smooth boundary.

AC—3 to 8 inches; light brownish gray (10YR 6/2) clay loam, grayish brown (10YR 5/2) moist; weak fine subangular blocky structure; very hard, firm, sticky and plastic; few fine mottles; neutral; clear wavy boundary.

C1—8 to 20 inches; light gray (10YR 6/1) clay, grayish brown (10YR 5/2) moist; massive; very hard, firm, sticky and plastic; few fine mottles; mildly alkaline; gradual irregular boundary.

C2—20 to 30 inches; light gray (10YR 7/2) clay, pale brown (10YR 6/3) moist; massive; very hard, firm, very sticky and very plastic; few fine mottles and few medium iron and manganese concretions; strongly effervescent; few fine calcium carbonate concretions; mildly alkaline; gradual irregular boundary.

C3—30 to 48 inches; very pale brown (10YR 7/3) clay, grayish brown (10YR 5/2) moist; massive; very hard, very firm, very sticky and plastic; few fine mottles and few fine iron and manganese concretions; mildly alkaline.

Depth to bedrock typically is more than 60 inches, but it is as little as 20 inches in the smaller playas.

Accumulation of carbonates and depth to them vary with the parent material. The control section is fine or fine-loamy.

The A horizon has hue of 10YR or 2.5Y, value of 6 or 7 when dry and 4 or 5 when moist, and chroma of 1 or 2. Texture is clay loam or clay. Reaction is neutral or mildly alkaline.

The C horizon has hue of 10YR or 2.5Y, value of 6 or 7 when dry and 4 to 6 when moist, and chroma of 1 to 3. Reaction is mildly alkaline to strongly alkaline.

Arvada Series

The Arvada series consists of deep, well drained, slowly permeable soils on alluvial flats, toe slopes, and dissected terraces adjacent to major and minor drainageways. These soils formed in alluvial sediment derived from sedimentary rock. Slope is 0 to 6 percent.

Typical pedon of an Arvada loam in an area of Absted-Arvada-Bone complex, 0 to 6 percent slopes, 1,100 feet south and 1,000 feet east of the northwest corner of sec. 35, T. 41 N., R. 70 W.

A—0 to 3 inches; light brownish gray (10YR 6/2) loam, brown (10YR 5/3) moist; moderate fine platy structure parting to moderate very fine granular; soft, friable, slightly sticky and slightly plastic; slightly effervescent; moderately alkaline; abrupt smooth boundary.

Btn1—3 to 7 inches; pale brown (10YR 6/3) clay, brown (10YR 5/3) moist; weak medium and coarse prismatic structure parting to strong fine angular blocky; continuous thick clay films on faces of peds;

hard, friable, sticky and plastic; strongly alkaline; slightly effervescent; clear smooth boundary.

12—7 to 15 inches; light brownish gray (10YR 6/2) clay, grayish brown (10YR 5/2) moist; strong fine angular blocky structure; continuous thick clay films on faces of peds; hard, friable, sticky and plastic; very strongly alkaline; slightly effervescent; clear wavy boundary.

Bk—15 to 22 inches; light brownish gray (10YR 6/2) clay, grayish brown (10YR 5/2) moist; weak fine subangular blocky structure; hard, friable, sticky and plastic; slightly effervescent; moderately alkaline; clear wavy boundary.

C—22 to 48 inches; pale brown (10YR 6/3) clay, grayish brown (10YR 5/2) moist; massive; hard, friable, sticky and plastic; slightly effervescent; strongly alkaline.

The depth to calcium carbonate ranges from 0 to 12 inches.

The A horizon has hue of 10YR, value of 5 or 6 when dry and 4 or 5 when moist, and chroma of 2 or 3. Reaction is mildly alkaline to strongly alkaline.

The Btn horizons have hue of 2.5Y or 10YR, value of 5 or 6 when dry and 4 or 5 when moist, and chroma of 2 to 4. They are typically clay or clay loam and are 10 to 40 percent sand. They are strongly alkaline or very strongly alkaline.

The C horizon is strongly alkaline or very strongly alkaline.

Bahl Series

The Bahl series consists of deep, well drained, slowly permeable soils on alluvial flats and toe slopes. These soils formed in local alluvium derived from calcareous shale. Slopes range from 0 to 6 percent.

Typical pedon of a Bahl clay in an area of Zigweid-Bahl association, 0 to 6 percent slopes, in the NE1/4NE1/4 of sec. 24, T. 40 N., R. 72 W.

A—0 to 4 inches; pale olive (5Y 6/3) clay, olive (5Y 5/3) moist; weak thick platy structure parting to weak medium and fine subangular blocky; hard, friable, sticky and plastic; strongly effervescent; moderately alkaline; gradual wavy boundary.

AC—4 to 9 inches; pale olive (5Y 6/3) clay, olive (5Y 5/3) moist; massive; hard, firm, sticky and plastic; strongly effervescent; strongly alkaline; gradual wavy boundary.

CK—9 to 40 inches; pale olive (5Y 6/3) clay, olive (5YR 5/3) moist; massive; hard, firm, sticky and plastic; strongly effervescent; few fine soft masses and filaments of calcium carbonate; strongly alkaline.

These soils typically are leached in the upper few inches, but in some areas they are calcareous throughout.

The A horizon has chroma of 2 or 3. Reaction is neutral to moderately alkaline.

The C horizon is mildly alkaline to strongly alkaline. The control section typically is about 45 percent clay and 15 to 25 percent sand.

Bidman Series

The Bidman series consists of deep, well drained, slowly permeable soils on alluvial flats, toe slopes, and foot slopes of upland hills. These soils formed in local alluvium derived from soft calcareous shale. Slope is 0 to 6 percent.

Typical pedon of a Bidman sandy loam in an area of Ulm-Bidman complex, 0 to 6 percent slopes, 2,500 feet east and 300 feet north of the southwest corner of sec. 1, T. 37 N., R. 68 W.

A—0 to 3 inches; light brownish gray (10YR 6/2) sandy loam, dark grayish brown (10YR 4/2) moist; weak fine granular structure; soft, very friable, nonsticky and nonplastic; neutral; abrupt smooth boundary.

E—3 to 7 inches; pale brown (10YR 6/3) sandy loam, brown (10YR 5/3) moist; weak medium subangular blocky structure; slightly hard, very friable, slightly sticky and slightly plastic; neutral; clear smooth boundary.

Bt—7 to 20 inches; light brownish gray (10YR 6/2) clay, grayish brown (10YR 5/2) moist and crushed; weak medium prismatic structure parting to strong medium and coarse angular blocky; very hard, firm, sticky and plastic; continuous thick clay films on faces of peds; neutral; clear wavy boundary.

Bk1—20 to 35 inches; light brownish gray (2.5Y 6/2) clay loam, grayish brown (2.5Y 5/2) moist; moderate medium and coarse angular blocky structure; very hard, firm, sticky and plastic; few medium hard iron concretions; strongly effervescent; common medium and fine filaments and seams of calcium carbonate; moderately alkaline; gradual wavy boundary.

Bk2—35 to 52 inches; light brownish gray (2.5Y 6/2) clay loam, grayish brown (2.5Y 5/2) moist; massive; hard, friable, slightly sticky and slightly plastic; few medium iron concretions; strongly effervescent; moderately alkaline; diffuse wavy boundary.

C—52 to 67 inches; light brownish gray (2.5Y 6/2) clay loam, grayish brown (2.5Y 5/2) moist; massive; hard, friable; slightly effervescent; moderately alkaline.

The depth to calcium carbonate ranges from 12 to 24 inches.

The A horizon has hue of 10YR or 2.5Y, value of 5 or 6 when dry and 3 to 5 when moist, and chroma of 2 or 3. It is sandy loam or loam.

The Bt horizon has value of 5 or 6 when dry and 4 or 5 when moist, and it has chroma of 2 to 4. It is

dominantly clay, but the range includes clay loam and sandy clay. It averages 37 to 47 percent clay. Reaction neutral to moderately alkaline.

The Bk horizon has hue of 10YR or 2.5Y, value of 5 or 6 when dry and 4 or 5 when moist, and chroma of 2 to 3. Texture is clay loam, sandy clay loam, or clay. Reaction is mildly alkaline to strongly alkaline.

Bigwinder Series

The Bigwinder series consists of deep, poorly drained, moderately permeable soils on flood plains and low stream terraces. These soils formed in recent stratified alluvium derived dominantly from sedimentary rock. Slope is 0 to 3 percent.

Typical pedon of a Bigwinder fine sandy loam in an area of Clarkelen-Haverdad-Bigwinder complex, 0 to 3 percent slopes; 1,250 feet north and 1,400 feet west of the southeast corner of sec. 24, T. 39 N., R. 75 W.

A—0 to 3 inches; light brownish gray (10YR 6/2) fine sandy loam, grayish brown (10YR 5/2) moist; common fine strong brown (7.5YR 5/8) mottles along root channels; moderate thick platy structure; slightly hard, very friable, nonsticky and nonplastic; strongly effervescent; mildly alkaline; clear smooth boundary.

AC—3 to 8 inches; light gray (10YR 7/2), stratified sandy loam and loam, grayish brown (10YR 5/2) moist; common fine strong brown (7.5YR 5/8) mottles along root channels; weak thick platy structure; hard, friable, slightly sticky and plastic; strongly effervescent; moderately alkaline; clear smooth boundary.

C1—8 to 17 inches; light gray (10YR 7/2), stratified loamy sand, loam, and sandy loam, pale brown (10YR 6/3) moist; common medium strong brown (7.5YR 5/8) mottles and faint organic stains on faces of fragments; massive; slightly hard, very friable, nonsticky and nonplastic; violently effervescent; moderately alkaline; clear wavy boundary.

C2—17 to 24 inches; light gray (10YR 7/2), stratified sandy loam and loamy sand, light brownish gray (10YR 6/2) moist; single grain; slightly hard, very friable, nonsticky and nonplastic; slightly effervescent; mildly alkaline; gradual smooth boundary.

C3—24 to 60 inches; mottled, light gray (10YR 7/2) and reddish yellow (7.5YR 6/8), stratified loamy sand, sandy loam, and sand, light brownish gray (10YR 6/2) and reddish yellow (5YR 6/8) moist; single grain; loose, nonsticky and nonplastic; slightly effervescent; mildly alkaline.

Depth to sand strata ranges from 30 to 40 inches.

The A horizon is fine sandy loam or sandy clay loam. Reaction is neutral to moderately alkaline. It has weak or moderate grades of platy structure.

The C horizon has value of 5 or 6 when moist. Matrix chroma is 2 or 3. Reaction is on mildly alkaline or moderately alkaline. Texture of the strata ranges from loam to sand.

Bone Series

The Bone series consists of deep, well drained, very slowly permeable soils on alluvial flats and toe slopes of dissected terraces adjacent to major and minor drainageways. These soils formed in alluvial sediment derived from sedimentary rock. Slope is 0 to 6 percent.

Typical pedon of a Bone clay loam in an area of Absted-Arvada-Bone complex, 0 to 6 percent slopes, 1,100 feet south and 500 feet west of the northeast corner of sec. 8, T. 36 N., R. 68 W.

E—0 to 2 inches; pale brown (10YR 6/3) light clay loam, brown (10YR 5/3) moist; weak thin platy structure; slightly hard, very friable, slightly sticky and slightly plastic; mildly alkaline; abrupt smooth boundary.

Bt—2 to 5 inches; light brownish gray (10YR 6/2) clay loam, brown (10YR 5/3) moist; moderate fine subangular blocky structure; few thin clay films on faces of peds; hard, friable, slightly sticky and slightly plastic; moderately alkaline; clear smooth boundary.

Bk—5 to 10 inches; light gray (10YR 7/2) clay loam, pale brown (10YR 6/3) moist; moderate fine subangular blocky structure; very hard, friable, sticky and plastic; strongly effervescent; calcium carbonate segregated in common fine soft masses; moderately alkaline; gradual smooth boundary.

C1—10 to 20 inches; very pale brown (10YR 7/3) heavy clay loam, pale brown (10YR 6/3) moist; massive; very hard, firm, sticky and plastic; strongly effervescent; calcium carbonate disseminated throughout matrix; very strongly alkaline; gradual smooth boundary.

C2—20 to 60 inches; very pale brown (10YR 7/3) clay, pale brown (10YR 6/3) moist; massive; very hard, friable, sticky and plastic; strongly effervescent; calcium carbonate disseminated throughout matrix; moderately alkaline.

The profile commonly is leached to a depth of 2 to 5 inches, or to the base of the Bt horizon, but many pedons are calcareous throughout. The solum has hue of 2.5Y or 10YR.

The E horizon has value of 6 or 7 when dry and 4 to 6 when moist. The Bt horizon has value of 5 or 6 when dry and 4 or 5 when moist, and it has chroma of 2 to 4. The Bk and C horizons are heavy clay loam or clay.

Bowbac Series

The Bowbac series consists of moderately deep, well drained, moderately permeable soils on shoulder slopes, back slopes, and pediment slopes of rolling uplands. These soils formed in residuum derived from soft sandstone. Slope is 0 to 15 percent.

Typical pedon of a Bowbac sandy loam (fig. 3) in an area of Hiland-Bowbac complex, 6 to 15 percent slopes, 2,450 feet north and 500 feet east of the southwest corner of sec. 27, T. 36 N., R. 70 W.

A—0 to 3 inches; brown (10YR 5/3) sandy loam, dark brown (10YR 4/3) moist; weak fine granular structure parting to single grain; soft, loose, slightly sticky and slightly plastic; neutral; abrupt smooth boundary.

Bt1—3 to 6 inches; brown (7.5YR 5/4) sandy clay loam, dark brown (7.5YR 4/4) moist; strong coarse subangular blocky structure parting to strong fine angular blocky; slightly hard, friable, sticky and plastic; few thin clay bridges between mineral grains; neutral; clear smooth boundary.

Bt2—6 to 18 inches; brown (7.5YR 5/4) sandy clay loam, dark brown (7.5YR 4/4) moist; strong coarse prismatic structure parting to strong fine subangular blocky; hard, friable, sticky and plastic; common moderately thick clay bridges between mineral grains; neutral; clear smooth boundary.

tk—18 to 26 inches; brown (10YR 5/3) sandy loam, dark brown (10YR 4/3) moist; moderate coarse subangular blocky structure parting to weak fine subangular blocky; slightly hard, very friable, slightly sticky and slightly plastic; thin clay bridges between mineral grains; slightly effervescent; disseminated calcium carbonate; mildly alkaline; gradual wavy boundary.

Bk—26 to 36 inches; light yellowish brown (2.5Y 6/4) loam, light olive brown (2.5Y 5/4) moist; weak coarse subangular blocky structure parting to weak very fine granular; soft, loose, slightly sticky and slightly plastic; strongly effervescent; disseminated calcium carbonate; moderately alkaline; gradual wavy boundary.

Cr—36 inches; soft calcareous sandstone.

The depth to calcium carbonate ranges from 14 to 26 inches. The depth to bedrock ranges from 24 to 37 inches.

The Bt horizon has chroma of 3 or 4. Texture is dominantly sandy clay loam that is 20 to 35 percent clay and more than 35 percent sand that is fine or coarser. The Bk horizon has hue of 2.5Y to 10YR, value of 6 or 7 when dry, and chroma of 2 to 4.

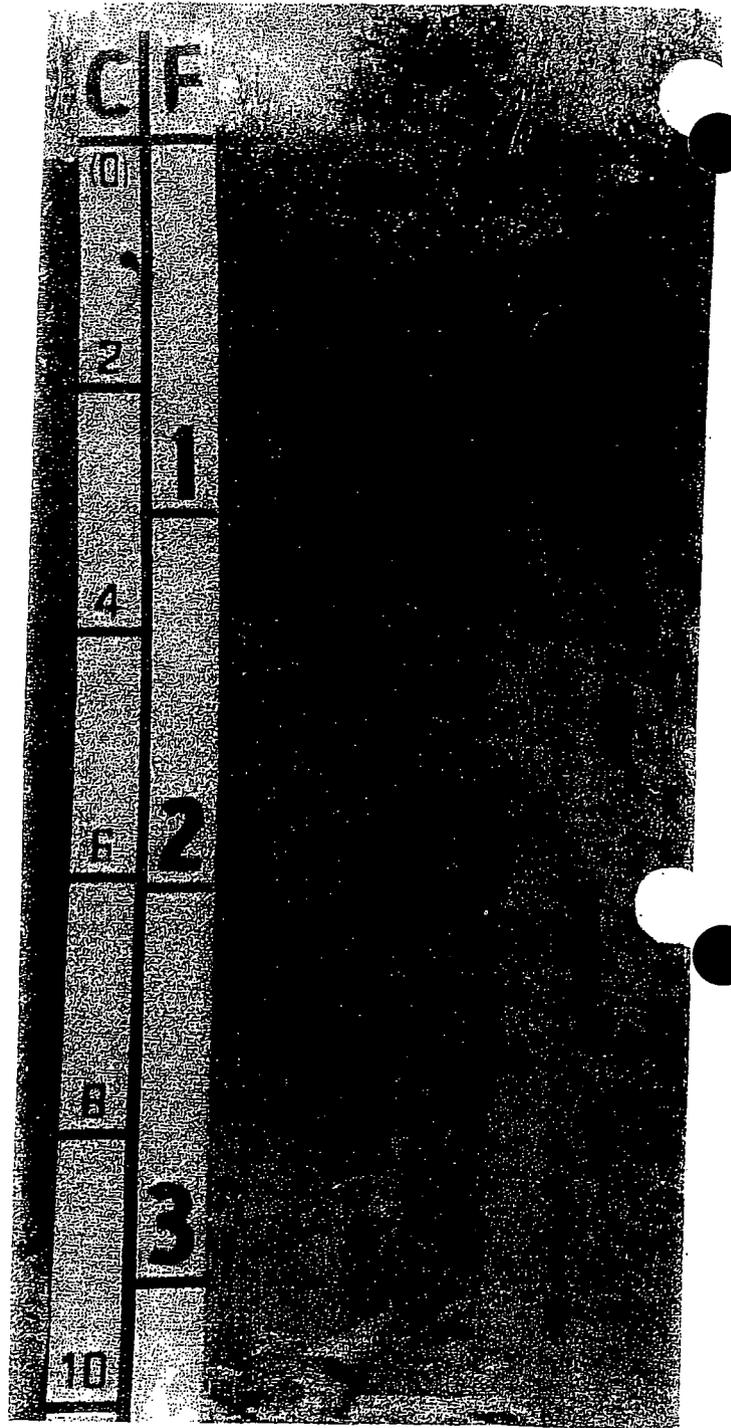

Figure 3.—Profile of Bowbac sandy loam. Soft sandstone is at depth of about 2.5 feet.

Cambria Series

The Cambria series consists of deep, well drained, moderately permeable soils on ridge crests, back slopes, foot slopes, and toe slopes of nearly level to rolling uplands. These soils formed in mixed residuum and local alluvium derived from shale and sandstone. Slope is 0 to 15 percent.

Typical pedon of a Cambria fine sandy loam in an area of Forkwood-Cambria fine sandy loams, 0 to 6 percent slopes, 2,000 feet south and 500 feet east of the northwest corner of sec. 10, T. 36 N., R. 70 W.

A—0 to 2 inches; grayish brown (10YR 5/2) fine sandy loam, dark grayish brown (10YR 4/3) moist; weak moderate subangular blocky structure parting to weak very fine granular; soft, very friable, slightly sticky and slightly plastic; neutral; clear wavy boundary.

Bt1—2 to 4 inches; brown (10YR 5/3) sandy clay loam, dark brown (10YR 4/3) moist; moderate coarse subangular structure parting to weak fine granular; soft, very friable, slightly sticky and slightly plastic; few thin clay films on faces of peds; neutral; clear wavy boundary.

Bt2—4 to 10 inches; brown (10YR 5/3) sandy clay loam, dark brown (10YR 4/3) moist; strong coarse prismatic structure parting to moderate medium subangular blocky; slightly hard, friable, sticky and plastic; many moderately thick clay films on faces of peds; mildly alkaline; clear wavy boundary.

Bk—10 to 14 inches; pale brown (10YR 6/3) loam, brown (10YR 5/3) moist; moderate coarse subangular blocky structure parting to moderate fine subangular blocky; slightly hard, friable, sticky and plastic; few thin clay films on faces of peds; strongly effervescent; common fine irregularly shaped calcium carbonate masses in the form of filaments and threads; moderately alkaline; gradual wavy boundary.

Bk1—14 to 29 inches; pale brown (10YR 6/3) loam, brown (10YR 5/3) moist; massive; soft, very friable, slightly sticky and slightly plastic; violently effervescent; few fine soft masses of calcium carbonate; moderately alkaline; gradual wavy boundary.

Bk2—29 to 60 inches; pale brown (10YR 6/3) loam, brown (10YR 5/3) moist; massive; soft, very friable, slightly sticky and slightly plastic; strongly effervescent; moderately alkaline.

The A horizon has value of 5 or 6 when dry and 4 or 5 when moist. It is fine sandy loam, sandy loam, loam, or clay loam.

The Bt horizon has hue of 2.5Y to 10YR, value of 5 or 6 when dry, and and chroma of 3 or 4. Texture is loam or clay loam. The Bt horizon is 24 to 34 percent clay.

The Bk horizon has hue of 2.5Y to 10YR, value of 5 to 7 when dry and 4 or 5 when moist, and chroma of 2 or 3.

Cambria Variant

The Cambria Variant consists of deep, well drained, moderately permeable soils in nearly level to undulating areas on toe slopes and alluvial flats. These soils formed in alluvium derived from interbedded shale and sandstone. Slope is 0 to 6 percent.

Typical pedon of a Cambria Variant fine sandy loam in an area of Cambria Variant-Forkwood Variant complex, 0 to 6 percent slopes; 1,150 feet west and 400 feet south of the northeast corner of sec. 27, T. 39 N., R. 71 W.

A—0 to 2 inches; light gray (10YR 7/2) fine sandy loam, grayish brown (10YR 5/2) moist; weak fine subangular blocky and granular structure; soft, very friable, nonsticky and nonplastic; neutral; abrupt smooth boundary.

Bw—2 to 5 inches; light brownish gray (2.5Y 6/2) clay loam, grayish brown (2.5Y 5/2) moist; moderate fine subangular blocky structure; slightly hard, friable, slightly sticky and slightly plastic; neutral; clear smooth boundary.

Bt—5 to 9 inches; light brownish gray (2.5Y 6/2) clay loam, grayish brown (2.5Y 5/2) moist; moderate medium and fine subangular blocky structure; hard, friable, sticky and plastic; common moderately thick clay films on faces of peds; neutral; clear smooth boundary.

Bt—9 to 16 inches; light brownish gray (2.5Y 6/2) loam, grayish brown (2.5Y 5/2) moist; fine medium subangular blocky structure; hard, friable, slightly sticky and slightly plastic; slightly effervescent; few fine soft masses of calcium carbonate; moderately alkaline; clear smooth boundary.

2Bk1—16 to 30 inches; light brownish gray (2.5Y 6/2), stratified clay loam, loam, and fine sandy loam, grayish brown (2.5Y 5/2) moist; massive; hard, friable, slightly sticky and slightly plastic; strongly effervescent; few fine soft masses of calcium carbonate; moderately alkaline; gradual smooth boundary.

2Bk2—30 to 60 inches; light brownish gray (2.5Y 6/2), stratified loam, sandy clay loam, and sandy loam, grayish brown (2.5Y 5/2) moist; massive; slightly hard, friable, slightly sticky and slightly plastic; strongly effervescent; few fine soft masses of calcium carbonate; moderately alkaline.

Depth to carbonates ranges from 8 to 12 inches.

Depth to stratified textures ranges from 12 to 24 inches. The profile is 0 to 5 percent coarse fragments.

The A horizon has hue of 10YR or 2.5Y, value of 6 or 7 when dry and 4 or 5 when moist, and chroma of 2 or

3. Texture is fine sandy loam or sandy loam. Reaction is neutral or mildly alkaline.

The Bt horizon has hue of 10YR or 2.5Y, value of 6 or 7 when dry and 4 or 5 when moist, and chroma of 2 or 3.

3. Texture is fine sandy loam or sandy loam. Reaction is neutral or mildly alkaline.

The 2Bk horizon and the C horizon, where present, have hue of 10YR or 2.5Y, value of 6 or 7 when dry and 5 or 6 when moist, and chroma of 2 or 3. Texture varies, but centers on loam or clay loam with thin coarser textured strata. Reaction is mildly alkaline or moderately alkaline.

Clarkelen Series

The Clarkelen series consists of deep, somewhat excessively drained, moderately rapidly permeable soils on flood plains and low stream terraces. These soils formed in stratified Recent alluvium derived from sedimentary rock. Slope is 0 to 3 percent.

Typical pedon of a Clarkelen sandy loam in an area of Clarkelen-Draknab complex, 0 to 3 percent slopes, 2,130 feet north and 285 feet east of the southwest corner of sec. 31., T. 41 N., R. 69 W.

A—0 to 1 inch; pale brown (10YR 6/3) sandy loam, grayish brown (10YR 5/2) moist; weak thin platy structure parting to moderate very fine granular; soft, very friable; slightly effervescent; mildly alkaline; clear smooth boundary.

—1 to 3 inches; grayish brown (10YR 5/2) sandy loam, dark grayish brown (10YR 4/2) moist; moderate medium subangular blocky structure; soft, very friable; slightly effervescent; mildly alkaline; clear smooth boundary.

C1—3 to 37 inches; light brownish gray (10YR 6/2) and pale brown (10YR 6/3), stratified sandy loam, loamy sand, sandy clay loam, and silt loam, grayish brown (10YR 5/2) and brown (10YR 5/3) moist; massive; soft, very friable; slightly effervescent; mildly alkaline; clear smooth boundary.

C2—37 to 60 inches; light brownish gray (10YR 6/2) sand, grayish brown (10YR 5/2) moist; single grain; loose; slightly effervescent; mildly alkaline.

The A horizon has value of 5 or 6 when dry and 4 or 5 when moist. It is sandy loam, loamy sand, or loam.

Cushman Series

The Cushman series consists of moderately deep, well drained, moderately permeable soils on upland ridges, back slopes, and pediment slopes. These soils formed in residuum derived dominantly from calcareous shale and sandstone. Slope is 0 to 15 percent.

Typical pedon of a Cushman loam in an area of Cambria-Cushman complex, 6 to 15 percent slopes, in the SW1/4 of sec. 15, T. 38 N., R. 72 W.

A—0 to 3 inches; pale brown (10YR 6/3) loam, dark brown (10YR 4/3) moist; moderate medium subangular blocky structure parting to weak fine granular; slightly hard, friable, slightly sticky and slightly plastic; neutral; clear smooth boundary.

Bt—3 to 9 inches; pale brown (10YR 6/3) clay loam, dark brown (10YR 4/3) moist; strong medium prismatic structure parting to coarse angular blocky; hard, firm, slightly sticky and slightly plastic; common moderately thick clay films on faces of peds and in pores; neutral; clear smooth boundary.

Btk—9 to 17 inches; light gray (2.5Y 7/2) clay loam, grayish brown (2.5Y 5/2) moist; moderate coarse angular blocky structure parting to moderate medium angular blocky; hard, firm, slightly sticky and slightly plastic; common thin clay films on faces of peds; effervescent; mildly alkaline; gradual wavy boundary.

Bk—17 to 25 inches; pale yellow (2.5Y 7/4) loam, light yellowish brown (2.5Y 6/4) moist; hard, friable, sticky and slightly plastic; strongly effervescent; moderately alkaline, clear smooth boundary.

Crk—25 to 35 inches; calcareous shale; common fine soft masses of calcium carbonate, abrupt smooth boundary.

2Cr—35 inches; calcareous sandstone.

The depth to bedrock ranges from 24 to 35 inches. The depth to calcium carbonate ranges from 9 to 18 inches.

The A horizon has chroma of 2 or 3.

The Bt and Btk horizons have value of 5 or 6 when dry and 4 or 5 when moist. Reaction is neutral to moderately alkaline. The Bk horizon has value of 5 to 7 when dry and 4 to 6 when moist.

Draknab Series

The Draknab series consists of deep, excessively drained, rapidly permeable soils on flood plains. These formed in Recent alluvium derived dominantly from calcareous sedimentary rock. Slope is 0 to 3 percent.

Typical pedon of a Draknab loamy sand in an area of Clarkelen-Draknab complex, 0 to 3 percent slopes, 1,900 feet north and 400 feet east of the southwest corner of sec. 5, T. 40 N., R. 74 W.

A1—0 to 2 inches; yellowish brown (10YR 5/4) loamy sand, brown (10YR 4/3) moist; weak medium and fine granular structure; soft, very friable, nonsticky and nonplastic; strongly effervescent; moderately alkaline; abrupt smooth boundary.

AC—2 to 8 inches; yellowish brown (10YR 5/4) sandy loam, brown (10YR 4/3) moist; weak medium subangular blocky structure parting to weak medium granular; soft, very friable, nonsticky and nonplastic; slightly effervescent; moderately alkaline; clear smooth boundary.

C1—8 to 18 inches; very pale brown (10YR 7/3) sand, yellowish brown (10YR 5/4) moist; single grain; loose; strongly effervescent; moderately alkaline (pH 8.0); clear wavy boundary.

C2—18 to 26 inches; pale brown (10YR 6/3) loamy coarse sand, dark yellowish brown (10YR 4/4) moist; massive; soft, very friable; strongly effervescent; moderately alkaline; gradual smooth boundary.

C3—26 to 60 inches; very pale brown (10YR 7/3), stratified coarse sand and loamy sand, pale brown (10YR 6/3) moist; single grain; loose; strongly effervescent; moderately alkaline.

The profile typically is calcareous throughout, but depth to calcium carbonate is as much as 10 inches. Coarse fragment content ranges from 0 to 15 percent.

The A horizon has hue of 10YR or 2.5Y, value of 5 to 7 when dry and 4 to 6 when moist, and chroma of 2 to 4. Texture is loam, sandy loam, or loamy sand. Reaction is mildly alkaline or moderately alkaline.

The C horizon has hue of 2.5Y to 7.5YR. Most pedons are highly stratified. Texture is loamy sand, loamy coarse sand, or sand. Thickness and texture of the strata are highly variable. Reaction is mildly alkaline to strongly alkaline.

Dwyer Series

The Dwyer series consists of deep, excessively drained, rapidly permeable soils on dunes. These soils formed in eolian sand. Slope is 0 to 15 percent.

Typical pedon of a Dwyer loamy sand in an area of Dwyer-Orpha loamy sands, 3 to 15 percent slopes, 50 feet west and 1,050 feet north of the southeast corner of sec. 29, T. 35 N., R. 73 W.

A—0 to 5 inches; brown (10YR 5/3) loamy sand, dark brown (10YR 4/3) moist; weak coarse granular structure parting to single grain; soft, loose; strongly effervescent; moderately alkaline; gradual wavy boundary.

AC—5 to 21 inches; pale brown (10YR 6/3) loamy sand, brown (10YR 5/3) moist; single grain; soft, loose; strongly effervescent; moderately alkaline; gradual wavy boundary.

C—21 to 60 inches; pale brown (10YR 6/3) loamy sand, brown (10YR 5/3) moist; single grain; soft, loose; strongly effervescent; moderately alkaline.

Carbonates commonly are throughout the profile, but in some pedons the carbonates are leached from the A and AC horizons.

The A horizon has value of 5 or 6 when dry and 4 or 5 when moist, and it has chroma of 3 or 4. It is loamy sand to fine sand. The C horizon has value of 5 or 6 when dry and 4 or 5 when moist, and it has chroma of 2 to 4. It is mildly alkaline or moderately alkaline. In some pedons a

layer of sandy clay loam, clay loam, loam, or clay is below a depth of 40 inches.

Forkwood Series

The Forkwood series consists of deep, well drained, moderately permeable soils on foot slopes and toe slopes of rolling uplands. These soils formed in local alluvium that is derived from calcareous shale and in some places has a thin mantle of eolian deposits. Slope is 0 to 15 percent.

Typical pedon of a Forkwood fine sandy loam in an area of Forkwood-Cambria fine sandy loams, 0 to 6 percent slopes, 1,050 feet west and 1,600 feet north of the southeast corner of sec. 35, T. 36 N., R. 68 W.

A—0 to 4 inches; pale brown (10YR 6/3) fine sandy loam, brown (10YR 5/3) moist; weak medium and fine granular structure; slightly hard, very friable, slightly sticky and slightly plastic; neutral; abrupt smooth boundary.

BA—4 to 7 inches; pale brown (10YR 6/3) fine sandy loam, brown (10YR 5/3) moist; moderate medium subangular blocky structure; slightly hard, friable, slightly sticky and slightly plastic; neutral; clear smooth boundary.

Bt—7 to 14 inches; pale brown (10YR 6/3) clay loam, brown (10YR 5/3) moist; strong medium and coarse subangular blocky structure; thin continuous clay films on faces of peds; very hard, firm, sticky and plastic; neutral; clear smooth boundary.

Bk1—14 to 20 inches; light brownish gray (10YR 6/2) clay loam; grayish brown (10YR 5/2) moist; moderate medium and coarse subangular blocky structure; very hard, firm, sticky and plastic; strongly effervescent; few fine calcium carbonate concretions; mildly alkaline; gradual wavy boundary.

Bk2—20 to 27 inches; light gray (10YR 7/2) clay loam, grayish brown (10YR 5/2) moist; weak coarse subangular blocky structure; very hard, friable, sticky and plastic; strongly effervescent; common fine soft masses and filaments of calcium carbonate; mildly alkaline; diffuse wavy boundary.

Bk3—27 to 60 inches; light gray (10YR 7/2) clay loam, grayish brown (10YR 5/2) moist; massive; very hard, friable, sticky and plastic; strongly effervescent; many medium soft masses of calcium carbonate; mildly alkaline.

The depth to calcium carbonate typically is 12 to 20 inches, but it is as much as 30 inches in some pedons.

The A horizon has hue of 10YR or less; it typically is 2.5Y. It has value of 3 to 5 when moist. Reaction is neutral or mildly alkaline.

The Bt horizon has hue of 10YR or 2.5Y, and it has value of 5 or 6 when dry.

The Bk horizon has hue of 10YR or 2.5Y. It is not present in some pedons that are deeply leached.

Forkwood Variant

The Forkwood Variant consists of deep, well drained, moderately slowly permeable soils in nearly level to undulating areas on toe slopes and alluvial flats. These soils formed in alluvium derived from shale with some interbedded sandstone. Slope is 0 to 6 percent.

Typical pedon of a Forkwood Variant clay loam in an area of Cambria Variant-Forkwood Variant complex, 0 to 6 percent slopes, 1,400 feet north and 1,100 feet west of the southeast corner of sec. 21, T. 39 N., R. 71 W.

- A—0 to 3 inches; light gray (10YR 7/2) clay loam, grayish brown (10YR 5/2) moist; weak medium and fine subangular blocky structure; slightly hard, friable, slightly sticky and plastic; neutral; abrupt smooth boundary.
- Bt1—3 to 9 inches; pale brown (10YR 6/3) clay loam, brown (10YR 5/3) moist; moderate medium subangular blocky structure; hard, firm, sticky and plastic; common thin clay films on faces of peds; neutral; clear smooth boundary.
- Bt2—9 to 16 inches; pale brown (10YR 6/3) clay loam, brown (10YR 5/3) moist; weak coarse prismatic structure parting to moderate medium subangular blocky; very hard, firm, sticky and plastic; common thin clay films on faces of peds; neutral; clear smooth boundary.
- 2Bk1—16 to 30 inches; light gray (2.5Y 7/2), stratified loam, clay loam, and fine sandy loam, grayish brown (2.5Y 5/2) moist; massive; hard, friable, slightly sticky and plastic; few fine soft masses of calcium carbonate and concretions of calcium carbonate in a noncalcareous matrix; mildly alkaline; gradual smooth boundary.
- 2Bk2—30 to 60 inches; light gray (10YR 7/2), stratified clay loam and loam, grayish brown (10YR 5/2) moist; massive; hard, firm, sticky and plastic; slightly effervescent; few fine soft masses of calcium carbonate and concretions of calcium carbonate; moderately alkaline.

Depth to carbonates and stratified material ranges from 12 to 24 inches. Coarse fragments typically are absent, but where present they make up as much as 5 percent of the profile.

The A horizon has hue of 10YR or 2.5Y, value of 6 or 7 when dry and 4 to 6 when moist, and chroma of 2 or 3. Texture is loam or clay loam. Reaction is neutral or mildly alkaline.

The Bt horizon has hue of 10YR or 2.5Y, value of 5 or 6 when dry and 4 or 5 when moist, and chroma of 2 or 3. Texture is clay loam or heavy loam. Reaction is neutral or mildly alkaline.

The 2Bk horizon has hue of 10YR or 2.5Y, value of 6 or 7 when dry and 5 or 6 when moist, and chroma of 2 or 3. Texture is stratified clay loam to fine sandy loam. Reaction is mildly alkaline or moderately alkaline.

Gateson Variant

The Gateson Variant consists of shallow, well drained, moderately permeable soils on upland shoulder slopes and back slopes. These soils formed in residuum derived dominantly from noncalcareous sandstone. Slope is 10 to 45 percent.

Typical pedon of a Gateson Variant loamy sand in an area of Gateson Variant-Tassel Variant association, 10 to 45 percent slopes, in the NE1/4NE1/4SW1/4 of sec. 12, T. 40 N., R. 77 W.

- Oi—1 inch to 0; forest litter consisting largely of undecomposed pine needles.
- E—0 to 4 inches; pinkish gray (7.5YR 7/2) loamy sand, pinkish gray (7.5YR 6/2) moist; weak medium platy structure; soft, very friable, nonsticky and nonplastic; neutral; clear smooth boundary.
- Bt—4 to 11 inches; reddish yellow (7.5YR 6/6) sandy clay loam, strong brown (7.5YR 5/6) moist; moderate medium and coarse subangular blocky structure; hard, friable, slightly sticky and plastic; common thin yellowish red (5YR 5/6) clay films on faces of peds; mildly alkaline; clear smooth boundary.
- 2C—11 to 16 inches; pinkish gray (5YR 7/2) clay, reddish brown (5YR 5/3) moist; massive; hard, friable, sticky and plastic; about 15 percent shale chips and sandstone channery fragments; mildly alkaline; gradual smooth boundary.
- 3Cr—16 inches; soft interbedded noncalcareous fractured sandstone and shale flagstones.

Depth to rock and thickness of the solum range from 15 to 24 inches. Coarse fragment content typically is less than 15 percent.

The Bt horizon typically is 18 to 35 percent clay, but in a few pedons it is as little as 15 percent clay. In some pedons there is a BK or CK horizon.

Haverdad Series

The Haverdad series consists of deep, well drained, moderately permeable soils on flood plains and low terraces. These soils formed in stratified Recent alluvium derived from sedimentary rock. Slope is 0 to 6 percent.

Typical pedon of a Haverdad fine sandy loam in an area of Haverdad-Lohmiller complex, 0 to 6 percent slopes, 1,300 feet east and 130 feet south of the northwest corner of sec. 31., T. 40 N., R. 68 W.

- A—0 to 6 inches; grayish brown (10YR 5/2) fine sandy loam, dark grayish brown (10YR 4/2) moist;

moderate medium and fine granular structure; soft, very friable, slightly sticky and slightly plastic; mildly alkaline; abrupt smooth boundary.

C1—6 to 10 inches; light brownish gray (10YR 6/2) clay loam, grayish brown (10YR 5/2) moist; weak medium and fine subangular blocky structure; slightly hard, friable, sticky and plastic; slightly effervescent; moderately alkaline; abrupt smooth boundary.

C2—10 to 60 inches; light brownish gray (10YR 6/2) loam stratified with sandy loam, clay loam, and loamy sand, grayish brown (10YR 5/2) moist; massive; soft, very friable, slightly sticky and slightly plastic; slightly effervescent; moderately alkaline.

The profile typically is leached in the A horizon, but some pedons are calcareous throughout.

The A horizon has chroma of 2 or 3. It is fine sandy loam, loam, silt loam, or sandy loam. Reaction is mildly alkaline or moderately alkaline.

The control section is clay loam, loam, or very fine sandy loam.

Heldt Series

The Heldt series consists of deep, well drained, slowly permeable soils on toe slopes and alluvial flats. These soils formed in local alluvium derived dominantly from calcareous shale. Slope is 0 to 6 percent.

Typical pedon of a Heldt clay loam in an area of Silhouette-Heldt association, 0 to 6 percent slopes; 1,200 feet east and 75 feet south of the northwest corner of sec. 15, T. 38 N., R. 71 W.

E—0 to 1 inch; light gray (10YR 7/2) clay loam, brown (10YR 5/3) moist; vesicular crust; massive; slightly hard, friable, sticky and plastic; slightly effervescent; neutral; abrupt smooth boundary.

AB—1 to 8 inches; light brownish gray (10YR 6/2) clay, grayish brown (10YR 5/2) moist; weak fine subangular blocky and granular structure; hard, firm, sticky and plastic; slightly effervescent; mildly alkaline; clear smooth boundary.

Bw1—8 to 15 inches; light brownish gray (10YR 6/2) clay, grayish brown (10YR 5/2) moist; weak medium and fine subangular blocky structure; very hard, very firm, sticky and plastic; slightly effervescent; mildly alkaline; gradual smooth boundary.

Bw2—15 to 26 inches; light gray (10YR 7/2) clay, pale brown (10YR 6/3) moist; weak medium angular blocky structure; very hard, very firm, sticky and plastic; slightly effervescent; mildly alkaline; gradual smooth boundary.

C—26 to 35 inches; pale brown (10YR 6/3) clay, brown (10YR 5/3) moist; massive; very hard, very firm, sticky and plastic; common distinct pressure faces at an angle of about 20 degrees from vertical;

slightly effervescent; mildly alkaline; gradual smooth boundary.

Ck—35 to 60 inches; very pale brown (10YR 7/3) clay, yellowish brown (10YR 5/4) moist; massive; very hard, very firm, sticky and plastic; slightly effervescent; common medium seams and filaments of calcium carbonate; mildly alkaline.

Electrical conductivity typically is less than 4 millimhos per centimeter, and cation exchange capacity per 100 grams of clay ranges from 90 to 100.

The E horizon has hue of 10YR or 2.5Y and chroma of 2 or 3.

The Bw horizon has hue of 10YR or 2.5Y and chroma of 2 or 3.

The Ck horizon has hue of 10YR or 2.5Y. It is mildly alkaline or moderately alkaline.

Hiland Series

The Hiland series consists of deep, well drained, moderately permeable soils on back slopes of rolling uplands and adjacent foot slopes. These soils formed in residuum and local alluvium derived from soft calcareous sandstone and in eolian material. Slope is 0 to 15 percent.

Typical pedon of a Hiland sandy clay loam in an area of Hiland-Bowbac complex, 6 to 15 percent slopes, 3,000 feet west and 600 feet south of the northeast corner of sec. 26, T. 35 N., R. 75 W.

A—0 to 3 inches; brown (10YR 5/3) sandy clay loam, dark brown (10YR 4/3) moist; weak medium granular structure; soft, very friable, nonsticky and nonplastic; neutral; clear wavy boundary.

BA—3 to 10 inches; brown (10YR 5/3) sandy loam, dark brown (10YR 4/3) moist; moderate coarse subangular blocky structure parting to weak fine granular; slightly hard, very friable, slightly sticky and slightly plastic; neutral; clear wavy boundary.

Bt—10 to 19 inches; brown (10YR 5/3) sandy clay loam, dark brown (10YR 4/3) moist; strong very coarse prismatic structure parting to moderate coarse subangular blocky; hard, friable, sticky and plastic; many moderately thick clay bridges between sand grains; mildly alkaline; clear smooth boundary.

Btk—19 to 24 inches; grayish brown (10YR 5/2) sandy loam, dark grayish brown (10YR 4/2) moist; moderate coarse subangular blocky structure; hard, friable, sticky and plastic; many moderately thick clay bridges between sand grains; strongly effervescent; common fine irregularly shaped calcium carbonate filaments and threads; moderately alkaline; gradual wavy boundary.

Bk1—24 to 36 inches; grayish brown (10YR 5/2) sandy clay loam, dark grayish brown (10YR 4/2) moist; moderate coarse subangular blocky structure; hard,

friable, sticky and plastic; strongly effervescent; common fine calcium carbonate filaments; moderately alkaline; gradual wavy boundary.

Bk2—36 to 60 inches; light brownish gray (10YR 6/2) sandy clay loam, grayish brown (10YR 5/2) moist; massive; slightly hard, friable, sticky and plastic; strongly effervescent; common fine irregularly shaped calcium carbonate filaments and threads; moderately alkaline.

The depth to calcium carbonate ranges from 15 to 30 inches.

The A horizon is sandy loam or sandy clay loam.

The Bt horizon has hue of 2.5Y to 10YR, and it has value of 5 or 6 when dry and 4 or 5 when moist. Clay content averages 24 to 34 percent. Reaction is neutral to moderately alkaline. The Bk horizon has hue of 2.5Y to 10YR, and it has value of 4 or 5 when moist. Reaction is mildly alkaline or moderately alkaline.

Keeline Series

The Keeline series consists of deep, somewhat excessively drained, moderately rapidly permeable soils on ridges and sides slopes of rolling uplands. These soils formed in wind-worked residuum derived dominantly from calcareous sandstone. Slope is 6 to 15 percent.

Typical pedon of a Keeline sandy loam in an area of Keeline-Tassel-Turnback complex, 6 to 15 percent slopes; 2,100 feet north and 400 feet west of the northeast corner of sec. 29, T. 40 N., R. 75 W.

A—0 to 3 inches; yellowish brown (10YR 5/4) sandy loam, brown (10YR 4/3) moist; weak fine subangular blocky and granular structure; soft, very friable, nonsticky and nonplastic; slightly effervescent; mildly alkaline; abrupt smooth boundary.

Bw—3 to 8 inches; pale brown (10YR 6/3) sandy loam, brown (10YR 5/3) moist; weak medium subangular blocky structure; slightly hard, friable, slightly sticky and slightly plastic; strongly effervescent; calcium carbonate disseminated throughout matrix; mildly alkaline; clear smooth boundary.

C1—8 to 17 inches; very pale brown (10YR 7/3) sandy loam, light yellowish brown (10YR 6/4) moist; massive; soft, very friable, nonsticky and nonplastic; strongly effervescent; calcium carbonate disseminated throughout matrix; moderately alkaline; gradual smooth boundary.

C2—17 to 30 inches; very pale brown (10YR 7/3) sandy loam, pale brown (10YR 6/3) moist; massive; soft, very friable, nonsticky and nonplastic; strongly effervescent; calcium carbonate disseminated throughout matrix; moderately alkaline; gradual smooth boundary.

C3—30 to 60 inches; very pale brown (10YR 7/3) sandy loam, light yellowish brown (10YR 6/4) moist; massive; soft, very friable, nonsticky and nonplastic;

strongly effervescent; calcium carbonate disseminated throughout matrix; moderately alkaline.

The profile is calcareous throughout in most pedons but in some pedons the upper few inches is leached.

The A horizon has hue of 7.5YR or 10YR and chroma of 3 or 4. Reaction is mildly alkaline or neutral.

The C horizon has hue of 7.5YR to 2.5Y. Reaction is moderately alkaline or strongly alkaline.

Kishona Series

Kishona series consists of deep, well drained, moderately permeable soils on upland hill slopes and on adjacent toe slopes, foot slopes, and alluvial flats and fans. These soils formed in calcareous local alluvium derived dominantly from sedimentary rock. Slope is 0 to 15 percent.

Typical pedon of a Kishona loam in an area of Theedle-Kishona association, 6 to 15 percent slopes; 2,600 feet east and 50 feet north of the southwest corner of sec. 35, T. 38 N., R. 75 W.

A—0 to 3 inches; brown (10YR 5/3) loam, brown (10YR 4/3) moist; weak fine and medium granular structure; soft, friable, slightly sticky and slightly plastic; violently effervescent; moderately alkaline; abrupt smooth boundary.

AC—3 to 12 inches; pale brown (10YR 6/3) clay loam, brown (10YR 5/3) moist; moderate fine and medium subangular blocky structure; hard, firm, sticky and plastic; violently effervescent; moderately alkaline; clear smooth boundary.

C1—12 to 36 inches; light yellowish brown (2.5Y 6/4) clay loam, light olive brown (2.5Y 5/4) moist; massive; hard, friable, slightly sticky and slightly plastic; violently effervescent; few fine soft masses of calcium carbonate; moderately alkaline; gradual smooth boundary.

C2—36 to 60 inches; light gray (2.5Y 7/2) clay loam, light yellowish brown (2.5Y 6/4) moist; massive; slightly hard, friable, slightly sticky and slightly plastic; violently effervescent; few fine soft masses of calcium carbonate; moderately alkaline.

The A horizon is loam or light clay loam.

The C horizon has hue of 10YR or 2.5Y. Reaction is moderately alkaline or strongly alkaline.

Lohmiller Series

The Lohmiller series consists of deep, well drained, moderately slowly permeable soils on narrow flood plains. These soils formed in stratified Recent alluvium derived from sedimentary rock. Slope is 0 to 6 percent.

Typical pedon of a Lohmiller clay loam in an area of Haverdad-Lohmiller complex, 0 to 6 percent slopes,

1,980 feet south and 1,580 feet west of the northeast corner of sec. 35, T. 37 N., R. 73 W.

—0 to 3 inches; grayish brown (2.5Y 5/2) clay loam, dark grayish brown (2.5Y 4/2) moist; moderate fine subangular blocky structure; slightly hard, friable, sticky and plastic; slightly effervescent; mildly alkaline; clear smooth boundary.

AC—3 to 16 inches; brown (10YR 5/3) clay, brown (10YR 4/3) moist; moderate medium and fine subangular blocky structure; hard, very firm, sticky and plastic; slightly effervescent; mildly alkaline; clear smooth boundary.

C1—16 to 19 inches; light yellowish brown (2.5Y 6/4) clay loam, light olive brown (2.5Y 5/4) moist; massive; hard, friable, slightly sticky and nonplastic; slightly effervescent; moderately alkaline; clear wavy boundary.

C2—19 to 60 inches; light yellowish brown (2.5Y 6/4) and brown (10YR 5/3), stratified sandy clay loam, sandy loam, and sandy clay, light olive brown (2.5Y 5/4) and brown (10YR 4/3) moist; massive; hard, friable, slightly sticky and plastic; slightly effervescent; moderately alkaline.

The profile commonly is calcareous throughout, but in some pedons the upper few inches is leached.

The A horizon has hue of 2.5Y or 10YR, value of 5 or 6 when dry and 4 or 5 when moist, and chroma of 2 or 3. Reaction is mildly alkaline to strongly alkaline.

The C horizon has hue of 2.5Y or 10YR. Reaction is moderately alkaline or strongly alkaline. The control section is heavy clay loam or silty clay.

Orella Series

The Orella series consists of shallow, well drained, slowly permeable soils on back slopes and ridgetops of uplands. These soils formed in residuum derived from sodic shale. Slope is 3 to 25 percent.

Typical pedon of an Orella clay loam in an area of Orella-Rock outcrop-Samday complex, 3 to 30 percent slopes, 1,800 feet north and 1,200 feet west of the southeast corner of sec. 2, T. 40 N., R. 71 W.

A—0 to 4 inches; light gray (2.5Y 7/2) clay loam, light brownish gray (2.5Y 6/2) moist; weak fine subangular blocky structure; slightly hard, friable, sticky and plastic; few medium and fine roots; slightly effervescent; moderately alkaline; clear smooth boundary.

ACk—4 to 13 inches; light gray (2.5Y 7/2) light clay, light brownish gray (2.5Y 6/2) moist; moderate fine angular blocky structure; hard, firm, sticky and plastic; few fine roots; content of shale fragments increases with increasing depth; strongly effervescent; common medium seams of calcium

carbonate; moderately alkaline; gradual smooth boundary.

Ck—13 to 20 inches; light brownish gray (2.5Y 6/2) clay between weathered shale fragments, grayish brown (2.5Y 5.2) moist; common medium yellowish red (5YR 5/6) oxide stains on shale fragments; massive; hard, firm, very sticky and very plastic; few fine and very fine roots; noneffervescent; few medium and fine calcium carbonate concretions; moderately alkaline; gradual smooth boundary.

Cr—20 to 60 inches; light gray (2.5Y 7/2) shale, grayish brown (2.5Y 5.2) moist; common medium and fine olive yellow (2.5Y 6/8) and brownish yellow (10YR 6/8) oxides and oxide stains; noneffervescent.

The depth to shale ranges from 10 to 20 inches. The profile commonly is calcareous throughout, but in some pedons it is leached to a depth of as much as 10 inches.

The A horizon has hue of 10YR or 2.5Y, value of 6 or 7 when dry and 5 or 6 when moist, and chroma of 2 or 3. It is typically clay loam or clay.

The Ck horizon has hue of 2.5Y or 10YR, value of 6 or 7 when dry and 5 or 6 when moist, and chroma of 2 or 3. It is clay or heavy clay loam.

Orpha Series

The Orpha series consists of deep, excessively drained, very rapidly permeable soils on dunes. These soils formed in eolian sand. Slope is 0 to 15 percent.

Typical pedon of an Orpha loamy sand in an area of Dwyer-Orpha loamy sands, 3 to 15 percent slopes, 200 feet west and 1,250 feet south of the northeast corner of sec. 31, T. 41 N., R. 67 W.

A—0 to 6 inches; grayish brown (10YR 5/2) loamy sand, dark grayish brown (10YR 4/2) moist; weak moderate and coarse granular structure parting to single grain; loose; mildly alkaline; gradual wavy boundary.

C—6 to 60 inches; light brownish gray (10YR 6/2) sand, grayish brown (10YR 5/2) moist; single grain; loose; mildly alkaline.

Depth to calcium carbonate ranges from 40 to 60 inches or more.

The A horizon has value of 5 or 6 when dry and 4 or 5 when moist, and it has chroma of 2 or 3. It is loamy sand or sand.

The C horizon has value of 6 or 7 when dry and 5 or 6 when moist, and it has chroma of 2 to 4. Clay content ranges from 3 to 10 percent. Reaction is neutral or mildly alkaline.

Renohill Series

The Renohill series consists of moderately deep, well drained, slowly permeable soils on upland ridgetops,

back slopes, and foot slopes. These soils formed in residuum derived from soft shale. Slope is 0 to 15 percent.

Typical pedon of a Renohill fine sandy loam in an area of Ulm-Renohill complex, 0 to 6 percent slopes, 2,640 feet south of the northeast corner of sec. 31, T. 38 N., R. 68 W.

A—0 to 5 inches; pale brown (10YR 6/3) fine sandy loam, brown (10YR 5/3) moist; weak fine and medium granular structure; soft, very friable, slightly sticky and slightly plastic; neutral; clear smooth boundary.

Bt—5 to 20 inches; brown (10YR 5/3) clay, dark brown (10YR 4/3) moist; strong coarse prismatic structure parting to coarse subangular blocky; very hard, very firm, sticky and plastic; common moderately thick clay films on faces of peds; mildly alkaline; gradual wavy boundary.

Bk—20 to 36 inches; pale brown (10YR 6/3) clay loam, brown (10YR 5/3) moist; moderate medium and coarse subangular blocky structure; hard, firm, sticky and plastic; slightly effervescent; few fine soft white filaments and threads of carbonates; moderately alkaline.

Cr—36 inches; calcareous shale.

The depth to bedrock ranges from 20 to 40 inches. The depth to calcium carbonate ranges from 10 to 20 inches.

The A horizon has value of 5 or 6 when dry and 4 or 5 when moist, and it has chroma of 2 or 3. It is fine sandy loam or clay loam.

The Bt horizon has hue of 10YR or 2.5Y, value of 4 to 7 when dry and 4 or 5 when moist, and chroma of 2 to 4. It is clay or clay loam and averages 37 to 46 percent clay. Reaction is neutral to moderately alkaline.

The Bk horizon has value of 6 or 7 when dry and chroma of 2 to 4. It is moderately alkaline or strongly alkaline.

The Cr horizon is calcareous shale or sandstone.

Samday Series

The Samday series consists of shallow, well drained, very slowly permeable soils on summits, shoulder slopes, and ridges of upland hills and on scarps where the shale beds have been exposed by geologic erosion. These soils formed in residuum derived from soft calcareous shale. Slope is 3 to 30 percent.

Typical pedon of a Samday clay loam in an area of Samday-Shingle-Worf complex, 3 to 15 percent slopes, 2,500 feet north and 1,600 feet west of the southeast corner of sec. 36, T. 37 N., R. 69 W.

A—0 to 2 inches; light brownish gray (10YR 6/2) clay loam, grayish brown (10YR 5/2) moist; moderate coarse platy structure parting to weak fine granular;

slightly hard, friable, sticky and plastic; effervescent; disseminated carbonates; moderately alkaline; gradual wavy boundary.

C—2 to 10 inches; light brownish gray (10YR 6/2) clay, grayish brown (10YR 5/2) moist; strong coarse subangular blocky structure parting to moderate fine subangular blocky; hard, firm, sticky and plastic; strongly effervescent; disseminated carbonates; moderately alkaline; gradual wavy boundary.

Cky—10 to 18 inches; light brownish gray (10YR 6/2) clay, grayish brown (10YR 5/2) moist; massive; hard, firm, sticky and plastic; strongly effervescent; gypsum crystals and many fine soft filaments and threads of carbonates and gypsum crystals; about 20 percent soft weathered shale chips; moderately alkaline, clear wavy boundary.

Cr—18 inches; calcareous shale and sandstone.

The A horizon has value of 6 or 7 when dry and 5 or 6 when moist. It is clay loam or clay.

The AC horizon has value of 6 or 7 when dry and 5 or 6 when moist, and it has chroma of 2 or 3. Reaction is moderately alkaline or strongly alkaline.

The Cky horizon has value of 5 or 6 when moist. Reaction is neutral to moderately alkaline.

The Cr horizon is calcareous shale or sandstone.

Savageton Series

The Savageton series consists of moderately deep, well drained, slowly permeable soils on toe slopes and alluvial flats. These soils formed in residuum or local alluvium derived from calcareous shale. Slope is 0 to 6 percent.

Typical pedon of a Savageton clay loam in an area of Bahl-Savageton complex, 0 to 6 percent slopes, 400 feet north and 750 feet west of the southeast corner of sec. 31, T. 37 N., R. 68 W.

A—0 to 2 inches; gray (10YR 5/1) clay loam, dark gray (10YR 4/1) moist; moderate medium platy structure and moderate medium granular; slightly hard, friable, sticky and plastic, mildly alkaline; clear wavy boundary.

Bw—2 to 22 inches; light brownish gray (2.5Y 6/2) clay, grayish brown (2.5Y 5/2) moist; moderate coarse prismatic structure that parts to moderate medium subangular blocky; hard, firm, sticky and plastic; slightly effervescent; moderately alkaline; abrupt wavy boundary.

Bk1—22 to 28 inches; light brownish gray (10YR 6/2) clay, grayish brown (10YR 5/2) moist; moderate coarse subangular blocky structure parting to fine subangular blocky; hard, firm, sticky and plastic; many moderately thick clay films on faces of peds; strongly effervescent; common fine irregularly

shaped filaments or threads of calcium carbonate; moderately alkaline; clear smooth boundary.

Bk2—28 to 32 inches; grayish brown (10YR 5/2) clay, dark brown (10YR 4/2) moist; massive; hard, firm, sticky and plastic; strongly effervescent; common fine irregularly shaped filaments or threads of calcium carbonate; moderately alkaline; abrupt wavy boundary.

Cr—32 inches; calcareous platy shale.

The depth to calcium carbonate ranges from 10 to 22 inches. Depth to bedrock ranges from 32 to 39 inches.

The A horizon has value of 4 to 6 when dry and chroma of 1 or 2.

The Bw horizon has value of 5 or 6 when dry. It averages 35 to 40 percent clay.

Sear Series

The Sear series consists of very shallow, well drained, moderately permeable soils on hill slopes and on the summit of buttes. These soils formed in residuum derived from porcellanite. Slope is 0 to 15 percent.

Typical pedon of a Sear loam in an area of Sear-Wibaux complex, 0 to 15 percent slopes, 1,825 feet north and 1,650 feet west of the southeast corner of sec. 2, T. 40 N., R. 71 W.

A—0 to 2 inches; pinkish gray (7.5YR 6/2) loam, brown (7.5YR 4/2) moist; weak fine granular structure; soft, very friable, slightly sticky and slightly plastic; common fine and very fine roots and few medium roots; about 15 percent reddish yellow (5YR 6/8) and red (2.5YR 6/8) porcellanite fragments 0.25 to 1.0 inch in diameter; neutral; clear smooth boundary.

Bt—2 to 9 inches; brown (7.5YR 5/4) channery loam, dark brown (7.5YR 4/4) moist; weak medium prismatic structure parting to moderate medium subangular blocky; slightly hard, friable, sticky and slightly plastic; few thin clay films on faces of peds; common fine and very fine roots; about 30 percent red (2.5YR 6/8) and brown (7.5YR 5/4) porcellanite fragments 0.25 inch to 2.0 inches in diameter; neutral; clear irregular boundary.

Bk1—9 to 35 inches; red (2.5YR 6/8) and reddish yellow (5YR 6/8) porcellanite fragments 0.5 inch to 4.0 inches in diameter; light brown (7.5YR 6/4) loam fills voids in upper part of horizon and decreases to a trace in lower part; calcium carbonate coating on undersides of larger fragments; diffuse wavy boundary.

Bk2—35 to 60 inches; red (2.5YR 5/6 and 5/8) porcellanite fragments 1 inch to 4 inches in diameter; traces of red (2.5YR 5/6) sandy loam in vertical and horizontal fractures in upper part.

Depth to calcium carbonate ranges mainly from 5 to 10 inches, but it is as much as 20 inches in some

pedons. Fragmented porcellanite makes up 90 percent or more of all horizons below a depth of 10 inches.

The A horizon has hue of 7.5YR or 10YR, value of 5 or 6 when dry and 4 or 5 when moist, and chroma of 2 or 3. Reaction is neutral or mildly alkaline.

The Bt horizon has hue of 5YR to 10YR, value of 5 or 6 when dry and 4 or 5 when moist, and chroma of 2 to 4. It is clay loam or loam and is 10 to 35 percent porcellanite fragments. Reaction is neutral to moderately alkaline.

The Bk horizon has traces of soil material between porcellanite fragments.

Shingle Series

The Shingle series consists of shallow, well drained, moderately permeable soils on ridgetops, shoulder slopes, and back slopes of uplands and on scarps in areas where the shale beds have been exposed by geologic erosion. These soils formed in residuum derived from soft calcareous shale. Slope is 3 to 45 percent.

Typical pedon of a Shingle clay loam in an area of Worf-Shingle-Tassel complex, 3 to 30 percent slopes, 1,320 feet west and 550 feet north of the southeast corner of sec. 30, T. 40 N., R. 68 W.

A—0 to 4 inches; light brownish gray (2.5Y 6/2) clay loam, grayish brown (2.5Y 5/2) moist; moderate very thin and thin platy structure parting to moderate very fine and fine granular; slightly hard, friable, slightly sticky and slightly plastic; slightly effervescent; disseminated carbonates; moderately alkaline; clear wavy boundary.

C—4 to 18 inches; light brownish gray (2.5Y 6/2) clay loam, grayish brown (2.5Y 5/2) moist; massive; hard, firm, sticky and plastic; strongly effervescent; disseminated carbonates; about 15 percent shale fragments; strongly alkaline, clear wavy boundary.

Cr—18 inches; calcareous shale.

The A horizon has hue of 10YR or 2.5Y, value of 5 to 7 when dry and 4 or 5 when moist, and chroma of 2 to 4. It is clay loam, very fine sandy loam, loam, or sandy clay loam.

The C horizon has hue of 10YR or 2.5Y, value of 5 to 7 when dry and 4 to 6 when moist, and chroma of 2 to 4. It is mildly alkaline to strongly alkaline.

Silhouette Series

The Silhouette series consists of deep, well drained, slowly permeable soils on foot slopes and alluvial flats. These soils formed in local alluvium derived dominantly from calcareous shale. Slope is 0 to 6 percent.

Typical pedon of a Silhouette clay loam in an area of Silhouette-Heldt association, 0 to 6 percent slopes, 150

feet west and 600 feet south of the northeast corner of ec. 20, T. 39 N., R. 71 W.

A—0 to 2 inches; light brownish gray (10YR 6/2) clay loam, brown (10YR 5/3) moist; weak medium and fine granular structure; slightly hard, very friable, slightly sticky and slightly plastic; slightly effervescent; mildly alkaline; abrupt smooth boundary.

BA—2 to 6 inches; pale brown (10YR 6/3) clay, brown (10YR 5/3) moist; weak medium subangular blocky structure; hard, friable, sticky and plastic; slightly effervescent; moderately alkaline; clear smooth boundary.

Bw1—6 to 14 inches; pale brown (10YR 6/3) clay, grayish brown (10YR 5/2) moist; weak fine prismatic structure; hard, friable, sticky and plastic; slightly effervescent; moderately alkaline; clear smooth boundary.

Bw2—14 to 22 inches; pale brown (10YR 6/3) clay, grayish brown (10YR 5/2) moist; weak fine angular blocky structure; very hard, firm, slightly sticky and slightly plastic; slightly effervescent; moderately alkaline; gradual smooth boundary.

Bk1—22 to 34 inches; very pale brown (10YR 7/3) clay, light brownish gray (10YR 6/2) moist; massive; very hard, firm, slightly sticky and slightly plastic; slightly effervescent; common medium seams and filaments of calcium carbonate; moderately alkaline; gradual smooth boundary.

2—34 to 60 inches; light gray (10YR 7/2) clay loam, light brownish gray (10YR 6/2) moist; massive; very hard, very firm, slightly sticky and slightly plastic; slightly effervescent; few medium soft calcium carbonate masses and iron concretions; mildly alkaline.

Electrical conductivity typically is less than 4 millimhos per centimeter, and cation exchange capacity per 100 grams of clay ranges from 80 to 90.

Tassel Series

The Tassel series consists of shallow, well drained, moderately rapidly permeable soils on shoulder slopes and ridgetops of uplands. These soils formed in residuum derived from soft calcareous sandstone. Slope is 3 to 30 percent.

Typical pedon of a Tassel loamy fine sand in an area of Tassel-Tullock-Vonalee association, 6 to 30 percent slopes, 1,950 feet east and 375 feet south of the northwest corner of sec. 8, T. 40 N., R. 68 W.

A—0 to 2 inches; light brownish gray (10YR 5/2) loamy fine sand, dark grayish brown (10YR 4/2) moist; weak medium and coarse granular structure; soft, very friable, nonsticky and nonplastic; slightly effervescent; disseminated carbonates; mildly alkaline; gradual wavy boundary.

AC—2 to 5 inches; light brownish gray (10YR 6/2) fine sandy loam, grayish brown (10YR 5/2) moist; weak medium and coarse granular structure; soft, very friable, nonsticky and nonplastic; slightly effervescent; disseminated carbonates; mildly alkaline; gradual wavy boundary.

C—5 to 16 inches; pale brown (10YR 6/3) fine sandy loam, brown (10YR 5/3) moist; weak very fine and fine subangular blocky structure; soft, very friable, slightly sticky and nonplastic; common very fine pores; slightly effervescent; disseminated carbonates; mildly alkaline, clear wavy boundary.

Cr—16 inches; soft, calcareous, light gray (5Y 7/1) sandstone.

The profile is neutral to moderately alkaline. It commonly has calcium carbonate throughout, but in a few areas it is noncalcareous.

The A horizon is loamy fine sand, loamy sand, sandy loam, or fine sandy loam.

The C horizon has chroma of 3 or 4. The control section is fine sandy loam or sandy loam.

Tassel Variant

The Tassel Variant consists of very shallow, well drained, moderately rapidly permeable soils on ridges of rolling and hilly uplands. These soils formed in residuum derived from calcareous sandstone interbedded with shale. Slope is 10 to 30 percent.

Typical pedon of a Tassel Variant very fine sandy loam in an area of Gateson Variant-Tassel Variant association, 10 to 45 percent slopes, in the S1/4 of sec. 11, T. 40 N., R. 77 W.

A—0 to 4 inches; light yellowish brown (10YR 6/4) very fine sandy loam, dark yellowish brown (10YR 4/4) moist; weak fine subangular blocky structure; soft, very friable, nonsticky and nonplastic; strongly effervescent; mildly alkaline; clear smooth boundary.

Ck—4 to 9 inches; gray (5YR 5/1) loam, dark gray (5YR 4/1) moist; massive; slightly hard, friable, slightly sticky and slightly plastic; strongly effervescent; few fine soft masses and filaments of calcium carbonate; moderately alkaline; gradual wavy boundary.

Cr—9 inches; interbedded sedimentary rock, dominantly shale.

Depth to soft sedimentary rock ranges from 5 to 10 inches. Content of coarse fragments does not normally exceed 5 percent, but in some areas as much as 10 percent of the surface is covered with ironstone flagstones.

The A horizon has hue of 10YR or 2.5Y, value of 6 or 7 when dry and 4 or 5 when moist, and chroma of 2 to 4. Texture is fine sandy loam or very fine sandy loam. Reaction is neutral or mildly alkaline.

The Ck horizon has hue of 5YR to 10YR, value of 5 or when dry and 4 or 5 when moist, and chroma of 1 to 3. Texture is loam or sandy loam. Reaction is mildly alkaline or moderately alkaline.

Terro Series

The Terro series consists of moderately deep, somewhat excessively drained, moderately rapidly permeable soils on ridges, hill slopes, and pediment slopes of uplands. These soils formed in residuum derived from soft calcareous sandstone. Slope is 0 to 30 percent.

Typical pedon of a Terro sandy loam (fig. 4) in an area of Vonalee-Terro complex, 0 to 15 percent slopes, 1,000 feet west and 1,250 feet south of the northeast corner of sec. 17, T. 31 N., R. 74 W.

A—0 to 4 inches; brown (10YR 5/3) sandy loam, dark brown (10YR 4/3) moist; weak medium and fine granular structure; loose, slightly sticky and slightly plastic; neutral; clear smooth boundary.

Bt1—4 to 10 inches; brown (10YR 5/3) sandy loam, dark brown (10YR 4/3) moist; moderate coarse subangular blocky structure; slightly hard, very friable, slightly sticky and slightly plastic, clear smooth boundary.

Bt2—10 to 23 inches; pale brown (10YR 6/3) sandy loam, brown (10YR 5/3) moist; weak coarse subangular blocky structure; slightly hard, very friable, slightly sticky and slightly plastic; common thin clay bridges between sand grains; mildly alkaline; clear smooth boundary.

Bk—23 to 34 inches; light gray (10YR 7/2) sandy loam, light brownish gray (10YR 6/2) moist; weak medium and coarse subangular blocky structure; slightly hard, very friable, slightly sticky and slightly plastic; violently effervescent; many fine irregularly shaped soft masses of calcium carbonate; moderately alkaline; clear irregular boundary.

Cr—34 inches; white (10YR 8/2) calcareous coarse-grained soft sandstone.

The depth to continuous carbonates ranges from 15 to 30 inches. Depth to bedrock ranges from 26 to 39 inches.

The A horizon has value of 5 or 6 when dry and chroma of 2 or 3. It is sandy loam or fine sandy loam.

The Bt horizon has value of 5 or 6 when dry and chroma of 3 or 4. Reaction is neutral to moderately alkaline.

The Bk horizon has value of 6 or 7 when dry and 5 or 6 when moist, and it has chroma of 2 to 4. It is neutral to moderately alkaline.

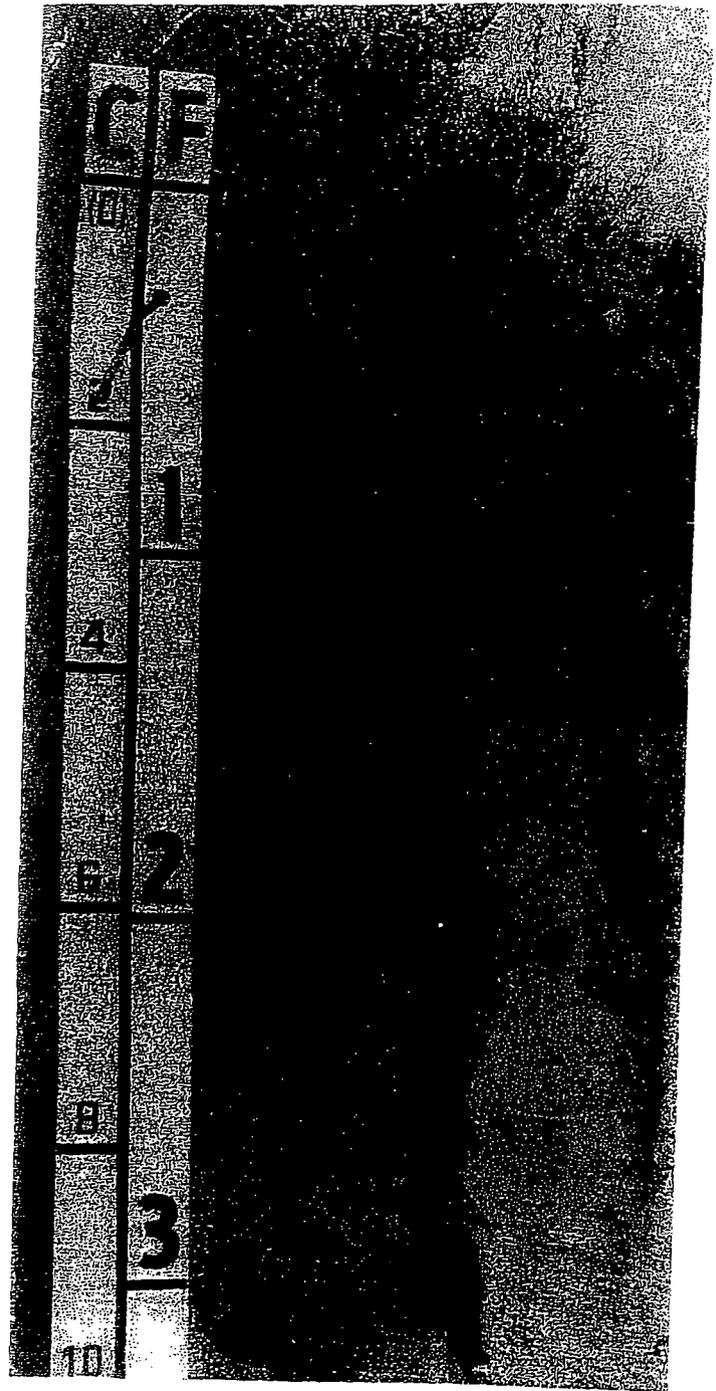

Figure 4.—Profile of Terro sandy loam. Soft sandstone is at depth of 2 feet; some roots have penetrated to depths of 3 feet in softer soils.

Theedle Series

The Theedle series consists of moderately deep, well drained, moderately permeable soils on ridges, hill slopes, and pediment slopes of uplands and on alluvial fans and foot slopes adjacent to major and minor drainageways. These soils formed in residuum derived from calcareous shale. Slope is 0 to 30 percent.

Typical pedon of a Theedle loam in an area of Zigweid-Cambria-Theedle association, 6 to 15 percent slopes, 1,580 feet south and 10 feet west of the northeast corner of sec. 19, T. 35 N., R. 67 W.

- A—0 to 2 inches; pale brown (10YR 6/3) loam, brown (10YR 5/3) moist; weak fine granular structure; slightly hard, very friable, slightly sticky and slightly plastic; strongly effervescent; calcium carbonate disseminated throughout matrix; mildly alkaline; clear wavy boundary.
- AC—2 to 5 inches; pale brown (10YR 6/3) loam, brown (10YR 5/3) moist; weak medium and fine subangular blocky structure; hard, friable, slightly sticky and slightly plastic; strongly effervescent; calcium carbonate disseminated throughout matrix; mildly alkaline; gradual wavy boundary.
- Ck—5 to 20 inches; light gray (10YR 7/2) loam, very pale brown (10YR 7/4) moist; massive; hard, friable, slightly sticky and slightly plastic; strongly effervescent; common fine masses and seams of calcium carbonate; moderately alkaline; gradual wavy boundary.
- ck2—20 to 28 inches; light brownish gray (10YR 6/2) clay loam, grayish brown (10YR 5/2) moist; massive; very hard, friable, sticky and plastic; strongly effervescent; few fine soft masses and seams of calcium carbonate; strongly alkaline; clear wavy boundary.
- Crk—28 to 48 inches; gray (10YR 5/1) clay shale changing with depth to light gray (10YR 6/1) noncalcareous; common medium seams and filaments of calcium carbonate that decrease in number and size as depth increases.

The C horizon has hue of 10YR to 5Y and value of 5 or 6 when moist. Reaction is moderately alkaline or strongly alkaline. Texture is loam or light clay loam.

Tulloch Series

The Tulloch series consists of moderately deep, excessively drained, rapidly permeable soils on shoulder slopes, back slopes, and ridges of upland hills. These soils formed in residuum derived from calcareous sandstone. Slope is 0 to 30 percent.

Typical pedon of a Tulloch loamy sand in an area of Tassel-Tulloch-Vonalee association, 6 to 30 percent slopes, 1,200 feet west and 1,000 feet north of the southeast corner of sec. 29, T. 35 N., R. 73 W.

- A—0 to 5 inches; brown (10YR 5/3) loamy sand, dark brown (10YR 4/3) moist; weak medium and fine crumb structure; soft, loose; slightly effervescent; disseminated calcium carbonate; mildly alkaline; clear wavy boundary.
- AC—5 to 20 inches; brown (10YR 5/3) sand, dark brown (10YR 4/3) moist; massive; soft, loose; strongly effervescent; disseminated calcium carbonate; mildly alkaline; clear wavy boundary.
- C—20 to 31 inches; pale brown (10YR 6/3) loamy sand, brown (10YR 5/3) moist; massive; soft, loose; strongly effervescent; disseminated calcium carbonate; mildly alkaline; clear wavy boundary.
- Cr—31 inches; soft calcareous sandstone.

The depth to bedrock ranges from 24 to 36 inches.

The A horizon has hue of 10YR or 2.5Y, value of 5 or 6 when dry and 4 or 5 when moist, and chroma of 2 to 4. Reaction is mildly alkaline or moderately alkaline.

The AC horizon has hue of 10YR or 2.5Y, value of 5 or 6 when dry and 4 or 5 when moist, and chroma of 2 to 4. It is loamy sand, fine sand, loamy fine sand, or fine sandy loam. Reaction is mildly alkaline or moderately alkaline.

The C horizon has hue of 10YR or 2.5Y, value of 6 or 7 when dry and 5 or 6 when moist, and chroma of 2 to 4. Reaction is mildly alkaline or moderately alkaline.

The Cr horizon is dominantly soft calcareous sandstone, but in some pedons it is interbedded with seams of calcareous shale.

Turnback Series

The Turnback series consists of moderately deep, well drained, moderately rapidly permeable soils on upland ridgetops and shoulders. These soils formed in wind-worked residuum derived from calcareous sandstone. Slope is 6 to 15 percent.

Typical pedon of a Turnback loamy fine sand in an area of Keeline-Tassel-Turnback complex, 6 to 15 percent slopes, 2,500 feet east and 1,900 feet north of the southwest corner of sec. 19, T. 39 N., R. 74 W.

- A—0 to 4 inches; pale brown (10YR 6/3) loamy fine sand, brown (10YR 5/3) moist; weak fine granular structure; loose, nonsticky and nonplastic; few fine calcium carbonate seams; moderately alkaline; clear smooth boundary.
- Bw1—4 to 8 inches; pale brown (10YR 6/3) sandy loam, yellowish brown (10YR 5/4) moist; weak medium and fine subangular blocky structure; loose, nonsticky and nonplastic; violently effervescent; few fine calcium carbonate seams; moderately alkaline; clear smooth boundary.
- Bw2—8 to 20 inches; light yellowish brown (2.5Y 6/4) sandy loam, light olive brown (2.5Y 5/4) moist; weak medium subangular blocky structure; soft, very

friable, slightly sticky and slightly plastic; strongly effervescent; common medium and fine calcium carbonate seams; moderately alkaline; clear wavy boundary.

Bk1—20 to 30 inches; pale yellow (2.5Y 7/4) sandy loam, light olive brown (2.5Y 5/4) moist; massive with some inherited rock structural planes; soft, very friable, slightly sticky and slightly plastic; strongly effervescent; few medium and coarse soft masses of calcium carbonate and few fine calcium carbonate seams; moderately alkaline; gradual wavy boundary.

Cr—30 inches; yellow (10YR 7/8) soft calcareous sandstone; moderately alkaline; very slightly effervescent.

The profile commonly is leached in the upper few inches, but in some pedons it is calcareous throughout. Coarse fragment content is typically less than 5 percent.

Ulm Series

The Ulm series consists of deep, well drained, moderately permeable to slowly permeable soils on alluvial flats and toe slopes and on foot slopes of rolling uplands. These soils formed in local alluvium derived from soft calcareous shale. Slope is 0 to 15 percent.

Typical pedon of an Ulm loam in an area of Ulm-Bidman complex, 0 to 6 percent slopes, 751 feet west and 203 feet north of the southeast corner of sec. 32, T. 35 N., R. 70 W.

—0 to 5 inches; brown (10YR 5/3) loam, dark brown (10YR 4/3) moist; weak fine and medium subangular blocky structure parting to moderate medium granular; slightly hard, very friable, slightly sticky and slightly plastic; neutral; gradual wavy boundary.

Bt1—5 to 9 inches; brown (10YR 5/3) clay loam, dark brown (10YR 4/3) moist; moderate fine and medium prismatic structure parting to moderate fine and medium subangular blocky; hard, friable, sticky and plastic; few thin clay bridges between mineral grains; neutral; clear wavy boundary.

Bt2—9 to 21 inches; brown (10YR 5/3) clay, dark brown (10YR 4/3) moist; strong fine and medium prismatic structure parting to strong fine and medium subangular blocky; very hard, very firm, very sticky and very plastic; many moderately thick clay films on faces of peds; mildly alkaline; gradual wavy boundary.

Bk1—21 to 36 inches; pale brown (10YR 6/3) clay loam, brown (10YR 5/3) moist; moderate fine and medium prismatic structure parting to moderate fine and medium subangular blocky; very hard, very firm, sticky and plastic; strongly effervescent; common medium masses of carbonates; moderately alkaline; clear wavy boundary.

Bk2—36 to 60 inches; light yellowish brown (10YR 6/4) sandy clay loam, yellowish brown (10YR 5/4) moist; massive; hard, friable, sticky and plastic; violently effervescent; common fine masses of carbonates; moderately alkaline.

The depth to calcium carbonate ranges from 15 to 28 inches.

The A horizon has value of 4 to 7 when dry and 4 or 5 when moist, and it has chroma of 2 or 3. It is loam or clay loam.

The Bt horizon has value of 5 or 6 when dry and 4 or 5 when moist, and it has chroma of 2 to 4. Texture is clay, clay loam, or sandy clay that averages 37 to 45 percent clay. Reaction is neutral or mildly alkaline.

The Bk horizon has hue of 10YR or 2.5Y, value of 5 to 7 when dry and 4 to 6 when moist, and chroma of 1 to 4. Texture is clay loam, fine sandy loam, sandy loam, loam, or sandy clay loam. Reaction is moderately alkaline or strongly alkaline.

Ustic Torriorthents

Ustic Torriorthents are mainly deep, well drained soils of variable permeability around coal and uranium strip mines and porcellanite borrow areas. These soils formed in recently reclaimed overburden from mining operations. Slope is 3 to 30 percent.

Reference pedon of Ustic Torriorthents, reclaimed, 3 to 30 percent slopes, 800 feet south and 250 feet west of the northeast corner of sec. 10, T. 35 N., R. 75 W.

A—0 to 5 inches; brown (10YR 5/3) sandy loam, brown (10YR 4/3) moist; massive; slightly hard, friable, slightly sticky and slightly plastic; moderately acid; clear wavy boundary.

C1—5 to 9 inches; light gray (10YR 7/2) loamy sand, light brownish gray (10YR 6/2) moist; massive; loose, very friable, nonsticky and nonplastic; extremely acid; gradual broken boundary.

C2—9 to 15 inches; reddish yellow (7.5YR 6/8) loamy sand, strong brown (7.5YR 6.8) moist; massive; loose, very friable, nonsticky and nonplastic; extremely acid; gradual broken boundary.

C3—15 to 20 inches; light brownish gray (10YR 6/2) loamy sand, grayish brown (10YR 5/2) moist; massive; loose, very friable, nonsticky and nonplastic; about 10 percent fine coal fragments; extremely acid; gradual broken boundary.

C4—20 to 60 inches; light gray (10YR 7/2) loamy sand, light brownish gray (10YR 6/2) moist; massive; loose, very friable, nonsticky and nonplastic; very strongly acid.

Reaction ranges from extremely acid to moderately alkaline. The control section is loamy sand to clay loam.

Thin seams of mostly shale or coal fragments are present in some pedons.

Vonalee Series

The Vonalee series consists of deep, somewhat excessively drained, rapidly permeable soils in undulating to rolling areas on uplands and high terraces. These soils formed in eolian sand and wind-reworked sandstone residuum. Slope is 0 to 15 percent.

Typical pedon of a Vonalee loamy sand in an area of Vonalee-Terro complex, 6 to 15 percent slopes, 100 feet west and 1,600 feet north of southeast corner of sec. 29, T. 35 N., R. 73 W.

- A—0 to 4 inches; yellowish brown (10YR 5/4) loamy sand, dark yellowish brown (10YR 4/4) moist; moderate thin platy structure parting to weak fine granular; soft, loose, nonsticky and nonplastic; neutral; gradual wavy boundary.
- BA—4 to 10 inches; yellowish brown (10YR 5/4) sandy loam, dark yellowish brown (10YR 4/4) moist; moderate coarse subangular blocky structure; soft, very friable, nonsticky and nonplastic; neutral; gradual wavy boundary.
- Bt1—10 to 17 inches; grayish brown (10YR 5/2) sandy loam, dark grayish brown (10YR 4/2) moist; moderate coarse subangular blocky structure; soft, very friable, slightly sticky and slightly plastic; few thin clay bridges between sand grains; mildly alkaline; gradual wavy boundary.
- Bt2—17 to 24 inches; yellowish brown (10YR 5/4) sandy loam, dark yellowish brown (10YR 4/4) moist; moderate coarse subangular blocky structure; slightly hard, very friable, slightly sticky and slightly plastic; few thin clay bridges between sand grains; moderately alkaline; clear wavy boundary.
- Bk1—24 to 44 inches; brown (10YR 5/3) loamy sand, dark brown (10YR 4/3) moist; moderate coarse prismatic structure; soft, loose, nonsticky and nonplastic; slightly effervescent; mildly alkaline; clear wavy boundary.
- Bk2—44 to 60 inches; light brownish gray (10YR 6/2) loam, grayish brown (10YR 5/2) moist; massive; slightly hard, friable, sticky and plastic; violently effervescent; many fine and medium irregularly shaped threads and filaments of calcium carbonate; moderately alkaline.

Wibaux Series

The Wibaux series consists of shallow, somewhat excessively drained, moderately permeable soils on hill slopes, buttes, and ridge crests of uplands. These soils formed in residuum derived from porcellanite. Slope is 0 to 45 percent.

Typical pedon of a Wibaux channery loam in an area of Sear-Wibaux complex, 0 to 15 percent slopes, 1,450

feet west and 1,300 feet south of the northeast corner of sec. 2, T. 40 N., R. 71 W.

- A—0 to 4 inches; pinkish gray (7.5YR 6/2) channery loam, brown (7.5YR 5/4) moist; weak fine granular structure; soft, friable; about 35 percent red (2.5YR 4/8) porcellanite fragments 0.5 inch to 1.5 inches in diameter; mildly alkaline; clear smooth boundary.
- AC—4 to 11 inches; light brown (7.5YR 6/4) very channery loam, brown (7.5YR 4/4) moist; very weak fine granular structure; soft, very friable; about 75 percent brown (7.5YR 4/4) porcellanite fragments 0.5 inch to 2.0 inches in diameter; neutral; clear smooth boundary.
- C—11 to 28 inches; dark yellowish brown (10YR 4/6) fragmented porcellanite grading to strong brown (7.5YR 5/6) in the lower part; single grain; yellowish brown (10YR 5/6) sandy loam occupies narrow voids between 1- to 3-inch fragments; neutral; gradual wavy boundary.
- Ck—28 to 60 inches; red (2.5YR 5/6) porcellanite flagstones underlain by red (2.5YR 5/6) fractured porcellanite; traces of light reddish brown (2.5YR 6/3) sandy loam, mostly along vertical fractures, extend to a depth of about 45 inches; calcium carbonate coatings on underside of larger flagstones.

Depth to calcium carbonate and porcellanite ranges from 10 to 20 inches.

The A horizon has hue of 2.5YR to 7.5YR, value of 6 when dry and 4 or 5 when moist, and chroma of 3 to 4. Reaction is neutral or mildly alkaline. Texture is commonly loam that has 20 to 60 percent porcellanite fragments.

The C horizon has hue of 10R to 5YR, value of 5 or 6 when dry and 4 or 5 when moist, and chroma of 3 to 6. Reaction is neutral to moderately alkaline. The horizon commonly is fractured porcellanite with loam or sandy loam in the voids in the upper part grading to largely in place fractured porcellanite with traces of soil in voids in the lower part.

Worf Series

The Worf series consists of shallow, well drained, moderately permeable soils on shoulder slopes, back slopes, and ridges and other summits of rolling uplands. These soils formed in residuum derived from interbedded shale and sandstone. Slope is 3 to 30 percent.

Typical pedon of a Worf fine sandy loam in an area of Worf-Shingle-Tassel complex, 3 to 30 percent slopes, in the NW1/4NW1/4NW1/4 of sec. 29, T. 35 N., R. 73 W.

- A—0 to 2 inches; grayish brown (10YR 5/2) fine sandy loam, dark grayish brown (10YR 4/2) moist; weak thin platy structure parting to weak fine granular;

soft, loose, slightly sticky and slightly plastic; neutral; clear wavy boundary.

Bt1—2 to 8 inches; brown (10YR 5/3) sandy clay loam, dark brown (10YR 4/3) moist; moderate coarse subangular blocky structure; slightly hard, friable, sticky and plastic; few thin clay films on ped faces; mildly alkaline; clear wavy boundary.

Bt2—8 to 14 inches; brown (10YR 5/3) sandy clay loam, dark brown (10YR 4/3) moist; strong coarse prismatic structure parting to moderate fine and medium subangular blocky; hard, firm, sticky and plastic; common moderately thick clay films on ped faces; mildly alkaline; clear wavy boundary.

Bk—14 to 18 inches; light yellowish brown (2.5Y 5/3) sandy clay loam, light olive brown (2.5Y 5/4) moist; massive; hard, firm, sticky and plastic; strongly effervescent; disseminated calcium carbonates and few fine calcium carbonate filaments; moderately alkaline; abrupt wavy boundary.

Cr—18 inches; soft calcareous shale.

Depth to calcium carbonate ranges from 7 to 18 inches, and depth to bedrock ranges from 14 to 19 inches. Rock fragment content is 0 to 18 percent but typically is less than 3 percent. In some areas gravel covers 15 percent of surface.

The A horizon has value 5 or 6 when dry and 3 to 5 when moist, and it has chroma of 2 or 3. It is fine sandy loam, sandy loam, or loam.

The Bt horizon has hue of 2.5Y to 7.5YR, value of 5 to 7 when dry and 4 or 5 when moist, and chroma of 2 to 4. It is sandy clay loam, clay loam, or loam and is 22 to 34 percent clay. Reaction is neutral to moderately alkaline.

The Bk horizon has hue of 2.5Y or 10YR, value of 5 to 7 when dry and 4 to 6 when moist, and chroma of 2 to 4.

The Cr horizon is soft, interbedded shale and sandstone.

Worfka Series

The Worfka series consists of shallow, well drained, slowly permeable soils on summits and back slopes of undulating to rolling uplands. These soils formed in residuum derived from interbedded shale and sandstone. Slope is 0 to 15 percent.

Typical pedon of a Worfka fine sandy loam in an area of Renohill-Worfka-Shingle complex, 6 to 15 percent slopes, 2,640 feet south and 300 feet east of the northwest corner of sec. 21., T. 36 N., R. 70 W.

A—0 to 3 inches; grayish brown (10YR 5/2) fine sandy loam, dark grayish brown (10YR 4/2) moist; weak coarse subangular blocky structure parting to moderate very fine granular; soft, very friable, slightly sticky and slightly plastic; neutral; abrupt smooth boundary.

Bt—3 to 8 inches; pale brown (10YR 6/3) clay, brown (10YR 5/3) moist; strong coarse subangular blocky structure parting to moderately fine subangular blocky; slightly hard, friable, sticky and plastic; many moderately thick clay films on faces of peds; mildly alkaline; gradual wavy boundary.

Btk—8 to 14 inches; light yellowish brown (10YR 6/4) clay loam, pale brown (10YR 6/3) moist; strong coarse subangular blocky structure parting to weak fine subangular blocky; slightly hard, friable, sticky and plastic; many moderately thick clay films on faces of peds; strongly effervescent; common fine irregularly shaped calcium carbonate in seams; moderately alkaline; gradual wavy boundary.

Cr—14 inches; soft calcareous shale.

Depth to bedrock ranges from 10 to 20 inches.

The A horizon has value of 5 or 6 when dry and 4 or 5 when moist, and it has chroma of 2 to 4. Texture is fine sandy loam, sandy loam, loam, or clay loam.

The Bt horizon has value 5 or 6 when dry and 4 or 5 when moist, and it has chroma of 2 to 4. It is clay or clay loam. Reaction is neutral to moderately alkaline.

The Btk horizon has hue of 2.5Y to 10YR, value of 5 to 7 when dry and 5 or 6 when moist, and chroma of 2 to 4. It is mildly alkaline to strongly alkaline.

The Cr horizon is soft interbedded shale and sandstone.

Zigweid Series

The Zigweid series consists of deep, well drained, moderately permeable soils on foot slopes, toe slopes, and alluvial flats. These soils formed in local alluvium derived dominantly from calcareous shale. Slope is 0 to 15 percent.

Typical pedon of a Zigweid clay loam in an area of Zigweid-Cambria-Theedle association, 6 to 15 percent slopes, 300 feet east and 1,800 feet north of the southwest corner of sec. 4, T. 38 N., R. 74 W.

A—0 to 3 inches; brown (10YR 5/3) clay loam, dark grayish brown (10YR 4/2) moist; weak medium platy structure parting to weak fine subangular blocky; hard, friable, sticky and plastic; neutral; abrupt smooth boundary.

Bw—3 to 9 inches; pale brown (10YR 6/3) clay loam, grayish brown (10YR 5/2) moist; moderate medium and fine subangular blocky structure; hard, friable, sticky and plastic; strongly effervescent; neutral; clear smooth boundary.

Bk1—9 to 28 inches; light brownish gray (2.5Y 6/2) clay loam, grayish brown (2.5Y 5/2) moist; weak fine subangular blocky structure; hard, friable, sticky and plastic; violently effervescent; common fine soft masses and filaments of calcium carbonate; moderately alkaline; gradual smooth boundary.

Bk2—28 to 60 inches; light brownish gray (2.5Y 6/2) clay loam, grayish brown (2.5Y 5/2) moist; massive; slightly hard, friable, sticky and plastic; violently effervescent; few fine soft masses and filaments of calcium carbonate; moderately alkaline.

The A horizon has hue of 10YR or 2.5YR. Some pedons have weak platy structure in the surface layer.

Texture is loam or clay loam. Reaction is neutral to moderately alkaline.

The Bw horizon has hue of 10YR or 2.5Y and chr of 2 to 4. Reaction is neutral to moderately alkaline.

The Bk horizon has hue of 2.5YR or 10YR. Reaction centers on moderately alkaline. A Ck horizon is present in some pedons.

1. INTRODUCTION

This report presents information on the soils occurring on the Reynold's Ranch permit extension area to the Smith Ranch Facility which is located approximately 40 miles northwest of Douglas, Wyoming. The area has been previously surveyed, on a large scale, by the U.S. Department of Agriculture (USDA), Natural Resource Conservation Service (NRCS) in 1982. The major objective of the 1997 assessment was to define the existing topsoil resource within the extension area and determine the extent, availability, and suitability of soils material for use in reclamation. The mapping and reporting for the 1997 extension area incorporated map unit information from previous site-specific soil surveys. 1997 soil sampling needs were determined from overall Smith Ranch permit sample numbers from 1979. However, this report has been compiled in order that the current extension area soil survey can be a stand-alone document.

2. METHODS

2.1. Review of Existing Literature

The soils in this portion of Converse County were studied and mapped to an Order 3 scale by the USDA, NRCS in 1982. The NRCS has recently centralized dissemination of nationwide soil series descriptions; county-wide information is available on the Internet through a site at Iowa State. Soil mapping of the original Smith Ranch Facility was conducted in 1979 by Woodward-Clyde Associates of Denver, Colorado.

2.2 1997 Project Participants

BKS Environmental Associates, Inc. performed the 1997 soil survey field work. All soil analysis was handled by Rio Algom Mining Corporation under separate contract with Energy Laboratories of Casper, Wyoming.

2.3. Soil Survey

Construction of the extension area soil map was accomplished according to techniques and procedures of the National Cooperative Soil Survey. Guideline No. 1 (November, 1984) of the Wyoming Department of Environmental Quality, Land Quality Division (WDEQ-LQD) was followed during all phases of the work.

A reconnaissance of the extension area was used to determine the validity of the previous NRCS soil survey and to familiarize the field personnel with the area. Soil profiles were examined on a widely scattered basis according to physiographic configuration. Information derived from these profiles was compared with previous mapping information to determine which soils were likely to occur on specific landscape positions. Previous mapping information for the extension area was available throughout the field survey.

Following the reconnaissance survey, an Order 1-2 soil survey was conducted. Actual soil boundaries were delineated in the field by exposing additional soil profiles to determine the nature

and extent of soil series present on the extension area. Soil map unit boundaries were delineated on a 1"=400' photographic base map. Refer to Table 1 for soil mapping unit designations and associated acreage. Table 2 describes the soil map units in terms of actual map designations and slope percentage.

2.4. Field Sampling

Per written communication with WDEQ-LQD personnel on October 15, 1997, all soils were sampled and described by exposing the solum with a shovel and then sampling below this point with a hand auger or by coring with a mechanical auger, i.e., truck-mounted Giddings. Refer to Addendum 1, Correspondence. The physical and, where possible, chemical nature of each horizon within the sampled profile was described and recorded in the field. The field location was plotted on the map. At least two quarts of sampled soil material were placed in clean, labeled, polyethylene plastic bags and kept cool and as dry as possible to limit chemical changes. Due to the timing of the sampling (i.e., fall 1997), ambient air temperatures were not considered excessive. Samples were kept out of direct sunlight and transported to the Gillette office of Energy for shipment to the Casper office for analysis. In general, samples were taken to Energy within two weeks of actual collection.

A total of 27 sites on the extension area was sampled in 1997 for analysis and corresponding soil profile descriptions written. These 27 locations supplemented previous permit sampling in 1979

2.5. Laboratory Analysis

Upon receipt at the Casper office of Energy, topsoil samples were logged into the computer system. Samples were placed into lined aluminum pans to air dry. Coarse fragments were measured with a 10 mesh screen prior to grinding; the entire sample was then hand ground to pass 10 mesh. An approximate 20 ounce subsample was obtained through splitting with a series of riffle splitters and subsequently analyzed. A second subsample was maintained in storage at Energy. Approximately 20 percent of the samples are run for duplicate analysis. Actual laboratory analysis follows the methodology outlined in WDEQ-LQD Guideline 1. Refer to the end of Addendum 2, Summary of Soil Analytical Results. In general, samples were analyzed within 30 days of receipt of the samples. All analytical data is also found in Addendum 2, Summary of Soil Analytical Results.

3. RESULTS AND DISCUSSION

3.1. Soil Survey - General

The soils occurring on the Reynold's Ranch extension area are typical of the semi-arid grasslands of the western United States. Due to prevailing climate and vegetation conditions, organic matter is accumulated slowly and is confined primarily to the surface horizon(s) resulting in light-coloration. Subsoil color is usually light brown.

The greatest proportion of the upland soils of the extension area are residual (i.e., developed in place) and are formed from weathered sedimentary bedrock, mostly sandstone and shale. Most developed soils reflect the character of the bedrock. Areas of sandy and medium-textured friable soils are underlain by sandstone and sandy shale. Typical toposequences under such conditions may be Taluce on the shallow end to Bowbac (moderately deep) to Hiland on the deep end. Heavy clay soils are underlain by clayey shale. A typical toposequence under such conditions may be Shingle on the shallow end to Cushman (moderately deep) to Forkwood on the deep end for medium textured soils. These soils vary widely in both depth and suitability of the material for topsoiling depending primarily on the parent material from which the soils have formed.

Major stream channels of the extension area are characterized by alluvial soils such as the Kishona (formerly Kim) series, Clarkelen series, and Draknab series. Smaller ephemeral channels in unstable landscapes are characterized by the moderately deep Theedle (formerly Thedalund) series or the deep Kishona series. These soils are developed from a variety of material washed from the uplands and redeposited along the stream courses. The soils formed in alluvium reflect the character of the weathered, transported material. These soils often have a generally dark friable surface that contains a larger amount of organic matter than upland soils.

3.2. Soil Mapping Unit Interpretation

The 1997 mapping did result in a number of new series, previously unmapped in the existing 1979 baseline, being described within the extension area. Previously derived mapping units within the

existing permit area and their existing series descriptions were utilized wherever possible. Refer to Addendums 3, 4, and 5

Since the actual amount of affected land within the extension area was not known at the time of the survey, it was difficult to base soil sample location numbers on an actual percent of the combined total affected area between the proposed extension and the main permit areas. Instead, sample numbers were based on percent of total permit acreage. The maximum number of soil pedons according to WDEQ Guideline 1 were sampled, wherever possible.

3.3. Analytical Results

Lab analyses of the 1997 soil samples did include percent very fine sands. The very fine sand fraction was useful in the differentiation between series. Laboratory information was used in part with field observations of fine sands within individual pedes as well as topographic position to determine series designation. None of the 1997 samples exceeded 50% very fine sand. Refer to Addendum 2, Summary of Soil Analytical Results for a complete collection of original laboratory data.

3.4. Evaluation of Soil Suitability as a Plant Growth Medium

Within the extension area, suitability of soil as a plant growth medium is generally limited by physical factors such as texture (sand or clay) or saturation percentage or chemical factors such as pH. In general, questionable chemical quality material is found within the high clay horizons

found at depth within deeper soils or sandy alluviated/residual material. No unsuitable material, according to WDEQ Guideline 1, was found. Marginal or unsuitable parameters are found in the following soil series and sample points:

<u>Series</u>	<u>Sample Point #</u>	<u>Parameter</u>
Aeric Haplaquept	23	saturation %/ texture (marginal)
Draknab sandy loam	51	saturation %/texture (marginal)
Ulm loam	57	texture (marginal)
Cambria loam	66	pH (marginal)

3.5. Topsoil Volume Calculations

Based on the extension area field work and subsequent chemical analysis, topsoil depths of previous permit sample locations were confirmed for the individual mapped soil series and revised, if necessary. Since the disturbed area was not known at the time of the survey, no volumes were determined. Every attempt was made to conform to previously determined stripping depths for a particular series; however, for purposes of the 1997 extension area, listed stripping depths may or may not match exactly to previously determined depths. Table 3 lists approximate stripping depths for each map unit.

3.6. Prime Farmland Assessment

No prime farmland determination was conducted since no cropland or hayland is located within the proposed extension area.

Table 1 Soil Series 1997 Sample Summary for the Reynolds Ranch Extension Area.

Map Unit/ Soil Series	Reynolds Ranch Existing Permit Acreage (%)	No. of Chemical Analysis Locations	Number of Samples/ Location	Total Number of Samples

Cheyenne, WY 82001

Dear Matt:

Attached is the soil methodology including proposed sample numbers associated with the Reynold's Ranch baseline soil assessment for Rio Algom Mining Corporation. The field mapping phase of this assessment has been completed and the sampling phase should be completed this fall. I am assuming you will have Lowell Spackman review this methodology.

I would appreciate any "short turn-around" comments you may have since we are formulating fall 1997 sampling plans. Thank you for your input. If you have any questions, please feel free to contact me in Gillette at (307)682-3810.

Sincerely,

Brenda K. Schladweiler / (P.W.)

1997 Soil Sampling Methodology
Rio Algom Mining Corporation's Reynold's Ranch Property
October 8, 1997

General

It is assumed the original baseline soils inventory for the Smith Ranch permit area, Permit No.304C was limited and conducted in the same timeframe as the baseline vegetation assessment, i.e., late 1970's and possibly 1990. As part of the limitations, it is assumed that the previous soil work is a general reproduction of previous Natural Resource Conservation Service (NRCS), formerly Soil Conservation Service (SCS), mapping and that little or no soil analytical data is available for the current Smith Ranch property. The Reynolds Ranch permit extension was proposed in 1996 and consists of approximately 13,440 acres that lie adjacent to the existing Smith Ranch permit area.

Review of Existing Literature

The northern portion of Converse County has been mapped by the NRCS. This material, as well as the existing soils section for the current permit area, if any, was reviewed prior to summer 1997 fieldwork.

Soil Survey

Field soil mapping will be accomplished according to techniques and procedures of the National Cooperative Soil Survey. Guideline No. 1 (November, 1984) of the Wyoming Department of Environmental Quality, Land Quality Division will be used as a general guide during all phases of the study.

A reconnaissance of the Reynolds Ranch extension area was used to determine the validity of the previous NRCS soil survey and to familiarize the field personnel with the area. Soil profiles were examined on a widely scattered basis according to physiographic configuration. Information derived from these profiles was used to determine which soils were likely to occur on specific landscape positions.

Following the reconnaissance survey, a higher intensity Order 1-2 soil survey was conducted. Actual soil boundaries were delineated in the field by exposing additional soil profiles to determine the nature and extent of soil series present on the extension area. The soil boundaries were delineated on the 1"=400' scale topographic basemap. The acreages of individual map units were compiled in Table 1.

Soil Sampling, Description, and Analysis

Profile sampling and description for the original baseline survey was limited, based on requirements of non-coal facilities. It is assumed that little or no previous analytical data exists and that existing profile descriptions would be a general reproduction of existing NRCS information. Since the 1997 assessment is an Order 1-2 survey, sampling for analysis and profile descriptions has been included.

1997 Soil Sampling Methodology
Rio Algom Mining Corporation's Reynold's Ranch Property
October 8, 1997 (cont.)

The extent of proposed disturbed area within the Reynold's Ranch permit extension is not known at this time. Therefore the proposed sample numbers proposed in Table 1 are based on total permit acreages. Sampling requirements for those series found within the Reynolds Ranch extension area will generally follow the acreage recommendations in Guideline 1, page 5 (November 1984). However, since actual disturbed acreage is not known at this time, the following sampling scheme is proposed:

If the extension area acreage of the mapping unit exceeds 10% of the total permit area or 1,344 acres, 3 pedons will be sampled for analysis. If the combined acreage ranges from 5-10% of the total permit area, 2 pedons will be sampled, and, if that acreage is less than 5% of the total permit area, 1 pedon will be sampled.

All soils will be sampled and described by exposing the solum with a shovel and then sampling below this point with a bucket auger to a maximum depth of 60". The physical and, where possible, chemical nature of each horizon within the sampled profile will be described and recorded in the field using standard NRCS survey techniques. Soil backhoe pits will not be utilized for sampling.

Necessary sample locations for written profile descriptions will be marked on the topographic base map and marked in the field with steel fence posts. The sampled soil material will be placed in clean, labeled, polyethylene plastic bags, and kept sealed to limit sample drying. Samples will not be iced down but will be kept as cool as possible. In addition, samples will be forwarded to the laboratory as soon as possible after collection to limit chemical changes. At the end of the sampling program, the samples will be transported to Energy Laboratories in Gillette or left at the mine site for Energy Laboratories in Casper to obtain. Analytical information will following Guideline 1, Table 1-2, Topsoil Suitability.

This soil assessment methodology correctly documents previous agreements as stated above and is hereby approved.

Subject: Review of Soil Sampling Methodology, Rio Algom Amendment, TFN

3 5/131 (e-mail)

Content-Disposition: inline
X-UIDL: 54fbb9028f7d2c87fae4a9fa4c04dc15

Dear Brenda (BKS Environmental Associates, INC):

I have reviewed the methodology for the Reynold's Ranch Property to be amended to the Rio Algom's Smith Ranch Permit. This methodology was outlined in your letter of October 15, 1997, to Matt Jankovsky.

I recently did an evaluation of the Smith Ranch permit soil survey information, to evaluate the effects of stripping only the upper four to six inches of the soil in the construction of access roads. There are no suitability data nor quality data in the permit for soils. My review suggested that each soil needs to be evaluated for quality. The quality of

the soil will dictate how much of the soil will need to be stripped for each road. I think it is essential that soil suitability be evaluated for this insitu mine.

Without having a map and specifics on the disturbance boundary, I concur with your sampling scheme for the Reynolds Ranch Amendment area. The general scheme is acceptable and should meet the requirement of the Noncoal Rules and Regulations/Guideline No. 1. Thank

you for the opportunity to comment on these methodologies before they are implemented.

Lowell K. Spackman

ADDENDUM 3
SOIL MAPPING UNIT DESCRIPTIONS

The following soil map units are based, in part, on the 1979 soil survey by Woodward-Clyde Associates on the Mill Site for Smith Ranch. These map units were utilized during 1978-1980 on various soil surveys related to the Smith Ranch Project. In order to maintain consistency with these earlier studies, the 1997 mapping of Reynold's Ranch utilized these map units with slight modifications, where appropriate for that specific area. The brief profile descriptions for the following map unit descriptions are based primarily on 1997 information.

Aeric Haplaquept, 0-3% (56)

The Aeric Haplaquept mapping unit consists of deep, poorly-drained soils that developed in calcareous recent alluvium derived from mixed sources. It occurs in depressions in the landscape at an elevation of approximately 5200. Slopes range from 0 to 3%.

A typical profile contains a 3 inch dark gray clay loam or clay surface layer with a relatively high amount of organic matter. The B subsoil is dark gray clay and is approximately 9 inches thick. The substratum is dark gray to brown clay to clay loam and extends to 48 inches in depth. The substratum is generally stratified.

Permeability of the Aeric Haplaquept soil is slow to moderate. Effective rooting depth is 60 inches or more. Average annual precipitation is 12 inches and mean annual air temperature is 46°F. Mean annual soil temperature is 49°F. The vegetation is western wheatgrass and salt-tolerant grasses.

Included in this map unit and making up about 15 percent of this unit are small areas of Forkwood clay loam and Cambria loam.

Bowbac Sandy Loam, 0-3% (23A); 3-6% (23B); 6-15% (23C)

This soil mapping unit consists of moderately deep, well drained soils on rolling upland ridges and backslopes. The soils have developed in residuum from calcareous sandstone. Slopes range from 0 to 15 percent. Elevation is about 5200 feet.

Typically, the Bowbac soil has a dark yellowish brown sandy loam surface layer about 3 inches thick. This is underlain by a dark yellowish brown to grayish brown sandy loam or sandy clay loam subsoil to approximately 26 inches. The substratum is a gray sandy clay loam which grades to shale and sandstone at 32 inches.

Permeability is moderate to moderately rapid. Effective rooting depth is 34 inches, although some roots do penetrate the shale and sandstone for a few inches. Average annual precipitation is 12 inches and the mean annual air temperature is about 46° F. Mean annual soil temperature is 49° F. The vegetation is needleandthread, yucca, big sagebrush and blue grama.

Included in the mapping and making up about 10 percent of the unit are small areas of Taluce sandy loam and Hiland sandy loam. The Taluce soils usually occur on ridgetops while the Hiland soils usually occur on the lower portions of the back slopes.

Cambria (Stoneham) Loam, 0-3% (15A); 3-6% (15B)

This soil mapping unit consists of deep well drained soils on gently sloping footslopes and toeslopes. The soil developed from gravelly, calcareous loamy parent material. Slopes range from 0 to 6 percent. Elevation is 5200 feet.

Typically, the Cambria soil has a yellowish brown heavy loam or loam surface layer about 3 inches thick. The subsoil is a pale brown or light gray loam or light clay loam about 16 inches thick. The substratum is a light brownish gray loam to approximately 60 inches thick.

Permeability is moderate. Effective rooting depth is more than 40 inches. Average annual precipitation is 12 inches. The mean annual temperature is 46° F, and the mean annual soil temperature is 49° F. The vegetation is typically big sagebrush and various cool-season grasses.

Included in the mapping and comprising 10 percent of the unit are small areas of Forkwood, Kishona and Cushman soils. Cushman soils usually occur above Cambria on the landscape, while Forkwood and Kishona soils are mixed; however, Kishona soils tend to be on less stable landscapes.

Clarkelen sandy clay loam, 0-3% (53A)

This soil mapping unit consists of deep, well or somewhat excessively drained soils formed in stratified recent stream alluvium on flood plains and terraces. Slopes range from 0 to 3 percent. Elevation is 5200 feet.

Typically, the Clarkelen soil has a brown sandy clay loam surface layer about 3 inches thick. The subsoil is a brown sandy loam or loam about 12 inches thick. The substratum is a brown to pale brown sandy loam to loamy sand to approximately 60 inches thick.

Permeability is moderate. Effective rooting depth is more than 40 inches. Average annual precipitation is 12 inches. The mean annual temperature is 46° F, and the mean annual soil temperature is 49° F. The vegetation is various cool-season grasses and forbs with scattered silver sagebrush.

Included in the mapping and comprising 10 percent of the unit are small areas of Draknab and Haverdad soils. Both occur in association with the Clarkelen soils but differ in the texture of the control sections.

Cushman Sandy Loam, 0-3% (21A); 3-6% (21B); 0-6% (21AB).

This soil mapping unit consists of moderately deep, well drained soils on rolling upland ridges and sideslopes. The soils have formed from mixed mineralogy. Slopes range from 0 to 6 percent. Elevation is about 5250 feet.

Typically, the Cushman soil has a light brownish gray sandy loam or loam surface horizon about 4 inches thick. The subsoil is a yellowish brown clay loam about 11 inches thick. The substratum is a very pale brown loam about 13 inches thick which grades to a soft, partially weathered shale at 28 inches.

Permeability is moderate. Effective rooting depth is 28 inches, but some roots penetrate the soft bedrock for a few inches. Average annual precipitation is 12 inches and the mean annual air temperature is 46° F. Mean annual soil temperature is 49° F. Vegetation is big sagebrush, western wheatgrass, and blue grama.

Included in the mapping and making up about 10 percent of this unit are small areas of Shingle loam and Forkwood clay loam. The Shingle soil usually occurs on the ridgetops, while the Forkwood soil usually occurs on the lower portions of the side slopes.

Draknab sandy loam, 0-3% (51A)

This soil mapping unit consists of deep, excessively drained soils formed in stratified recent stream alluvium on flood plains and terraces. Slopes range from 0 to 3 percent. Elevation is 5200 feet.

Typically, the Draknab soil has a brown sandy loam surface layer about 2 inches thick. The subsoil is a brown sandy clay loam about 4 inches thick. The substratum is a gray, grayish brown to light olive brown sandy loam to loamy sand to approximately 60 inches thick.

Permeability is moderate to rapid. Effective rooting depth is more than 40 inches. Average annual precipitation is 12 inches. The mean annual temperature is 46° F, and the mean annual soil temperature is 49° F. The vegetation is various cool-season grasses and forbs with scattered silver sagebrush.

Included in the mapping and comprising 10 percent of the unit are small areas of Dwyer, Clarkelen and Haverdad soils. Both occur in association with the Clarkelen soils but differ in the texture of the control sections.

Dwyer clay loam. 0-3% (18A)

This soil mapping unit consists of very deep, excessively drained soils that formed in eolian sand on slopes and alluvial terraces. Slopes range from 0 to 3 percent. Elevation is 5200 feet.

Typically, the Dwyer soil has a brown clay loam surface layer about 5 inches thick. The subsoil is a brown sandy loam about 15 inches thick. The substratum is a brown sandy loam to approximately 60 inches thick.

Permeability is moderate to rapid. Effective rooting depth is more than 40 inches. Average annual precipitation is 12 inches. The mean annual temperature is 46° F, and the mean annual soil temperature is 49° F. The vegetation is various cool-season grasses and forbs with scattered silver sagebrush.

Included in the mapping and comprising 10 percent of the unit are small areas of Draknab and Hiland soils. Both occur in association with the Clarkelen soils but differ in the texture or textural arrangement of the control sections.

Forkwood (Fort Collins) Clay Loam. 0-3% (19A)

This soil mapping unit consists of deep, well drained soils on gently sloping to nearly level alluvial fans. Slopes range from 0 to 3 percent. Elevation is 5200 feet.

Typically, the Forkwood soil has a pale brown clay loam (or fine sandy loam) surface layer about 4 inches thick. The subsoil is a light brownish gray to yellowish brown clay loam about 32 inches thick. The stratum is a light yellowish brown clay loam to loam that extends to 60 inches.

Permeability is moderate. Effective rooting depth is 60 inches. Average annual precipitation is 12 inches and the mean annual air temperature is 46° F. Mean annual soil temperature is 49° F. Vegetation is blue grama, big sagebrush, western wheatgrass and Sandberg bluegrass.

Included in the mapping and comprising 10 percent of the unit is Cushman sandy loam. The Cushman soil usually occurs above the Forkwood soil on the landscape.

Haverdad sandy loam, 0-3% (52A)

This soil mapping unit consists of deep, well drained soils formed in loamy, recently deposited, stratified alluvium derived dominantly from sedimentary rock and is located on flood plains and terraces. Slopes range from 0 to 3 percent. Elevation is 5200 feet.

Typically, the Haverdad soil has a grayish brown sandy loam surface layer about 6 inches thick. The underlying material is light brownish gray loam with lenses of clay loam and sandy loam to a depth of approximately 60 inches.

Permeability is moderate. Effective rooting depth is more than 40 inches. Average annual precipitation is 12 inches. The mean annual temperature is 46° F, and the mean annual soil temperature is 49° F. The vegetation is various cool-season grasses and forbs with scattered silver sagebrush.

Included in the mapping and comprising 10 percent of the unit are small areas of Clarkelen and Draknab soils. Both occur in association with the Haverdad soils but differ in the texture of the control sections.

Hiland (Olney) Sandy Loam, 0-3% (16A); 3-6% (16B)

This soil mapping unit consists of deep, well drained soils occurring on gently to moderately sloping uplands. The soils have formed in residuum from calcareous sandstone. Slopes range from 0 to 6 percent. Elevation is 5200 feet.

Typically, the Hiland soil has a brown fine sandy loam surface layer about 5 inches thick. The subsoil is a pale brown to very pale brown sandy loam (or sandy clay loam) about approximately 24 inches thick (Note: typical profile location to 48 inches if B3ca is included). The substratum is a light yellowish brown sandy loam that extends to 60 inches.

Permeability is moderate to moderately rapid. Effective rooting depth is 60 inches. Average annual precipitation is 12 inches and the mean annual air temperature is 46° F. Mean annual soil temperature is 49° F. The vegetation is big sagebrush, blue grama, needleandthread, and prairie junegrass.

Included in mapping and making up 10 percent of the unit are small areas of Bowbac sandy loam. The Bowbac soil occurs above the Hiland soil on the landscape.

Kishona (Kim) Loam, 0-3% (14A)

This mapping unit consists of deep, well drained soils occurring on nearly level alluvial fans to moderately steep sideslopes. The soils developed in mixed calcareous alluvial material. Slopes range from 0 to 3 percent.

Typically, the Kishona soil has a pale brown, mildly alkaline loam surface layer about 5 inches thick. The underlying soil is a light brownish gray to light yellowish brown, moderately alkaline light clay loam to loam that extends to 60 inches.

Permeability is moderate. Effective rooting depth is 60 inches. Average annual precipitation is 12 inches and the mean annual air temperature is 46° F. Mean annual soil temperature is 49° F. Vegetation is big sagebrush, blue grama, western wheatgrass, and prairie junegrass.

Included in mapping and comprising 15 percent of the unit are small areas of Theedle loam and Forkwood clay loam. The Theedle usually occurs above the Kishona soil on the landscape. The Forkwood soil occurs in association with the Kishona soil.

Renohill Clay Loam, 0-3% (22A)

This soil mapping unit consists of moderately deep, well drained soils on gently sloping upland hills and ridges. The soil developed in sediments weathered residually or which were locally transported from sedimentary bedrock. Slopes range from 0 to 3 percent. Elevation is 5200 feet.

Typically, the Renohill soil has a light brownish gray clay loam surface layer about 4 inches thick. The subsoil is a light yellowish brown to light gray clay to heavy clay loam about 16 inches thick. The substratum is a pale brown clay loam that grades to weathered calcareous shale at 26 inches.

Permeability is slow. Effective rooting depth is 26 inches. Average annual precipitation is 12 inches. The mean annual air temperature is 46° F and the mean annual soil temperature is 49° F. The vegetation is western wheatgrass, green needlegrass, and Wyoming big sagebrush.

Included in the mapping and comprising 10 percent of the unit are small areas of Heldt sandy clay loam and Shingle loam. The Heldt soil usually occurs below the Renohill soil on the landscape, while the Shingle soil occurs on the ridgetops or ridges above the Renohill soil.

Exposed Sandstone or Rock Outcrop (50)

Rock Outcrop occurs throughout the project area, mainly on ridgetops and sideslopes. The rock is primarily sandstone. Included in mapping and making up about 15 percent of the unit are small areas of Taluce and Lesset soils. These soils support yucca, pricklypear, and scattered sand dropseed.

Shingle Loam, 0-3% (30A)

This soil mapping unit consists of shallow, well drained soils that generally occur on upper sideslopes and ridgetops. Slopes range from 0 to 3 percent. Elevation ranges from 5200 to 5300 feet.

In a typical profile, the Shingle soil has a light brownish gray loam surface about 3 inches. The underlying soil is a light yellowish brown clay loam about 7 inches thick which grades into soft, calcareous shale at 10 inches.

Permeability is moderate. Effective rooting depth is 10 inches, but some roots penetrate the shale fragments. Average annual precipitation is 12 inches. The mean annual air temperature is 46° F, and the mean annual soil temperature is 49° F. Vegetation is Wyoming big sagebrush, western wheatgrass, and some buffalograss.

Included in mapping and making up 15 percent of the unit are small areas of Cushman sandy loam, Taluce sandy loam and Rock Outcrop. The Cushman soil occurs on the sideslopes below the Shingle soil on the landscape. The Taluce soil and Rock Outcrop occur in association with the Shingle soil on ridgetops and upper sideslopes.

Taluca (Tassel) Sandy Loam, 0-3% (32A); 3-6% (32B); 6-15% (32C); 15-30% (32D)

This soil mapping unit consists of shallow, well drained soils occurring on sideslopes and ridgetops. Slopes range from 0 to 30 percent. This soil formed in residuum from calcareous sandstone. Elevations range from 5200 to 5300 feet.

Typically, the Taluca soil has a pale brown sandy loam surface layer about 4 inches thick. The underlying soil is a pale brown sandy loam about 7 inches thick. Sandstone bedrock occurs at 11 inches.

Permeability is moderate. Effective rooting depth is 11 inches, but some roots penetrate the weathered sandstone bedrock. Average annual precipitation is 12 inches. The mean annual air temperature is 46° F, and the mean annual soil temperature is 49° F. Vegetation is yucca, pricklypear, sand dropseed, and needleandthread.

Included in mapping and making up 15 percent of the unit (about 5 percent each) are small areas of Tullock fine sandy loam and Rock Outcrop. The Rock Outcrop occurs in association with Taluca. The Tullock soil occurs on the sideslopes below the Taluca soil on the landscape.

Terro (Terry) Fine Sandy Loam. 0-3% (17A); 3-6% (17B); 6-15% (17C)

This soil mapping unit consists of moderately deep, well drained soil occurring on rolling uplands and sideslopes. The soils were formed in residuum from soft sandstone bedrock. Slopes range from 0 to 15 percent. Elevation is about 5200 feet.

Typically, the Terro soil has a light brownish gray fine sandy loam surface layer about 2 inches thick. The underlying subsoil is a pale brown or very pale brown fine sandy loam to sandy loam about 12 inches thick. The underlying substratum is a light brownish gray fine sandy loam which grades to calcareous sandstone at 28 inches.

Permeability is rapid. Effective rooting depth is 28 inches, but some roots penetrate the sandstone bedrock for a few inches. Average annual precipitation is 12 inches. The mean annual air temperature is 46° F, and the mean annual soil temperature is 48° F. Vegetation is needleandthread, yucca, pricklypear, and blue grama.

Included in mapping and comprising 15 percent of the unit are small areas of Taluce sandy loam and Tullock fine sandy loam. The Taluce soil usually occurs on the ridgetops above the Terro soil. The Tullock soil occurs in association with the Terro soil.

Theedle (Thedalund) Loam, 0-3% (49A)

This soil mapping unit consists of moderately deep, well drained soils on gently to moderately sloping upland hills and ridges. The soil formed in alluvium from sedimentary rock. Slopes range from 0 to 3 percent. Elevation is 5200 feet.

Typically, the Theedle soil has a very pale brown sandy loam about 3 inches thick. The underlying subsoil is a yellowish brown about 8 inches thick. The underlying substratum is a light gray loam about 23 inches thick which grades to mixed paralithic sources.

Permeability is moderate. Effective rooting depth is 34 inches, but some roots penetrate the weathered shale for a few inches. Average annual precipitation is 12 inches. The mean annual air temperature is 46° F and the mean annual soil temperature is 49° F. Vegetation is blue grama, western wheatgrass, and big sagebrush.

Included in mapping and comprising 10 percent of the unit are small areas of Shingle loam and Cushman sandy loam. The Shingle soil usually occurs above the Theedle soil on the ridgetops. The Cushman soil occurs in association with the Theedle soil.

Tullock Fine Sandy Loam, 0-3% (25A), 3-6% (25B)

This soil mapping unit consists of moderately deep, well drained soils occurring on sideslopes and ridges. The soils developed in residuum from weakly consolidated calcareous sandstone. Slopes range from 0 to 6 percent. Elevation is 5200 to 5300 feet.

Typically, the Tullock soil has a light brownish gray fine sandy loam surface layer about 4 inches thick. The underlying soil is a pale brown to pale gray fine sandy loam about 30 inches thick which grades to calcareous sandstone bedrock at 34 inches.

Permeability is rapid. Effective rooting depth is 34 inches, but some roots penetrate the sandstone bedrock for a few inches. Average annual precipitation is 12 inches. The mean annual air temperature is 46° F. and the mean annual soil temperature is 49° F. Vegetation is yucca, pricklypear, sand dropseed, and needleandthread.

Included in mapping and comprising 15 percent of the unit are small areas of Taluce sandy loam and Terro sandy loam. The Taluce soil usually occur above the Tullock soils on the ridgetops. The Terro soil occurs in association with the Tullock soil.

Ulm Clay Loam, 0-3% (20A)

This soil mapping unit consists of a deep, well drained soil occurring on alluvial fans and valley filling foot slopes. The soil developed in alluvium mainly from sedimentary rock. Slopes range from 0 to 3 percent. Elevation is 5200 feet.

Typically, the Ulm soil has a light brownish gray loam (or clay loam) surface layer about 4 inches thick. The subsoil is a light brownish gray, brown, or grayish brown heavy loam or clay loam about 20 inches thick. The substratum is a light brownish gray light clay loam that extends to 60 inches.

Permeability is low to moderate. Effective rooting depth is 60 inches. Average annual precipitation is 12 inches. The mean annual air temperature is 46° F and the mean annual soil temperature is 49° F. Vegetation is western wheatgrass, green needlegrass, pricklypear, and blue grama.

Included in mapping and comprising 10 percent of the unit are small areas of Renohill clay loam. The Renohill soil usually occurs on the valley filling foot slopes above the Ulm soil.

Vonalee (Vona) Sandy Loam, 0-3% (13A); 3-6% (13B); 0-6% (13AB)

This soil mapping unit consists of a deep, well drained soil that occurs on sideslopes. Elevation is about 5200 feet. The soil developed in loamy, wind-worked residuum and local alluvium derived from mixed sources. Slopes range from 0 to 6%.

Typically, the Vonalee soil has a pale brown, sandy loam surface horizon about 4 inches thick. The subsoil is a light brownish gray to pale brown sandy loam or fine sandy loam about 18 inches thick. The substratum is a pale brown sandy loam that extends to 60 inches.

Permeability is rapid. Effective rooting depth is 60 inches. Average annual precipitation is 12 inches. The mean annual air temperature is 46° F and the mean annual soil temperature is 49° F. Vegetation is needleandthread, yucca, big sagebrush and sand dropseed.

Included in the mapping and making up about 10 percent of the unit are small areas of Terro sandy loam. The Terro soil usually occurs above the Vonalee soil on the landscape.

Worf Loam, 0-3% (31A); 3-6% (31B); 6-15% (31BC)

The Worf soil is a shallow, well drained soil on upland ridges and sideslopes. Elevation is 5200 feet. The soil developed in loamy residuum derived dominantly from interbedded shale and sandstone. Slopes range from 0 to 15%.

In a typical profile, the surface layer is a light yellowish brown loam about 4 inches thick. The underlying subsoil is a pale brown clay loam about 5 inches thick. The substratum is a pale brown loam 7 inches thick grading to partially weathered calcareous shale at 16 inches.

Permeability is moderate. Effective rooting depth is 16 inches, but some roots penetrate the bedrock for a few inches. Average annual precipitation is 12 inches. The mean annual air temperature is 46° F and the mean annual soil temperature is 49° F. Vegetation is blue grama, prairie junegrass and big sagebrush.

Included in the mapping and comprising about 15 percent of the unit are small areas of Shingle loam, Cushman sandy loam and Rock Outcrop. The Shingle soil occurs in association with the Worf soil. The Cushman soil usually occurs below the Worf soil on the landscape. The Rock Outcrop occurs on the ridgetops or just below them.

ADDENDUM 4
1997 SOIL SERIES DESCRIPTIONS

The following soil series descriptions are based on sampling conducted on the proposed Reynold's Ranch Extension Area in 1997. The Haverdad series was not included in the 1997 sampling; however, that corresponding map unit consists of less than one percent of the proposed extension area.

AERIC HAPLAQUEPT

Soil Mapping Unit 56

Typical Pedon: Aeric Haplaquept, rangeland.

(Colors are for dry soil unless otherwise indicated)

A - 0-3 inches. Dark gray (10YR 4/1) clay, dark gray (10YR 4/1) moist; strong, coarse angular blocky structure parting to strong medium granular; hard, firm, sticky, plastic; mildly alkaline (pH 7.40), noneffervescent.

B - 3-12 inches. Dark gray (10YR 4/1) clay, dark gray (10YR 4/1); strong, coarse angular blocky structure parting to strong medium granular; hard, firm, sticky, plastic; mildly alkaline (pH 7.40), noneffervescent.

C1 - 12-24 inches. Dark gray (10YR 4/1) clay, dark gray (10YR 4/1) moist; massive; hard, firm, very sticky and very plastic, mildly alkaline (pH 7.37), noneffervescent.

C2 - 24-33 inches. Brown (10YR 4/3) clay loam, dark brown (10YR 3/3) moist; massive; hard, firm, very sticky, very plastic; mildly alkaline (pH 7.66), noneffervescent.

C3 - 33-48 inches. Light yellowish brown (10YR 6/4) sandy clay loam, yellowish brown (10YR 5/4) moist; massive, hard, firm, sticky, plastic; mildly alkaline (pH 7.81), noneffervescent.

Type Location - 10 (23 on the map)

Range in Soil Characteristics - Depth of bedrock ranges from 40 to 60 plus inches. Coarse fragments are generally less than 5 percent. Clay content of the control section ranges from 35 to 45 percent. The control section texture is clay. When dry, surface cracks extend to depths of 12 inches or more.

Taxonomic Class - fine, montmorillonitic, mesic Aeric Haplaquept.

Suitability for Topsoil - The Aeric Haplaquept series is generally not suitable for topsoil due to high clay content and the approximate recommended stripping depth is 0 foot. The Aeric Haplaquept series rates poor according to Wyoming Department of Environmental Quality Guideline 1.

BOWBAC SERIES

Soil Mapping Unit 23A, 23B, 23AB, 23C

Typical Pedon: Bowbac sandy loam, rangeland.

(Colors are for dry soil unless otherwise indicated)

A - 0-3 inches. Dark yellowish brown (10YR 3/6) sandy loam, dark yellowish brown (10YR 3/4) moist; weak fine and very fine granular structure; soft, very friable, nonsticky, nonplastic; moderately alkaline (pH 8.13), noneffervescent.

B1 - 3-12 inches. Dark yellowish brown (10YR 3/6) sandy loam, dark yellowish brown (10YR 3/4) moist; weak medium subangular blocky structure; slightly hard, friable, slightly sticky, slightly plastic; moderately alkaline (pH 8.00), noneffervescent.

B2 - 12-20 inches. Dark yellowish brown (10YR 3/4) sandy loam, dark yellowish brown (10YR 3/4) moist; moderate medium subangular blocky structure; slightly hard, friable, slightly sticky, slightly plastic; moderately alkaline (pH 8.00), noneffervescent.

Bk - 20-26 inches. Grayish brown (10YR 5/2) sandy loam, dark grayish brown (10YR 4/2) moist; weak subangular blocky; soft, friable, slightly sticky, slightly plastic; CaCO₃ threads; moderately alkaline (pH 7.97), slightly effervescent.

C - 26-32 inches. Gray (10YR 6/1) sandy clay loam, gray (10YR 5/1) moist; partially weathered sandstone; moderately alkaline (pH 8.02), moderately effervescent.

Type Location - 21 (63 on map)

Range in Soil Characteristics - Depth to a paralithic contact ranges from 20 to 40 inches. More than 60 percent of the sand fraction is fine sand or coarser. Content of coarse fragments is less than 2 percent. Texture of the control section is a sandy loam. Clay content of the control section ranges from 15 to 17 percent which is generally less than what is typical for the series.

Taxonomic Class - fine-loamy, mixed, mesic Ustic Haplargid.

Suitability for Topsoil - The Bowbac sandy loam soil is suitable for topsoil and the recommended stripping depth is 2.5 feet. The Bowbac series rates fair or better according to Wyoming Department of Environmental Quality Guideline 1. Depth of stripping would be limited by bedrock material.

BOWBAC SERIES

Soil Mapping Unit 23A, 23B, 23AB, 23C

Typical Pedon: Bowbac sandy loam, rangeland.

(Colors are for dry soil unless otherwise indicated)

A1 - 0-3 inches. Dark brown (7.5YR 3/2) sandy loam, very dark brown (7.5YR 2/2) moist; weak fine and very fine granular structure; soft, very friable, nonsticky, nonplastic; mildly alkaline (pH 7.78), noneffervescent.

BA - 3-6 inches. Dark brown (7.5YR 3/2) sandy loam, very dark brown (7.5YR 2/2) moist; weak medium subangular blocky structure; slightly hard, friable, slightly sticky, slightly plastic; mildly alkaline (pH 7.79), noneffervescent.

B - 6-20 inches. Brown (7.5YR 4/4) sandy loam, dark brown (7.5YR 3/4) moist; moderate medium subangular blocky structure; slightly hard, friable, slightly sticky, slightly plastic; mildly alkaline (pH 7.79), noneffervescent.

Bk - 20-28 inches. Light brownish gray (10YR 6/2) sandy loam, grayish brown (10YR 5/2) moist; massive; soft, friable, slightly sticky, nonplastic; CaCO₃ threads; mildly alkaline (pH 7.50), slightly effervescent.

C - 28-36 inches. Light gray (10YR 7/1) sandy loam, gray (10YR 6/1) moist; massive; slightly hard, friable, nonsticky, nonplastic; moderately alkaline (pH 7.93), slightly effervescent.

Cr - 36+ inches. Soft sandstone.

Type Location - 26 (78 on the map)

Range in Soil Characteristics - Depth to a paralithic contact ranges from 20 to 40 inches. More than 35 percent of the sand fraction is fine sand or coarser. Content of coarse fragments is less than 5 percent. Texture of the control section is a sandy loam. Clay content of the control section ranges from 13 to 17 percent.

Taxonomic Class - fine-loamy, mixed, mesic Ustollic Haplargid.

Suitability for Topsoil - The Bowbac sandy loam soil is suitable for topsoil and the recommended stripping depth is 2.5 feet. The Bowbac series rates fair or better according to Wyoming Department of Environmental Quality Guideline 1. Depth of stripping would be limited by bedrock material.

CAMBRIA (STONEHAM) SERIES

Soil Mapping Unit 15A, 15B

Typical Pedon: Cambria (Stoneham) clay loam, rangeland
(Colors are for dry soil unless otherwise indicated)

A - 0-3 inches. Dark yellowish brown (10YR 3/6) sandy clay loam, dark yellowish brown (10YR 3/4) moist; weak fine granular structure; soft, very friable; slightly sticky, slightly plastic; moderately alkaline (pH 8.25), noneffervescent.

AB - 3-6 inches. Brown (10YR 4/3) clay loam, dark brown (10YR 3/3) moist; moderate coarse subangular structure parting to weak fine granular; soft, very friable, slightly sticky, slightly plastic; moderately alkaline (pH 8.38), noneffervescent.

Bt - 6-13 inches. Brown (10YR 4/3) clay loam, dark brown (10YR 3/3) moist; strong coarse prismatic structure parting to moderate medium subangular structure; slightly hard, friable, sticky, plastic; moderately alkaline (pH 8.38), noneffervescent.

Bk - 13-15 inches. Brown (10YR 4/3) clay loam, dark brown (10YR 3/3) moist; moderate coarse subangular blocky structure parting to moderate fine subangular blocky; slightly hard, friable, sticky, plastic; seams and nodules of CaCO₃; strongly alkaline (pH 8.38), strongly effervescent.

Ck - 15-31 inches. Light gray (10YR 7/1) sandy clay loam, gray (10YR 6/1) moist; massive; soft, very friable, slightly sticky, slightly plastic; seams and nodules of CaCO₃; strongly alkaline (pH 8.52), strongly effervescent.

C - 31-48 inches. Light gray (10YR 7/1) sandy clay loam, gray (10YR 6/1) moist; massive; soft, very friable, slightly sticky, slightly plastic; seams and nodules of CaCO₃; strongly alkaline (pH 8.52), strongly effervescent.

Type Location - 23 (66 on the map)

Range in Soil Characteristics - Depth to a paralithic contact is more than 40 inches. Content of coarse fragments ranges from 0 to 5 percent. Texture of the control section is a clay loam or sandy clay loam. Clay content of the control section ranges from 25 to 35 percent.

Taxonomic Class - fine-loamy, mixed, mesic Ustic Haplargid.

Suitability for Topsoil - The Cambria loam soil is suitable for topsoil and the recommended stripping depth is 4 feet. The Cambria series rates fair or better according to Wyoming Department of Environmental Quality Guideline 1

CLARKELEN SERIES

Soil Mapping Unit 53A

Typical Pedon: Clarkelen sandy loam, rangeland.

(Colors are for dry soil unless otherwise indicated)

A - 0-3 inches. Brown (10YR 4/3) sandy clay loam, dark brown (10YR 3/3) moist; moderate, medium granular structure; soft, friable, slightly sticky, slightly plastic; moderately alkaline (pH 8.03), noneffervescent.

AC - 3-15 inches. Brown (10YR 5/3) sandy loam, brown (10YR 4/3) moist; weak, medium blocky structure; soft, friable, slightly sticky, slightly plastic; moderately alkaline (pH 8.21), noneffervescent.

C1 - 15-32 inches. Pale brown (10YR 6/3) sandy loam, brown (10YR 5/3) moist; massive; soft, friable, nonsticky, nonplastic; moderately alkaline (pH 8.19), noneffervescent.

C2 - 32-38 inches. Brown (10YR 5/3) sandy loam, brown (10YR 4/3) moist; loose structure; soft, friable, nonsticky, nonplastic; moderately alkaline (pH 8.11), slightly effervescent.

C3 - 38-60 inches. Pale brown (10YR 6/3) sandy loam, brown (10YR 5/3) moist; loose structure; soft, friable, nonsticky, nonplastic; moderately alkaline (pH 8.20), slightly effervescent.

Type Location - 14 (50 on the map)

Range in Soil Characteristics - There is no bedrock present within 60 inches of the surface. More than 35 percent of the sand fraction is fine sand or coarser. Content of coarse fragments is less than 5 percent. Texture of control section is a sandy loam.

Taxonomic Class - coarse-loamy, mixed, calcareous, mesic Ustic Torrifuvent.

Suitability for Topsoil - The Clarkelen series is generally suitable for topsoil to approximately 30-42 inches and the recommended stripping depth is 3 feet depending upon the stratification of lower horizons. The Clarkelen series rates fair according to Wyoming Department of Environmental Quality Guideline 1.

CUSHMAN SERIES

Soil Mapping Unit 21

Typical Pedon: Cushman sandy loam, rangeland.

(Colors are for dry soil unless otherwise indicated)

A - 0-5 inches. Brown (10YR 4/3) sandy loam, dark brown (10YR 3/3) moist; weak, fine granular structure; soft, very friable, nonsticky, nonplastic; moderately alkaline (pH 7.96), noneffervescent.

B2t - 5-18 inches. Brown (10YR 4/3) clay loam, dark brown (10YR 3/3) moist; moderate, medium angular blocky structure; slightly hard, friable, sticky, plastic; moderately alkaline (pH 7.92), noneffervescent.

Cca - 18-31 inches. Brown (10YR 5/3) sandy clay loam, dark brown (10YR 3/3) moist; weak, medium angular blocky structure; slightly hard, friable, slightly sticky, slightly plastic wet; seams of CaCO₃, moderately alkaline (pH 8.05), strongly effervescent.

Cr - 31 inches plus. Soft, partially weathered shale.

Type Location - 3 (4 on the map)

Range in Soil Characteristics - Depth to paralithic contact ranges from 20 to 40 inches. Content of coarse fragments is less than 5 percent. Texture of control section is a clay loam or sandy clay loam. Clay content of control section ranges from 18 to 35 percent.

Taxonomic Class - fine-loamy, mixed mesic Ustic Haplargid.

Suitability for Topsoil - The Cushman series is suitable for topsoil and the recommended stripping depth is 2.5 feet. The Cushman series rates fair or better according to Wyoming Department of Environmental Quality Guideline 1. Depth of stripping would be limited by bedrock material.

CUSHMAN SERIES

Soil Mapping Unit 21

Typical Pedon. Cushman sandy loam, rangeland.

(Colors are for dry soil unless otherwise indicated)

A - 0-3 inches. Dark yellowish brown (10YR 3/4) clay loam, dark brown (10YR 3/3) moist; weak, fine granular structure; soft, very friable, slightly sticky, slightly plastic; mildly alkaline (pH 7.66), noneffervescent.

Bt - 3-10 inches. Dark yellowish brown (10YR 3/4) clay loam, dark brown (10YR 3/3) moist; moderate, medium angular blocky structure; slightly hard, slightly friable, slightly sticky, slightly plastic; moderately alkaline (pH 8.33), noneffervescent.

Bk - 10-16 inches. Brown (10YR 5/3) clay loam, dark brown (10YR 3/3) moist; weak, medium angular blocky structure; slightly hard, friable, slightly sticky, slightly plastic; seams of CaCO₃, moderately alkaline (pH 8.26), moderately effervescent.

C - 16-27 inches. Grayish brown (10YR 5/2) clay loam, dark grayish brown (10YR 4/2) moist; massive; slightly hard, slightly friable, sticky, plastic; moderately alkaline (pH 8.38), strongly effervescent.

Cr - 27 inches plus. Soft, partially weathered shale.

Type Location - 12 (49 on the map)

Range in Soil Characteristics - Depth to paralithic contact ranges from 20 to 40 inches. Content of coarse fragments is generally less than 5 percent. Texture of control section is a clay loam or sandy clay loam. Clay content of control section ranges from 18 to 35 percent.

Taxonomic Class - fine-loamy, mixed mesic Ustic Haplargid.

Suitability for Topsoil - The Cushman series is suitable for topsoil and the recommended stripping depth is 2.5 feet. The Cushman series rates fair or better according to Wyoming Department of Environmental Quality Guideline 1. Depth of stripping would be limited by bedrock material.

CUSHMAN SERIES

Soil Mapping Unit 21A, 21B, 21AB

Typical Pedon: Cushman sandy loam, rangeland.

(Colors are for dry soil unless otherwise indicated)

A - 0-3 inches. Dark brown (10YR 3/3) sandy loam, very dark brown (10YR 2/2) moist; moderate medium granular structure; soft, friable, slightly sticky, slightly plastic; moderately alkaline (pH 8.00), noneffervescent.

AB - 3-8 inches. Dark brown (10YR 3/3) sandy clay loam, very dark brown (10YR 2/2) moist; weak medium prismatic structure parting to moderate medium subangular; slightly hard, friable, slightly sticky, slightly plastic; moderately alkaline (pH 8.15), noneffervescent.

Bt - 8-15 inches. Brown (10YR 4/3) sandy clay loam, very dark brown (10YR 3/3) moist; moderate, coarse prismatic structure parting to strong medium angular blocky; hard, firm, sticky, plastic; moderately alkaline (pH 8.15), moderately effervescent.

Btk - 15-20 inches. Brown (10YR 4/3) clay loam, very dark brown (10YR 3/3) moist; moderate coarse prismatic structure parting to moderate fine and very fine subangular blocky; hard, firm, sticky, plastic; seams of CaCO₃, moderately alkaline (pH 8.19), slightly effervescent.

Ck - 20-36+ inches. Light brownish gray (10YR 6/2) sandy clay loam, grayish brown (10YR 5/2) moist; soft, thickly stratified gray and brown calcareous shale; moderately alkaline (pH 8.29), strongly effervescent.

Type Location - 19 (60 on the map)

Range in Soil Characteristics - Depth to paralithic contact ranges from 20 to 40 inches. Content of coarse fragments is generally less than 5 percent. Texture of control section is a clay loam or sandy clay loam. Clay content of control section ranges from 21 to 28 percent.

Taxonomic Class - fine-loamy, mixed mesic Ustic Haplargid.

Suitability for Topsoil - The Cushman series is suitable for topsoil and the recommended stripping depth is 2.5 feet, although this location could be deeper. The Cushman series rates fair or better according to Wyoming Department of Environmental Quality Guideline 1. Depth of stripping would be limited by bedrock material.

DRAKNAB SERIES

Soil Mapping Unit 51

Typical Pedon: Draknab sandy loam, rangeland.

(Colors are for dry soil unless otherwise indicated)

A - 0-2 inches. Brown (10YR 4/3) sandy loam, dark brown (10YR 3/3) moist; moderate, medium granular structure; soft, friable, slightly sticky, slightly plastic; moderately alkaline (pH 8.28), slightly effervescent.

AC - 2-6 inches. Brown (10YR 4/3) sandy loam, dark brown (10YR 3/3) moist; weak, medium blocky structure; soft, friable, slightly sticky, slightly plastic; moderately alkaline (pH 8.28), slightly effervescent.

C1 - 6-14 inches. Grayish brown (10YR 5/2) sandy clay loam, dark grayish brown (10YR 4/2) moist; massive; soft, friable, slightly sticky, slightly plastic; moderately alkaline (pH 8.22), slightly effervescent.

C2 - 14-30 inches. Grayish brown (10YR 5/2) loamy sand, dark grayish brown (10YR 4/2) moist; loose structure; soft, friable, nonsticky, nonplastic; moderately alkaline (pH 7.89), noneffervescent.

C3 - 30-36 inches. Gray (10YR 5/1) clay loam, gray (10YR 5/1) moist; massive structure; hard, firm, sticky, plastic; moderately alkaline (pH 8.11), noneffervescent.

C4 - 36-44 inches. Brown (10YR 5/3) loamy sand, brown (10YR 5/3) moist; loose structure; soft, friable, nonsticky, nonplastic; moderately alkaline (pH 8.02), noneffervescent.

C5 - 44-48 inches. Light olive brown (2.5Y 5/3) clay, light olive brown (2.5Y 5/3) moist; massive structure; hard, firm, sticky, plastic; moderately alkaline (pH 8.15), noneffervescent.

Type Location - 15 (51 on the map)

Range in Soil Characteristics - There is no bedrock present within 60 inches of the surface. More than 35 percent of the sand fraction is fine sand or coarser. Content of coarse fragments is varied and can exceed 5 percent. Texture of control section is a sandy loam. Stratification in lower horizons is common and varied.

Taxonomic Class - sandy, mixed, mesic Ustic Torrifuvent.

Suitability for Topsoil - The Draknab series is generally suitable for topsoil to approximately 1 foot and the recommended stripping depth is 1 foot depending upon the stratification of lower horizons. The Draknab series rates poor according to Wyoming Department of Environmental Quality Guideline 1.

DWYER SERIES

Soil Mapping Unit 18A

Typical Pedon: Dwyer loam, grassland

(Colors are for dry soil unless otherwise indicated)

A- 0-5 inches. Brown (10YR 4/3) clay loam, very dark brown (10YR 3/3) moist; weak fine granular; soft, friable, slightly sticky, slightly plastic; moderately alkaline (pH 8.16), slightly effervescent.

C1 - 5-20 inches. Brown (10YR 5/3) sandy loam, brown (10YR 4/3) moist; massive; soft, friable, nonsticky, nonplastic; moderately alkaline (pH 8.09), slightly effervescent.

C2 - 20-30 inches. Pale brown (10YR 6/3) sandy loam, brown (10YR 5/3) moist; massive; soft, friable, nonsticky, nonplastic; moderately alkaline (pH 8.03), slightly effervescent.

C3 - 30-60 inches. Pale brown (10YR 6/3) loamy sand, brown (10YR 5/3) moist; loose single grain; moderately alkaline (pH 8.17), slightly effervescent.

Type Location - 24 (72 on the map)

Range in Soil Characteristics - Depth to a paralithic contact is more than 60 inches. Content of coarse fragments ranges from 0 to 5 percent. Texture of the control section is a sandy loam. Clay content of the control section ranges from 11 to 20 percent. The texture of the A horizon is slightly heavier than typical for the series.

Taxonomic Class - mixed, mesic Ustic Torripsamment

Suitability for Topsoil - The Dwyer loam soil is suitable for topsoil and the recommended stripping depth is approximately 1 foot. The Dwyer series rates fair according to Wyoming Department of Environmental Quality Guideline 1

FORKWOOD (FT COLLINS) SERIES

Soil Mapping Unit 19

Typical Pedon: Forkwood (Ft. Collins) clay loam, rangeland.

(Colors are for dry soil unless otherwise indicated)

A - 0-3 inches. Pale brown (10YR 6/3) loam, grayish brown (10YR 5/2) moist; weak, medium granular structure; soft, very friable, slightly sticky, slightly plastic; moderately alkaline (pH 7.91), noneffervescent.

AB - 3-7 inches. Light brownish gray (10YR 6/2) sandy clay loam, grayish brown (10YR 5/2) moist; weak, medium angular blocky structure; slightly hard, friable, sticky and plastic; neutral (pH 7.33), noneffervescent.

Bt - 7-26 inches. Yellowish brown (10YR 5/4) clay loam, dark grayish brown (10YR 4/2); moderate, medium angular blocky structure; hard, slightly friable, sticky, plastic; moderately alkaline (pH 7.99), noneffervescent.

Bk - 26-30 inches. Light yellowish brown (10YR 6/4) clay loam, brown (10YR 5/3); moderate, medium angular blocky structure; slightly hard, slightly friable, slightly sticky, slightly plastic; moderately alkaline (pH 8.12), slightly effervescent.

Ck - 30-45 inches. Light yellowish brown (10YR 6/4) clay loam, yellowish brown (10YR 5/4) moist; massive; slightly hard, friable, slightly sticky, slightly plastic; seams and nodules of CaCO₃; moderately alkaline (pH 8.27), strongly effervescent.

C - 45-60 inches. Light yellowish brown (2.5Y 6/3) clay loam, light yellowish brown (2.5Y 6/3) moist; massive; slightly hard, friable, slightly sticky, slightly plastic; moderately alkaline (pH 8.12), strongly effervescent.

Type Location - 11 (48 on the map)

Range in Soil Characteristics - There is generally no bedrock present within 60 inches. Content of coarse fragments is less than 5 percent. Texture of control section is a clay loam. Clay content of control section ranges from 18 to 35 percent.

Taxonomic Class - fine-loamy, mixed, mesic Ustic Haplargid.

Suitability for Topsoil - The Forkwood series is suitable for topsoil and the recommended stripping depth is 5 feet. The Forkwood series rates fair or better according to Wyoming Department of Environmental Quality Guideline 1

HILAND (OLNEY) SERIES

Soil Mapping Unit 12

Typical Pedon: Hiland (Olney) sandy loam, rangeland.

(Colors are for dry soil unless otherwise indicated)

A - 0-4 inches. Dark brown (10YR 3/3) sandy loam, dark brown (10YR 3/3) moist; moderate, medium granular structure; soft, very friable, nonsticky, nonplastic when wet; moderately alkaline (pH 8.30), noneffervescent.

AB - 4-8 inches. Dark yellowish brown (10YR 3/4) sandy loam, dark yellowish brown (10YR 3/4) moist; moderate, medium granular structure; soft, very friable, nonsticky, nonplastic when wet; mildly alkaline (pH 7.80), noneffervescent.

Bt1 - 8-18 inches. Brown (10YR 4/3) sandy loam, brown (10YR 3/3) moist; moderate, medium angular blocky structure; slightly hard, friable, slightly sticky, slightly plastic; mildly alkaline (pH 7.80), noneffervescent.

Bt2 - 18-26 inches. Yellowish brown (10YR 5/4) sandy loam, dark yellowish brown (10YR 4/4) moist; moderate, medium angular blocky structure; slightly hard, friable, slightly sticky, slightly plastic; mildly alkaline (pH 7.6), noneffervescent.

Bk - 26-34 inches. Brown (10YR 5/3) sandy loam, brown (10YR 4/3) moist; moderate, medium angular blocky structure; slightly hard, friable, slightly sticky, slightly plastic; mildly alkaline (pH 7.53), slightly effervescent.

C - 34-54 inches. Light olive brown (2.5YR 5/4) sandy loam, olive brown (10YR 4/4) moist; massive structure; slightly hard, friable, slightly sticky, slightly plastic; moderately alkaline (pH 8.03), slightly effervescent.

Type Location - 8 (7 on the map)

Range in Soil Characteristics - There is no bedrock present within 60 inches of the surface. More than 35 percent of the sand fraction is fine sand or coarser. Content of coarse fragments is less than 5 percent. Texture of control section is a sandy clay loam. Clay content of control section ranges from 18 to 35 percent.

Taxonomic Class - fine-loamy, mixed, mesic Ustollic Haplargid.

Suitability for Topsoil - The Hiland sandy loam soil is suitable for topsoil and the recommended stripping depth is 5 feet. The Hiland series rates fair or better according to Wyoming Department of Environmental Quality Guideline 1

HILAND (OLNEY) SERIES

Soil Mapping Unit 16A, 16B

Typical Pedon: Hiland (Olney) sandy loam, rangeland.

(Colors are for dry soil unless otherwise indicated)

A - 0-3 inches. Dark brown (10YR 3/3) sandy clay loam, very dark brown (10YR 2/2) moist; weak fine granular structure; soft, very friable, slightly sticky, slightly plastic; mildly alkaline (pH 7.67), noneffervescent.

AB - 3-10 inches. Dark brown (10YR 3/3) sandy loam, very dark brown (10YR 2/2) moist; moderate medium subangular blocky structure; slightly hard, friable, slightly sticky, nonplastic; mildly alkaline (pH 7.60), noneffervescent.

Bt - 10-24 inches. Dark yellowish brown (10YR 4/4) sandy clay loam, dark yellowish brown (10YR 3/4) moist; strong medium prismatic structure parting to moderate medium angular blocky; hard, firm, sticky, plastic; moderately alkaline (pH 8.10), noneffervescent.

Bk - 24-30 inches. Yellowish brown (10YR 5/4) sandy clay loam, dark yellowish brown (10YR 4/4) moist; moderate medium subangular blocky structure; slightly hard, friable, sticky, plastic; seams and nodules of CaCO₃; moderately alkaline (pH 8.25), moderately effervescent.

Ck - 30-48 inches. Grayish brown (10YR 5/2) sandy clay loam, dark grayish brown (10YR 4/2) moist; massive; soft, very friable, slightly sticky, slightly plastic; threads of CaCO₃; moderately alkaline (pH 8.34), strongly effervescent.

C - 48-60 inches. Light brownish gray (2.5Y 6/2) sandy clay loam, grayish brown (2.5Y 5/2) moist; massive; soft, very friable, slightly sticky, slightly plastic; moderately alkaline (pH 8.33), strongly effervescent.

Type Location - 22 (64 on the map)

Range in Soil Characteristics - There is no bedrock present within 60 inches of the surface. More than 60 percent of the sand fraction is fine sand or coarser. Content of coarse fragments is less than 5 percent. Texture of control section is a sandy clay loam. Clay content of control section ranges from 20 to 24 percent.

Taxonomic Class - fine-loamy, mixed, mesic Ustollic Haplargid.

Suitability for Topsoil - The Hiland sandy loam soil is suitable for topsoil and the recommended stripping depth is 4 feet. The Hiland series rates fair or better according to Wyoming Department of Environmental Quality Guideline 1.

KISHONA (KIM) SERIES

Soil Mapping Unit 14

Typical Pedon: Kishona (Kim) loam, rangeland.

(Colors are for dry soil unless otherwise indicated)

A - 0-6 inches. Brown (10YR 4/3) clay loam, dark brown (10YR 3/3) moist; moderate, fine granular structure; soft, friable, slightly sticky slightly plastic; moderately alkaline (pH 8.20), slightly effervescent.

AC - 6-19 inches. Dark yellowish brown (10YR 4/6) clay loam, dark yellowish brown (10YR 3/6); moderate, medium subangular blocky structure; slightly hard, friable, sticky, slightly plastic; moderately alkaline (pH 8.23), moderately effervescent.

C1 - 19-44 inches. Pale brown (10YR 6/3) clay loam, brown (10YR 5/3) moist; massive; slightly hard, slightly friable, slightly sticky, slightly plastic; seams of CaCO₃; moderately alkaline (pH 8.23), strongly effervescent.

C2 - 44-54 inches. Light yellowish brown (10YR 6/4) loam, brown (10YR 5/3) moist; massive; soft, friable, slightly sticky, slightly plastic; seams of CaCO₃; moderately alkaline (pH 8.28), strongly effervescent.

Type Location - 16 (52 on the map)

Range in Soil Characteristics - Depth to bedrock will vary from 40 to 60 inches plus. Content of coarse fragments is less than 5 percent. Texture of control section is a clay loam. Clay content of control section ranges from 18 to 35 percent.

Taxonomic Class - fine-loamy, mixed (calcareous), mesic Ustic Torriorthent.

Suitability for Topsoil - The Kishona loam soil is suitable for topsoil and the recommended stripping depth is 4 feet. The C horizon suitability may have a poor rating due to a high content of calcium carbonate. However, this property is not believed to be of serious concern to the overall topsoil suitability. Otherwise, the Kishona series rates fair or better according to Wyoming Department of Environmental Quality Guideline 1.

RENOHILL SERIES

Soil Mapping Unit 22A

Typical Pedon: Renohill loam, rangeland.

(Colors are for dry soil unless otherwise indicated)

A - 0-3 inches. Brown (10YR 4/3) sandy loam, dark brown (10YR 3/3) moist; strong fine granular structure; soft, very friable, nonsticky, nonplastic; neutral (pH 7.09), noneffervescent.

AB - 3-8 inches. Brown (10YR 4/3) sandy clay loam, dark brown (10YR 3/3) moist; moderate medium subangular blocky structure parting to moderate medium angular; slightly hard, friable, slightly sticky, slightly plastic; moderately alkaline (pH 7.92), noneffervescent.

Bt - 8-20 inches. Dark brown (10YR 3/3) sandy clay loam, very dark brown (10YR 2/2) moist; moderate, medium prismatic parting to moderate medium angular blocky; very hard, firm, sticky, plastic; moderately alkaline (pH 7.92), noneffervescent.

Bk - 20-26 inches. Brown (10YR 5/3) clay loam, brown (10YR 4/3) moist; massive; very hard, firm, sticky, plastic; threads of CaCO₃; moderately alkaline (pH 8.05), moderately effervescence.

C - 26-33 inches. Light brownish gray (10YR 6/2) clay loam, grayish brown (10YR 5/2) moist; weathered soft calcareous shale; moderately alkaline (pH 8.17), strongly effervescent.

Type Location - 18 (58 on map)

Range in Soil Characteristics - Depth to paralithic contact ranges from 20 to 40 inches. Content of coarse fragments is less than 5 percent. Texture of control section is sandy clay loam or clay loam. Clay content of control section ranges from 35 to 50 percent. Texture of the A horizon is lighter than typical for the series.

Taxonomic Class - fine, smectitic, mesic Ustic Haplargid

Suitability for Topsoil - The Renohill clay loam soil is suitable for topsoil and the recommended stripping depth is approximately 2 feet. All soil parameters of Renohill rate fair or better according to Wyoming Department of Environmental Quality Guideline 1. Depth of stripping would be limited by bedrock material.

SHINGLE SERIES

Soil Mapping Unit 30

Typical Pedon: Shingle loam, rangeland.

(Colors are for dry soil unless otherwise indicated)

A - 0-3 inches. Yellowish brown (10YR 5/4) clay loam, dark yellowish brown (10YR 3/4) moist; moderate, fine granular structure; soft, very friable, slightly sticky, slightly plastic; moderately alkaline (pH 8.09), moderately effervescent.

C - 3-6 inches. Light yellowish brown (10YR 6/4) clay loam, dark yellowish brown (10YR 4/4) moist; moderate, medium granular structure; soft, friable, slightly sticky, slightly plastic; moderately alkaline (pH 8.09), strongly effervescent.

Cr - 6 inches plus. Soft calcareous gray shale.

Type Location - 1 (1 on the map)

Range in Soil Characteristics - Depth to paralithic contact ranges from 6 to 20 inches. Content of coarse fragments is less than 5 percent. Texture of control section is a clay loam. Clay content of control section ranges from 18 to 35 percent.

Taxonomic Class - loamy, mixed (calcareous) mesic, shallow Ustic Torriorthent.

Suitability for Topsoil - The Shingle loam soil is suitable for topsoil and the approximate recommended stripping depth is 1 foot. The Shingle series rates fair or better according to Wyoming Department of Environmental Quality Guideline 1. Depth of stripping would be limited by bedrock material.

TALUCE (TASSEL) SERIES

Soil Mapping Unit 32

Typical Pedon: Taluce (Tassel) sandy loam, Rangeland.

A1 - 0-5 inches. Dark yellowish brown (10YR 4/4) sandy loam, dark yellowish brown (10YR 3/4) moist; weak, fine granular structure; loose, friable, slightly sticky, nonplastic; moderately alkaline (pH 8.09), noneffervescent.

C - 5-16 inches. Yellowish brown (10YR 5/4) sandy clay loam, brown (10YR 4/3) moist; weak, subangular blocky structure; soft, friable, slightly sticky, slightly plastic; CaCO₃ threads throughout; moderately alkaline (pH 8.24), strongly effervescent.

Cr- 16 inches plus. Calcareous sandstone.

Typic Location - 6 (43 on the map)

Range in Soil Characteristics - Depth to paralithic contact ranges from 6 to 20 inches. More than 35 percent of the sand fraction is fine or coarser. Content of coarse fragments is less than 5 percent. Texture of the control section is sandy loam.

Taxonomic Class - fine, mixed, mesic, shallow Ustic Torriorthent.

Suitability for Topsoil - The Taluce sandy loam soil is suitable for topsoil and the recommended stripping depth is generally 0.5 to 1 foot. The Taluce series rates fair or better according to Wyoming Department of Environmental Quality Guideline 1. Depth of stripping would be limited by bedrock material.

TALUCE (TASSEL) SERIES

Soil Mapping Unit 32

Typical Pedon: Taluce (Tassel) sandy loam, Rangeland.

A - 0-3 inches. Olive brown (2.5Y 4/3) sandy loam, dark olive brown (10YR 3/3) moist; weak, fine granular structure; loose, friable, nonsticky, nonplastic; moderately alkaline (pH 7.93), slightly effervescent.

C - 3-6 inches. Light olive brown (2.5Y 5/4) loamy sand, olive brown (2.5Y 4/4) moist; loose, coarse granular structure; soft, friable, nonsticky, nonplastic; moderately alkaline (pH 7.93), moderately effervescent.

Cr- 6 inches plus. Calcareous sandstone.

Typic Location - 13 (29 on the map)

Range in Soil Characteristics - Depth to paralithic contact ranges from 6 to 20 inches. More than 35 percent of the sand fraction is fine or coarser. Content of coarse fragments is less than 5 percent. Texture of the control section is sandy loam.

Taxonomic Class - fine, mixed, mesic, shallow Ustic Torriorthent.

Suitability for Topsoil - The Taluce sandy loam soil is suitable for topsoil and the recommended stripping depth is generally 0.5 to 1 foot. The Taluce series rates fair or better according to Wyoming Department of Environmental Quality Guideline 1. Depth of stripping would be limited by bedrock material.

TERRO (TERRY) SERIES

Soil Mapping Unit 24

Typical Pedon: Terro (Terry) fine sandy loam, rangeland.

(Colors are for dry soil unless otherwise indicated)

A - 0-5 inches. Dark yellowish brown (10YR 3/4) sandy loam, dark yellowish brown (10YR 3/4) moist; moderate, fine granular structure; soft, very friable, nonsticky, nonplastic; moderately alkaline (pH 7.93), noneffervescent.

Bt - 5-14 inches. Yellowish brown (10YR 5/4) sandy loam, dark yellowish brown (10YR 4/4) moist; moderate, medium angular structure; slightly hard, friable, slightly sticky and slightly plastic; moderately alkaline (pH 8.24), noneffervescent.

Bck - 14-20 inches. Yellowish brown (10YR 5/4) sandy loam, dark yellowish brown (10YR 4/4) moist; weak medium, subangular blocky structure; slightly hard, friable, slightly sticky and slightly plastic; moderately alkaline (pH 8.24), strongly effervescent.

Ck - 20-38 inches. Light brownish gray (10YR 6/3) sandy loam, brown (10YR 5/3) moist; massive structure; slightly hard, friable, slightly sticky and slightly plastic; moderately alkaline (pH 8.15); strongly effervescent.

C - 38 inches. Calcareous sandstone.

Type Location - 5 (40 on the map)

Range in Soil Characteristics - Depth to paralithic contact ranges from 20 to 40 inches. More than 35 percent of the sand fraction is fine sand or coarser. Content of coarse fragments is less than 5 percent. Texture of the control section is sandy loam. Clay content of the control section ranges from 7 to 18 percent.

Taxonomic Class - coarse-loamy, mixed, mesic Ustic Haplargid.

Suitability for Topsoil - The Terro sandy loam soil is suitable for topsoil and the recommended stripping depth is 2.5 feet. The Terro series rates fair or better according to Wyoming Department of Environmental Quality Guideline 1. Depth of stripping would be limited by bedrock material.

TERRO (TERRY) SERIES

Soil Mapping Unit 17A, 17B, 17AB, 17BC

Typical Pedon: Terro (Terry) fine sandy loam, rangeland.

(Colors are for dry soil unless otherwise indicated)

A - 0-3 inches. Dark brown (10YR 3/3) sandy loam, very dark brown (10YR 2/2) moist; weak fine granular structure; soft, very friable, nonsticky, nonplastic; mildly alkaline (pH 7.78), noneffervescent.

Bt - 3-8 inches. Brown (10YR 4/3) sandy clay loam, dark brown (10YR 3/3) moist; weak medium prismatic structure parting to weak medium subangular blocky; slightly hard, very friable, slightly sticky, slightly plastic; moderately alkaline (pH 8.09), noneffervescent.

Btk - 8-18 inches. Yellowish brown (10YR 5/4) sandy clay loam, dark yellowish brown (10YR 4/4) moist; weak fine subangular blocky structure; slightly hard, very friable, slightly sticky, slightly plastic; seams and nodules of CaCO₃; moderately alkaline (pH 8.09), slightly effervescent.

Bk - 18-27 inches. Yellowish brown (10YR 5/4) sandy loam, dark yellowish brown (10YR 4/4) moist; massive structure; slightly hard, friable, slightly sticky, slightly plastic; seams and nodules of CaCO₃; moderately alkaline (pH 8.21), slightly effervescent.

C - 27-40 inches. Pale brown (10YR 6/3) sandy loam, brown (10YR 5/3) moist; massive; soft, friable, nonsticky, nonplastic; moderately alkaline (pH 8.03), slightly effervescent.

Cr - 40+ inches. Soft calcareous sandstone.

Type Location - 25 (77 on the map)

Range in Soil Characteristics - Depth to paralithic contact ranges from 20 to 40 inches. More than 35 percent of the sand fraction is fine sand or coarser. Content of coarse fragments is less than 5 percent. Texture of the control section is sandy clay loam to sandy loam. Clay content of the control section ranges from 12 to 20 percent.

Taxonomic Class - coarse-loamy, mixed, mesic Ustic Haplargid.

Suitability for Topsoil - The Terro sandy loam soil is suitable for topsoil and the recommended stripping depth is 2.5 feet. The Terro series rates fair or better according to Wyoming Department of Environmental Quality Guideline 1. Depth of stripping would be limited by bedrock material.

THEEDLE (THEDALUND) SERIES

Soil Mapping Unit 49A

Typical Pedon: Theedle (Thedalund) loam, rangeland.

(Colors are for dry soil unless otherwise indicated)

A - 0-3 inches. Dark brown (7.5YR 3/3) sandy clay loam, very dark brown (7.5YR 2/2) moist; weak fine granular structure; slightly hard, friable, slightly sticky, slightly plastic; moderately alkaline (pH 8.14), slightly effervescent.

AC - 3-12 inches. Grayish brown (10YR 5/2) clay loam, dark grayish brown (10YR 4/2) moist; weak moderate subangular structure; slightly hard, friable, sticky, plastic; moderately alkaline (pH 8.11), moderately effervescent.

Ck - 12-30 inches. Light brownish gray (10YR 6/2) loam, grayish brown (10YR 5/2) moist; massive; slightly hard, friable, sticky, nonplastic; CaCO₃ seams; moderately alkaline (pH 8.30), strongly effervescent.

C - 30-32+ inches. Light gray (10YR 7/1), gray (10YR 6/1) moist; soft calcareous mixed sandstone and shale.

Type Location - 20 (61 on map)

Range in Soil Characteristics - Depth to paralithic contact ranges from 20 to 40 inches but is typically less than 32 inches. Content of coarse fragments is less than 6 percent. Texture of the control section is clay loam or loam. Clay content of the control section ranges from 25 to 28 percent.

Taxonomic Class - fine-loamy, mixed, calcareous, mesic Ustic Torriorthent.

Suitability for Topsoil - The Theedle loam soil is suitable for topsoil and the recommended stripping depth is 2.5 feet. The Theedle series rates fair or better according to Wyoming Department of Environmental Quality Guideline 1. Depth of stripping would be limited by bedrock material.

TULLOCK SERIES

Soil Mapping Unit 25

Typical Pedon: Tullock sandy loam, rangeland.

(Colors are for dry soil unless otherwise indicated)

A1 - 0-4 inches. Dark yellowish brown (10YR 4/4) sandy loam, dark yellowish brown (10YR 3/4) moist; weak, fine crumb structure; soft, friable, nonsticky, nonplastic; mildly alkaline (pH 7.51), noneffervescent.

C1 - 4-21 inches. Yellowish brown (10YR 5/4) sandy loam, dark yellowish brown (10YR 4/4) moist; massive structure; soft, friable, nonsticky, nonplastic; mildly alkaline (pH 7.79), noneffervescent.

C2 - 21-39 inches. Pale brown (10YR 6/3) loam, brown (10YR 5/3) moist; weak fine crumb structure; soft, friable, slightly sticky, slightly plastic; moderately alkaline (pH 8.18), slightly effervescent.

Cr - 39 inches. Weakly consolidated calcareous sandstone.

Type Location - 4 (36 on the map)

Range in Soil Characteristics - Depth to paralithic contact ranges from 20 to 40 inches. Content of coarse fragments is less than 5 percent. Texture of the control section is sandy loam.

Taxonomic Class - mixed, mesic Ustic Torripsamments.

Suitability for Topsoil - The Tullock fine sandy loam soil is suitable for topsoil and the recommended stripping depth is 2.5 feet. The Tullock series rates fair or better according to Wyoming Department of Environmental Quality Guideline 1. Depth of stripping would be limited by bedrock material.

ULM SERIES

Soil Mapping Unit 20A

Typical Pedon. Ulm clay loam, rangeland.

(Colors are for dry soil unless otherwise indicated)

A - 0-3 inches. Brown (10YR 4/3) sandy clay loam, dark brown (10YR 3/3) moist; strong fine granular structure; slightly hard, friable, sticky, plastic; mildly alkaline (pH 7.78), noneffervescent.

AB - 3-10 inches. Brown (10YR 4/3) clay, dark brown (10YR 3/3) moist; strong medium coarse angular blocky; very hard, very firm, very sticky, very plastic; moderately alkaline (pH 8.27), noneffervescent.

Bt - 10-20 inches. Dark brown (10YR 3/3) clay, very dark brown (10YR 2/2) moist; strong coarse prismatic structure parting to strong medium coarse angular blocky; very hard, very firm, very sticky, very plastic; moderately alkaline (pH 8.27), noneffervescent.

Bk - 20-24 inches. Dark brown (10YR 3/3) clay loam, very dark brown (10YR 2/2) moist; moderate medium prismatic parting to strong medium angular blocky structure; very hard, firm, very sticky, very plastic; calcium carbonate mostly disseminated with CaCO₃ threads; moderately alkaline (pH 8.09), moderately effervescent.

Ck - 24-42 inches. Very dark grayish brown (10YR 3/2) clay, very dark brown (10YR 2/2) moist; massive; hard, firm, sticky, plastic; seams and streaks of CaCO₃; moderately alkaline (pH 8.13), strongly effervescent.

C - 42-48 inches. Dark brown (10YR 3/3) sandy clay, very dark brown (10YR 2/2) moist; massive; hard, firm, sticky, plastic; moderately alkaline (pH 8.08), strongly effervescent.

Type Location - 17 (57 on map)

Range in Soil Characteristics - There is no bedrock present within 60 inches of the surface. Coarse fragments are less than 5 percent. The control section is a clay. Clay content of the control section ranges from 40 to 42 percent.

Taxonomic Class - fine, smectitic, mesic Ustic Haplargid.

Suitability for Topsoil - The Ulm clay loam soil is suitable for topsoil and the recommended stripping depth is 4 feet. The suitability rating for texture from 3-20 and 24-42 inches is marginal due to a high clay content which limits soil workability. However, this property is not believed to be of serious concern to the overall topsoil suitability.

VONALEE (VONA) SERIES

Soil Mapping Unit 13

Typical Pedon. Vonalee (Vona) sandy loam, rangeland.

(Colors are for dry soil unless otherwise indicated)

A - 0-4 inches. Dark yellowish brown (10YR 4/4) sandy loam, dark yellowish brown (10YR 3/4) when moist; weak, fine crumb structure; loose consistence, very friable, nonsticky and nonplastic; moderately alkaline (pH 7.88), noneffervescent.

Bt1 - 4-17 inches. Dark yellowish brown (10YR 4/4) sandy clay loam, dark yellowish brown (10YR 3/4) moist; moderate, medium subangular blocky structure; soft, very friable, nonsticky and nonplastic; moderately alkaline (pH 8.12), noneffervescent.

Bt2 - 17-28 inches. Yellowish brown (10YR 5/4) sandy clay loam, dark yellowish brown (10YR 4/4) moist; moderate, medium angular blocky structure; slightly hard, friable, slightly sticky, slightly plastic; moderately alkaline (pH 8.15), slightly effervescent.

Bk1 - 28-42 inches. Pale brown (10YR 6/3) sandy clay loam, brown (10YR 5/3) moist; moderate, medium subangular blocky structure; slightly hard, very friable, slightly sticky and slightly plastic; moderately alkaline (pH 8.13), moderately effervescent.

Bk2 - 42-60 inches. Light yellowish brown (10YR 6/4) sandy clay loam, brown (10YR 5/3) moist; massive structure; slightly hard, friable, slightly sticky and slightly plastic; moderately alkaline (pH 8.13), slightly effervescent.

Type Location - 7 (45 on map)

Range in Soil Characteristics - There is no bedrock present within 60 inches of the surface. More than 35 percent of sand fraction is fine sand or coarser. Coarse fragments are less than 5 percent. The control section is sandy clay loam with a clay content ranging from 21 to 26 percent.

Taxonomic Class - coarse-loamy, mixed, mesic Ustic Haplargid.

Suitability for Topsoil - The Vonalee sandy loam soil is suitable for topsoil and the recommended stripping depth is 5 feet. The Vonalee series rates fair or better according to Wyoming Department of Environmental Quality Guideline 1. Depth of stripping would be limited by bedrock material.

WOLF SERIES

Soil Mapping Unit 31

Typical Pedon: Worf loam, rangeland.

(Colors are for dry soil unless otherwise indicated)

A - 0-2 inches. Brown (10YR 4/3) sandy clay loam, dark brown (10YR 3/3) moist; moderate, fine granular structure; soft, friable, sticky, plastic; moderately alkaline (pH 7.96), noneffervescent.

Bt - 2-6 inches. Brown (10YR 4/3) sandy clay loam, dark brown (10YR 3/3); moderate, medium angular blocky structure; slightly hard, friable, sticky, plastic; moderately alkaline (pH 8.04), noneffervescent.

Bk - 6-11 inches. Brown (10YR 5/3) sandy clay loam, dark brown (10YR 3/3) moist; moderate, medium angular blocky structure; slightly hard, friable, slightly sticky, slightly plastic; seams of CaCO₃ throughout horizon, moderately alkaline (pH 8.01), strongly effervescent.

Cr - 11 inches. Calcareous shale.

Type Location - 2 (2 on the map)

Range in Soil Characteristics - Depth of bedrock ranges from 10 to 20 inches. Coarse fragments are less than 5 percent. Clay content of the control section ranges from 18 to 35 percent. The control section texture is clay loam to sandy clay loam.

Taxonomic Class - loamy, mixed, mesic, shallow Ustic Haplargid.

Suitability for Topsoil - The Worf series is suitable for topsoil and the approximate recommended stripping depth is 1 foot. The Worf series rates fair or better according to Wyoming Department of Environmental Quality Guideline 1. Depth of stripping would be limited by bedrock material.

WORF SERIES

Soil Mapping Unit 31

Typical Pedon: Worf loam, rangeland.

(Colors are for dry soil unless otherwise indicated)

A - 0-2 inches. Brown (10YR 4/3) sandy clay loam, dark brown (10YR 3/3) moist; moderate, fine granular structure; soft, friable, sticky, plastic; moderately alkaline (pH 8.13), noneffervescent.

Bt - 2-6 inches. Brown (10YR 4/3) sandy clay loam, dark brown (10YR 3/3); moderate, medium angular blocky structure; slightly hard, friable, sticky, plastic; moderately alkaline (pH 8.13), noneffervescent.

Bk - 6-15 inches. Brown (10YR 5/3) clay loam, dark brown (10YR 3/3) moist; moderate, medium angular blocky structure; slightly hard, friable, slightly sticky, slightly plastic; seams of CaCO₃ throughout horizon, moderately alkaline (pH 8.15), strongly effervescent.

Cr - 15 inches. Calcareous shale.

Type Location - 9 (47 on the map)

Range in Soil Characteristics - Depth of bedrock ranges from 10 to 20 inches. Coarse fragments are less than 5 percent. Clay content of the control section ranges from 18 to 35 percent. The control section texture is clay loam to sandy clay loam.

Taxonomic Class - loamy, mixed, mesic, shallow Ustic Haplargid.

Suitability for Topsoil - The Worf series is suitable for topsoil and the approximate recommended stripping depth is 1 foot. The Worf series rates fair or better according to Wyoming Department of Environmental Quality Guideline 1. Depth of stripping would be limited by bedrock material.

ADDENDUM 5
1979 SOIL SERIES DESCRIPTIONS

The following soil series descriptions are based, in part, on the 1979 soil survey by Woodward-Clyde Associates on the Mill Site for Smith Ranch. These series descriptions were utilized during 1978-1980 on various soil surveys related to the Smith Ranch Project. Note that much of the taxonomic nomenclature is no longer accepted, e.g., B3ca is now Bk.

BOWBAC SERIES

Soil Mapping Unit 23A, 23B, and 23C

Typical Pedon: Bowbac sandy loam, rangeland.

(Colors are for dry soil unless otherwise indicated)

A1 - 0-4 inches. Light yellowish brown (10YR 6/4) sandy loam, yellowish brown (10YR 5/4) when moist; moderate fine granular structure; soft consistency when dry, very friable when moist, slightly sticky when wet; mildly alkaline (pH 7.7), noneffervescent.

B2t - 4-16 inches. Pale brown (10YR 6/3) sandy loam, grayish brown (10YR 5/2) when moist; moderate medium angular blocky structure; slightly hard consistence when dry, friable when moist, sticky and plastic when wet; mildly alkaline (pH 7.7), noneffervescent.

B3ca - 16-25 inches. Pale brown (10YR 6/4) sandy loam, brown (10YR 5/3) when moist; medium subangular blocky structure; slightly hard consistence when dry, friable when moist, slightly sticky when wet; moderately alkaline (pH 8.0), strongly effervescent.

Cca - 25-34 inches. Light yellowish brown (10YR 6/4) sandy clay loam, yellowish brown when moist; medium subangular blocky structure; hard consistence when dry, firm when moist, slightly sticky when wet; moderately alkaline (pH 8.4), strongly effervescent.

Cr - 34 inches. Shale and sandstone.

Range in Soil Characteristics - Depth to a paralithic contact ranges from 20 to 40 inches. More than 35 percent of the sand fraction is fine sand or coarser. Content of coarse fragments is less than 5 percent. Texture of the control section is a sandy clay loam. Clay content of the control section ranges from 18 to 35 percent. There is no evidence of a water table.

Taxonomic Class - fine-loamy, mixed, mesic Ustollic Haplargid.

Suitability for Topsoil - The Bowbac sandy loam soil is suitable for topsoil and the recommended stripping depth is 2.5 feet. The Bowbac series rates fair or better according to Wyoming Department of Environmental Quality Guideline 1. Depth of stripping would be limited by bedrock material.

CAMBRIA (STONEHAM) LOAM

Soil Mapping Unit 15A and 15B

Typical Pedon: Cambria (Stoneham) loam, rangeland

(Colors are for dry soil unless otherwise indicated)

A1 - 0-3 inches. Yellowish brown (10YR 5/4), heavy loam, dark grayish brown (10YR 4/2) when moist; moderate medium granular structure; soft consistence when dry, very friable when moist; sticky and plastic when wet; mildly alkaline (pH 7.7), noneffervescent.

B2t - 3-8 inches. Pale brown (10YR 6/3) loam, brown (10YR 5/3) when moist; moderate subangular blocky structure; slightly hard consistence when dry, firm when moist, slightly sticky, slightly plastic when wet; mildly alkaline (pH 7.8), noneffervescent.

B3ca - 8-19 inches. Light gray (10YR 7/2) loam, brown (10YR 5/3) when moist; moderate subangular blocky structure; slightly hard consistence when dry, firm when moist, slightly sticky, slightly plastic when wet; strongly alkaline (pH 8.6), strongly effervescent.

Cca - 19-60 inches. Light brownish gray (10YR 6/2) loam, grayish brown (10YR 5/2) when moist; massive structure; slightly hard consistence when dry, friable when moist, slightly sticky, slightly plastic when wet; strongly alkaline (pH 8.6), strongly effervescent.

Range in Soil Characteristics - Depth to a paralithic contact is more than 40 inches. Content of coarse fragments ranges from 0 to 15 percent. Texture of the control section is a clay loam or sandy clay loam. Clay content of the control section ranges from 15 to 35 percent. There is no evidence of a water table.

Taxonomic Class - fine-loamy, mixed, mesic Ustollic Haplargid.

Suitability for Topsoil - The Cambria loam soil is suitable for topsoil and the recommended stripping depth is 5 feet. The Cambria series rates fair or better according to Wyoming Department of Environmental Quality Guideline 1

CUSHMAN SERIES

Soil Mapping Unit 21A, 21B, and 21C

Typical Pedon: Cushman sandy loam, rangeland.

(Colors are for dry soil unless otherwise indicated)

A1 - 0-4 inches. Light brownish gray (10YR 6/2) loam, Yellowish brown (10YR 5/4) when moist; weak, fine granular structure; soft consistence when dry, very friable when moist, slightly sticky, slightly plastic when wet; mildly alkaline (pH 7.8), noneffervescent.

B2t - 4-15 inches. Yellowish brown (10YR 5/4) clay loam, dark grayish brown (10YR 4/2) when moist; moderate, medium angular blocky structure; slightly hard consistence when dry, friable when moist, slightly sticky, slightly plastic when wet; mildly alkaline (pH 7.6), noneffervescent.

Cca - 15-28 inches. Very pale brown (10YR 7/3) loam, brown (10YR 5/3) when moist; weak, medium angular blocky structure; slightly hard consistence when dry, friable when moist, slightly sticky, slightly plastic when wet; seams of CaCO₃, strongly alkaline (pH 8.8), strongly effervescent.

Cr2 - 28 inches. Soft, partially weathered shale.

Range in Soil Characteristics - Depth to paralithic contact ranges from 20 to 40 inches. Content of coarse fragments is less than 5 percent. Texture of control section is a sandy clay loam. Clay content of control section ranges from 18 to 35 percent. There is no evidence of a water table.

Taxonomic Class - fine-loamy, mixed mesic family Ustollic Haplargid.

Suitability for Topsoil - The Cushman sandy loam soil is suitable for topsoil and the recommended stripping depth is 2.5 feet. The Cushman series rates fair or better according to Wyoming Department of Environmental Quality Guideline 1. Depth of stripping would be limited by bedrock material.

FORKWOOD (FT COLLINS) SERIES.

Soil Mapping Unit 10A, 10B, and 10C (19 is 1997 designation)

Typical Pedon: Forkwood (Ft. Collins) clay loam, rangeland.

(Colors are for dry soil unless otherwise indicated)

A1 - 0-4 inches. Pale brown (10YR 6/3) fine sandy loam, grayish brown (10YR 5/2) when moist; weak, medium granular structure; soft consistence when dry, very friable when moist, slightly sticky when wet; mildly alkaline (pH 7.4), noneffervescent.

B2t - 4-27 inches. Light brownish gray (10YR 6/2) clay loam, grayish brown (10YR 5/2) when moist; moderate medium angular blocky structure; slightly hard consistence when dry, friable when moist, sticky and plastic when wet; mildly alkaline (pH 7.7), noneffervescent.

B3ca - 27-36 inches. Yellowish brown (10YR 5/4) clay loam, dark grayish brown (10YR 4/2) when moist; moderate, medium angular blocky structure; slightly hard consistence when dry, friable when moist, slightly sticky, slightly plastic when wet; moderately alkaline (pH 8.0), strongly effervescent.

Clca - 36-49 inches. Light yellowish brown (10YR 6/4) loam, brown (10YR 5/3) when moist; moderate medium angular blocky structure; slightly hard consistence when dry, friable when moist, slightly sticky when wet; seams of CaCO₃, moderately alkaline (pH 8.2), strongly effervescent.

C2ca - 49-60 inches. Light yellowish brown (10YR 6/4) loam, yellowish brown (10YR 5/4) when moist; massive structure; slightly hard consistence when dry, friable when moist, slightly sticky when wet; seams and nodules of CaCO₃; moderately alkaline (pH 8.3), strongly effervescent.

Range in Soil Characteristics - There is no bedrock present within 60 inches. Content of coarse fragments is less than 5 percent. Texture of control section ranges from clay loam to a loam. Clay content of control section ranges from 18 to 35 percent. There is no evidence of a water table.

Taxonomic Class - fine-loamy, mixed, mesic Ustollic Haplargid.

Suitability for Topsoil - The Forkwood clay loam soil is suitable for topsoil and the recommended stripping depth is 5 feet. The Forkwood series rates fair or better according to Wyoming Department of Environmental Quality Guideline 1.

HILAND (OLNEY) SERIES

Soil Mapping Unit 12A, 12B, and 12CD (16 is 1997 designation)

Typical Pedon: Hiland (Olney) sandy loam, rangeland.

(Colors are for dry soil unless otherwise indicated)

A1 - 0-5 inches. Brown (10YR 5/3) fine sandy loam, brown (10YR 5/3) when moist; moderate, medium granular structure; soft consistence when dry, very friable when moist, slightly sticky, slightly plastic when wet; mildly alkaline (pH 7.7), noneffervescent.

B2t - 5-29 inches. Pale brown (10YR 6/3) sandy loam, brown (10YR 5/3) when moist; moderate, medium angular blocky structure; slightly hard consistence when dry, friable when moist, slightly sticky when wet; strongly alkaline (pH 8.6), strongly effervescent.

B3ca - 29-48 inches. Very pale brown (10YR 7/3) sandy loam, brown (10YR 5/3) when moist; moderate, medium angular blocky structure; slightly hard consistence when dry, friable when moist, slightly sticky when wet; strongly alkaline (pH 8.6), strongly effervescent.

Cca - 48-60 inches. Light yellowish brown (10YR 6/4) sandy loam, brown (10YR 5/3) when moist; massive structure; slightly hard consistence when dry, friable when moist, slightly sticky when wet; strongly alkaline (pH 8.4), strongly effervescent.

Range in Soil Characteristics - There is no bedrock present within 60 inches of the surface. More than 35 percent of the sand fraction is fine sand or coarser. Content of coarse fragments is less than 5 percent. Texture of control section is a sandy clay loam. Clay content of control section ranges from 18 to 35 percent.

Taxonomic Class - fine-loamy, mixed, mesic Ustollic Haplargid.

Suitability for Topsoil - The Hiland sandy loam soil is suitable for topsoil and the recommended stripping depth is 5 feet. The Hiland series rates fair or better according to Wyoming Department of Environmental Quality Guideline 1.

KISHONA (KIM) SERIES

Soil Mapping Unit 14A and 14B

Typical Pedon: Kishona (Kim) loam, rangeland.

(Colors are for dry soil unless otherwise indicated)

A1 - 0-5 inches. Pale brown (10YR 6/3) loam, grayish brown (10YR 5/2) when moist; moderate, fine granular structure; soft consistence when dry, very friable when moist, slightly sticky slightly plastic when wet; moderately alkaline (pH 8.2), strongly effervescent.

C1 - 5-13 inches. Light brownish gray (10YR 6/2) light clay loam, brown (10YR 5/3) when moist; moderate, medium subangular blocky structure; slightly hard consistence when dry, very friable when moist, slightly sticky, slightly plastic when wet; moderately alkaline (pH 8.2), strongly effervescent.

Clca - 13-60 inches. Light yellowish brown (10YR 6/4) loam, brown (10YR 5/3) when moist; massive structure; soft consistence when dry, friable when moist, slightly sticky when wet; seams of CaCO₃, strongly alkaline (pH 8.8), violently effervescent.

Range in Soil Characteristics - There is no bedrock present within 60 inches. Content of coarse fragments is less than 5 percent. Texture of control section is a heavy loam or light clay loam. Clay content of control section ranges from 18 to 35 percent. There is no evidence of a water table.

Taxonomic Class - fine-loamy, mixed (calcareous), mesic Ustic Torriorthent.

Suitability for Topsoil - The Kishona loam soil is suitable for topsoil and the recommended stripping depth is 5 feet. The Clca horizon suitability is given a poor rating due to a high content of calcium carbonate. This property is not believed to be of serious concern to the overall topsoil suitability. Otherwise, the Kishona series rates fair or better according to Wyoming Department of Environmental Quality Guideline 1

RENOHILL SERIES

Soil Mapping Unit 22A, 22B, and 22C

Typical Pedon: Renohill clay loam, rangeland.

(Colors are for dry soil unless otherwise indicated)

A1 - 0-4 inches. Light brownish gray (10YR 6/2) clay loam, brown (10YR 5/3) when moist; moderate, fine granular structure; soft consistence when dry, very friable when moist, slightly sticky, slightly plastic when wet; neutral (pH 7.1), noneffervescent.

B2t - 4-14 inches. Light yellowish brown (10YR 6/4) clay, yellowish brown when moist; strong, coarse angular blocky to prismatic structure; very hard consistence when dry, very firm when moist, sticky and plastic when wet; mildly alkaline (pH 7.6), noneffervescent.

B3ca - 14-20 inches. Light gray (10YR 7/2) heavy clay loam, pale brown (10YR 6/3) when moist; strong subangular blocky structure; very hard consistence when dry, firm when moist, sticky and plastic when wet; moderately alkaline (pH 8.1), strong effervescence.

Cca - 20-26 inches. Pale brown (10YR 6/3) clay loam, yellowish brown (10YR 5/4) when moist; massive structure; very hard consistence when dry, firm when moist, sticky and plastic when wet; moderately alkaline (pH 8.1), strongly effervescent.

C - 26 inches. Calcareous shale.

Range in Soil Characteristics - Depth to paralithic contact ranges from 20 to 40 inches. Content of coarse fragments is less than 5 percent. Texture of control section is clay or a heavy clay loam. Clay content of control section ranges from 35 to 50 percent. There is no evidence of a water table.

Taxonomic Class - fine, montmorillonitic mesic Ustollic Haplargid

Suitability for Topsoil - The Renohill clay loam soil is suitable for topsoil and the recommended stripping depth is 2 feet. The suitability rating for observed dry consistence is poor below the top 4 inches. This property is not believed to be of a serious concern to the overall topsoil suitability. All other soil parameters of Renohill rate fair or better according to Wyoming Department of Environmental Quality Guideline 1. Depth of stripping would be limited by bedrock material.

SHINGLE LOAM

Soil Mapping Unit 30B

Typical Pedon: Shingle loam, rangeland.

(Colors are for dry soil unless otherwise indicated)

A1 - 0-3 inches. Light brownish gray (10YR 6/2) loam, dark grayish brown (10YR 4/2) when moist; moderate, fine granular structure; soft consistence when dry, friable when moist, slightly sticky, slightly plastic when wet; moderately alkaline (pH 8.0), strongly effervescent.

C1 - 3-10 inches. Light yellowish brown (10YR 6/4) clay loam, brown (10YR 5/3) when moist; moderate, medium granular structure; soft consistence when dry, friable when moist, slightly sticky, slightly plastic when wet; moderately alkaline (pH 8.4), strongly effervescent.

C2r - 10 inches. Soft calcareous shale.

Range in Soil Characteristics - Depth to paralithic contact ranges from 10 to 20 inches. Content of coarse fragments is less than 5 percent. Texture of control section is a clay loam. Clay content of control section ranges from 18 to 35 percent. There is no evidence of a water table.

Taxonomic Class - loamy, mixed (calcareous) mesic Ustic Torriorthent, shallow.

Suitability for Topsoil - The Shingle loam soil is suitable for topsoil and the recommended stripping depth is 1 foot. The Shingle series rates fair or better according to Wyoming Department of Environmental Quality Guideline 1. Depth of stripping would be limited by bedrock material.

TALUCE (TASSEL) SERIES

Soil Mapping Unit 32B and 32C

Typical Pedon: Taluce (Tassel) sandy loam, Rangeland.

A1 - 0-4 inches. Pale brown (10YR 6/3) sandy loam, yellowish brown (10YR 5/4) when moist; weak, fine granular structure; loose consistence when dry, friable when moist, slightly sticky nonplastic when wet; mildly alkaline (pH 7.6), strongly effervescent.

C - 4-11 inches. Pale brown (10YR 6/3) sandy loam, brown (10YR 5/3) when moist; weak, subangular blocky structure; soft consistence when dry, friable when moist, slightly sticky, slightly plastic when wet.

Cr- 11 inches. Calcareous sandstone.

Range in Soil Characteristics - Depth to paralithic contact ranges from 10 to 20 inches. More than 35 percent of the sand fraction is fine or coarser. Content of coarse fragments is less than 5 percent. Texture of the control section ranges from 18 to 35 percent. There is no evidence of a water table.

Taxonomic Class - fine, mixed, mesic Ustic Torriorthent, shallow

Suitability for Topsoil - The Taluce sandy loam soil is suitable for topsoil and the recommended stripping depth is 1 foot. The Taluce series rates fair or better according to Wyoming Department of Environmental Quality Guideline 1. Depth of stripping would be limited by bedrock material.

TERRO (TERRY) SERIES

Soil Mapping Unit 24C (17 is 1997 designation)

Typical Pedon: Terro (Terry) fine sandy loam, rangeland.

(Colors are for dry soil unless otherwise indicated)

A1 - 0-2 inches. Light brownish gray (10YR 6/2) fine sandy loam, dark grayish brown (10YR 4/2) when moist; moderate, fine granular structure; soft consistence when dry, very friable when moist, slightly sticky, nonplastic when wet; neutral (pH 7.1), noneffervescent.

B2t - 2-8 inches. Pale brown (10YR 6/3) fine sandy loam, dark grayish brown (10YR 5/4) when moist; moderate, medium angular structure; slightly hard consistence when dry, friable when moist, slightly sticky and slightly plastic when wet; neutral (pH 7.1), noneffervescent.

B3ca - 8-14 inches. Very pale brown (10YR 7/3) sandy loam, pale brown (10YR 6/3) when moist; weak medium, subangular blocky structure; slightly hard consistence when dry, friable when moist, slightly sticky and slightly plastic when wet; mildly alkaline (pH 7.9), strongly effervescent.

Cca - 14-28 inches. Light brownish gray (2.5Y 6/2) fine sandy loam, dark grayish brown (2.5Y 4/2) when moist; massive structure; slightly hard consistence when dry, friable when moist, slightly sticky and slightly plastic when wet; moderately alkaline (pH 8.0), strongly effervescent.

C - 28 inches. Calcareous sandstone.

Range in Soil Characteristics - Depth to paralithic contact ranges from 20 to 40 inches. More than 35 percent of the sand fraction is fine sand or coarser. Content of coarse fragments is less than 5 percent. Texture of the control section is fine sandy loam. Clay content of the control section ranges from 7 to 18 percent. There is no evidence of a water table.

Taxonomic Class - coarse-loamy, mixed, mesic Ustollic Haplargid.

Suitability for Topsoil - The Terro sandy loam soil is suitable for topsoil and the recommended stripping depth is 2.5 feet. The Terro series rates fair or better according to Wyoming Department of Environmental Quality Guideline 1. Depth of stripping would be limited by bedrock material.

THEEDLE (THEDALUND) SERIES

Soil Mapping Unit 26B and 26C (49 is 1997 designation)

Typical Pedon. Theedle (Thedalund) loam, rangeland.

(Colors are for dry soil unless otherwise indicated)

A1 - 0-3 inches. Very pale brown (10YR 7/3) sandy loam, light brownish gray (10YR 6/2) when moist; weak, fine granular structure; soft consistence when dry, very friable when moist, slightly sticky, slightly plastic when wet; mildly alkaline (pH 8.0), strongly effervescent.

AC - 3-11 inches. Yellowish brown (10YR 5/4) loam, dark grayish brown when moist; moderate, fine subangular blocky structure; soft consistence when dry, very friable when moist, slightly sticky, slightly plastic when wet; moderately alkaline (pH 8.0), strongly effervescent.

Cca - 11-34 inches. Light gray (10YR 7/2) loam, pale brown (10YR 6/3) when moist; massive structure; soft consistence when dry, friable when moist, slightly sticky, slightly plastic when wet; strongly alkaline (pH 8.5), strongly effervescent.

Cr - 34 inches. Sandstone.

Range in Soil Characteristics - Depth to paralithic contact ranges from 20 to 40 inches. Content of coarse fragments is less than 5 percent. Texture of the control section is clay loam. Clay content of the control section ranges from 18 to 35 percent. There is no evidence of a water table.

Taxonomic Class - fine-loamy, mixed, (calcareous), mesic Ustic Torriorthent.

Suitability for Topsoil - The Theedle loam soil is suitable for topsoil and the recommended stripping depth is 2.5 feet. The Theedle series rates fair or better according to Wyoming Department of Environmental Quality Guideline 1. Depth of stripping would be limited by bedrock material.

TULLOCK SERIES

Soil Mapping Unit 25C

Typical Pedon: Tullock fine sandy loam, rangeland.

(Colors are for dry soil unless otherwise indicated)

A1 - 0-4 inches. Light brownish gray (2.5Y 6/2) fine sandy loam, dark grayish brown (2.5Y 4/2) when moist; weak, fine crumb structure; soft consistence when dry, friable when moist, nonsticky, nonplastic when wet; neutral (pH 7.0), noneffervescent.

C1 - 4-24 inches. Pale brown (10YR 6/3) fine sandy loam, brown (10YR 5/3) when moist; massive structure; soft consistence when dry, friable when moist, nonsticky, nonplastic when wet; mildly alkaline (pH 7.4), slightly effervescent.

C2 - 24-34 inches. Pale gray (2.5Y 6/2) fine sandy loam, dark grayish brown (2.5Y 4/2) when moist; weak fine crumb structure; soft consistence when dry, friable when moist, nonsticky, nonplastic when wet; neutral (pH 7.0), noneffervescent.

Cr - 34 inches. Weakly consolidated calcareous sandstone.

Range in Soil Characteristics - Depth to paralithic contact ranges from 20 to 40 inches. Content of coarse fragments is less than 5 percent. Texture of the control section is loamy fine sand to a light sandy loam.

Taxonomic Class - mixed, mesic Ustic Torripsamments.

Suitability for Topsoil - The Tullock fine sandy loam soil is suitable for topsoil and the recommended stripping depth is 2.5 feet. The Tullock series rates fair or better according to Wyoming Department of Environmental Quality Guideline 1. Depth of stripping would be limited by bedrock material.

ULM CLAY LOAM

Soil Mapping Unit 11 (20 is 1997 designation)

Typical Pedon: Ulm clay loam, rangeland.

(Colors are for dry soil unless otherwise indicated)

A1 - 0-4 inches. Light brownish gray (10YR 6/2) loam, dark grayish brown (10YR 4/2) when moist; weak, granular structure; soft consistence when dry, very friable when moist, sticky and plastic when wet; neutral (pH 7.2), noneffervescent.

B1 - 4-9 inches. Light brownish gray (10YR 6/2) heavy loam, dark grayish (10YR 4/2) when moist; moderate, subangular blocky structure; slightly hard consistence when dry, very friable when moist, sticky and plastic when wet; neutral (pH 7.2), noneffervescent.

B2t - 9-15 inches. Brown (10YR 5/3) clay loam, brown to dark brown (10YR 4/3) when moist; moderate, fine prismatic structure; very hard consistence when dry, friable when moist, sticky and plastic when wet; mildly alkaline (pH 7.7), noneffervescent.

B3ca - 15-24 inches. Grayish brown (10YR 5/2) clay loam, dark grayish brown (10YR 4/2) when moist; moderate, subangular blocky structure; very hard consistence when dry, firm when moist, sticky and plastic when wet; moderately alkaline (pH 8.0), strongly effervescent.

Clca - 24-46 inches. Light brownish gray (10YR 6/2) light clay loam, grayish brown (10YR 5/2) when moist; massive structure; hard consistence when dry, friable when moist, sticky and plastic when wet; moderately alkaline (pH 8.4), violently effervescent.

C2ca - 46-60 inches. Light brownish gray (10YR 6/2) light clay loam, grayish brown (10YR 5/2) when moist; massive structure; hard consistence when dry, very friable when moist, sticky and plastic when wet; moderately alkaline (pH 8.4), violently effervescent.

Range in Soil Characteristics - There is no bedrock present within 60 inches of the surface. Coarse fragments are less than 5 percent. The control section is a heavy clay loam or clay. Clay content of the control section ranges from 35 to 50 percent. There is no evidence of a water table.

Taxonomic Class - fine, montmorillonitic mixed, mesic Ustollic Haplargid.

Suitability for Topsoil - The Ulm clay loam soil is suitable for topsoil and the recommended stripping depth is 4 feet. The suitability rating for texture from 46 to 60 inches deep is poor due to a high clay content which limits soil workability. Stripping depth should be kept above this zone. The suitability rating for observed dry consistence is poor in the B2t and B3ca soil horizons. This property is not believed to be of serious concern to the overall topsoil suitability.

VONALEE (VONA) SERIES

Soil Mapping Unit 13

Typical Pedon: Vonalee (Vona) sandy loam, rangeland.

(Colors are for dry soil unless otherwise indicated)

A1 - 0-4 inches. Pale brown (10YR 6/3) sandy loam, brown (10YR 5/3) when moist; weak, fine crumb structure; loose consistence when dry, very friable when moist, nonsticky and nonplastic when wet; neutral (pH 7.0), noneffervescent.

B1 - 4-7 inches. Light brownish gray (10YR 6/2) sandy loam, brown (10YR 5/3) when moist; moderate, medium subangular blocky structure; soft consistence when dry, very friable when moist, nonsticky and nonplastic when wet; neutral (pH 7.0), noneffervescent.

B2t - 7-14 inches. Pale brown (10YR 6/3) fine sandy loam, grayish brown (10YR 5/2) when moist; moderate, medium angular blocky structure; slightly hard consistence when dry, friable when moist, slightly sticky, slightly plastic when wet; neutral (pH 7.2), noneffervescent.

B3ca - 14-22 inches. Pale brown (10YR 6/3) fine sandy loam, brown (10YR 5/3) when moist; moderate, medium subangular blocky structure; slightly hard consistence when dry, very friable when moist, nonsticky and nonplastic when wet; mildly alkaline (pH 7.8), strongly effervescent.

Cca - 22-60 inches. Pale brown (10YR 6/3) sandy loam, brown (10YR 5/3) when moist; massive structure; slightly hard consistence when dry, friable when moist, slightly sticky and slightly plastic when wet; mildly alkaline (pH 7.6), slightly effervescent.

Range in Soil Characteristics - There is no bedrock present within 60 inches of the surface. More than 35 percent of sand fraction is fine sand or coarser. Coarse fragments are less than 5 percent. The control section is sandy loam with a clay content ranging from 7 to 18 percent. There is no evidence of a water table.

Taxonomic Class - coarse-loamy, mixed, mesic Ustollic Haplargid.

Suitability for Topsoil - The Vonalee soils are deep, somewhat excessively drained soils formed in eolian and partially reworked alluvial parent materials. The mean annual precipitation is about 12 inches and the mean annual air temperature is 46° F.

WORF SERIES

Soil Mapping Unit 31

Typical Pedon: Worf loam, rangeland.

(Colors are for dry soil unless otherwise indicated)

A1 - 0-4 inches. Light yellowish brown (10YR 6/4) loam, yellowish brown (10YR 5/3) when moist; moderate, fine granular structure; soft consistence when dry, very friable when moist, slightly sticky, slightly plastic when wet; neutral (pH 7.2), noneffervescent.

B2t - 4-9 inches. Pale brown (10YR 6/3) clay loam, brown (10YR 5/3) when moist; moderate, medium angular blocky structure; slightly hard consistence when dry, friable when moist, slightly sticky, slightly plastic when wet; seams of CaCO₃ throughout horizon, mildly alkaline (pH 7.8), strongly effervescent.

(9-16 inch interval information not available)

C2r - 16 inches. Calcareous shale.

Range in Soil Characteristics - Depth of bedrock ranges from 10 to 20 inches. Coarse fragments are less than 5 percent. Clay content of the control section ranges from 18 to 35 percent. The control section texture is loam or light clay loam. There is no evidence of a water table.

Taxonomic Class - loamy, mixed, mesic Ustollic Haplargid, shallow

Suitability for Topsoil - The Worf soils are shallow, well drained soils formed residually from sedimentary rock on upland hills and ridges. The mean annual precipitation is about 12 inches and the mean annual air temperature is 46° F.

Baseline vegetation Assessment of the Reynolds Ranch Area – December 1998

APPENDIX D-8 VEGETATION

1.0 GENERAL

Several different baseline vegetation studies were conducted (for Kerr McGee) in the western portion of the permit area by Woodward-Clyde Consultants in 1976, 1978 and 1979. Additional vegetation surveys were conducted during the summer of 1990 by Beartooth Environmental (Beartooth). The results of the 1990 work, in addition to portions of the previous vegetation surveys, were submitted in Appendix D-8 to define the vegetation baseline data available for the western part of the permit area. A final Baseline Vegetation Assessment for the Smith Ranch **Permit** was prepared by BKS Environmental Associates, Inc. in 1997 to satisfy Condition 2 of Permit No. 633.

Vegetation communities have been extensively studied and mapped in the eastern portion of the permit area. Several studies were done on parcels of land comprising the original Highland permit area (which was originally permitted by Everest Minerals Corporation), the approved amended permit area (Section 14 Amendment) and the West Highland Amendment area. Eggleston, Holmes and Associates completed a vegetation assessment in the Highland permit area in 1987 (**Addendum D-8 B3**). United Nuclear Corporation (UNC) completed a vegetation inventory for lands comprising the North Morton property, and this information was utilized for the Section 14 Amendment area and for portions of the West Highland Amendment area. Areas covered by this study are shown on **Plate D8-1** of **Addendum D-8 B2**. In addition, supplemental vegetation information is provided for Mine Unit-J in **Addendum D-8 B3**. **Figure D8-1 provides the complete permit boundary, including the Proposed Reynolds Ranch Amendment area. Notes on the index map indicate when individual plates and figures for either Smith Ranch, Highland or Reynolds can be found in the addenda.**

2.0 VEGETATION INVENTORIES

1976 - Woodward-Clyde Consultants - Field surveys of the original Permit No. 304C permit area were conducted by Woodward-Clyde Consultants in 1976 to obtain site-specific vegetation information. Three areas were surveyed including site V-1, a proposed surface mine in the Hornbuckle area (3-10 Mine, Sections 3 and 10 of T37N, R73W - to the north of current permit boundary); site V-2, a proposed site for a uranium milling operation (Sections 13, 14, 23 and 24 of T36N, R74W - within current permit boundary); areas D8-1 02-15-91 within Section 17, T35N, R74W and Section 34, T36N, R74W for underground mine shafts (within current permit boundary); and site V-3, located in the southern most portion of the original Permit 304C area, now outside of the current permit boundary. Vegetation surveys at these locations included quantitative analysis of dominant vegetation types using the line intercept

(percent cover), belt transect and circular plot methods (density), and quadrant (standing crop) methods. Additionally, a list of plant species observed or expected to occur on the original Permit 304C area was compiled.

Results from the 1976 sampling are presented in; **Tables D-8.1** (shrub density), **D-8.1A** (standing crop estimates), **D-8.2** (cover) and **D-8.3** (species list) of **Addendum D-8 A1**. The portion of the baseline studies, which are most applicable to this application pertains to site V-2, located within the current permit boundary. **Figure D8.1** of **Addendum D-8 A2**, Updated Vegetation Survey Map, shows the location of site V2 (noted as Woodward-Clyde sampling area). **Figure D-8.1A** of **Addendum D-8 A2**, shows the location of sites V-1, V-2 and V-3 from the Woodward-Clyde studies in relation to the original Permit 304C boundary.

1978 - Woodward-Clyde Consultants - During 1978, Woodward-Clyde Consultants initiated additional vegetation studies for the 304C permit area designed to achieve compliance with WDEQ Land Quality Division Guideline No. 2 (Vegetation). Pre-mining vegetative ground cover mapping was completed for the 3-10 Mine (V-1), located to the north of the current permit area, in September 1978. The final baseline vegetation report for the 3-10 Mine, dated November 1978, was submitted to the WDEQ under Permit 304C. It is not included with this application.

1979 - Woodward-Clyde Consultants - In April and September, 1979, the additional vegetation studies to achieve compliance with WDEQ Guideline No. 2 were continued at the proposed mill site (V-2) located in the northern portion of the permit area, and the associated surface mine area (the middle pit area located in Sections 28 and 33, T37N, R73W). Vegetation measurements included cover, annual productivity and shrub height. Additionally, control site locations were established for future reference in areas not expected to be disturbed by mining activities. Data collected at the proposed mill site, V-2, is very applicable as baseline data for the current permit application due to its inclusion in the current permit boundary (see **Figure D-8.1** of **Addendum D-8 A2**).

Various vegetation communities were sampled in the eastern portion of the permit area in order to determine species composition, percent cover, and vegetation production as part of the studies included in **Addendum D-8 B3** to this appendix. During meetings with the WDEQ staff in September 1988 (site visit) and November 17, 1988 it was determined that the vegetation sampling data included in the reports in **Addendum D-8 B3** for the original permit area and North Morton property adequately represented the entire permit area, including the West Highland Amendment area.

1990 – Beartooth Environmental Consultants – Aerial photographs and ground truthing were used to complete vegetation mapping in the Smith Ranch permit area. Results of the mapping determined that the Smith Ranch project is located in a short-grass prairie region with a regional climate characterized by having wide ranges in temperature and relatively low annual precipitation (12-14 inches). Vegetation was dominated by grasses such as various wheatgrasses and blue grama, with big sagebrush as codominant in many areas. Isolated cottonwood/willow stands occurred along local drainages. Sagebrush/Grassland vegetation was clearly the dominant vegetation type, occupying 82% of the permit area. Grassland accounted for 15% of the permit area, with the other vegetation and land use units comprising the remaining 13%.

1992 – BKS Environmental Associates, Inc. Consultants – A baseline vegetation inventory was contracted in 1992 in compliance with Condition 2 of Permit 633. Vegetation sampling was performed according to the WDEQ/LQD methodology letter dated January 21, 1992. The original BKS report summarizing these findings was dated October 1, 1992. A subsequent rewrite in 1996 addresses WDEQ comments dated November 2, 1992.

1997 - BKS Environmental Associates, Inc. Consultants - A baseline vegetation inventory was completed in the Smith Ranch portion of the permit area, in order to comply with Condition 2 of Permit No. 633. Vegetative sampling was performed at locations approved by WDEQ in a letter dated January 21, 1992. A report was submitted in November 1992. The final report was completed in March 1997 and is included as Addendum D-8 A3. In addition to the survey described above in the Smith Ranch portion of the permit area, BKS also completed an additional vegetation survey in the Reynolds Ranch portion of the permit area in 1997. The final report, completed in December 1998 is included in Addendum D-8 C.

2011 – Hayden Wing and Associates, LLC - Hayden-Wing and Associates, LLC (Hayden-Wing) has been contracted to complete an updated vegetation survey once conditions are appropriate in the spring of 2011. Cameco Resources and Hayden-Wing met with the Wyoming Game and Fish Department (WGFD) and the WDEQ-LQD on December 2, 2010 to discuss specific issues relative to the combined Smith Ranch Permit. The U.S. Fish and Wildlife Service (USFWS) was invited but declined to attend, preferring to correspond in writing. Based on this meeting and the WGFD and USFWS correspondence letters dated June 2010, a draft Vegetation and Wetlands Survey Methodology was written and submitted to WGFD and USFWS for approval. WGFD and USFWS were asked to critically review and suggest any additions or modifications to the survey methodology and monitoring plan submitted March 9, 2011 (correction submitted March 10, 2011).

Dialogue with the WGFD and USFWS will continue throughout the permitting process. A copy of all correspondence with the WGFD and USFWS is included in Attachment 1. The Vegetation and Wetlands Survey Methodology are included in Attachment 2.

CR received a letter from the WDEQ/LQD on April 7, 2011 with comments on the Draft Vegetation and Wetland Survey Methodology that had been submitted to USFWS and WGFD on March 9, 2011. At the time of submittal of this Combined Permit amendment, CR is awaiting feedback from the USFWS and WGFD. When these comments are received, CR will modify the draft plan to incorporate these agencies' comments as well as those from the LQD's April 5, 2011 letter and will add the final plan to this appendix. A copy of the draft plan and agency correspondence are included in the Supplemental Information portion of this appendix.

3.0 VEGETATION INVENTORY RESULTS

Results from the 1979 sampling of the V-2 site and the middle pit area in the western portion of the permit area were combined into a report submitted to the WDEQ in late 1979. A copy of the report is included with this application in **Addendum D-8 A3**. Twenty eight of the fifty six transects run on the affected area for the mine and mill sites were located in V-2 (see **Figure D-8.1** of **Addendum D-8 A2**). Additionally, twelve of the twenty control area transects were located outside of the V-2 area (also see **Figure D-8.1** of **Addendum D-8 A2**). Although the results of the mine and mill transects are combined on the results tables in **Attachment 1, Addendum D-8 A3**, individual data from the mill site (V-2) can be identified. In summary, the 1979 vegetation studies indicated that the study area was primarily grassland, with sagebrush/grassland vegetation present throughout the affected area, as well as the following quantitative results:

Cover - Cover averaged approximately 68% of the ground. Grass covered approximately 56% of the ground and accounted for about 82% of all vegetative cover. The dominant grass and grass-like species were Western wheatgrass, Blue grama, Sedge, and Needle-and-Thread. Shrubs covered an average of less than 8 percent of the ground in the area to be disturbed. Big sagebrush was the dominant shrub species. Other less common shrubs included fringed sagebrush, birdfoot sagebrush, rabbitbrush, plains prickly pear and snakeweed. Forbs were the least dominant form of vegetation on the affected area and had an average ground cover of less than 5 percent. Rock and litter covered an average of 9 percent of the ground on the affected area. Approximately 23 percent of the ground was void of any vegetation, litter or rock. The total average ground cover, relative abundance of grasses, etc., and the dominant species on the control areas were very similar to those on the affected area.

Productivity - Vegetation productivity averaged about 560 lbs./acre for the affected area, and slightly more than 450 lbs./acre for the control area. Western wheatgrass, Blue grama, Sedge and Needle-and-Thread grasses were the major species contributing to the productivity. Shrubs accounted for only about 10 percent of the productivity.

Shrub Height - Shrub height in the affected area averaged about 6 inches. The most common shrub, big sagebrush, averaged 8 inches. Most other shrubs were less than 3 inches in height. Shrub height on the control areas averaged about 6 inches, similar to shrub heights on the affected areas.

4.0 VEGETATION MAPPING

1990 - Beartooth Environmental - During the summer of 1990, vegetation mapping was conducted by Beartooth on the western portion of the permit area. Aerial photographs and ground truthing were used to complete the mapping. Beartooth used mapping units that were different than those established in the Soil Conservation Service Range Site Inventory. For this permit application and the establishment of baseline conditions on the western portion of the permit area **Table D-8.4** of **Addendum D-8 A1** and **Figure D-8.3** of **Addendum D-8 A2**, are the most appropriate for vegetation typing.

The results of the vegetation mapping for the western portion of the permit area are shown on **Figure D-8.1** of **Addendum D-8 A2**. Additionally, **Figure D-8.2** of **Addendum D-8 A2** shows the proposed areas of disturbance, primarily mine unit areas, in relation to the vegetation units potentially affected by the disturbance. **Table D-8.5** of **Addendum D-8 A1** provides the areal extent of the vegetation types and other mapping units, as well as the percentages of each mapping unit to be potentially affected by ISR activities in the western portion of the permit area.

The entire eastern portion of the permit area vegetation baseline has been mapped according to plant communities on **Plate D8-1** of **Addendum D-8 B2**. The mapping was accomplished by Applied ECOSystems of Casper, Wyoming with the use of information contained in **Addendum D-8 B3**. The mapping was ground-truthed prior to finalization. **Table D8-1** of **Addendum D-8 B1** contains the areal extent and percent of area of the vegetation types for that portion of the permit area.

Mapping units used and their descriptions are as follows:

SG (SBGL) - Sagebrush/Grassland - This unit is a mixture of grasses and sagebrush. Big sagebrush is the dominant shrub species and is present in varying densities. Common grasses and grass-like species found were wheat grasses, bluegrass, prairie junegrass, needle and thread grass, blue grama, and threadleaf sedge.

G (GL) - Grassland - This mapping unit is composed primarily of grasses and grass-like species. Sagebrush is also present but to a lesser extent than found in the sagebrush/grassland unit.

I (R) - Impoundment/Reservoir - This unit consists of man made impoundments that may contain water throughout most of the year.

RO - Reclaimed Oil Well Site - This unit consists of a reclaimed oil well drill site that was seeded with crested wheatgrass.

DL - Disturbed Land - This unit consists of lands which have been disturbed by past activities. This includes those areas associated with the Glenrock Coal Company mine and the Bill Smith mine.

H - Hay Meadow - This unit consists of areas along Sage Creek that are harvested by the landowner for hay.

RD - Road Right of Way - The road right of way consists of improved roads and adjacent lands consisting of a grassland community type.

P - Playa - The playa unit consists of shallow depressions which may contain water during a portion of the year. The D8-1E 02-15-91 vegetation consists primarily of grasses but they may contain scattered sagebrush around the edges.

RY - Ranch Yard - This unit consists of various buildings, corrals and grounds associated with ranch facilities.

CW - Cottonwood/Willow - This symbol marks the location of small groups or individual cottonwood and/or willow trees.

SB - Shelterbelt - This symbol denotes the location of shelterbelts planted around ranch facilities.

D - Drainage - The drainage unit is characterized by sagebrush, grasses, and forbs along and adjacent to drainages and generally has a higher percentage of vegetative cover than other units. A few scattered cottonwoods and willows are found in this unit.

AG - Agricultural - The agricultural unit consists of cultivated land used for growing small grain and/or hay.

CW - Crested Wheat - This unit consists of lands that have been planted to crested wheatgrass.

PLC - Pipeline Corridor - This unit can generally be considered a grassland that was created by right-of-way clearing and reclamation after construction. These activities were associated with oil and gas activity, not operations at the Highland Uranium Project. The primary species on these corridors is crested wheatgrass.

RDC - Road Corridor - Road corridors consist of public roads and adjacent right-of-ways consisting of a grassland community type.

ARDC - Abandoned Road Corridor - This unit is a grassland community which consists of an old roadway that was in use prior to the present alignment of Highway 93.

RL - Reclaimed Land - Lands reclaimed from past disturbances.

GP - Gravel Pit - This unit consists of a small area where gravel or other material has been excavated.

C/W - Cottonwood/Willow - This symbol marks the location of small groups or individual cottonwood and willow trees.

RO - Russian Olive - This symbol marks the location of Russian Olive trees.

Existing disturbances at several locations across the permit area have resulted in the replacement of the sagebrush/grassland vegetation by a variety of successional species or weeds, such as cheatgrass, curly dock, Rocky Mountain bee plant and thistle. These successional or weedy species are generally confined to areas near roads, old buildings, spoil piles and cattle tanks. No noxious weeds were noted during the 1990 surveys.

5.0 PHOTOGRAPHS

Photographs of the vegetation types in the western portion of the permit area, used for mapping are provided in **Addendum D-8 A2**. The photographs are typical of the Grassland, Sagebrush/Grassland, Hay Meadow and Cottonwood/Willow vegetation types found on the permit area. Actual locations of the photographs are indicated on **Figures D-8.1 and D-8.2** of **Addendum D-8 A2** by the P-1 through P-4 designations.

Color photographs of the four major vegetation types in the eastern portion of the site to be potentially affected (sagebrush/grassland, grassland, drainage, and agricultural land) are shown in photographs D8-1 through D8-4, respectively in **Addendum D-8 B2**.

6.0 THREATENED AND ENDANGERED SPECIES

The Smithsonian Institution (1975) lists several threatened and endangered plant species that may occur in Wyoming. Although some of these species may occur in the short-grass prairie of eastern Wyoming, none was observed on the permit area during September, 1976 field surveys. The herbarium at the University of Wyoming at Laramie does not have any collections of these species from Converse County. (E. Nelson, Curator, University of Wyoming, Personal Communication, 1977). It is unlikely that any protected plant species are present on the permit area.

7.0 NOXIOUS WEEDS

Eleven species were encountered during the vegetation studies which are considered noxious weeds, including; western ragweed, white-leaved ragweed, common burdock, Canada thistle, poverty weed, field bindweed, quackgrass, Russian knapweed, hounds tongue, tansy mustard and wild oat. The occurrence of these noxious species within the project area is limited, and they do not occur in such abundance or distribution as to make them a serious range management problem.

8.0 SELENIUM INDICATOR SPECIES

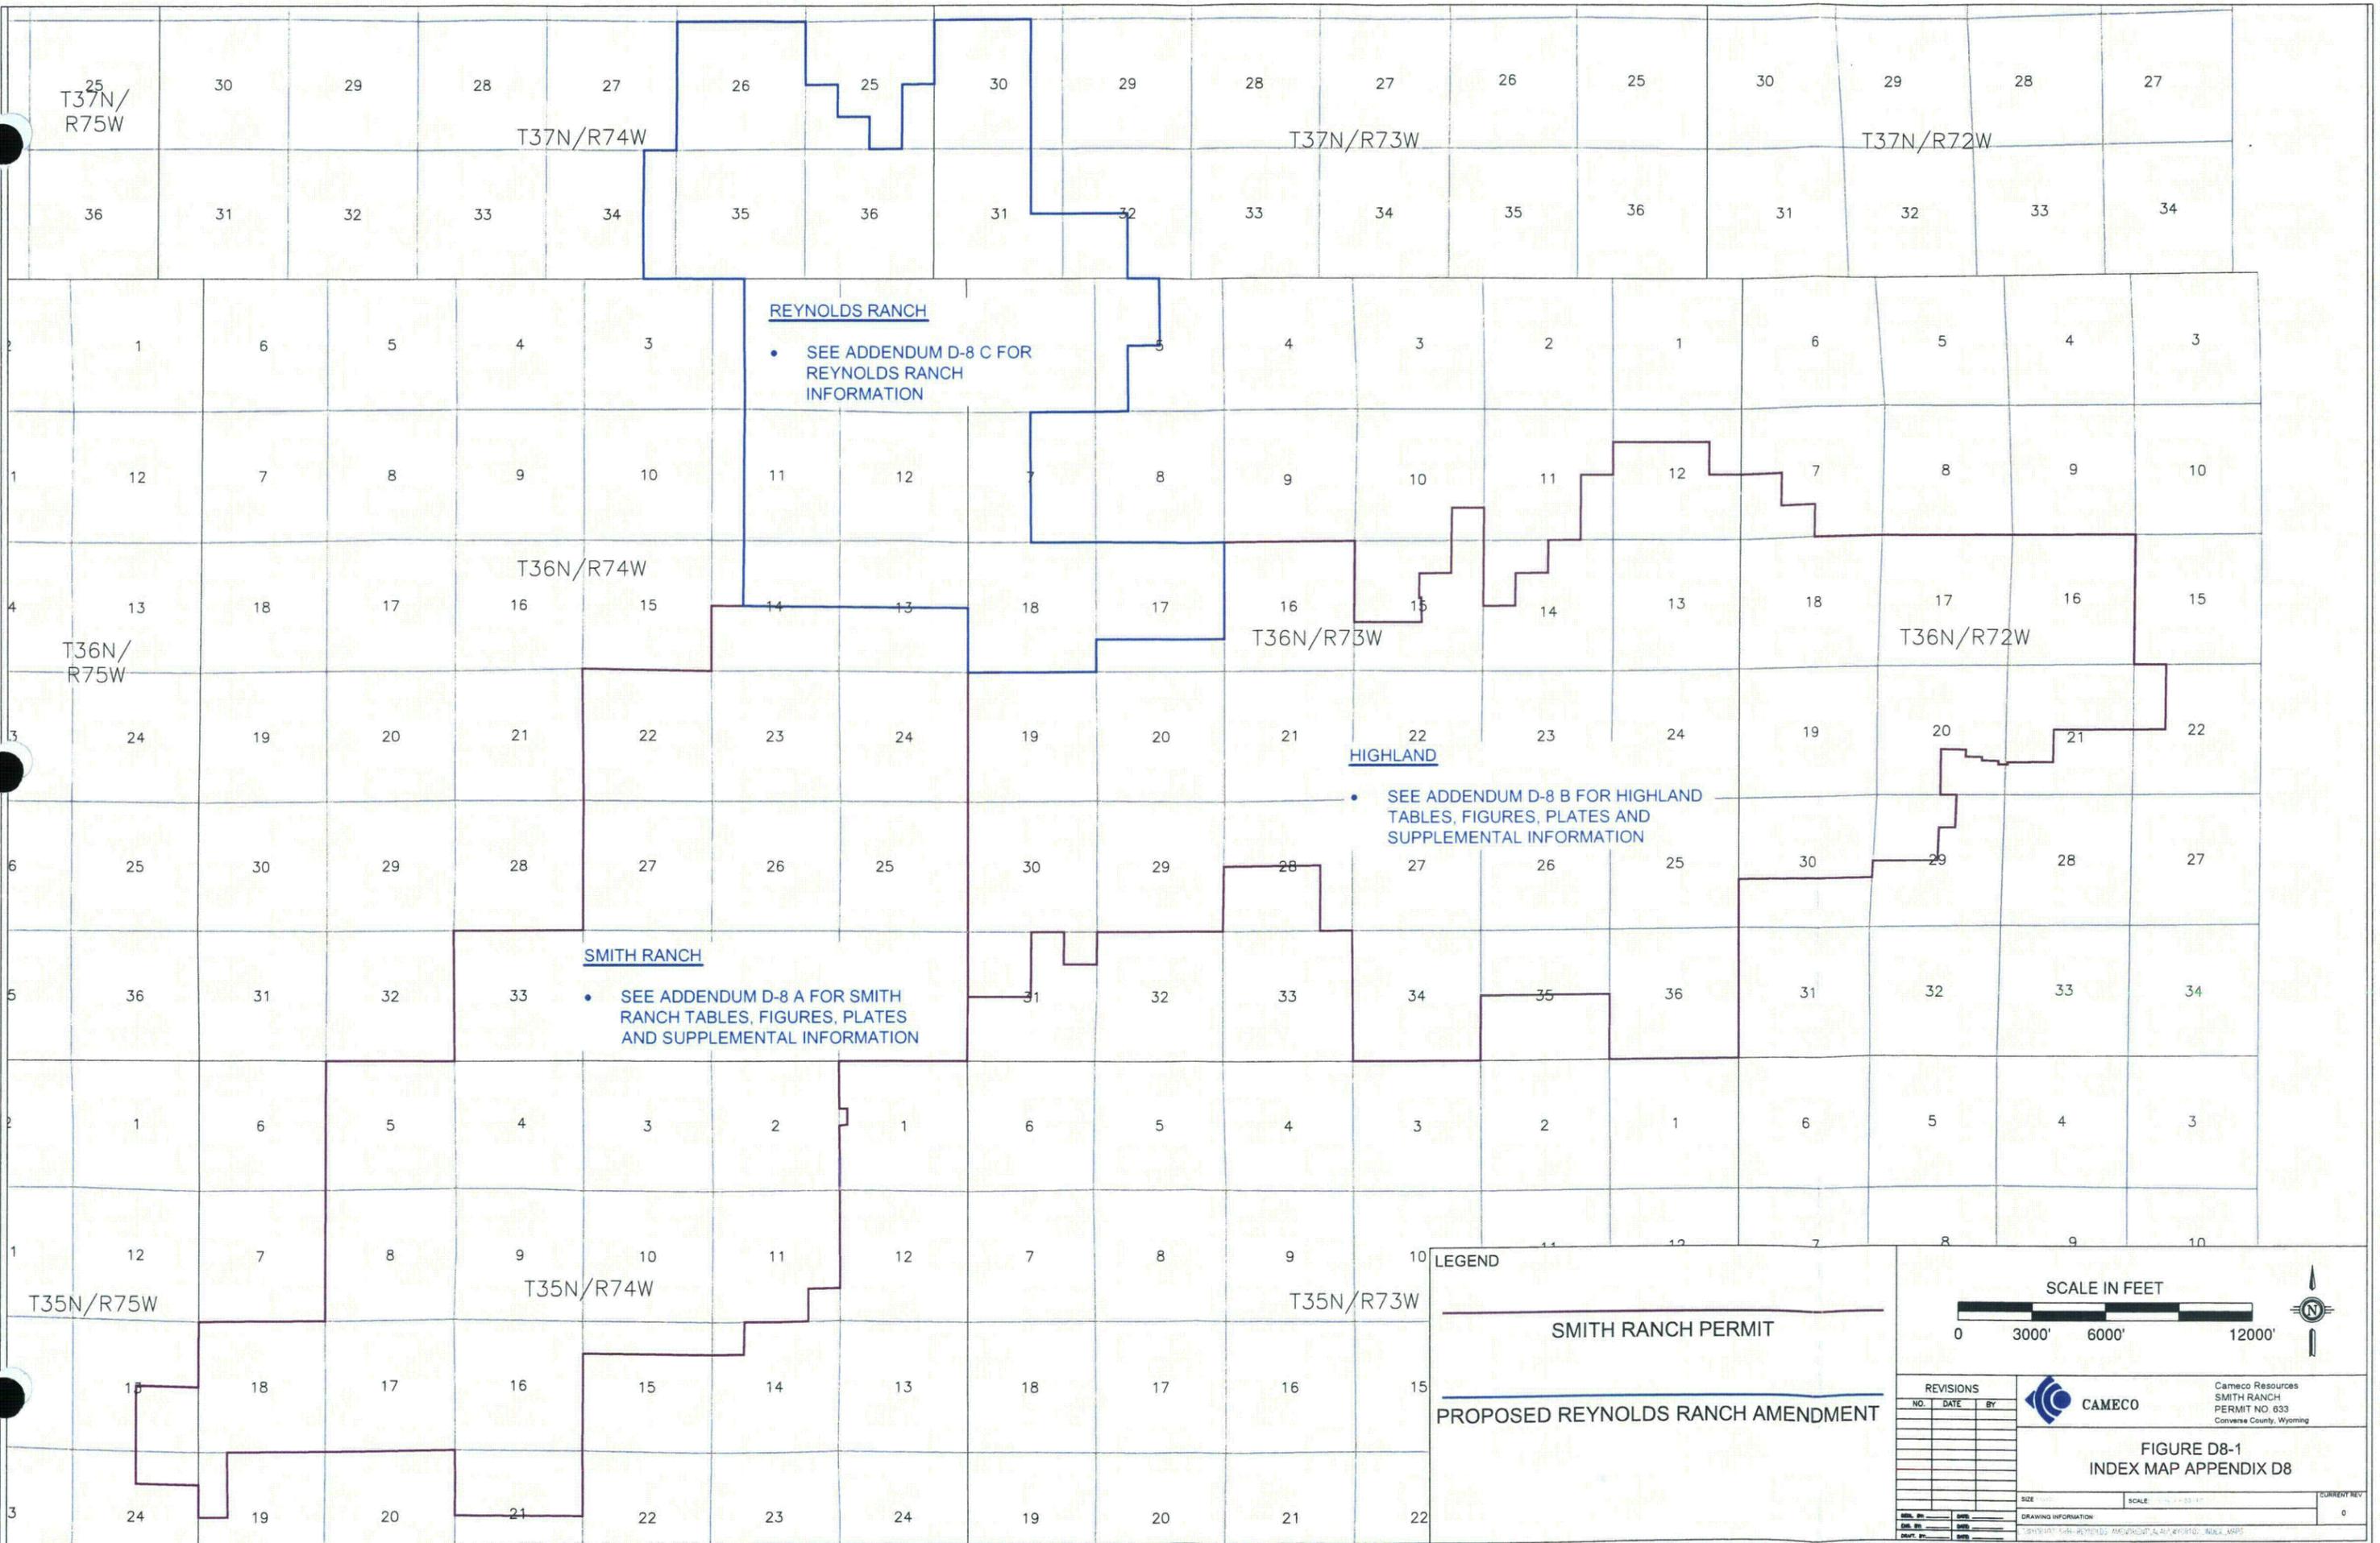

As discussed in the reports included in **Addendum D-8 B3**, two selenium indicator species, two grooved milkvetch and golden weed, were only occasionally found and are relatively uncommon to the project area. Their lack of abundance precludes any agricultural or wildlife concerns.

9.0 VEGETATION IN THE REYNOLDS RANCH PORTION OF THE PERMIT AREA

Two primary native vegetation types occur within the Reynolds Ranch portion of the permit area. Well drained, upland areas are characterized by grassland on ridgetops and flat areas with sagebrush/grassland on sloped areas and drainages. The playa map unit is found on poorly drained, upland areas. Rock outcrop areas are generally sandstone.

Table 1 in Addendum D8-C lists acreage for each vegetation mapping unit within the study areas which totals 13,400 acres. Grassland is the dominant native vegetation type (7, 295 acres or 54.4%), followed by sagebrush/grassland (6,045 acres or 45.1%). Rock outcrops and plays encompass 82 acres (0.6%) and 17 acres (0.1%), respectively. Although a jurisdictional wetland survey was not conducted as part of the baseline assessment, no possible areas were observed in the field, based on vegetative characteristics alone.

INTRODUCTION

The Land Quality Division was copied on the Draft Wildlife Monitoring Plan and Draft Vegetation and Wetland Survey Methodology sent to Wyoming Game and Fish (WGFD), United States Fish and Wildlife Service (USFWS) and the US Army Corp of Engineers (USACE) on March 11, 2011. The LQD staff reviewers Robin Jones, Jonathan Stauffer and Jennifer Bowers were asked for comment at their discretion. The following comments are forwarded for your consideration.

COMMENTS

1. The protocol Cameco Resources used for surveying Ute-ladies Tresses (*Spiranthes diluvialis*) contained only the features that serve to disqualify potential orchid habitat. Please include the three Categories: Surveys Required, Survey Recommended, and Survey Encouraged, the Survey Procedures, and the description of potential habitat in this section associated with the Ute-ladies Tresses Survey Protocol. **(JB)**
2. In the section of the draft proposal containing the methods to be used for each type of survey LQD recommends more detail of the proposed survey methods and/or literature citations of the methods to be used. The LQD Guideline 5 states "*Sufficient detail should be provided so the sample could be replicated by another investigator, or a methods description within the literature should be cited. If data are taken from another baseline study, a description of methods used in that study should be included. The discussion of methods should indicate the intensity of sampling and conditions under which sampling was conducted in each habitat type, and the sample locations should be plotted on a topographic map. ... Results and discussion should follow the methods section for each group of animals.*" Please provide sufficient detail of the methods for the wildlife and vegetation surveys so that the surveys could be replicated by another investigator. **(JB)**
3. The LQD Guideline 5 requires a list of potential and actual species likely to occur in the area. Please provide a list of potential vertebrate fauna for the area and place an asterisks by the species observed during surveys or opportunistic observations. **(JB)**

Re: Correction to draft Vegetation and Wetlands Survey Methodology Provided in Letter dated March 9, 2011

Dear Mr. Sattelberg:

On March 9, 2011, Power Resources, Incorporated (d.b.a. Cameco Resources [CR]) submitted, among other items, a draft Vegetation and Survey Methodology document to you for your critique. I have discovered an error in the land description on the first page of that document. Corrections to that language are shown below with strikeout and double underline.

The combined Permit Area is located approximately 25 miles north-northwest of Douglas and 22 miles northeast of Glenrock, Wyoming (T37N:R74W, Sections 25, 26, 35, 36; T37N:R73W, Sections 30-32; T36N:R74W, Sections 1, 2, 11-14, 22-27, 33-36; T36N:R73W, Sections 5-7, 10-31, 34-36; T36N:R72W, Sections 7, ~~12~~, 16-21, 29, 30; T35N:R75W, Sections 13, 24; T35N:R74W, Sections 2-5, 8-11, 14-18, 21).

Enclosed with this letter is a page correction for the document. The changed sentence is shown in bold. Please replace the old first page to the plan with the corrected page and discard the incorrect version. I apologize for the inconvenience. If you have any questions, please contact me at 307.333.7643.

Sincerely,

A handwritten signature in cursive script that reads "Miriam Whatley".

Re: Request to verify USFWS species of concern list and to review of draft Wildlife Monitoring Plan and draft Vegetation and Wetlands Survey Methodology (WDEQ/LQD Rules and Regulations Chapter 2, Section 1(f))

Dear Mr. Sattelberg:

The Smith Ranch Highland/Reynolds Permit Area of Power Resources, Incorporated (d.b.a. Cameco Resources [CR]) is located in the Highland Flats area of the southern Powder River Basin in Converse County, Wyoming. CR is currently extracting uranium via an in-situ recovery process on the Highland Uranium Permit Area (#603) and the Smith Ranch Permit Area (#633). CR is in the process of combining these two permits and adding the Reynolds Ranch as an amendment, resulting in the combined Smith Ranch Highland/Reynolds Permit Area (#633). The combined Permit Area is located approximately 25 miles north-northwest of Douglas and 22 miles northeast of Glenrock, Wyoming (T37N:R74W, Sections 25, 26, 35, 36; T37N:R73W, Sections 30-32; T36N:R74W, Sections 1, 2, 11-14, 22-27, 33-36; T36N:R73W, Sections 5-7, 10-31, 34-36; T36N:R72W, Sections 7, 16-22, 29, 30; T35N:R75W, Sections 13, 24; T35N:R74W, Sections 2-5, 8-11, 14-19, 21). The combined Permit Area encompasses 39,870 acres and the primary vegetation cover types are intermixed grassland and mixed sagebrush/grassland.

As part of the permit amendment process, CR is updating their wildlife, vegetation and wetlands baseline database for the entire Smith Ranch Highland/Reynolds Permit Area. Hayden-Wing Associates, LLC (HWA) has been contracted to assist in this process. Species and/or issues addressed in the attached draft Vegetation and Wetland Survey Methodology and draft Wildlife Monitoring Plan, are designed to respond to the Land Quality Division requirements referenced above and the concerns of the United States Fish and Wildlife Service (USFWS; see June 2010 letter of Brian T. Kelly to Pam Rothwell with WDEQ-LQD) and Wyoming Game and Fish Department (WGFD; see June 2010 letter of John Emmerich to Pam Rothwell [letters are attachments to the Wildlife Plan]) for the Smith Ranch-Highland portion of this Permit (see attachments). Included are special status plant species (threatened, endangered, and Bureau of Land Management sensitive species), general vegetation, invasive/noxious weeds, greater sage-grouse, black-tailed prairie dogs, mountain plovers, raptors, eagles, other avian

species protected by the Migratory Bird Treaty Act, wetlands and riparian areas, and the disposal and storage of wastewater from in-situ uranium recovery. This will include identifying wetlands and producing an updated vegetation map and a wildlife habitat map.

CR would appreciate your formal review and critique of the draft Wildlife Monitoring Plan and draft Vegetation and Wetlands Survey Methodology. Please advise as to additions, corrections, or methods by which we can enhance our efforts for the wildlife and vegetation resources. Your responses will serve as formal verification of our consultation with you in accordance with the Wyoming Department of Environmental Quality Land Quality Division Rules and Regulations Chapter 2, Section 1(f).

Additionally, in consideration of the addition of the Reynolds Ranch to the Smith Ranch-Highland Permit Area, I am requesting from you a list of USFWS species of concern for the combined Permit Area in the southern Powder River Basin area of Converse County, Wyoming. To assist you in formulating this list I have attached two area maps showing the permit area in relation to landscape features and local topography.

If you require additional materials for your determination or have questions, please contact me at 307.333.7643.

Sincerely,

Miriam Whatley
Permitting Manager

DRAFT

Vegetation & Wetlands Survey Methodology and Schedule for
Cameco Resources' Smith Ranch Highland/Reynolds
Uranium In-Situ Recovery Project
Converse County, Wyoming
March, 2011

1.0 INTRODUCTION

Cameco Resources (CR) is currently mining uranium via an in-situ leach process on the Highland Uranium Permit Area (Permit #603) and Smith Ranch Permit Area (Permit #633) located in the Highland Flats area of the southern Powder River Basin in Converse County. This area has been the site of numerous uranium mining operations involving various companies since the early 1970s. CR acquired the Highland Uranium Permit Area in 1997 and the Smith Ranch portion in 2002 (CR Operations Plan 2010).

CR is in the process of combining these two permits and adding the Reynolds Ranch as an amendment, resulting in the combined Smith Ranch Highland/Reynolds Permit Area (Permit #633). The combined Permit Area is located approximately 25 miles north-northwest of Douglas and 22 miles northeast of Glenrock, Wyoming (T37N:R74W, Sections 25, 26, 35, 36; T37N:R73W, Sections 30-32; T36N:R74W, Sections 1, 2, 11-14, 22-27, 33-36; T36N:R73W, Sections 5-7, 10-31, 34-36; T36N:R72W, Sections 7, 16-22, 29, 30; T35N:R75W, Sections 13, 24; T35N:R74W, Sections 2-5, 8-11, 14-18, 21). The proposed combined Permit Area encompasses 39,868 acres. The primary vegetation cover types are intermixed grassland and mixed sagebrush/grassland. CR is currently updating their Wyoming Department of Environmental Quality (WDEQ) compliance protocols and Hayden-Wing Associates LLC (HWA), Laramie, Wyoming, has been requested by CR to assist in completing required vegetation surveys. The following text discusses the vegetation and wetland survey methodology proposed by HWA to achieve this goal.

2.0 SPECIAL STATUS PLANT SPECIES

Special status plant species include: (1) threatened, endangered, proposed, experimental and candidate plants identified for protection by the U.S. Fish and Wildlife Service (FWS) under the Endangered Species Act (ESA) of 1973, as amended, and (2) sensitive species identified by the Bureau of Land Management (BLM) Wyoming State Sensitive Species List (BLM 2010). HWA biologists are familiar with all special status plant species in the Green River, Great Divide, and Powder River Basins of Wyoming and Montana, the Uinta/Piceance Basin of Colorado and Utah, and the Judith Valley of northern Montana. Table 1 lists the current T/E plants and animals that may occur within the Permit Area in Converse County.

Re: Request to verify WGFD species of concern list and to review of draft Wildlife Monitoring Plan and draft Vegetation and Wetlands Survey Methodology (WDEQ/LQD Rules and Regulations Chapter 2, Section 1(f))

Dear Mr. Emmerich,

The Smith Ranch Highland/Reynolds Permit Area of Power Resources, Incorporated (d.b.a. Cameco Resources [CR]) is located in the Highland Flats area of the southern Powder River Basin in Converse County, Wyoming. CR is currently extracting uranium via an in-situ recovery process on the Highland Uranium Permit Area (#603) and the Smith Ranch Permit Area (#633). CR is in the process of combining these two permits and adding the Reynolds Ranch as an amendment, resulting in the combined Smith Ranch Highland/Reynolds Permit Area (#633). The combined Permit Area is located approximately 25 miles north-northwest of Douglas and 22 miles northeast of Glenrock, Wyoming (T37N:R74W, Sections 25, 26, 35, 36; T37N:R73W, Sections 30-32; T36N:R74W, Sections 1, 2, 11-14, 22-27, 33-36; T36N:R73W, Sections 5-7, 10-31, 34-36; T36N:R72W, Sections 7, 16-22, 29, 30; T35N:R75W, Sections 13, 24; T35N:R74W, Sections 2-5, 8-11, 14-19, 21). The combined Permit Area encompasses 39,870 acres and the primary vegetation cover types are intermixed grassland and mixed sagebrush/grassland.

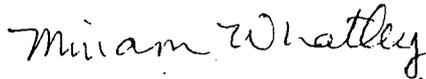

As part of the permit amendment process, CR is updating their wildlife, vegetation and wetlands baseline database for the entire Smith Ranch Highland/Reynolds Permit Area. Hayden-Wing Associates, LLC (HWA) has been contracted to assist in this process. Species and/or issues addressed in the attached draft Vegetation and Wetland Survey Methodology and draft Wildlife Monitoring Plan, are in response to concerns by the United States Fish and Wildlife Service (USFWS; see June 2010 letter of Brian T. Kelly to Pam Rothwell with WDEQ-LQD) and Wyoming Game and Fish Department (WGFD; see June 2010 letter of John Emmerich to Pam Rothwell [letters are attachments to the Wildlife Plan]) for the Smith Ranch-Highland portion of this Permit. Included are special status plant species (threatened, endangered, and Bureau of Land Management sensitive species), general vegetation, invasive/noxious weeds, greater sage-grouse, black-tailed prairie dogs, mountain plovers, raptors, eagles, other avian species protected by the Migratory Bird Treaty Act, wetlands and riparian areas, and the disposal and storage of wastewater from in-situ uranium recovery. This will include identifying wetlands and producing an updated vegetation map and a wildlife habitat map.

CR would appreciate your formal review and critique of the draft Wildlife Monitoring Plan and draft Vegetation and Wetlands Survey Methodology. Please advise as to additions, corrections, or methods by which we can enhance our efforts for the wildlife and vegetation resources.

Additionally, in consideration of the addition of the Reynolds Ranch to the Smith Ranch-Highland Permit Area, I am requesting from you a list of WGFD species of concern for the combined Permit Area in the southern Powder River Basin area of Converse County, Wyoming. To assist you in formulating this list I have attached two area maps showing the permit area in relation to landscape features and local topography.

If you require additional materials for your determination or have questions, please contact me at 307.333.7643.

Sincerely,

Miriam Whatley
Permitting Manager

**Vegetation & Wetlands Survey Methodology and Schedule for
Cameco Resources' Smith Ranch Highland/Reynolds
Uranium In-Situ Recovery Project
Converse County, Wyoming
March, 2011**

1.0 INTRODUCTION

Cameco Resources (CR) is currently mining uranium via an in-situ leach process on the Highland Uranium Permit Area (Permit #603) and Smith Ranch Permit Area (Permit #633) located in the Highland Flats area of the southern Powder River Basin in Converse County. This area has been the site of numerous uranium mining operations involving various companies since the early 1970s. CR acquired the Highland Uranium Permit Area in 1997 and the Smith Ranch portion in 2002 (CR Operations Plan 2010).

CR is in the process of combining these two permits and adding the Reynolds Ranch as an amendment, resulting in the combined Smith Ranch Highland/Reynolds Permit Area (Permit #633). The combined Permit Area is located approximately 25 miles north-northwest of Douglas and 22 miles northeast of Glenrock, Wyoming (T37N:R74W, Sections 25, 26, 35, 36; T37N:R73W, Sections 30-32; T36N:R74W, Sections 1, 2, 11-14, 22-27, 33-36; T36N:R73W, Sections 5-7, 10-31, 34-36; T36N:R72W, Sections 7, 12, 16-21, 29, 30; T35N:R75W, Sections 13, 24; T35N:R74W, Sections 2-5, 8-11, 14-18, 21). The proposed combined Permit Area encompasses 39,868 acres. The primary vegetation cover types are intermixed grassland and mixed sagebrush/grassland. CR is currently updating their Wyoming Department of Environmental Quality (WDEQ) compliance protocols and Hayden-Wing Associates LLC (HWA), Laramie, Wyoming, has been requested by CR to assist in completing required vegetation surveys. The following text discusses the vegetation and wetland survey methodology proposed by HWA to achieve this goal.

2.0 SPECIAL STATUS PLANT SPECIES

Special status plant species include: (1) threatened, endangered, proposed, experimental and candidate plants identified for protection by the U.S. Fish and Wildlife Service (FWS) under the Endangered Species Act (ESA) of 1973, as amended, and (2) sensitive species identified by the Bureau of Land Management (BLM) Wyoming State Sensitive Species List (BLM 2010). HWA biologists are familiar with all special status plant species in the Green River, Great Divide, and Powder River Basins of Wyoming and Montana, the Uinta/Piceance Basin of Colorado and Utah, and the Judith Valley of northern Montana. Table 1 lists the current T/E plants and animals that may occur within the Permit Area in Converse County.

Table 1. Endangered Species Act listed plant species that may occur within the Permit Area^A.

Common Name	Scientific Name	Federal Status	Heritage Status	Habitat
Blowout penstemon	<i>Penstemon haydenii</i>	E	G1/S1	Sand dunes or blowouts
Ute ladies'-tresses	<i>Spiranthes diluvialis</i>	T	G2/S1	Seasonally moist soils and wet meadows of drainages below 7,000 ft. elevation.

^A USDI-FWS. July 2010. Federal endangered, threatened, proposed, and candidate species and designated critical habitats that occur in or may be affected by projects in Converse County, Wyoming. <http://www.fws.gov/wyoming/pdfs/CountySpecialLists/Converse.sp.pdf>.

Blowout penstemon: Blowout penstemon (*Penstemon haydenii*) is a perennial herb associated with active sand dune blowouts. The current known populations of blowout penstemon in Wyoming are located in the Ferris dunes of northwest Carbon County. The sand hills of Natrona and Converse counties are part of a greater Quaternary eolian sand deposit system that stretches in an east-west line across central Wyoming from Converse and Natrona counties into eastern Fremont County. Additional larger sand hill formations are located in Sweetwater County (i.e., Killpecker Dunes). Smaller quaternary sand deposits are located in areas throughout the state, with a few more extensive fields located in Platte and Goshen Counties.

Surveys for blowout penstemon are planned for mid-June to early-July which is the flowering period for the plants in Wyoming (Fertig 2001, Heidel 2005). Prior to initiating these surveys, consultation with WYNDD personnel will be initiated to determine if a proposed model of the plant's potential distribution in Converse County is available which will be utilized and ground truthed for the surveys.

Ute ladies'-tresses: Ute ladies'-tresses (*Spiranthes diluvialis*) is a perennial, terrestrial orchid with white or ivory flowers clustered into a spike arrangement at the top of the stem. HWA biologists have conducted numerous surveys for this species throughout Wyoming beginning in 2003. Bloom at the nearest Ute-ladies'-tresses population (Antelope Creek, Converse County) site usually occurs within the first two weeks of August each year (12 August for both the 2009 and 2010 growing seasons).

In the event either blowout penstemon or Ute ladies' tresses are found within the Permit Area, the FWS and appropriate land management office (if applicable) will be notified as soon as feasible to determine an appropriate management action. The plant(s) location will be precisely documented and delineated with GPS technology. Prior to beginning the surveys for Ute ladies'-tresses in August, potential habitat(s) for the plants will be evaluated in conjunction with the wetland delineation component of this project. All NWI-identified waterbody features will be evaluated and deemed suitable or unsuitable based on the presence/absence of these specific disqualifying factors (USDI-FWS 1995):

- A. Appropriate hydrology not present**
 - upland site dominated by upland plant species,
 - ephemeral/intermittent draw,
 - water table > 12 inches, site dry by mid-July,
 - sub-irrigation not observed,
 - >15m from perennial stream

B. Soils strongly alkaline

Whitish (alkali) residue on ground surface where pools have receded
salt marks present along water body's shoreline and water's edge
Halophytic plants present (e.g., Saltcedar)

C. Site heavily disturbed (Stream banks channelized and stabilized by riprap, etc.)

D. Stream banks steep, transition area from upland to stream margin abrupt (typical incised channel)

E. Apparent non-moving water where cattails, bulrushes are dominant (e.g., separated backwater areas along river systems)

F. Riparian area or streambank vegetated with dense rhizomatous species (e.g., Reed canarygrass, cattails, etc.)

G. Riparian areas heavily used by livestock (common where year-long grazing is allowed)

H. Potential habitat no longer in a natural condition (converted to alfalfa, native grass hay production, etc.)

I. Wetland is a brackish playa or pothole with no fresh water source.

Potential suitable habitats will be re-surveyed during the bloom period for presence/absence of the plant(s). In all cases, landowner permission will be obtained before surveying private lands.

3.0 VEGETATION (INCLUDING INVASIVE AND POSIONOUS PLANT SPECIES)

General vegetation

General vegetation of the combined Permit Area will be mapped using ArcGIS 10[®] and National Agriculture Imagery Program (NAIP-2009) imagery. Ground truthing will occur throughout the growing season at random computer-generated locations to verify primary cover types and to determine vegetation vigor. Spot checking of previously surveyed mapped areas will also be performed to verify accuracy and determine vegetation condition. The primary objective of this component is to provide updated high-quality color vegetation maps to CR and DEQ for analysis and use.

Invasive/Noxious Weeds

Invasive/noxious weeds are very aggressive and invading infestations tend to exclude other native plant species thereby reducing the overall forage production of desirable shrubs, herbaceous grasses and forbs. The combined Permit Area is vulnerable to infestations of noxious weeds, especially on newly disturbed surfaces. Extended drought conditions in Wyoming have favored the establishment of noxious weeds in stressed or disturbed habitats. In Wyoming, some 428 species have been documented as invasive (Hartman and Nelson 2000). Of these 428 plants, 25 are designated as noxious by the State of Wyoming and are shown in Table 2. In addition to the 25 state-designated species, Converse County has designated 43 weed species as noxious.

Noxious weed surveys are planned to begin approximately mid-July and continue through mid-September, 2011. The primary target areas to be surveyed will include all previously disturbed sites (e.g., pipeline and fiber optic line rights-of-way (ROWS), access road ROWs, construction and production

installations, topsoil piles, etc. Special attention will be given to all riparian and aquatic sites including springs (developed and undeveloped) and seeps within the Permit Area. Based upon recent communications with the Converse County Weed and Pest Control District, it is not anticipated that any significant noxious weed infestations will be encountered. In addition to conducting the above mentioned surveys, all HWA field personnel, including wildlife biologists, will report all noxious weed opportunistic sightings in both aquatic and upland habitats that will be consequently recorded and mapped by HWA weed survey personnel. In addition to surveying/monitoring existing disturbances, noxious weed surveys are also highly recommended for all proposed new soil disturbing actions to prevent future infestations.

Noxious weed occurrences locations will be closely coordinated with designated CR personnel and the Converse County Weed and Pest Control District Supervisor located in Douglas to assist in appropriate management action decisions. All management actions that involve chemical control will be performed by a certified Wyoming Commercial Pesticide Applicator. All HWA GIS weed survey data (shapefiles), including surveyor tracks, will be provided to the Converse County Weed and Pest Control District for upload into their GIS to reflect current conditions. Noxious weed surveys (dates and locations) will be closely coordinated with designated CR personnel and the Converse County Weed and Pest Control District Supervisor located in Douglas.

During the course of the growing season, surveys will also be conducted in conjunction with the noxious weed component to record selenium indicator plants. Certain species of plants are considered indicators of high selenium content of the soil, since they require high levels of selenium to thrive. The primary selenium indicator plants are *Astragalus* species (including some locoweeds), prince's plume (*Stanleya* sp.), woody asters (*Xylorhiza* sp.), and false goldenweed (*Oenopsis* sp.). Several of the potential selenium-indicator plants that may occur on the combined Permit Area are shown in Table 3. In addition to GPS locations, data collection for selenium-accumulator plants will include the species and population size.

Table 2. State of Wyoming designated noxious weeds

Common Name	Scientific Name
Field bindweed	<i>Convolvulus arvensis</i> L.
Canada thistle	<i>Cirsium arvense</i> L.
Leafy spurge	<i>Euphorbia esula</i> L.
Perennial sowthistle	<i>Sonchus arvensis</i> L.
Quackgrass	<i>Agropyron repens</i> (L.) Beauv.
Hoary cress (whitetop)	<i>Cardaria draba</i> & <i>Cardaria pubescens</i> (L.) Desv.
Perennial pepperweed (giant whitetop)	<i>Lepidium latifolium</i> L.
Ox-eye daisy	<i>Chrysanthemum leucanthemum</i> L.
Skeletonleaf bursage	<i>Franseria discolor</i> Nutt.
Russian knapweed	<i>Centaurea repens</i> L.
Yellow toadflax	<i>Linaria vulgaris</i> L.
Dalmatian toadflax	<i>Linaria dalmatica</i> (L.) Mill.
Scotch thistle	<i>Onopordum acanthium</i> L.
Musk thistle	<i>Carduus nutans</i> L.
Common burdock	<i>Arctium minus</i> (Hill) Bernh.
Plumeless thistle	<i>Carduus acanthoides</i> L.
Dyers woad	<i>Isatis tinctoria</i> L.
Houndstongue	<i>Cynoglossum officinale</i> L.
Spotted knapweed	<i>Centaurea maculosa</i> Lam.
Diffuse knapweed	<i>Centaurea diffusa</i> Lam.
Purple loosestrife	<i>Lythrum salicaria</i> L.
Saltcedar	<i>Tamarix</i> spp.
Common St. Johnswort	<i>Hypericum perforatum</i>
Common Tansy	<i>Tanacetum vulgare</i>
Russian olive	<i>Elaeagnus angustifolia</i> L.

Table 3. Potential selenium-accumulator plants that may occur within the combined Permit Area.

Common Name	Scientific Name
Two-grooved milkvetch	<i>Astragalus bisculatus</i>
Shadscale	<i>Atriplex confertifolia</i>
Winterfat	<i>Krascheninnikovia lanata</i>
Stickleaf	<i>Mentzelia dicapetala</i>
Princesplume	<i>Stanleya pinnata</i>
Yellow bean (spreadseed goldenbanner)	<i>Thermopsis divaricarpa</i>
Arrowgrass	<i>Triglochin maritima</i> and <i>T. palustris</i>
Gumweed	<i>Grindelia squarrosa</i>
Poverty weed	<i>Iva axillaris</i>
Woody aster	<i>Xylorhiza glabriuscula</i>

4.0 WETLAND IDENTIFICATION METHODOLOGY

The following protocol is based upon meeting with Mr. Thomas Johnson and Mr. Matthew Bilodeau (ACOE, Wyoming Regulatory Office, Cheyenne, WY) on 9 February 2011, in Cheyenne. The meeting was attended by Ms. Miriam Whatley (Permitting Manager, CR), Larry Bennett and Jon Knudsen (HWA).

The ACOE stated that because this project is an in-situ operation that a formal wetland delineation of the entire land surface of the Permit Area would not be required. However, the ACOE suggested a course of action that would fulfill their mandated regulatory requirements and streamline the process. The sequence of action as suggested by the ACOE is to:

1. Provide a letter of request to the ACOE outlining the proposed methods to conduct an *Aquatic Resource Inventory*, including a general location map of the proposed Permit Area (this document). This document will initiate correspondence between the ACOE with the Land Quality Division (LQD) of the Wyoming Department of Environmental Quality, United States Fish and Wildlife Service, Wyoming Game and Fish Department (WGFD) and CR.
2. Download, print and review color near-infrared (CIR) imagery of the Permit Area collected during the 2009 agricultural growing season by the National Agriculture Imagery Program. This phase will enable a first round identification of potential wetlands within the Permit Area with on-site verification to follow to determine accuracy and classification of the imagery. This step will be conducted with the office assistance of the ACOE. On-site verification of potential wetlands is planned to occur principally during June and July, 2011
3. Review CR's plan of development and determine if any proposed project-associated disturbance will be located in or near a CIR-identified and verified potential wetland site. If this is the case, the ACOE would then require a formal wetland delineation of the site conducted in accordance with the *Field Guide for Wetland Delineation: 1987 Corps of Engineers Manual* as supplemented by the *Regional Supplement: Great Plains Region (Version 2.0)* (2010). The wetland identification methodology outline in these manuals requires an evaluation of communities for the presence of: (1) hydrophytic vegetation, (2) hydric soils, and (3) wetland hydrology. Under normal circumstances, for an area to be classified as wetland by the ACOE, the presence of these three parameters is mandatory.
4. Following completion of the formal delineation process and jurisdictional determination by the ACOE, an applicable Nation Wide Permit (NWP) may be issued for the action. A complete review of the 2007 NWPs, conditions, further information and definitions may be found online at:

www.usace.army.mil/CECW/Pages/nw_permits.aspx

LEGEND FOR RANGE SITE

Range sites are kinds of native rangelands that differ from each other in their ability to produce significant different kinds or amounts of original vegetation. Soils, precipitation, and geographical location are combined to designate a specific range site. The following range sites are listed in the normally presumed order of the productivity in "Excellent" condition.

Name of the range sites occurring on your ranch are underlined, and these sites are separated by solid lines on your conservation plan map.

<u>Symbol</u>	<u>Range Site Name</u>	<u>Brief Description for NORTHERN PLAINS 10" - 14" p.z.</u>
WL	Wetland	This site usually occurs on soils which are poorly drained with water tables above the surface for part of the growing season. In excellent condition the main grasses are Nebraska sedge, northern reedgrass, bluejoint reedgrass, and tufted hairgrass. Spike sedge, inland sedge, Baltic rush, and forbs usually dominate this site as condition deteriorates.
Sb	Subirrigated	These are deep soils with water tables that are within reach of the plant roots for most of the growing season. In excellent condition the main grasses are prairie cordgrass, basin wildrye, slender wheatgrass, and tufted hairgrass. Western wheatgrass, inland sedge, forbs, and willows usually dominate the site when condition deteriorates.
SS	Saline Subirrigated	These are deep saline soils with water tables within reach of the plant roots for most of the growing season. In excellent condition the main grasses are alkali sacaton, alkali cordgrass, western wheatgrass, and Nuttalls alkaligrass. Inland saltgrass, mat muhly grass, and rubber rabbitbrush usually dominate the site when condition deteriorates.
LL	Lowland	These are deep soils that lay adjacent to streams that have a water table within reach of deep rooted trees and shrubs. In excellent condition the main vegetation is green needlegrass, slender wheatgrass, basin wildrye, and perennial forbs. Western wheatgrass, needleandthread, forbs, cottonwoods, and wild rose dominate as condition deteriorates.
SL	Saline Lowland	These are deep saline soils that receive extra water from adjacent slopes. In excellent condition the main vegetation is alkali sacaton, western wheatgrass, and fourwing saltbush. Inland saltgrass, bottlebrush squirreltail, alkali bluegrass, and greasewood dominate the site when condition deteriorates.
OV	Overflow	The soils of this site are deep loams which receive extra water from overflow of streams or adjacent slopes. In excellent condition the main vegetation is basin wildrye, green needlegrass, Cusick bluegrass, and perennial forbs. Western wheatgrass, needleandthread, forbs, and silver sagebrush usually dominate this site when condition deteriorates.
Cy0	Clayey Overflow	The soils of this site are fine textured loams that receive extra water. In excellent condition the main vegetation is basin wildrye, green needlegrass, Cusick bluegrass, and perennial forbs. Western wheatgrass, Sandberg bluegrass, needleleaf sedge, forbs, and snowberry usually dominate this site when condition deteriorates.
Sa	Sands	The soils of this site are deep loose sands on level to rolling topography. In excellent condition the main vegetation is prairie sandreed, sand bluestem, Indian ricegrass, and perennial forbs. Needleandthread, Sandberg bluegrass, sand dropseed, and silver sagebrush usually dominate the site when condition deteriorates.
Sy	Sandy	The soils of this site are deep sandy loams. In excellent condition the main vegetation is Indian ricegrass, prairie sandreed, little bluestem, perennial forbs, and needleandthread. Western wheatgrass, blue grama, forbs, and Silver sagebrush dominate this site when condition deteriorates.

TABLE D-8.4 (Cont'd)

Ly	Loamy	The soils of this site are deep loams that occur on level to gentle slopes. In excellent condition the main vegetation is western wheatgrass, thickspike wheatgrass, green needlegrass, and perennial forbs. Needleandthread, blue grama, forbs, and big sagebrush usually dominate this site when condition deteriorates.
Cy	Clayey	The soils of this site are deep clays and fine textured loams. In excellent condition the main vegetation is western wheatgrass, green needlegrass, thickspike wheatgrass, and perennial forbs. Blue grama, plains reedgrass, forbs, and big sagebrush usually dominate this site when condition deteriorates.
DC	Dense Clay	The soils of this site are deep dense clays that tend to be droughty. In excellent condition the main vegetation is green needlegrass, thickspike wheatgrass, western wheatgrass, and winter fat. Sandberg bluegrass, bottlebrush squirreltail, needleleaf sedge, and birdfoot sagebrush usually dominate this site when condition deteriorates.
SwSy	Shallow Sandy	The soils of this site are shallow sandy loams that usually occur on steep slopes and ridge tops. In excellent condition the main vegetation is needleandthread, prairie sandreed, Indian ricegrass, and perennial forbs. Blue grama, sand dropseed, threadleaf sedge, and big sagebrush usually dominate as condition deteriorates.
SwLy	Shallow Loamy	The soils of this site are shallow, well drained loams. In excellent condition the main vegetation is bluebunch wheatgrass, needleandthread, western wheatgrass, and perennial forbs. Blue grama, threadleaf sedge, forbs, and big sagebrush usually dominate as condition deteriorates.
SwCy	Shallow Clayey	The soils of this site are shallow fine textured clay loams and clays that usually occur on steep slopes and ridge tops. In excellent condition the main vegetation is green needlegrass, western wheatgrass, and perennial forbs. Blue grama, plains reedgrass, forbs, and big sagebrush usually dominate as condition deteriorates.
VS	Very Shallow	The soils of this site are very shallow with exposed bedrock and pockets of deep soil. In excellent condition the main vegetation is curleaf mountainmahogany, bluebunch wheatgrass, western wheatgrass, and needleandthread. Blue grama, stoneyhills muhly, forbs, and shrubs usually dominate as condition deteriorates.
Sh	Shale	The soils of this site are very shallow fine textured clays over clay shale bedrock. In excellent condition the main vegetation is western wheatgrass, plains reedgrass, thickspike wheatgrass, and winterfat. Threadleaf sedge, Sandberg bluegrass, forbs, and birdfoot sagebrush usually dominate this site as condition deteriorates.
SU	Saline Upland	The soils of this site are deep, slowly permeable, and alkaline. In excellent condition the main vegetation is Gardners saltbush, alkali sacaton, and western wheatgrass. Inland saltgrass, Sandberg bluegrass, and greasewood usually dominate this site as condition deteriorates.

LEGEND FOR RANGE CONDITION

Range condition is the present stage of vegetation in relation to climax condition for the range site. Range condition provides an approximate measure of any deterioration that has taken place in plant cover and serves as a basis for predicting the degree of improvement possible.

<u>Map Symbol</u>	<u>Range Condition Class</u>	<u>Percent of Present Composition that is Potential for the Range Site</u>
EC	Excellent Condition	76 - 100
GC	Good Condition	51 - 75
FC	Fair Condition	26 - 50
PC	Poor Condition	0 - 25

Range condition classes, within the same range site, are separated by a dotted line.

The Wyoming Department of Environmental Quality (DEQ) has requested vegetation information for the middle pit area and mill site of Kerr-McGee's South Powder River Basin uranium project.

Vegetation studies were conducted in April and September of 1979 and included measurements of cover, annual productivity, and shrub height. The methods, results, and conclusions of the vegetation studies conducted at the middle pit area and mill site are presented below.

METHODS

The sampling methods used for this study and discussed below with regard to sample locations, cover, productivity, and shrub height were based on DEQ Guideline Number 2 (Vegetation).

Sample Location

Sixty sample stations were located in the sagebrush-grassland vegetation type on the middle pit area and mill site ("affected area"), and 20 stations were located in two control areas in the same vegetation type. No other vegetation types are present in the affected area

(Figures 1 and 2). The 60 mine and mill sample locations were selected randomly by the use of a grid placed on a topographic map (1" = 500') showing the areas to be disturbed. The size of each square in the grid corresponded to a ground area of 2500 m² (50 m x 50 m). Each square in the area to be disturbed was assigned a number. Sixty squares were randomly chosen with the use of a random numbers table. Each of the 60 squares was also assigned two random numbers between 1 and 50 to serve as x,y coordinates. The center of each selected square was located in the field and served as the "origin" so the x,y numbers could be paced out to locate each sample location. Four of the 60 affected area sites could not be relocated in September and were not sampled; thus, the number of affected sites was reduced to 56.

The 20 control site locations were identified in the same manner in two areas adjacent to the mill site and middle pit areas that were not expected to be disturbed by mining activities (Figures 1 and 2).

Cover

Data on the type of ground cover at each sample location was obtained by recording the first object encountered at 5-meter intervals along a 50-meter tape centered on the randomly selected point. The direction of the transect was selected by the use of random numbers between 1 and 8, with the numbers corresponding to preassigned compass directions (1 = north, 2 = northeast, 3 = east, ..., 8 = northwest). Objects were categorized as plants (and identified to species), litter or rock, or bare ground. The percent ground cover for each

category or species was calculated by dividing the total number of "hits" for each category or species by the total number of hits possible (560 on the mine site and 200 in the control area). Standard deviations were calculated using $n = 56$ and $n = 20$ on the mine site and control areas, respectively.

Productivity

Data on vegetation productivity was obtained at each sample location by placing cages on 1-meter-square plots at the randomly selected point. The cages were used to keep livestock and other large herbivores, such as antelope, from eating the vegetation. The cages were placed on site in April 1979 and vegetation was clipped by major species in September 1979. The entire plant was taken for herbaceous species; new growth only was clipped from shrubs. The samples were bagged and labeled and returned to the laboratory. The samples were then dried for 24 hours at 105°C and weighed. The productivity in grams per square meter (g/m^2) for each species was calculated by dividing the total weight for each species by the number of sample sites.

Shrub Height

The height of all shrubs (including succulents) intercepted by each 50-meter transect was recorded to the nearest 5 centimeters. The average height and standard deviation based on the number of plants were calculated for each shrub species.

RESULTS

Cover

Vegetation covered an average of approximately 68 percent of the ground on the middle pit and mill site in September 1979. Greater cover was recorded during this period than for the 3-10 mine site in September 1978, probably due to the more than 3 inches of rainfall that occurred in late July and early August of 1979. Grass covered approximately 56 percent of the ground and accounted for about 82 percent of all vegetation cover. The dominant grass and grass-like species were western wheatgrass (Agropyron smithii), blue grama (Bouteloua gracilis), sedge (Carex filifolia), and needle-and-thread (Stipa comata).

Shrubs covered an average of less than 8 percent of the ground in the area to be disturbed by mining (Table 1). Big sagebrush (Artemisia tridentata) was the dominant shrub species. Other less common shrubs included fringed sagebrush (A. frigida), birdfoot sagebrush (A. pedatifida), rabbitbrush (Chrysothamnus viscidiflorus), plains prickly pear (Opuntia polyacantha), and snakeweed (Gutierrezia sarothrae).

Forbs were the least dominant form of vegetation on the affected area and had an average ground cover of less than 5 percent (Table 1).

Rock and litter covered an average of 9 percent of the ground on the affected area. Approximately 23 percent of the ground was void of any vegetation, litter, or rocks.

D-165

The total average ground cover; relative abundance of grasses, shrubs, and forbs; and the dominant species on the control areas were very similar to those on the affected area (Tables 2 and 3).

Productivity

Vegetation productivity averaged about 62 g/m² (560 lbs/acre) for the affected area, and slightly more than 50 g/m² (450 lbs/acre) for the control area (Tables 4, 5 and 6). Agropyron smithii, Bouteloua gracilis, Carex filifolia, and Stipa comata were the major species contributing to the productivity. Shrubs accounted for only about 10 percent of the productivity.

Shrub Height

Shrub height in the affected area averaged about 16 cm (6 in.) (Table 7). The most common shrub, big sagebrush (Artemisia tridentata) averaged 19.9 cm (8 in.). Most other shrubs were less than 10 cm in height.

Shrub height on the control area averaged about 14 cm (6 in.) (Table 8), which is similar to shrub heights on the affected area.

POSTMINING VEGETATION

Following mining operations, areas to be reclaimed will be revegetated to a condition suitable for the continuation of present land uses, livestock grazing, and wildlife habitat. Vegetation reestablishment will not only provide forage for livestock, but is also expected

*Total = average height for all individual shrubs in each transect

**Grand total = average shrub height for 20 transects

to provide suitable wildlife habitat for many of the species present in the area prior to mining.

Data from this vegetation survey will not only serve as a guideline for determining the appropriate reseeding mixture, but will also provide one method for evaluation of the reclamation program's success.

The following sections discuss the adequacy of the number of samples and the ratio of the amount of vegetation in the affected area to that in the control areas.

Cover Data Analysis (Vegetation Only)

Estimating Adequate Sample Size. The following inequality was used to determine if the samples sizes (affected = 56, control = 20) were sufficient for statistical analysis:

$$n_{\min} \geq \frac{2(sz)^2}{(d\bar{x})^2},$$

where

n_{\min} = minimum number of transects to measure in this
vegetation type

s = standard deviation

z = the z statistic

d = amount of reduction that it is desired to detect

\bar{x} = sample mean of percent cover.

AFFECTED

$$n_{\min} > \frac{2(20.04 \times 1.28)^2}{(0.1 \times 68.57)_2} = 27.99$$

$n_{\min} > 28$ transects

Thus, 56 transects in the affected area are sufficient for detecting
a 10 percent change in vegetation cover

CONTROL

$$n_{\min} > \frac{2(17.95 \times 1.28)^2}{0.1 \times 68.00} = 22.83$$

$n_{\min} > 23$ transects

These 20 transects in the control area provide a level of confidence
of 87 percent for detecting a 10 percent change in vegetation cover.

Statistical tests provided by Department of Environmental Quality are given below:

$$\bar{x} = \frac{\bar{x}_1}{\bar{y}_1} \circ \bar{y}_2$$

where

\bar{x} = the average percent cover on land that has been reclaimed

\bar{x}_1 = average percent cover in the premining "affected" area

\bar{y}_1 = average percent cover in the premining control area

\bar{y}_2 = average percent cover in the postmining control area.

Since $\bar{x}_1 = 68.57$ and $\bar{y}_1 = 68.00$, then

$$\bar{x} = \frac{68.57}{68.00} \circ y_2 = 1.01\bar{y}_2$$

*Land Quality Division Guideline Number 2 (March 1978)

Cover Data Analysis (Vegetation, Litter, and Rock)

Estimating Adequate Sample Size.

$$n_{\min} \geq \frac{2(sz)^2}{(dx)^2}$$

AFFECTED

$$n_{\min} \geq \frac{2(19.20 \circ 1.28)^2}{(0.1 \circ 76.42)^2} = 20.68$$

$$n_{\min} \geq 21 \text{ transects}$$

Thus, 56 transects in the affected area are sufficient for detecting a 10 percent change in the cover of vegetation, litter, and rock.

CONTROL

$$n_{\min} \geq \frac{2(20.39 \circ 1.28)^2}{0.1 \circ 75.00} = 24.21$$

$$n_{\min} \geq = 24 \text{ transects}$$

These 20 transects in the control area provide a level of confidence of 87 percent for detecting a 10 percent change in cover of vegetation, litter, and rocks.

$$\bar{x} = \frac{\bar{x}_1}{\bar{y}_1} \circ \bar{y}_2$$

Since $x_1 = 76.42$ and $y_1 = 75.00$, then

$$\bar{x} = \frac{76.42}{75.00} \circ \bar{y}_2 = 1.02\bar{y}_2$$

Productivity Data Analysis

Estimating Adequate Sample Size. By:

$$n_{\min} \geq \frac{2(sz)^2}{(d\bar{x})^2}$$

where

n_{\min} = minimum number of plots to sample in this vegetation type

s = sample deviation

z = the z statistic

d = amount of reduction that it is desired to detect

\bar{x} = sample mean of productivity per plot

AFFECTED

$$n_{\min} = \frac{2(38.77 \circ 1.28)^2}{(0.1 \circ 62.33)^2} = 126.78$$

$$n_{\min} > 127 \text{ plots}$$

Thus, due to the large variability in productivity, nearly three times as many plots would be required to detect a 10% change in productivity at the desired confidence interval. The confidence level based on 56 plots is 80 percent.

CONTROL

$$n_{\min} = \frac{2(31.34 \circ 1.28)^2}{(0.1 \circ 51.34)^2} > 122.11 \text{ plots}$$

$$n_{\min} = 122$$

Thus, as with the affected area, the control plots were highly variable in productivity and an unusually large sample size would be needed to obtain the desired degree of confidence. The confidence level based on 20 plots is 70 percent.

$$\bar{x} = \frac{\bar{x}_1}{y_1} \circ \bar{y}_2$$

Since $\bar{x}_1 = 69.66$ and $\bar{y}_1 = 50.91$ (from Tables 4 and 5), then

$$\bar{x} = \frac{62.33}{51.31} \circ \bar{y}_2 = 1.21 \bar{y}_2$$

CONCLUSIONS AND SUMMARY

The data collected provides quantitative information on the vegetation in the area that will be affected by the middle pit and mill site areas. This information will serve as a guideline for determining the appropriate reseeding mixture and will provide one method for evaluation of reclamation program success.

The vegetation data collected indicates that the area is a grassland (i.e., the total shrub cover is less than 30 percent). Sagebrush-grassland vegetation type is present throughout the "affected" area.

The sample sizes of 56 for the "affected" area and 20 for the control area provide a level of confidence varying from 70 to 98 percent.

Document History
Baseline Vegetation Assessment
of the
Smith Ranch Project Permit Area

TFN 3 3/13/94

Note: In areas of conflict the attached report supersedes previous reports.

The attached report is the final version of the Baseline Vegetation Assessment for the Smith Ranch Project Area. This report reflects the changes required to satisfy Condition 2 of the permit. This condition was placed on the permit as a result of incomplete baseline vegetation data and reads as follows:

"The operator shall submit a final baseline vegetation study using methods discussed in the March 20, 1991 memo from Gene Weglinski to Ursula Wiersma and in guidelines 2 and 4. This study must be submitted to WDEQ/LQD for review no later than October 1, 1992. Prior to field sampling, a site visit will be arranged between the operator and a WDEQ/LQD Plant Ecologist. The approved study shall be included into "Appendix D-8."

On June 13, 1991, the required site visit was conducted to establish criteria to satisfy Permit Condition 2. Paige Smith, Jim Luther and Gene Weglinski and Donna Wichers participated in the tour. Based on this site visit, the methodology for conducting the vegetation survey and collecting the data was established. This methodology was outlined in a letter from Roger Schaffer to Donna Wichers dated 8/13/1991.

A letter from Marvin Freeman to Roger Schaffer dated September 3, 1991 concurred with the methodology outlined in the August 13, 1991. Rio Algom subsequently submitted the required report on September 30, 1992. (Cover letter from Bill Ferdinand to Pat Bauman.)

On July 22, 1996, Rio Algom received a letter from Matt Jankovsky (dated July 18, 1996) transmitting the November 1992 WDEQ/LQD comments on the September 30, 1992 submittal.

A meeting was held with WDEQ/LQD, Rio Algom and BKS Environmental to reach some agreement on the appropriate responses to the November 1992 comments.

The attached report reflects the agreements reached at that meeting and fulfills the obligations in Condition 2 of the permit.

a. INTRODUCTION

Vegetation inventories have been conducted on the Smith Ranch Project Area since 1976. Early studies were performed by consultants for the Kerr-McGee South Powder Basin uranium project under Wyoming Permit No. 304C. Following acquisition of the mine by the Rio Algom Mining Corporation (RAMC), an additional vegetation survey was conducted within the current Permit No. 633 boundary during the summer of 1990. The following summary of these historical vegetation surveys is paraphrased from the current Appendix D-8:

Woodward-Clyde Consultants, 1976. Original vegetation surveys of the Permit No. 304C area were conducted by Woodward-Clyde Consultants in 1976. Three areas were surveyed: site V-1, a proposed surface mine in the Hornbuckle area located to the north of the current permit area; site V-2, a proposed site for a uranium milling operation located in the northern portion of the permit area; and site V-3, located in the southern most portion of the original 304C permit area. Vegetation surveys included quantitative analysis of dominant vegetation types using line intercept transects to measure cover, circular plots to measure density, and quadrats to measure production. A list of plant species observed or expected to occur on the original Permit 304C area was also compiled.

Woodward-Clyde Consultants, 1978. During 1978, Woodward-Clyde Consultants performed additional vegetation studies for the 304C permit area in compliance with Wyoming Department of Environmental Quality (WDEQ) Land Quality Division Guideline No. 2. The final report for this site was submitted to WDEQ under Permit 304C; however, the sampled area is not applicable to the current Permit No. 633 area.

Woodward-Clyde Consultants, 1979. In April and September, 1979, vegetation assessments continued at site V-2 and the associated surface mine area. Vegetation measurements included cover, annual productivity and shrub height. In addition, control areas were established for future comparison to areas disturbed by mining. Results from 1979 sampling of site V-2 and the middle pit area indicated that the study area was primarily grassland, with sagebrush/grassland vegetation scattered throughout the affected area.

a. INTRODUCTION (cont.)

Beartooth Environmental, 1990. During the summer of 1990, vegetation mapping was conducted on RAMC's permit area 633. Aerial photographs and ground truthing were used to complete the mapping. Mapping units included: Sagebrush/ Grassland, Grassland, Impoundment, Reclaimed, Disturbed, Hay Meadow, Road Right of Way, Playa, Ranch Yard, Cottonwood/ Willow, and Shelterbelt. Results of this mapping determined that the Smith Ranch project is located in a short-grass prairie region with a regional climate characterized by having wide ranges in temperature and relatively low annual precipitation (12-14 inches). Vegetation was dominated by grasses such as various wheatgrasses and blue grama, with big sagebrush as codominant in many areas. Isolated cottonwood/willow stands occurred along local drainages. Sagebrush/ Grassland vegetation was clearly the dominant vegetation type, occupying 82% of the permit area. Grassland accounted for 15% of the permit area, with the other vegetation and land use units comprising the remaining 3%.

BKS Environmental Associates, Inc. was contracted in 1992 to perform a baseline vegetation inventory in compliance with Condition 2 of Permit No. 633. Vegetative sampling was performed at locations approved by WDEQ/LQD's letter dated January 21, 1992. The original BKS report summarizing these findings was dated October 1, 1992. This rewrite addresses WDEQ comments dated November 2, 1992. In response to the WDEQ comments dated November 2, 1992, tables have been revised by removing second hit information.

b. METHODOLOGY

The following information is derived from WDEQ/LQD written correspondence dated August 13, 1991.

In June, 1991, a tour of the Smith Ranch Project Area was conducted to establish criteria for satisfying Permit Conditions No. 2 and No. 3 of Permit No. 633. Permit Condition No. 2 was placed on the permit as a result of incomplete baseline vegetation data and the need to establish an extended reference area. Mining plans indicated that disturbance was anticipated in two distinct portions of the permit area. Mine related disturbance would be accompanied by disturbance related to lined irrigation ponds, topsoil stockpile locations, and the land application irrigation circle. The two general areas to be affected plus a buffer zone around each was defined as the northeast and southwest sectors. WDEQ/LQD recognized that two dominant vegetation types (grassland and sagebrush/grassland) were initially mapped and occur in each sector.

11/21/97-633

D-8-21

Permit No.

33/287

b. METHODOLOGY (cont.)

However, since the sagebrush/grassland type varied between the two sectors, two study areas were proposed.

A 2,000 foot buffer around the northern areas and a 2,000 foot buffer around the one southern area were sampled for cover, production, and shrub density. Scattered trees, if present in the area, were surveyed by complete census. These two general areas were sampled separately due to major differences in the sagebrush/grassland types. No separate reference area was established for each sampled area. Instead, the extended reference area concept was employed; undisturbed portions of the sampled 2,000 foot buffer are considered the extended reference area and were not sampled separately.

(i) Additional Vegetative Type Determination and Mapping

A sampling location map was submitted to the WDEQ/LQD on January 7, 1992, and approved by the Division on January 21, 1992, prior to initiation of the 1992 baseline sampling. Vegetative sampling was performed at these approved locations, including the 2,000 foot buffer zone for the northeast and southwest sectors. These sectors were each sampled for cover and production within the grassland and sagebrush/grassland vegetation types. The sampling location map contains the starting location of the cover transects. Tables 16 and 17 outlines the number of cover transects sampled for each vegetation type.

Mapping unit acreages were derived by planimetering the mapping units on the vegetation map. Table 1 was then constructed.

Photographs of native vegetation types (ie. Grassland and Sagebrush/Grassland) taken during 1992 fieldwork are included in Addendum 2 and photo locations illustrated on the vegetation map.

(ii) Species Composition

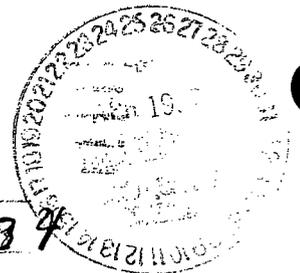

Plant identification was confirmed by the Rocky Mountain Herbarium in Laramie, WY. All scientific nomenclature followed current nomenclature in use at the Herbarium during 1992 with the exception of the genus Agropyron. Whenever possible, voucher specimens were collected for those species not previously encountered. Refer to Addendum 3, 1992 Species List.

Any encountered federally designated threatened and endangered species, state plants of concern, noxious weeds and primary selenium indicators were identified.

11-21/97 683

D-8-22

33/184

(iii) Study Area Sampling Design

All sampling procedures were designed according to the Wyoming Department of Environmental Quality, Land Quality Division, Rules and Regulations, Appendix A (March, 1989).

Sampling locations were randomly determined by placing a grid over the 1"-1000' vegetation map. The x-axis was generally east-west, while the y-axis generally ran north and south. Grid interval at the scale utilized was approximately 250 feet on the ground. Sampling location coordinates were randomly generated by the HP15C hand calculator. Sample point selection was repeated until the desired number of points for each vegetation type was attained. All sample locations are plotted on the vegetation map.

(iv) Extended Reference Area Establishment

During the original vegetation assessments in 1979, control areas were established to monitor reclamation success. During the initial planning for the 1992 assessment, it was determined through various discussions with WDEQ/LQD personnel that the extended reference area (EXREFA) concept may be more appropriate.

(v) Extended Reference Area Sampling Design

The EXREFA was included in the total 1992 study area. Sampling locations were randomly determined similar to the study area sampling and are described in the approved methodology, Addendum 1, Correspondence.

(vi) Time of Sampling

Production cages within the individual study areas were placed prior to mid-April, 1992. Sampling occurred for all communities at various intervals mid-June through July, 1992. The earlier than normal sampling was approved by the WDEQ and confirmed by Rio Algom letter dated May 8, 1992, due to the unusually severe drought conditions in April and May, 1992.

(vii) Plot Size and Shape

Circular production enclosures were made from 5 foot welded wire and placed to protect the one meter squared circular production plot and 3-inch buffer zone. At least four 18" iron stakes were used to secure the enclosures in the ground.

11-21/97-633

D-8-23

Permit No.

TFP

33/034

(viii) Measurements

Collection and Analysis of Cover Data

A minimum of 20 transects for cover were sampled within each study area vegetation type. If statistical adequacy was not obtained, as defined in the WDEQ Rules and Regulations, Appendix A, March 1989, additional transects were sampled, in increments, up to the maximum number of 50. All field sampling for cover occurred after June 15, 1992.

Sample locations for cover within each study area were chosen by randomly selecting points within a grid. Grid intervals did not exceed 250 feet on the ground. Random sample location coordinates were plotted on a map and located in the field by pacing from a known location. Random numbers between 1 and 360 were generated to orient the transect. A compass was then used in the field to orient the transect to the nearest 1/8 of 360 degrees.

Sample hits were read at 1 meter intervals along the entire length of the 50 meter transect. First hit (50) readings constituted the absolute cover values for total vegetation and total cover. The first hit information was used to compile the overall plant list for the study areas. Litter, rock, and bare ground percentages were recorded. Transects that exceeded designated vegetation boundaries were randomly reoriented to be within the sampled vegetation type.

In the cover tables, "importance value" (I.V.) is the sum of relative cover and relative frequency, giving the overall importance in a vegetation community. Lichen was included in cover sampling and is included in the summarization of total vegetation cover and total cover but not sum of species cover. Total vegetation equals sum of species cover plus lichen. Total cover equals total vegetation cover plus litter/rock. In Tables 2, and 6-11 there is a discrepancy in totals due to rounding of the spread sheet. A footnote concerning the rounding functions has been added to the tables where it applies. The excess rounding error was not found in Tables 3-5.

Lichen data, without second hit information, were reentered in the latest version of RIMA in order to address 1992 WDEQ comments. Lichen data were originally entered to specifications of the version of RIMA software in use in 1992. As a result, the 1992 report mean cover and value range had changed during 1996 revisions.

11 21 97 683

D-8-24

(x) Cropland and Prime Farmland Productivity

No cropland or prime farmland were noted within the 2,000 foot buffer zone study areas.

c. RESULTS

(i) Description of Vegetation Types

Two native vegetation types occur within each study area. The better drained, gently rolling upland areas are characterized by Sagebrush/Grassland and Grassland. The Sagebrush/Grassland varies between the north and south study areas. The north is characterized by silver sagebrush and the south by big sagebrush.

Table 1 lists acreage for each vegetation mapping unit within each study area. The north study area totalled 4,452.6 acres. Sagebrush/Grassland is the dominant native vegetation type (3,190 acres or 71.6 %), followed by Grassland (1,161.6 acres or 26.1%). Disturbed areas encompass 101.0 acres or 2.3%.

The south study area totalled 2,178.6 acres. Sagebrush/Grassland is the dominant native vegetation type (1,625.3 acres or 80.6%), followed by Grassland (236.5 acres or 11.7%). Disturbed areas encompass 153.8 acres or 7.7%.

Grassland North

Within the north study area, rolling upland terrain is characterized by the Grassland vegetation type with limited shrub cover. This native vegetation type covers 1,161.6 acres within the north study area. Dominant perennial graminoids include blue grama (*Bouteloua gracilis*), threadleaf sedge (*Carex filifolia*), and needle-and-thread (*Stipa comata*).

Grassland South

Within the south study area, the Grassland vegetation type occupies 236.5 acres. Dominant perennial graminoids include blue grama, threadleaf sedge, and needle-and-thread. A small portion of the southeast corner of the south study area consists of an "ironstone phase" of the Grassland vegetation type. This phase is characterized by ironstone outcrops vegetated by birdsfoot sagebrush.

Sagebrush/Grassland North

Within the north study area, the Sagebrush/Grassland vegetation type occupies 3,190.0 acres. Major species include big sagebrush (*Artemisia tridentata*), silver sage (*Artemisia cana*), threadleaf sedge, blue grama, and needle-and-thread.

11721187-683

23/284

Sagebrush/Grassland South

Within the south study area, a variable Sagebrush/Grassland community occupies 1,625.3 acres. Major species include big sagebrush, blue grama, and threadleaf sedge.

(ii) Vegetation Map

Study area vegetation types and sampling sites are outlined on the vegetation map.

(iii) Weeds, Selenium Indicators, Endangered or Threatened Species

Encountered species cited as "noxious" weeds in the Agricultural Experiment Station, University of Wyoming, 1979, Bulletin 498, "Weeds of Wyoming" include Canada thistle (*Cirsium arvense*). However, it had a low frequency with extremely limited cover.

Primary selenium indicator species identified during the 1992 survey include twogrooved milkvetch (*Astragalus bisulcatus*).

None of the plants identified on the two study areas appear on the U.S. Department of Interior's "Endangered and Threatened Species Plants", as published in the Federal Register. Legal coordinates for the study areas were run through the Wyoming Natural Diversity Database in Laramie, Wyoming. Previously encountered plants of concern found in the region include *Astragalus barrii*. This plant is currently listed as a Federal Category 2 plant.

(iv) Species Composition

Addendum 3 lists species of plants encountered during this baseline survey. This list is arranged by lifeform.

(v) Native Vegetation Type Cover Analysis

All native vegetation types were quantitatively sampled to determine composition and cover.

Grassland North

Absolute total vegetation cover (40.53 percent) was dominated by cool season perennial grasses (55.48 percent of relative cover for individual lifeform sub-totals). Major cool season perennial species included threadleaf sedge and needle-and-thread. Warm season perennial grasses accounted for 23.16 percent of relative species cover, and was dominated by blue grama. Twelve species of perennial forbs comprised 8.26 percent of relative cover, while four annual forbs provided less than one percent of relative species cover. One species of annual grass, cheatgrass (*Bromus tectorum*), provided less than one percent of relative cover. Six shrub species, dominated by silver sagebrush (*Artemisia cana*) and big sagebrush, provided 4.49 percent relative species cover.

11/21/97:633

D-8-27

3 2/12 4

Grassland North (cont.)

Halfshrubs, primarily fringed sagewort (*Artemisia frigida*), contributed 5.92 percent relative species cover. Succulents provided less than one percent relative species cover. Bare soil and litter/rock percentages were 31.13 and 28.33, respectively.

Utilizing the minimum sample number formula outlined in WDEQ, LQD Rules and Regulations, Appendix A (March, 1989), sample adequacy was attained for total vegetation and total cover. Based on sample data, 25 and 16 points were required to attain adequacy for total vegetation and total cover, respectively. Thirty points were actually sampled.

Refer to Table 2 for a summary of the Grassland North study area cover data. Refer to Table 16 for sample adequacy figures for Total Vegetation Cover and Total Cover.

Grassland South

Absolute total vegetation cover (37.44 percent) was dominated by cool season perennial grasses (59.70 percent of relative cover for individual lifeform sub-totals). Major cool season perennial species included threadleaf sedge and needle-and-thread. Warm season perennial grasses accounted for 23.77 percent of relative species cover, and was dominated by blue grama. One introduced perennial grass and one annual grass (Kentucky bluegrass (*Poa pratensis*) and cheatgrass, respectively) each accounted for 0.1 percent of relative species cover. Eight species of perennial forbs comprised 4.36 percent of relative cover. Four shrub species, dominated by big sagebrush and birdsfoot sagebrush (*Artemisia pedatifida*), provided 7.12 percent relative species cover. Two halfshrubs, fringed sagewort and granite pricklygilia (*Leptodac-tylon pungens*), contributed 1.15 percent relative species cover. Succulents provided 3.67 percent relative species cover. Bare soil and litter/rock percentages were 31.48 and 30.84, respectively.

Utilizing the minimum sample number formula outlined in WDEQ, LQD Rules and Regulations, Appendix A (March, 1989), sample adequacy was not attained for total vegetation cover but was attained for total cover. Based on sample data, 54 and 16 points were required to attain adequacy for total vegetation and total cover, respectively. The maximum of 50 points, as outlined in the WDEQ rules and regulations, was actually sampled.

Refer to Table 3 for a summary of the Grassland south study area cover data. Refer to Table 16 for sample adequacy figures for Total Vegetation Cover and Total Cover.

11/21/97*683

Sagebrush/Grassland North

Absolute total vegetation cover (40.17 percent) was dominated by cool season perennial grasses (54.99 percent of relative cover for individual lifeform sub-totals). Major cool season perennial species included threadleaf sedge and needle-and-thread. Warm season perennial grasses accounted for 11.75 percent of relative species cover, and was dominated by blue grama. Two species of annual grasses accounted for 1.33 percent of relative species cover. Eight species of perennial forbs comprised 4.21 percent of relative cover. Three shrub species, dominated by big sagebrush, provided 24.39 percent relative species cover. Two halfshrubs, Gardner's saltbush (*Atriplex gardneri*) and granite pricklygilia, contributed less than one percent relative species cover. Succulents provided 2.22 percent relative species cover. Bare soil and litter/rock percentages were 20.92 and 38.92, respectively.

Utilizing the minimum sample number formula outlined in WDEQ, LQD Rules and Regulations, Appendix A (March, 1989), sample adequacy was attained for total vegetation and total cover. Based on sample data, 22 and 3 points were required to attain adequacy for total vegetation and total cover, respectively. Twenty-four points were actually sampled.

Refer to Table 4 for a summary of the Sagebrush/Grassland north study area cover data. Refer to Table 16 for sample adequacy figures for Total Vegetation Cover and Total Cover.

Sagebrush/Grassland South

Absolute total vegetation cover (37.07 percent) was dominated by cool season perennial grasses (48.48 percent of relative cover for individual lifeform sub-totals). Major cool season perennial species included threadleaf sedge and needle-and-thread. Warm season perennial grasses accounted for 19.51 percent of relative species cover, and was dominated by blue grama. Five species of perennial forbs comprised 1.52 percent of relative cover. Three shrub species, dominated by big sagebrush, provided 24.62 percent relative species cover. Three halfshrubs, fringed sagewort, common name (*Artemisia ludoviciana*), and broom snakeweed (*Gutierrezia sarothrae*), contributed less than one percent relative species cover. Succulents provided 5.3 percent relative species cover. Bare soil and litter/rock percentages were 30.67 and 31.93, respectively.

Utilizing the minimum sample number formula outlined in WDEQ, LQD Rules and Regulations, Appendix A (March, 1989), sample adequacy was attained for total vegetation and total cover. Based on sample data, 27 and 10 points were required to attain adequacy for total vegetation and total cover, respectively. Thirty points were actually sampled.

11/21/97-633

D-8-29

23/18

Grassland South (cont.)

Refer to Table 8 for a summary of the Grassland south study area production data. Refer to Table 17 for sample adequacy figures for production.

Sagebrush/Grassland North

The ANP of the Sagebrush/Grassland north study area averaged 35.10 g/m² or 313 lbs./ acre. Cool season perennial grasses accounted for 26.42 g/m² (approx. 78%) of the total productivity; warm season perennial grasses 2.12 g/m² (approx. 6%); perennial forbs 2.67 g/m² (approx. 8%); and halfshrubs 1.01 g/m² (approx. 3%). Annuals, including grasses and forbs, accounted for 1.59 g/m² (approx. 4%) of the total productivity. Perennial species with the greatest productivity included needle-and-thread, prairie junegrass (*Koeleria macrantha*), threadleaf sedge, and western wheatgrass.

Utilizing the minimum sample number formula outlined in WDEQ, LQD Rules and Regulations, Appendix A (March, 1989), sample adequacy was attained for production in the north study area. Based on sample data, 8 sample points were required to attain adequacy for production based on the recommended d and Z values for shrublands. Therefore, 23 points were sampled.

Refer to Table 9 for a summary of the Sagebrush/Grassland north study area production data. Refer to Table 17 for sample adequacy figures for production.

Sagebrush/Grassland South

The ANP of the Sagebrush/Grassland south study area averaged 28.99 g/m² or 258 lbs./ acre. Cool season perennial grasses accounted for 20.15 g/m² (approx. 72%) of the total productivity; warm season perennial grasses 6.46 g/m² (approx. 23%); perennial forbs 1.07 g/m² (approx. 4%); and halfshrubs 0.12 g/m² (less than 1%). Annuals, including grasses and forbs, accounted for 0.07 g/m² (less than 1%) of the total productivity. Perennial species with the greatest productivity included needle-and-thread, threadleaf sedge, prairie junegrass, and blue grama.

Utilizing the minimum sample number formula outlined in WDEQ, LQD Rules and Regulations, Appendix A (March, 1989), sample adequacy was attained for production in the south study area based on WDEQ suggested d and Z values for shrublands. Based on sample data, 11 sample points were required to attain adequacy for production, and, therefore, 21 points were sampled.

Refer to Table 10 for a summary of the Sagebrush/Grassland south study area production data. Refer to Table 17 for sample adequacy figures for production.

(vii) Trees, Shrubs, Stock Ponds, Disturbed, and Developed Sites

Trees

Scattered plains cottonwood (*Populus deltoides*) are present in the region but not within the boundaries of the individual study areas. Often individuals are partially dead and trunks are twisted and deformed. Peachleaf willow (*Salix amygdaloides*), with a characteristic clumped growth habit (several tree trunks sprouting from a central root system), are present in the region also but not within the individual study areas.

Shrubs

Shrub density information was collected on the individual study areas. Raw data are presented in Tables 12 through 15.

Within the Grassland north study area, an average of 18,673 shrubs/hectare was determined. Fringed sagewort was the most frequently encountered shrub. Other shrubs, full or half, encountered during sampling include birdsfoot sagebrush, silver sagebrush, granite pricklygilia, wild buckwheat (*Eriogonum sp.*), big sagebrush, Gardner's saltbush, green rabbitbrush (*Chrysothamnus viscidiflorus*), broom snakeweed, rubber rabbitbrush (*Chrysothamnus nauseosus*), black sagebrush (*Artemisia nova*), common winterfat (*Ceratoides lanata*) and Wood's rose (*Rosa woodsii*).

Within the Grassland South study area, an average of 8,968 shrubs/hectare were determined. Birdfoot sagebrush and big sagebrush were the most frequently encountered shrubs. Other shrubs, full or half, encountered during sampling include fringed sagewort, green rabbitbrush, granite pricklygilia, silver sagebrush, wild buckwheat, Gardner's saltbush, rubber rabbitbrush, common winterfat, and yucca (*Yucca glauca*).

Within the Sagebrush/Grassland north study area, an average of 21,069 shrubs/hectare was determined. Big sagebrush and fringed sagewort were the most frequently encountered shrubs. Other shrubs, full or half, encountered during sampling include silver sage, birdsfoot sagebrush, green rabbitbrush, Gardner's saltbush, wild buckwheat, granite pricklygilia, common winterfat, broom snakeweed, and rubber rabbitbrush.

Within the Sagegrass South study area, an average of 17,966 shrubs/hectare were determined. Big sagebrush and birdsfoot sagebrush were the most frequently encountered shrubs. Other shrubs, full or half, encountered during sampling include green rabbitbrush, fringed sagewort, granite pricklygilia, broom snakeweed, silver sagebrush, common winterfat, rubber rabbitbrush, and Gardner's saltbush.

11/21/97-633

D-8-32

(vi) Sample Adequacy

Sample adequacy was tested for each of the study area vegetation types using the following formula:

$$n_{\min} \geq \frac{2(sz)^2}{(dx)^2}$$

Where n_{\min} = minimum number of sampled line transects or clipping quadrats needed to adequately represent a given vegetation type.

s = sample standard deviation,

z = the z statistic (see table below),

d = amount of reduction desired (see table below),

x = sample mean for cover and production,

Note Standard deviation presented in all the tables uses "n" in the denominator rather than "n-1". The more recent handheld calculators use "n-1" while the older version of LOTUS (spread sheet) program, used to derive the table figures, uses "n". This applies to all cover, production, and density summary tables.

z Statistic and d Table

	<u>z</u>	<u>d</u>
Productivity, grasslands	0.84	0.2
Productivity, shrublands	0.84	0.2
Cover, grasslands	1.28	0.1
Cover, shrublands	1.28	0.1

d. DISCUSSION.

Within the two individual study areas, transition between the two major vegetation types is dynamic and boundaries are often obscure. Every effort was made to refine existing mapping; however, it should be noted that map boundaries are often gross estimations of actual boundaries. Small inclusions of either vegetation type were not mapped. Although narrow drainage bottoms support generally higher productivity, these areas were not delineated in mapping and may contain actual sample points.

Locations of the major vegetation types were often linked to existing geologic features and resulting soil formation. Ridgetops often contained sandy soil material and were associated with the Grassland vegetation type, specifically in the south study area. Flatter topography with generally deeper soils were more characteristic of the north study area. The loamy or clay loamy soils supported more deeply rooted species and resulted in more expanses of the Sagebrush/Grassland vegetation type. Silver sagebrush is often associated with deeper soils and is present in the north study area.

11-21-00-683

3 2/73

d. DISCUSSION. (cont.)

Higher sampling variability was found in the Grassland south study area, specifically with productivity. This may be due, in part, to the topographic extremes noted in the south study area. Some points may have fallen within the "ironstone phase" which would result in very small productivity levels. The same variability was noted within the Sagebrush/Grassland points for similar reasons. Extreme required sample numbers were not noted within the Sagebrush/Grassland vegetation type since the formula used to derive those numbers takes into account that variability in shrublands.

Shrub density was generally higher in the north study area. Within the Grassland vegetation type, halfshrubs were much higher in number within the north study area. Full shrubs were approximately equal between the two study areas within the Sagebrush-/Grassland vegetation type. However, the amount of silver sagebrush was approximately 9-10 times higher in the north study area.
