**Figure 2.5.1-266 Magnetic Reversal Map of Oceanic Crust and Fracture Zones East of Bahama Platform**

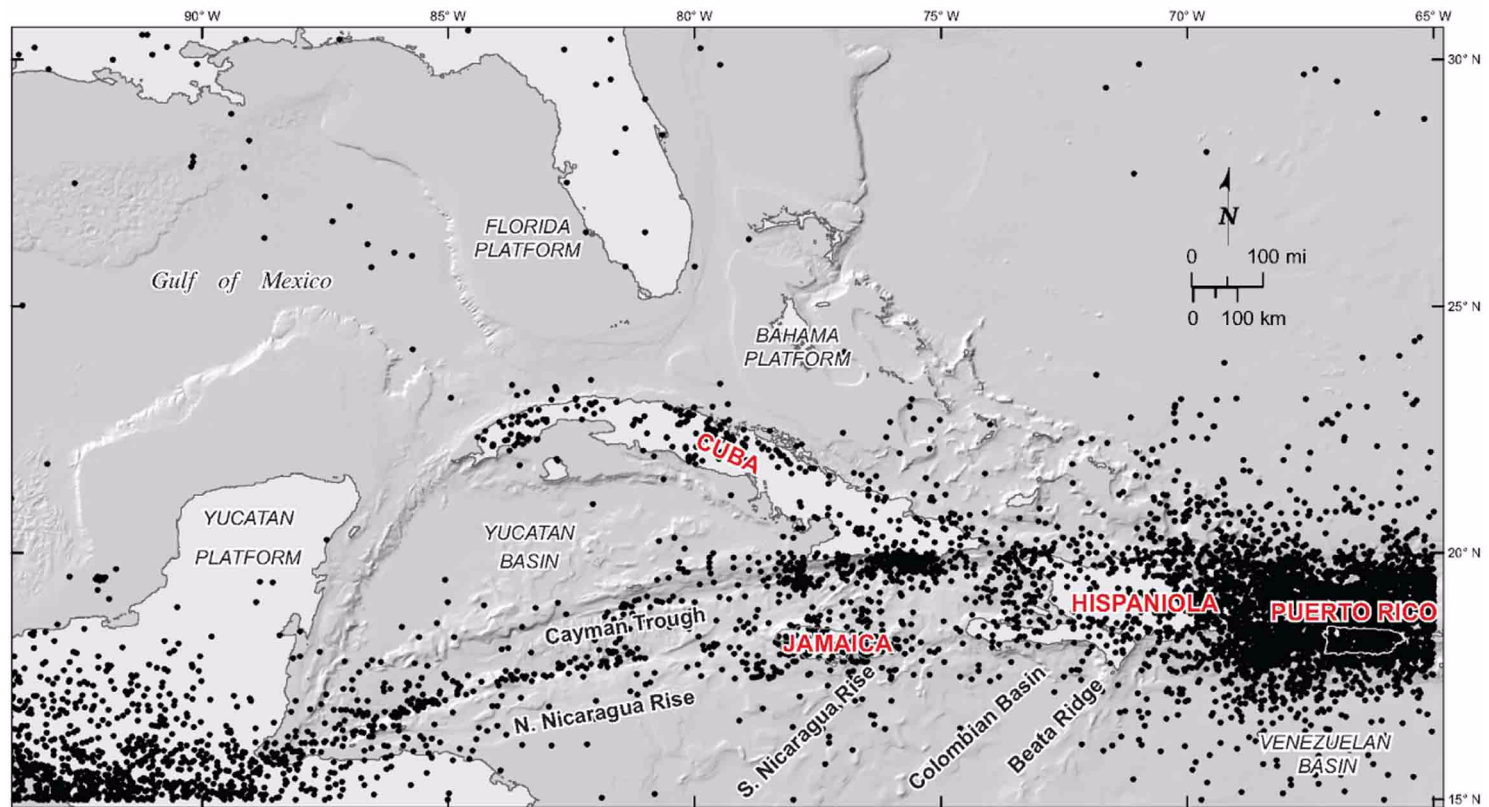

Notes: Fracture zones (thick black) and geomagnetic isochrons—North America. Chrons mapped by [Reference 466](#) are blue; global Chrons are green. Control points used for plate reconstructions are located at the intersections of fracture zones, and isochrons are yellow circles. Inverted red triangles and heavy red lines are locations of refraction data that indicate oceanic crust. The East Coast Magnetic Anomaly (ECMA) and the Blake Spur Magnetic Anomaly (BSMA) are subparallel to the coast (magenta). Dark-purple lines are the mappable limits of continental (CB) and oceanic crust (OB). The Blake Spur Fracture Zone (BSFZ) is indicated by heavy, dashed, light-gray line. Yellow shaded area corresponds to continental extension of the Blake Plateau. The magnetic anomaly correlation example is outlined by the green box.

**Figure 2.5.1-268 Seismic Line and Interpretation, with Correlation to Great Isaac 1 Well, Bahama Platform**

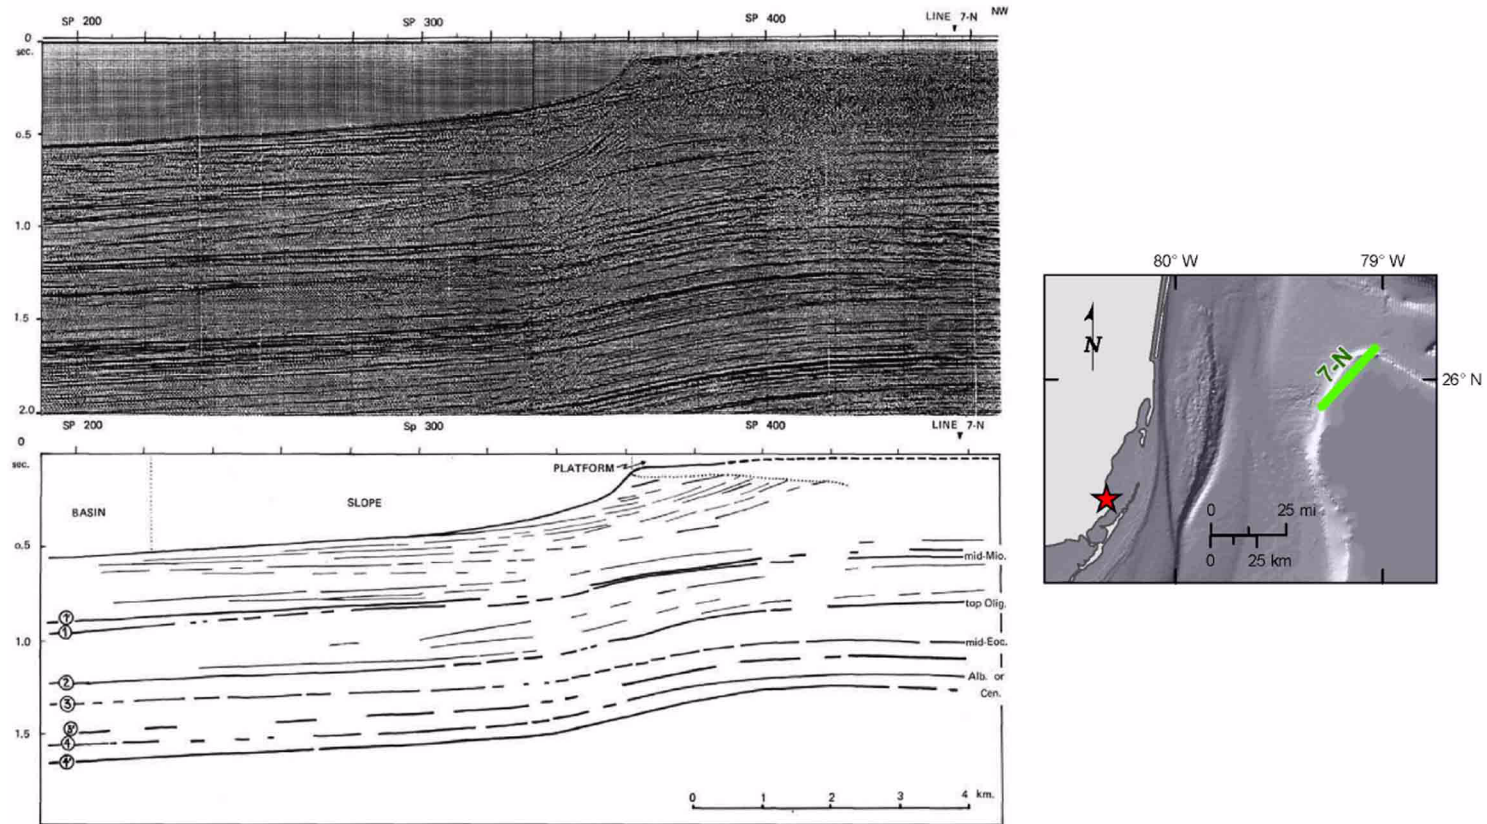

Notes:

- Circled numbers refer to reflectors traced to line 7-N (Figure 2.5.1-269).
- Dotted line delimits diachronous boundary of incoherent slope facies.
- Line cuts across lobe of Great Bahama Bank so that well represents innermost position on bank with thickest development of proximal slope facies.
- South-southwest and north-northwest ends of line approach present bank margin where only upper section is developed as proximal slope facies.

**Figure 2.5.1-269 Seismic Line of Northwest Great Bahama Bank**

**Notes:**

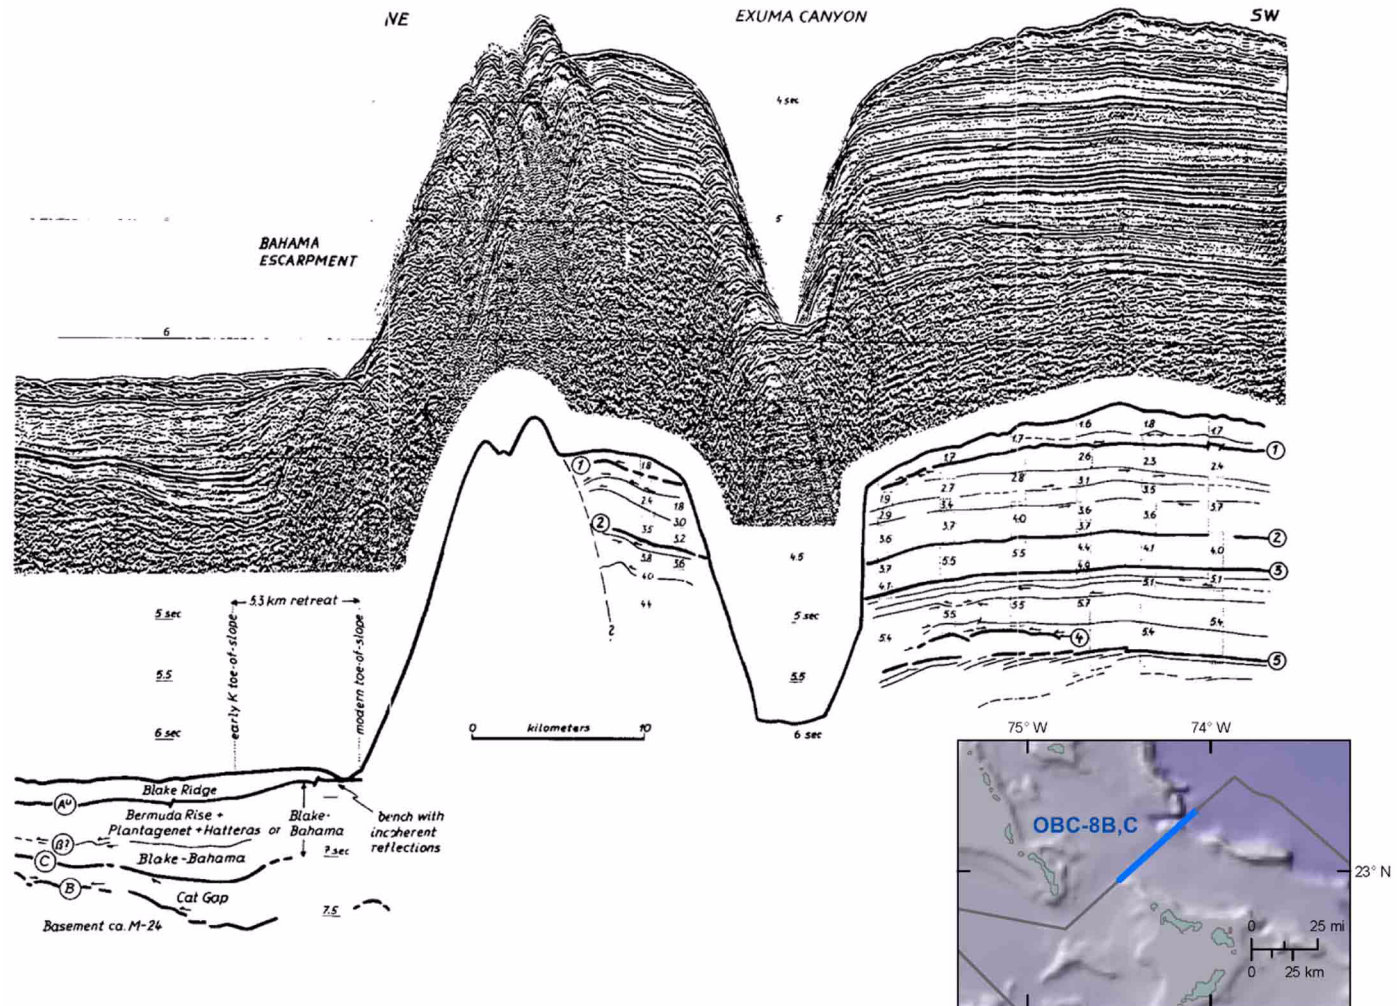

- Circled numbers indicate reflectors identified on line 5A-N (Figure 2.5.1-268).
- Basin, slope, and platform environments are separated according to present-day topography.
- Boundary between basin and slope is drawn at a slope tangent of 0.025 (1.4°) and marked by a dotted line.

**Figure 2.5.1-271 Seismic Line and Interpretation across Bahama Plateau**

Note: Line showing complex filled Straits of Andros separating Andros bank from Bimini bank and westward-prograding margin of Bimini bank. Note that basal, high-amplitude reflector E is on same elevation within both banks but is displaced at western side of Andros bank and dips into Straits of Andros, where it underlies first reflectors of filling deposits. Compare structural similarities of western margin of Bimini and Andros banks and evolution of prograding sequences over slope deposits.

**Figure 2.5.1-273 Seismic Line and Interpretation across Florida Platform**

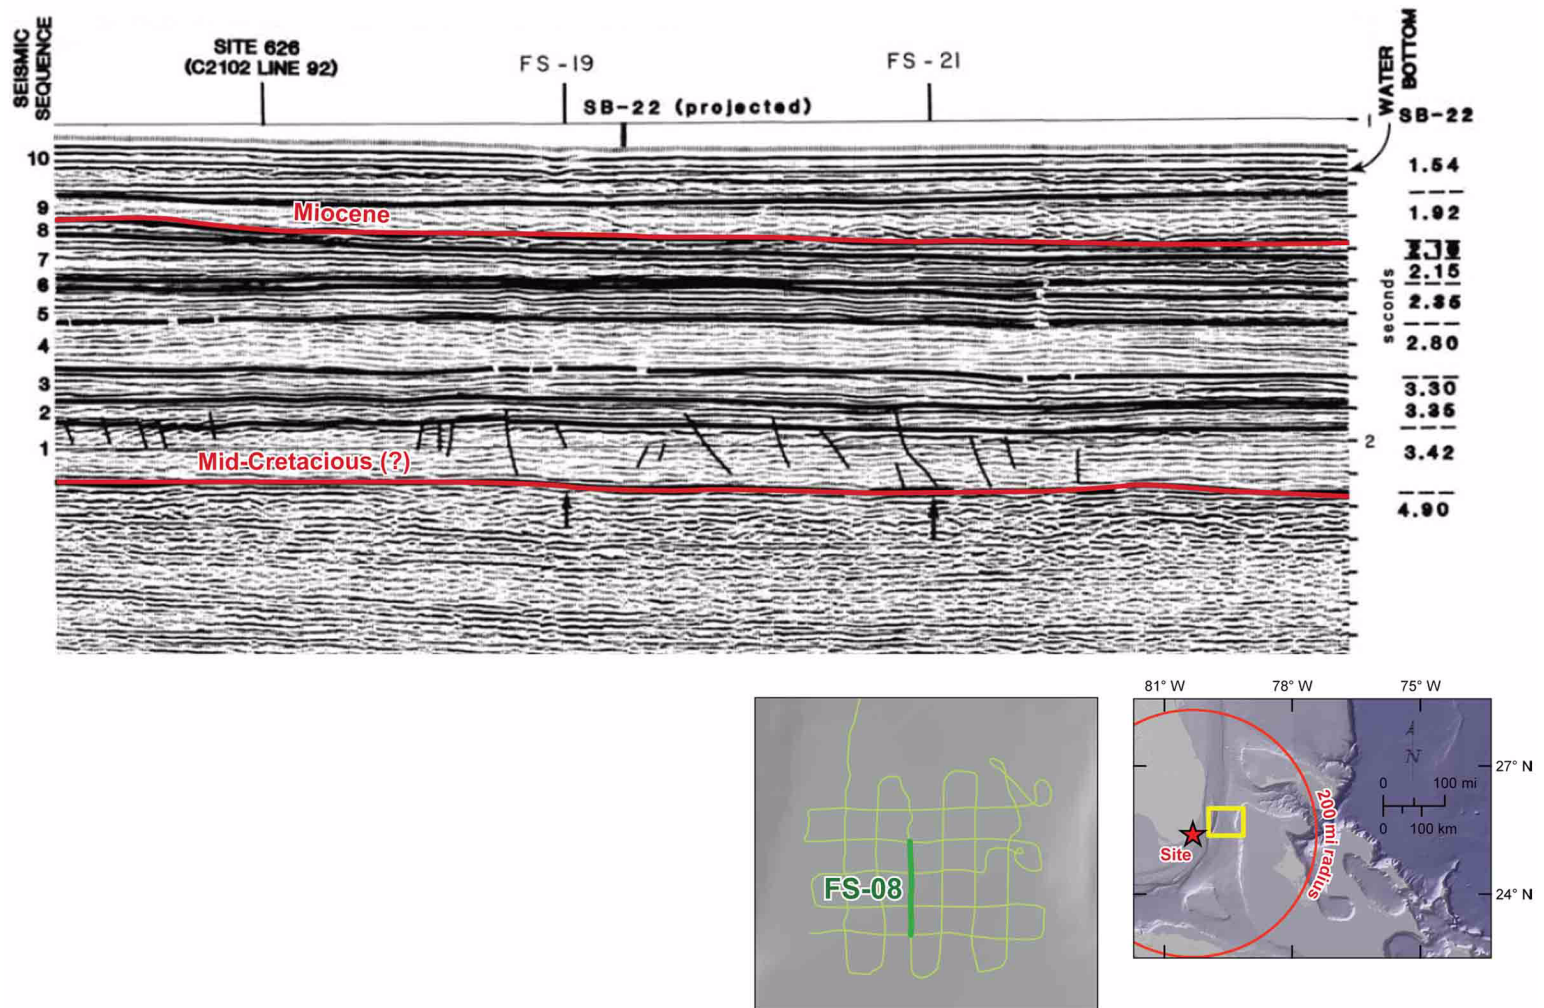

Note: Truncation of lower Paleocene–lower Eocene (?) sediments by S.4 may be related to erosion beneath a proto–Florida Current, which appears to have been concentrated over the central part of the southern Straits of Florida. Offset of S.5 and older horizons suggests a down-to-the-west normal fault at shot point 3210. At similar water depths (i.e., shot points 3400 and 3150), S.1 is at a deeper two-way travel time on the downthrown side of an inferred fault than on the upthrown side, suggesting this feature is not merely a velocity anomaly beneath the submarine canyon. Truncation by S.5 on the western flank of the submarine canyon may indicate this feature was active by the late middle Eocene.
