River level is effected mainly by rains in northeast Ga. The plant enters the abnormal low river level procedure at 62.5, the level may actually go above this level (it did last week) but they will stay in the procedure throughout the summer normally (past two dry years). The procedure essentially has them clean/run screens and monitor level frequently.

Did the rains this week-end raise the river level?

Are they in any abnormal/off-normal/alarm response procedures due to low river level?

Respectfully,
