## 1.0 INTRODUCTION

### 1.1 Purpose

The purpose of this document is to provide estimated inventories of radiological and chemical constituents in the residual material in the H-Area Tank Farm (HTF) waste tanks and ancillary equipment at the time of closure to support Performance Assessment (PA) modeling.

### 1.2 Scope

The estimated inventories apply to the 29 underground waste tanks and specified ancillary equipment in HTF and include radiological and chemical waste constituents based on projections of total HTF tank residual material at closure.

### 1.3 Waste Tank Closure Inventory Approach

The Savannah River Site (SRS) used the following general approach for estimating radiological and chemical inventories for use in the HTF PA:

- The contaminant screening process consisted of several steps to arrive at an appropriate list of isotopes to be included in the HTF closure inventory estimates to be used in the HTF PA modeling. An initial radionuclide screening process was developed and performed to evaluate 849 isotopes. [CBU-PIT-2005-00228]
- A screening process was also utilized to develop the list of chemical constituents.
- Initial inventory estimates were developed using both residual material concentrations and volumes estimates.
- Adjustments were made to the initial inventory estimates to develop the final inventory estimates. These adjustments were made to produce reasonable conservative estimates.
- The Type II tank annuli (Tanks 13 through 16) were assumed to contain residual material, including the sand bed beneath the primary liner.
- The sand bed beneath the Tank 16 secondary liner was assumed to contain residual material.

This methodology incorporated lessons learned from previous PA inventory estimates and recent closure sample analyses from Tanks 5, 18, and 19.

After a waste tank is cleaned, the estimated inventory used in the HTF PA will be replaced with the actual inventory for that tank, which will be developed using the residual material volume and analytical data from a statistically based sampling program of the residual material after cleaning the tank. During the closure process for each waste tank, this actual tank inventory will be used to determine projected dose and risk impacts for that tank.

Key elements of this approach are discussed, beginning with the residual solids initial inventory. The estimated radiological and chemical inventories in each HTF waste tank developed using this approach appear in Tables 3.3-1 and 3.3-2, respectively.

## 2.0 INITIAL RESIDUAL INVENTORY ESTIMATES

This section begins with a summary of how the tank waste initial inventory estimates have been made, identifying the residual volume and concentration estimates to be used to support the

development of the inventory estimates used in the HTF PA. This section concludes with a discussion of residual material in areas other than the tank floor.

## 2.1 Constituent Selection

An initial radionuclide screening process was developed and performed to evaluate 849 isotopes. [CBU-PIT-2005-00228] Following the steps described in detail in Appendix A, the list of isotopes to be evaluated was reduced to 159 isotopes of concern for additional evaluation. The 159 isotopes are presented in the Table A.0-1.

The 159 isotopes resulting from the initial screening were further evaluated to determine which isotopes could be eliminated from the initial list. This process eliminated additional isotopes based on short half-life, the presence or absence of parent radionuclides, and the expectation in the waste inventory. The elimination process is described in Appendix B and presented in Table B.0-1.

In addition to the isotopes eliminated in Table B.0-1, the following daughters were also eliminated: Nb-93m, Sb-126, and Sb-126m. At the conclusion of the elimination process, only the radionuclides that required further evaluation remained for inclusion in the HTF PA and are shown in Table 2.1-1.

**Table 2.1-1: Radionuclides of Concern for the HTF PA**

Ac-227	Cl-36	Eu-152	Pa-231	Ra-226	Th-232
Al-26	Cm-243	Eu-154	Pd-107	Ra-228	U-232
Am-241	Cm-244	H-3	Pt-193	Se-79	U-233
Am-242m	Cm-245	I-129	Pu-238	Sm-151	U-234
Am-243	Cm-247	K-40	Pu-239	Sn-126	U-235
Ba-137m	Cm-248	Nb-94	Pu-240	Sr-90	U-236
C-14	Co-60	Ni-59	Pu-241	Tc-99	U-238
Cf-249	Cs-135	Ni-63	Pu-242	Th-229	Y-90
Cf-251	Cs-137	Np-237	Pu-244	Th-230	Zr-93

The list of chemical constituents that were included in the PA modeling was derived from a screening process consisting of several steps to arrive at an appropriate list of constituents to be included in the waste tank closure inventory estimates. The approach was used for screening the chemicals of interest in Tanks 18 and 19 and since the chemical constituents for both F-Area Tank Farm (FTF) and HTF are the same; therefore using the developed list was appropriate.

During the closure process for each waste tank, the actual tank inventory will be used to determine projected dose and risk impacts for that tank.

Chemical and radiological constituents in the waste tanks are known from tracking waste data based on process sample analysis, process histories, composition studies and theoretical relationships. The screening process originated using the current listing of the chemical and radiological constituents found in the tank waste listed in Information on the Radiological and Chemical Characterization of the Savannah River Site Tank Waste as of July 5, 2011. [SRR-LWE-2011-00201]

The constituents' list was compared to the chemicals list in the State Primary Drinking Water Regulation (SCDHEC R.61-58) maximum contaminant level (MCL) table, the United States

Environmental Protection Agency (EPA) Region 9 Regional Screening Levels (RSL) Summary Table June 2011 (<http://www.epa.gov/region9/superfund/prg/>) and the Resource Conservation and Recovery Act (RCRA) Identification and Listing of Hazardous Waste, Appendix VIII – Hazardous Constituents (40 CFR 261\_App VIII). If any of the chemical constituents existed on the regulatory lists, the chemical was added to the chemicals of concern list. Several constituents, benzene, tributyl phosphate (TBP), and n-butanol, have been excluded based on process knowledge. [SRR-CWDA-2011-00162] In HTF, tetraphenylborate (TPB) was used as part of a previous Cs-137 separation process and is currently present in Tank 48. Some TPB was sent to Tanks 49 and 50 as part of the process. This chemical degrades into benzene. Both of these constituents, tetraphenylborate and benzene, are expected to be completely removed and therefore are not included in this inventory estimate. However, these tanks will need to address both of the constituents at the time of closure. Table 2.1-2 lists the chemical constituents of concern for the HTF PA.

**Table 2.1-2: Chemical Constituents of Concern for the HTF PA**

Ag	Co	Mn	Sb
Al	Cr	Mo	Se
As	Cu	Ni	SO <sub>4</sub>
B	F	NO <sub>2</sub>	Sr
Ba	Fe	NO <sub>3</sub>	U
Cd	Hg	Pb	Zn
Cl	I	PO <sub>4</sub>	

At the time of tank closure, sampling and analysis will be performed. During residual characterization for closure, constituents listed in Tables 2.1-1 and 2.1-2 will be analyzed, although only highly radioactive radionuclides (HRRs) will be quantified. Those that are not detectable or below detection limits will be determined via special analysis (e.g., ratios to other radionuclides or fission yields) in order to conduct an appropriate comparison to the PA estimated residual inventory.

## **2.2 Initial Constituent Concentration Estimates**

The concentration for each constituent was estimated by using the Waste Characterization System (WCS) or using physical relationships. The concentration (in Ci/gal) is calculated by dividing the dry sludge activity (curie) by the corresponding settled sludge volume (gallon) extracted from WCS. Where appropriate, zeolite volume is taken into account.

### **2.2.1 The Waste Characterization System**

The WCS is an electronic information system that tracks waste tank data, including projected radiological and chemical inventories, based on sample analyses, process histories, composition studies, and theoretical relationships. The system (initially developed in 1995) tracks the dry sludge concentrations of 40 radionuclides and of 37 chemical waste compounds in each of the SRS waste tanks. The 40 radionuclides tracked in the WCS were selected primarily based on their impact on tank safety basis source term, inhalation dose potential, or on the E-Area Vault Waste Acceptance Criteria.

### ***2.2.1.1 Use of the Waste Characterization System***

The WCS consists of two functional areas: (1) a sample data repository and (2) waste characterization. The waste characterization area contains inputs and calculations used to represent real-time conditions in the waste tanks. These real-time conditions are used to determine compliance (as input to safety basis calculations) with several nuclear safety administrative control programs such as tank flammability control and a waste tank corrosion control. Tracked dry sludge activity inventories for each tank and volume of settled sludge for each tank are extracted directly from WCS.

### ***2.2.1.2 Updating the System***

The WCS is routinely updated to reflect changes in waste inventory resulting from the receipt of new waste from the SRS canyon facilities, the Effluent Treatment Project (ETP), or recycle waste from the Defense Waste Processing Facility (DWPF). Additionally, WCS is updated to reflect changes due to the transfer of waste for processing at the DWPF or Saltstone Disposal Facility (SDF), and new characterization information in the form of sample analysis results, field measurements, waste tank video inspections, or technical reports. The tank contents in WCS are also adjusted to reflect the impacts of evaporator operation and to account for tank to tank transfers. [WSRC-TR-2003-00048]

### ***2.2.1.3 Quality Assurance***

The WCS is a controlled database that complies with strict Quality Assurance (QA) requirements. The QA requirements apply to not only data entry but also configuration control of the database software itself. All data entries into WCS must be independently verified. A Software Quality Assurance Plan governs the methods that must be utilized to maintain the database baseline configuration and to ensure the proper handling of the database. [B-SQP-H-00041]

### ***2.2.1.4 Conservatism***

The WCS generated values are generally conservative because each reactor spent fuel assembly that was reprocessed is assumed to have received the maximum burn-up possible, and therefore the amounts of actual fission products contained in an assembly were actually less than those entered into WCS. [LWO-PIT-2007-00025] Another factor expected to provide additional conservatism is the likelihood that actual concentrations for some constituents in the residual sludge on the waste tank bottoms after tank cleaning will be significantly less than the concentrations for dried sludge currently given in the WCS. This condition is expected to result from the use of Oxalic Acid (OA) to clean the tanks.

## **2.2.2 Other Constituents Not Addressed in the WCS**

### ***2.2.2.1 Radionuclides and Chemicals***

In addition to the nuclides tracked in WCS, updated special analysis methods provided estimates for additional isotopes. Methods used to estimate the inventories of the additional 30 isotopes, as described in the report for the updated HTF inventory projections, are shown in Table 2.2-1. [SRR-LWE-2009-00014] These inventories were based on the tank entrained sludge radiological contents and radiological alpha contents.

For a number of radionuclide concentrations (i.e., Cl-36, K-40, Pd-107, Pt-193, and Zr-93) not estimated in the report for the updated HTF inventory projections, detection limits based on Tanks 5, 18 and 19 were used to estimate their inventories. The detection limits used are discussed in Section 3.0.

Also, there were other constituents for which WCS did not estimate an inventory for all HTF tanks. Therefore, these radionuclide concentrations were estimated only for waste tanks where no values were present in WCS. The isotopes requiring additional estimates were Ba-137m, Cl-36, H-3, K-40, Pd-107, Pt-193, Ra-226, Ra-228, Th-229, Th-230, Th-232, U-232, U-234, U-236, Y-90, and Zr-93. Also, additional estimates were required for the antimony, arsenic, barium, boron, cadmium, fluorine, nickel, manganese, molybdenum, nitrate, nitrite, selenium, silver, and zinc chemical inventories. These estimates were based on the average concentration of similar tank types and material.

The estimate methods used are described in Table 2.2-1.

**Table 2.2-1: Initial Concentration Estimate Method**

Constituent	Estimate Method
Ba-137m	Secular equilibrium with Cs-137 based on its decay chain.
C-14	An average C-14 HTF concentration. [SRR-LWE-2009-00014]
H-3	Interstitial liquid concentration. [X-ESR-G-00004]
Y-90	Secular equilibrium with Sr-90.
B	Conservative concentration based on Tanks 5, 18, 19, 40, and 51 sample analysis
Mo	Conservative concentration based on Tanks 5, 18, 19, 40, and 51 sample analysis

Tank 16 underwent sludge removal and cleaning which was completed in 1980. After the final acid wash in 1980 and prior to the final water rinse, a 3 inch diameter sample pan was installed on the bottom of Tank 16 and remained there until the waste tank bottom had dried. Analysis of the material was performed and an estimated inventory was generated. The analysis was performed on a limited number of radionuclides. [DPST-81-441] Due to the number of constituents needed to be estimated and lack of actual sample analysis, Tank 15 was designated as a surrogate for Tank 16. Tank 15 was chosen because during sludge removal from Tank 16, material was transferred to Tank 15.

**2.2.2.2 Accounting for Zeolite**

Certain waste tanks contain zeolite in addition to the sludge material. Liquid overheads from the evaporator systems were treated in cesium removal columns containing zeolite, which functions as a molecular sieve. In HTF, these columns were located on Tanks 24, 32, and 42.

When the zeolite became loaded, the spent zeolite resins and captured cesium were discarded into the waste tanks. Spent zeolite was transferred into Tanks 38, 40, and 51. [CBU-PIT-2005-00099]

The estimated radiological and chemical concentrations for Tanks 24, 32, 38, 40, 42, and 51 have been adjusted to account for the zeolite and corresponding captured cesium.

The solids (sludge and zeolite) concentrations assume that zeolite will remain unchanged during the waste removal processes. Experience with Tanks 18 and 19 has shown that the only element that accumulated on zeolite under actual in-tank conditions was cesium. The

zeolite volume fractions were calculated with the assumption that zeolite weight and volume fractions are the same in residual material.

### 2.3 Estimated Residual Volumes

The initial residual volume estimates were based on waste removal experience. Tanks 5, 6, 16, 18, and 19 have been through the waste removal process. The residual volumes from those events are listed in Table 2.3-1.

**Table 2.3-1: Waste Removal Process Residual Volumes**

Tank	Residual Volume (gal)
5	1900
6	3000
16	220*
18	3900
19	2000

\* Estimated

Based on this experience, the projection for the residual material volume was conservatively estimated to be 4000 gallons. The residual volume in Tank 16 has been estimated at 220 gallons. To provide a reasonably conservative estimate for Tank 16, 1000 gallons was used as an estimate of residual material volume.

The inventories of radiological and chemical constituents in residual liquid were assumed to be included in the final closure solids inventory as the residual liquid has typically evaporated by the time samples are taken from the tank.

Inventories inside failed cooling coils and on the surface of the waste tank walls, cooling coils, and columns were assumed to be encompassed by the estimated total tank inventories shown in Tables 3.3-1 and 3.3-2 for the following reasons: (1) cooling coils with the potential for waste holdup will be internally inspected and/or flushed and (2) flushing is expected to remove essentially all waste that may have entered damaged coils. Flushing of damaged coils will include both inlets and outlets to ensure both sides of damaged coils are flushed.

Inventories associated with the surfaces of waste tank walls, cooling coils, and support columns are considered encompassed within the reasonably conservative volume of floor material. Based on the analysis of samples taken from the Tank 19 wall and Tank 5 cooling coils, the additional inventory present would be insignificant relative to the reasonable conservative volume of tank floor residuals. The results from the Tank 5 Inventory Determination showed the wall and cooling coil inventory was insignificant (<1 % of the total inventory). [SRR-CWDA-2012-00027]

### 2.4 Initial Tank Inventory

The estimated volume of residual solids was multiplied by the concentrations established, as discussed in the previous section, to estimate the inventory of radiological and chemical constituents remaining in the tanks.

## 2.5 Residual in Tank Annuli and Type II Sand Layers

Wall inspections of the waste tanks have found cracks where material has leaked in the secondary containment or annulus. The amount of material contained in the each tank's annulus has been estimated. Based on these estimates, inventories within the appropriate annuli were estimated.

All Type II tanks have both a primary and secondary sand layer. The 1 inch thick primary sand layer is between the primary and secondary liners and the 1 inch thick secondary sand layer is between the secondary liner and the basemat. Due to the material that leaked from the Type II tanks, residual material has been assumed to be present within these sand layers.

### 2.5.1 Annulus Inventories

To estimate each tank's annulus inventory, estimates of the residual volume and constituent concentrations were prepared.

#### 2.5.1.1 Annulus Volumes

Current estimates of the amount of material within the tank annuli were used to estimate the residual volumes at closure. [C-ESR-G-00003] The Type I and II tanks are known to have leaksites and material in their annuli. Table 2.5-1 shows the current material volume estimates and the assumed residual material volume estimates for estimating the annuli inventories. Type IV tanks do not have annuli and the Type III/IIIA tanks are assumed to have insignificant quantities of residual material within their annuli. Appendix C has pictures from the annuli of Tanks 9 – 15.

**Table 2.5-1: Tank Annuli Material Volume Estimates**

	Current Volume Estimate	Residual Volume Estimate (gal)
Tank 9	Material depth of 8 – 10 inches	3300
Tank 10	Material depth of 2 – 3 inches	3300
Tank 11	trace	100
Tank 12	trace	100
Tank 13	trace	100
Tank 14	Material depth of 12 – 13 inches	3300
Tank 15	trace	100
Tank 16	3300 gallons	3300

The amount of material currently in the Tank 16 annulus has been most recently estimated to be 3300 gallons. [SRR-LWE-2012-00039] For other annuli with significant volume, this volume was also used. Except of the Tank 16, the material in the annuli is expected to be highly soluble. This is due to the material originally being supernate that leaked into each annulus and dried. Therefore the 3300 gallon estimate for all other tanks is believed to be reasonably conservative. Tank 16 is expected to be an exception due to the mixture of silicon from sand blasting activities. This material is expected to limit the quantity of material removed and, is therefore the reason to use its volume as the reasonably conservative estimate for the appropriate annuli volume.

For those tank annuli with a trace amount of material, a reasonably conservative volume of 100 gallons was used.

**2.5.1.2 Annulus Concentrations**

Characterization of the material within the various annuli is limited. Few samples have been taken from annulus material and even when taken, constituents analyzed have also been limited. Recently, samples were collected from the Tank 16 annulus. Four samples were taken around the annulus and numerous constituents analyzed. These sample results were used for all tanks with annulus material. The constituents analyzed are listed in Table 2.5-2. [SRNL-STI-2012-00178]

**Table 2.5-2: Constituents Analyzed in the Tank 16 Annulus Samples**

Cs-137	Tc-99	Ag	Co	Mn	Pb
Np-237	U-233	Al	Cr	Mo	Sb
Pu-238	U-234	B	Cu	Ni	Sr
Pu-239	U-235	Ba	Fe	NO <sub>2</sub> *	U
Pu-240	U-236	Cd	Hg	NO <sub>3</sub> *	Zn
Sr-90	U-238				

\* From separate analysis [WSRC-STI-2008-00203]

The constituent concentrations assumed for the annulus material was based on these recent samples. For those constituents analyzed, the concentration reported provided the estimate of that constituent's concentration. Since the sample analysis did not include all constituents of concern, the remaining constituents were estimated.

The type of adjustment made to each constituent in the primary residual inventory estimate (Section 3.0) determined the method to estimate each constituent's concentration.

Those constituents, whose Tank 16 primary inventory was estimated by using detection limits, concentrations were estimated by taking a ratio of the primary residual volume estimate to the annulus residual volume estimate. For example, Cl-36 was estimated in the Tank 16 primary residual material via a detection limit. So, a ratio of the Tank 16 primary residual volume estimate (1000 gallons) to the annulus residual volume estimate (3300 gallons) was used to estimate the Cl-36 concentration in the annulus material.

For those constituents estimated in the Tank 16 primary via the unit curie adjustment (Section 3.0) were estimated with an equal inventory in the annulus. For example, Ac-227 was estimated in the Tank 16 primary inventory estimate at 1 Curie. Therefore, the Tank 16 annulus inventory estimate of Ac-227 was also 1 Curie.

Those constituents, with sample analysis results or considered significant to dose analysis, concentrations were based on a ratio of a chemically similar element, within the analysis, and the applicable tank primary floor residual estimate. A ratio to the Pu-238 analysis was used for the radionuclides that would tend to be insoluble, while a ratio for the Tc-99 analysis was used for the soluble components. For example, Am-241 was not analyzed in the Tank 16 annulus samples. Since Am-241 can be significant to dose analysis, its annulus concentration was estimated by using the Pu-238 sample concentration and a ratio of the Am-241 to Pu-238 primary inventories. That is the Am-241 concentration in the Tank 16

annulus material was estimated by multiplying the Pu-238 concentration by a ratio of the Am-241 Tank 16 primary inventory to the Pu-238 Tank 16 primary inventory. A ratio to the iron measurement was used for the chemical constituents not analyzed.

**2.5.1.3 Annulus Inventories**

The annulus inventories were estimated by multiplying the volume and concentration estimates and are presented in Tables 2.5-3 and 2.5-4. The decay date for these inventories is 2032.

**Table 2.5-3: Estimated Annulus Radiological Inventories (2032)**

Radionuclide	Tank 9 (Ci)	Tank 10 (Ci)	Tank 11 (Ci)	Tank 12 (Ci)	Tank 13 (Ci)	Tank 14 (Ci)	Tank 15 (Ci)	Tank 16 (Ci)

### 2.5.2 Type II Sand Layer Inventories

Based on the operational history where all the Type II tanks have formed leak sites and resulted in material accumulating on the annulus floor; the sand layer inventories were estimated by multiplying the residual concentrations by the estimated residual quantity.

#### 2.5.2.1 Sand Layer Concentration

The residual material within the sand layer was assumed to have the same concentrations as determined for the annulus material (Section 2.5.1.2).

#### 2.5.2.2 Sand Layer Quantity

The quantity estimate within the Type II tank sand layers was based on the operational history of each tank. For Tanks 14 and 16, a significant quantity of material leaked from the primary tank into the secondary containment and was sufficient to deposit material at a depth of several inches. For Tanks 13 and 15, a minimal quantity of material has leaked from the

primary tank. This is based on the inspections of the annulus floor where negligible quantities of material have been observed. The different material depths can be observed in the Appendix C pictures.

The Type II tanks have a grout pad that surrounds the primary sand layers. This grout pad would limit the flow of material into sand material. The top part of the grout pad met the bottom of the primary tank liner. For material to reach the primary sand layer, the liquid level would need to be higher than the top part of the grout pad. In Tanks 13 and 15, since the quantity of material that leaked from the primary is limited, the amount of material that moved into the sand layer is considered negligible. Following the reasonably conservative approach, 100 gallons was assumed to be present within the sand layer for Tanks 13 and 15. For Tanks 14 and 16, the depth of material in the annulus suggests the possibility of material movement into the sand layer. It is thought that little liquid material moved into the sand layer due to the tight, although not sealed, fit between the group pad and primary tank liner. Although to be reasonably conservative, the void space within these sand layers was estimated to be completely saturated with residual material.

The Type II tanks also have a secondary sand layer that is beneath the secondary liner or annulus. Tank 16 experienced the largest quantity of material leaving the tank and gathering in the annulus. In 1960, enough material filled the annulus that tens of gallons overflowed the annulus pan. [DPSPU-77-11-17\_OUO] For the purpose of this inventory evaluation, it is conservatively assumed that all of the material (26 gallons) that overflowed the annulus pan entered the secondary sand layer below Tank 16. For Tanks 13 through 15, no material has leaked beyond the secondary containment; therefore, it is assumed that the secondary sand layers below these tanks contain no inventory.

### ***2.5.2.3 Sand Layer Inventories***

The primary sand layer and annulus inventories are presented in Tables 2.5-5 and 2.5-6; however, the secondary sand layer inventory only applies to Tank 16. The decay date for these inventories is 2032.

### 3.0 INVENTORY ADJUSTMENTS

Following the development of the initial inventory estimates, adjustments were made to add a reasonable conservatism to the inventory estimates. Below is a summary of the adjustments with more detailed explanations following.

A methodical approach was used to construct estimates of HTF waste tank closure inventories to be used in PA modeling. Independent steps were developed to systematically construct the HTF tank inventories, with each step adjusting inventory either by tank or by radionuclide. The steps used in inventory development were as follows:

1. The inventory adjustment used the initial inventory estimates as the starting point (Section 2.0).
2. The waste tanks were grouped according to waste tank use and design (Section 3.2).
3. To account for uncertainty surrounding future operations and movement of material within the HTF, the maximum concentration of each radionuclide or chemical from any tank within a group was applied to the other tanks within the tank grouping (Section 3.2.1.1).

#### 3.1 Nominal Activities and Detection Limits for Radionuclides

Allowing for more efficient and cost effective means of confirming radionuclide concentrations with a limited potential impact to dose, the inventories for a group of radionuclides were adjusted to either 1 curie or used an analytical detection limit. If the radionuclide inventory estimated was less than the detection limit, then it was adjusted up to the detection limit. However, if the radionuclide inventory estimated was at least at the detection limit, then it was adjusted up to 1 curie. Recent sample analyses from Tanks 5, 18, and 19 were reviewed for appropriate detection limits. [SRNL-STI-2012-00034, SRNL-STI-2010-00386, SRNL-STI-2010-00439] The adjustments to either the detection limit or to 1 curie exclusively increased residual inventories estimates. Inventory estimates were not adjusted lower, only higher.

For those radionuclides that have been observed (through previous analyses or scoping studies) to have greater potential impact on the overall dose, the inventory was adjusted to the analytical detection limit.

Note that those radionuclides with estimated inventories greater than 1 curie were not adjusted in this step. In addition, this adjustment only applied to the radiological inventories and not to the chemical inventories.

The applicable detection limits for each radionuclide is listed in Table 3.1-1.

**Table 3.1-1: Radionuclide Detection Limit**

Radionuclide	Detection Limit ( $\mu\text{Ci/g}$ )
Cl-36	1E-04

U-235	1E-03
U-236	1E-03
U-238	1E-04

A density of 1.4 g/ml was used to estimate inventories

### 3.2 Tank Groupings

The tank type generally had an effect on the type of waste received and therefore guided the grouping. In general, each waste tank type was built at approximately the same time. The waste tanks were grouped based on use and design and are presented in Table 3.2-1.

**Table 3.2-1: Waste Tank Groupings**

Types I & II	Type III/IIIA	Type IV
Tanks 9, 10, 11, 12, 13, 14, and 15	Tanks 29, 30, 31, 32, 35, 36, 37, 38, 39, 40, 41, 42, 43, 48, 49, 50, and 51	Tanks 21, 22, 23, and 24

Note: Tank 16 is a special case with its own grouping

Based on experience with previous Performance Assessments, overestimating the Pu-238 inventories can ultimately exaggerate the projected overall dose. To reduce this exaggeration for the purpose of estimating Pu-238 inventories in the Type III/IIIA tanks, the grouping was split based on the two different waste types (salt and sludge). The groupings of the waste tanks is presented in Table 3.2-2

**Table 3.2-2: Waste Tank Groupings for Pu-238**

Types I and II	Type III/IIIA		Type IV
N/A*	Salt	Sludge	N/A*
Tanks 9 and 10, 11, 12, 13, 14, and 15	Tanks 29, 30, 31, 36, 37, 38, 41, 48, 49, and 50	Tanks 32, 35, 39, 40, 42, 43, and 51	Tanks 21, 22, 23, and 24

Note: Tank 16 is a special case with its own grouping

\*No additional criteria was attributed to this tank type group

### 3.2.1 Adjustments within each Grouping

The following adjustments were made to each tank’s inventory within each grouping.

#### 3.2.1.1 Future Operations

Within each tank group, the maximum tank inventory for any one tank was used to estimate inventory for the other tanks within the grouping due to the uncertain order of waste removal and closure activities. While a waste tank is in the closure process, material will be removed and transferred to another waste tank. This will cause the concentrations of the two waste tanks to become more similar. Since the order of waste tank closure and the transfer sequences are uncertain, all the radiological and chemical waste tank inventory within each group were adjusted to match the maximum waste tank inventory within each group.

#### 3.2.1.2 Waste Removal Process

Based on the differences in concentrations observed during the waste removal process in Tank 5, decreases in concentrations are anticipated for cesium, strontium, and zirconium. [WSRC-STI-2007-00192, SRNL-STI-2009-00492] Based on this observation, all the tank inventories of these elements were adjusted one order of magnitude lower to reflect the effect of the waste removal process.

#### 3.2.1.3 Basis Adjustment

Based on results from the Tank 5 inventory determination and FTF PA inventory estimates, the Tc-99 and Zr-93 inventories required adjustment. For Tc-99, the initial inventory estimates are believed to be overly conservative. The FTF PA estimated inventory for Tc-99 was close to three orders of magnitude higher than the final inventory. To reduce the overestimate while maintaining a reasonably conservative inventory estimate for Tc-99, each tank’s inventory was reduced by one order of magnitude. In previous versions of PA inventory estimates, Zr-93 inventory estimates were based on a detection limit value. In Tanks 5, 18, and 19, Zr-93 was measured. Therefore, using these sample results, Zr-93 was estimated by using a ratio to the Sr-90 concentrations.

### 3.3 Final Tank Inventory Estimates

The system plan calls for the last waste tank to be grouted at the end of fiscal year 2032. Therefore, all the radiological inventories have been decay corrected to 2032. After all waste inventory adjustments, the final radionuclide inventory estimates are provided in Table 3.3-1. The estimated chemical constituent inventories are provided in Table 3.3-2.

It should be kept in mind that the curies of residual radiological and the mass of residual chemical waste constituents are important to the analyses, not the estimated residual waste volume.

## 4.0 ANCILLARY EQUIPMENT

Ancillary equipment includes transfer lines, transfer line secondary containment, pump tanks, pump pits (PPs), a catch tank, diversion boxes (DBs), valve boxes, concentrate transfer system (CTS) tanks, and the evaporator systems. Over the operating life of the facility, radioactive waste comes in physical contact with some of these components, leaving behind varying degrees of contamination depending on the service life of the component, the material of construction, and the type of waste in contact with the component. Components that directly contacted waste material and were assigned an estimated modeling inventory are:

1. Transfer lines
2. Pump tanks
3. CTS tanks
4. Evaporator vessels

Other ancillary equipment, such as transfer line secondary containment, PPs, HTF catch tank, DBs, and valve boxes were not considered as part of the source term for the PA modeling.

### 4.1 Representative Sludge Slurry

The initial estimates of each tank are used to establish the characterization of the residual material in the ancillary equipment. [SRR-LWE-2009-00014] The results of a review of waste transfers within HTF and between FTF and HTF were sorted to determine the percent of the volume of all waste transfers that can be attributed to each HTF waste tank. The representative concentration was then determined by applying a weighted average to each radiological distribution in the HTF tanks. Because the characterization of dry sludge was used for each tank for conservatism, it was assumed that the sludge would have to be slurried in order to remove it from the tanks through the ancillary equipment. It is important to note that, while the sludge concentrations were used, dry sludge is only a small portion of the total waste that passes through the transfer lines that are routinely flushed with a high volume of supernate. Using the dry sludge concentrations provided a conservative representation of the actinides and long-lived isotopes. The short-lived radionuclides, which are more concentrated in the supernate than the sludge, will have decayed significantly during the 100 year active institutional control period.

The Technical Safety Requirements (TSR) limit waste transfers to less than or equal to 16.7 wt% solids and operational conditions are typically well below TSR limits. [S-TSR-G-00001] Conservatively, the slurry concentration was reduced to 20% of the dry sludge concentration. As part of this document, the weighted concentrations of radiological and chemical constituents in the slurried sludge were developed and are presented in Tables 4.1-1 and 4.1-2, respectively.

## 4.2 Transfer Line Inventory

The amount of residual material in the piping systems was determined analytically. [CBU-PIT-2005-00120] The methodology in the referenced document was used for transfer lines. The transfer line inventory estimate was based on estimating the particle residuals remaining after a transfer line is flushed.

### 4.2.1 Residue of Particles After Flushing

The transfer line core piping is flushed three times the line volume following each transfer as normal operating procedure. By performance of a mass balance, the waste concentrations follow an exponential decay curve with respect to time. [HLW-STE-99-0023]

$$C(t) = C_o e^{-\frac{Qt}{V}}$$

Where:

$$\begin{aligned} Q &= \text{Volumetric flow rate} \\ V &= \text{Volume of liquid} \\ t &= \text{time} \end{aligned}$$

Let  $F$  equal the number of flush volumes, and since  $Q = V/t$ , the previous equation becomes,

$$C = C_o e^{-F}$$

Where:

$$\begin{aligned} C_o &= \text{initial concentration} \\ F &= \text{number of flush volumes. Here, } F = 3 \text{ for the number of volumes.} \end{aligned}$$

To convert the concentration from a volume basis to a surface area basis, the following equation applies:

$$C \times \frac{\text{Volume}}{\text{Area}} = C \times \frac{\pi \frac{d^2}{4} l}{\pi dl} = C \times \frac{d}{4} = C \left( \frac{\text{Ci}}{\text{gal}} \text{ or } \frac{\text{kg}}{\text{gal}} \right) \times \frac{d}{4} (\text{in}) \times \frac{7.48 \text{ gal}}{\text{ft}^3} \times \frac{1 \text{ ft}}{12 \text{ in}}$$

-Or-

$$C_{\text{per area}} = 0.156Cd$$

Where:

$$\begin{aligned} C_{\text{per area}} &= \text{surface area concentrations (Ci/ft}^2 \text{ or kg/ft}^2\text{)} \\ C &= \text{concentration (Ci/gal or kg/gal)} \\ d &= \text{pipe diameter (inches)} \end{aligned}$$

Tables 4.2-1 and 4.2-2 present the remaining surface concentration following three flush volumes.

The gravity drain lines (GDLs) leading from the evaporators to the waste tanks have been plugged with salt waste in the past. However, they have been easily cleaned and are expected to be at least as clean as the bulk waste transfer lines after three volume

flushes. For the purpose of this calculation of transfer line inventory, the GDLs are assumed to be the same as the bulk waste transfer lines.

**Table 4.2-1: Radiological Surface Concentration by Residue After Three Volume Flush**

The total affected surface area of the transfer lines is approximately 74,100 square feet. The HTF transfer line data was obtained from the Structural Integrity Database (M-ML-G-0005), an engineering database developed to help control and maintain the technical baseline of the Savannah River Site (SRS) facilities including HTF.

The total radiological (decayed to 2032) and chemical inventories in the transfer lines using analytical methods are presented in Tables 4.2-3 and 4.2-4.

#### 4.2.2 Previous Transfer Line Inventory Methodology

The methodology in the referenced document used for transfer lines inventory used three methods to estimate the residual inventory. [CBU-PIT-2005-00120] These methods are:

1. Residue by diffusion into metal
2. Residue in the oxide film formed on the carbon steel and the stainless steel
3. Residue of particles remaining after the transfer lines are flushed

Diffusion calculations assumed a 100 year contact time and a 100°C exposure temperature. Appendix B of CBU-PIT-2005-00120 describes the methodology in which diffusion estimates are made.

Based on the previous version of this document, the principal source for the transfer line inventory is the residue particles. Diffusion into the metal and an oxide film residual were shown to be insignificant contributors to the overall transfer line inventory. For this reason, only the residue particles technique was used to estimate the transfer line inventory. [SRR-CWDA-2010-00023 Rev. 1]

To illustrate, Table 4.2-5 presents the contribution from each transfer line inventory contributor developed in a previous version of this document. [SRR-CWDA-2010-00023 Rev. 1]

**Table 4.2-5: Distribution of Estimate Contributions**

#### 4.3 Pump Tank and CTS Tank Inventory

Pump tanks differ from piping systems with respect to such features as geometry and usage. Only residue left behind after rinsing and flushing was considered for these components. After tanks are cleaned and inspected, it is expected that residual inventory will be very low. It is assumed that 0.0625 inch of residual material will remain in these vessels, consistent with the waste tank residual depth.

The representative material concentrations presented in Tables 4.1-1 and 4.1-2 were used to determine the residual inventory in pump tanks HPT-2 through HPT-10 (HTP-1 has been removed from HTF). All of these tanks are accessible for waste removal and cleaning. As described for the waste tanks, the residual for the nine pump tanks was estimated as 0.0625 inch of residue remaining on the floor of the tank. The diameter of

the base of the pump tanks is 12 feet. The residue for each pump tank was therefore estimated at approximately 4.4 gallons each.

The HTF has two CTS tanks. The CTS tanks are comparable in capacity to the pump tanks, thus a similar residual inventory is expected. Therefore, the estimated inventory, decayed to 2032, was the same for each pump tank and each CTS tank as presented in Tables 4.3-1 and 4.3-2.

#### 4.4 Evaporators

##### 4.4.1 Evaporator System Inventory

Sample characterization data for the FTF 242-F evaporator was used to estimate the residual material in each of the three evaporators in HTF. Samples were taken to estimate the characterization of residual solids for 242-F (Figure 4.4-1). Analytical results for the 242-F evaporator are shown in Tables 4.4-1 and 4.4-2. The HTF evaporators were assigned the same values as the 242-F evaporator.

A sample of the overheads was also taken during the heel removal campaign. Due to the low activity and low volume in the overheads and CTS tanks, compared to evaporators, the inventory of the overheads was not included in the inventory. Residual liquids will be removed prior to closure.

**4.4.2 242-16H and 242-25H Evaporator & Vessel**

The 242-16H and 242-25H evaporator cells and vessels remain operational. It is expected that the 242-16H and 242-25H evaporator systems will meet or exceed the decontamination levels achieved in the 242-F evaporator system. To support the PA modeling, the estimate of residues remaining in 242-F were used to estimate the residues that will remain in 242-16H and 242-25H at the time of closure.

The total remaining inventory for each evaporator vessel was estimated based on 0.3 gallons of sludge and a dry sludge density of 6.83 lb/gal. [CBU-LTS-2004-00078] The radiological (decayed to 2032) and chemical inventories are presented in Tables 4.4-3 and 4.4-4.

#### **4.4.3 242-H Evaporator and Vessel**

The 242-H evaporator cell and vessel is non-operational. It is expected that the 242-H evaporator system will meet or exceed the decontamination levels achieved in the 242-F evaporator system. To support the PA modeling, the estimate of residues remaining in 242-F were used to estimate the residues that will remain in 242-H evaporator at the time of closure.

The total remaining inventory for the 242-H evaporator vessel is estimated based on 0.3 gallons of sludge and a dry sludge density of 6.83 lb/gal. [CBU-LTS-2004-00078] The inventory has been decayed to the expected year of closure, 2032, and is previously presented in Tables 4.4-3 and 4.4-4.

### **4.5 Other Ancillary Equipment**

#### **4.5.1 Pump Pits**

The PPs are shielded reinforced concrete structures located below grade at the low points of transfer lines and are lined with stainless steel. These structures are secondary containments that house the pump tanks, and are accessible for cleaning at the time of closure. No inventory was assigned to these structures.

#### **4.5.2 Catch Tank**

There is a single catch tank in HTF designed to collect drainage from HDB-1 and the Type I tank transfer line encasements. These transfer lines run primarily from Tanks 9 through 16 to HDB-1 and HDB-2. The transfer line encasement slopes towards the catch tank to collect leakage from the transfer line core pipe and in-leakage from ground water. The catch tank is located west of HDB-1. No significant contamination has been collected in this waste tank and it was not modeled as a source for contamination in the HTF PA.

#### **4.5.3 Diversion Boxes**

The DBs are shielded reinforced concrete structures containing transfer line nozzles to which jumpers are connected in order to direct waste transfers to the desired location. The majority of DBs are located below ground and are either stainless steel lined or sealed with water proofing compounds to prevent ground contamination. These structures are accessible for cleaning at the time of closure. No inventory was assigned to these structures.

#### **4.5.4 Valve Boxes**

Transfer valve boxes facilitate specific waste transfers that are conducted frequently. The valves are generally manual ball valves in removable jumpers with flush water connections on the transfer lines. The valve boxes provide secondary containment. These structures are accessible for cleaning at the time of closure. No inventory was assigned to these structures.

## **5.0 DECAY DATE**

The system plan calls for the last waste tank to be grouted at the end of fiscal year 2032. Therefore, all the radiological inventories have been decayed to 2032.

## **6.0 RESULTING ESTIMATES**

As noted previously, Table 3.3-1 provides the estimated radionuclide inventories for HTF developed using the processes described above. Table 3.1-2 provides the estimated chemical constituent inventory in the residual waste.

Tables 2.5-3 and 2.5-5 provide the estimated radionuclide inventories within the tank annuli and Type II sand layers. Tables 2.5-4 and 2.5-6 provide the estimate chemical inventories within the tank annuli and Type II sand layers.

The transfer lines, pump tanks, CTS tanks, and evaporators residual inventory estimates are provided in Tables 4.2-3, 4.2-4, 4.3-1, 4.3-2, 4.4-3, and 4.4-4.

## **7.0 INVENTORY ESTIMATE USE**

The inventory estimates are for use in the HTF PA modeling. In using these in the PA, it should be kept in mind that the curies of residual radionuclides and the kilograms of residual chemical waste constituents are important to the analyses, not the estimated residual waste volume. While the estimated solids volume is used to calculate the residual radiological and chemical waste constituent inventories, the volume estimate is not significant in its own right.

## **8.0 INTRUDER INVENTORY**

For the intruder scenarios, an inventory removed by the intruder was estimated using a tank from the Type I/II tank grouping represented by Tank 13, a Type IV tank represented by Tank 24, a 3-inch transfer line, and a 4-inch transfer line. The residual material was assumed to be uniformly distributed across the tank floor. The well diameter was assumed to be 8 inches. The inventories used for the well drilling scenarios are provided in Tables 8.0-1 and 8.0-2.

## 9.0 INVENTORY STOCHASTICS

The waste tank and ancillary equipment inventories in the GoldSim HTF transport model control the total amount of contaminants available for release. Sections 3.0 and 4.0 describe the basis for estimates of residual radiological inventory in the HTF waste tanks and ancillary equipment.

The process used to estimate each waste tanks' residual material at operational closure created estimates that were both bounding and reasonable. Estimates were developed for all radionuclides and chemicals expected to occur in the HTF, but those components expected to affect dose are closely scrutinized, and the values selected are intended to provide conservatism over what is expected to remain at operational closure.

The initial inventories are considered conservative estimates. For instance, in estimating residuals from reprocessed reactor spent fuel, maximum burn-up is assumed, consequently certain radionuclide byproducts are also maximized. An unknown amount of residual material characterized as fission products bearing Plutonium Recovery and Extraction (PUREX) Low Heat Waste actually originated as cladding waste or other low radionuclide bearing wastes that contain relatively small amounts of fission products. [LWO-PIT-2007-00025] Additional conservatism is added to the estimate of residuals assumed to remain in the waste tanks after cleaning. It is probable that less residuals, and thus a lower inventory of contaminants, will actually remain. These process-related uncertainties have not been quantified; instead, this uncertainty is accounted for by applying a lower and upper bound to the initial inventory estimates, using a log uniform distribution.

A comparison between actual waste tank samples and WCS estimated values was completed. Tanks 5, 18 and 19 contents have been sampled and tested to allow for a comparison. Figure 9.1-1 shows a ratio of the actual sample measure values over the

predicted WCS values for each constituent (i.e., values less than 1.0 are overestimated by WCS). The comparison of data shows that 75% of the approximately 215 sample results indicate WCS conservatively overestimated or closely matched the sample measure values. Excluding less than detection limit values, less than 25% of the sample results indicate that WCS underestimated the sample measure values. [SRS-REG-2007-00008]

Discrete multipliers are applied (between 0.01 and 10 are applied to both radionuclide and chemical elements) to the initial inventory for each radionuclide and chemical constituent. The multipliers are presented in Tables 9.1-1 and 9.1-2 and are based on the confidence in the initial estimate.

### **9.1 Revision 2 Update**

Tank 5 is in the final stages of operational closure which include sample and analysis activities. The final Tank 5 inventory determination has been completed. [SRR-CWDA-2012-00027] A comparison between the inventory estimate in the FTF PA and the final Tank 5 inventory was performed. Although Tank 5 is in F-Tank Farm, the PA inventory estimate process was similar and a comparison between estimate and final inventories provide an indication to the confidence in the multipliers used here. This comparison is presented in Figure 9.1-2. Inspection of the figure generally shows an underestimate maximum of 10. One significant underestimate, Zr-93, was resolved with this revision by adjusting the inventory basis (Section 3.2.1.3). Otherwise, a maximum of one order of magnitude is believed to a good high multiplier.

Figure 9.1-1: Sample to WCS Prediction Ratio

Figure 9.1-2: Tank 5 Sample to WCS Prediction Ratio

\*Although the Pu-238 estimates in the Type III/IIIA tanks were separated into salt and sludge tanks, the multiplier is the same for both groupings

**Table 9.1-2: HTF Chemical Inventory Multipliers**

	Probability	Multiplier
All Chemicals	0.25	0.01
	0.25	0.1
	0.25	1
	0.25	10

An initial inventory is modeled to exist in the sand pads, and in the ancillary equipment including the transfer lines. Because peak dose is driven by the initial inventory in the tanks, and because of lack of sample data to better define the uncertainty of these components, it was determined that applying uncertainty to the ancillary equipment and sand pad initial inventory was unjustified.

## APPENDIX A SOURCE TERM SCREENING

The initial radionuclide screening process developed and performed to support characterization efforts is applicable for HTF PA modeling. CBU-PIT-2005-00228 identifies how SRS performed a screening of radionuclides by initially evaluating 849 isotopes. Of the original 849 isotopes, 159 remained on the list and 690 were excluded from further consideration.

This screening process used the following information:

- physical properties of each radioisotope such as half-life and decay mechanism,
- source and handling of the waste was used in the decisions based on isotope production mechanisms and time since the isotope was produced, and
- screening factors for ground disposal of radionuclides developed in NCRP-123 which convert a quantity of each radionuclide to a dose.

The screening process performed in the initial screening was presented in CBU-PIT-2005-00228 as follows:

Step 1. Identify isotopes that were part of any of the four decay series (Actinium, Neptunium, Thorium, or Uranium) and retained for further analysis because the HTF waste was known to contain the first member of each of the series.

Step 2. Identify isotopes for which there was high-level waste sludge characterization information and retain for further analysis since these have been determined to likely be present in the waste and of importance to some aspect of the program. Note that this step may identify isotopes for inclusion that could have been screened out at some later step if they had not been so designated.

Next, the remaining list of radionuclides was examined to eliminate those isotopes which can be excluded based on the criteria presented in the following steps. Those that have very long half-lives (and correspondingly low specific activity) and those that have been screened out using the most up-to-date method presented in NCRP-123 were identified for exclusion.

Step 3. Identify isotopes for which there is no dose conversion information (typically very long lived and essentially stable isotopes). The two most comprehensive sources of information are the NCRP-123 and EPA Risk Assessment Web Site ([www.epa.gov/radiation/health](http://www.epa.gov/radiation/health)), and both of these sources were consulted. Dose Conversion Factors do not exist for these isotopes because they were not considered to merit the development of factors.

Step 4. Identify isotopes that have been screened out in NCRP-123 using the screening methodology for ground disposal.

The next part of the screening process employs some general information about an assumed residual inventory of radionuclides in high-level waste sludge that is an order of magnitude or more than expected at closure.

Step 5. Assuming a large activity level (one million curies) of any isotope remaining in the residual material, and using the screening factors from NCRP-123, identify

those that would result in a hypothetical exposure to a Member of the Public (MOP) of 1 mrem/yr or less and eliminate them from the list. Note that this analysis includes the exposure due to all daughter radionuclides.

Step 6. Assuming a large mass (1,000 lbs) of any isotope remaining in the residual material, and using the screening factors from NCRP-123, identify those that would result in a hypothetical exposure to a MOP of 1 mrem/yr or less and eliminate them from the list. Note that this analysis includes the exposure due to all daughter radionuclides.

Step 7. Identify isotopes that would not be in the waste due to their physical properties (e.g., present as a gas and released in the reactor or during fuel processing).

More specific information about the waste at the SRS is used to identify those radionuclides which can be excluded based on history of the site waste.

Step 8. Employ information about the age of the HTF waste (minimum of 15 years) to identify those radionuclides that would not be expected to be in the waste at the time of closure due to their short half-lives. Restrict this analysis to those isotopes that have no on-going source and decay directly to stable products so that no isotopes with significant daughters are prematurely eliminated.

Step 9. Employ information about the age of the HTF waste (minimum of 15 years) to identify those radionuclides that would not be expected to be in the waste at the time of closure due to their short half-lives. Apply this analysis to those isotopes that have no on-going source and decay to short-lived daughters (less than 1 year) and then to stable products so that no isotopes with significant daughters are prematurely eliminated.

Next, some basic information about the duration of institutional control combined with specific isotope characteristics can be used to eliminate radionuclides that are not going to be of future concern to MOP or worker exposure.

Step 10. Employ detailed decay scheme information to identify short-lived isotopes with no ongoing sources that will decay to stable isotopes in multiple short steps. This step requires the careful review of each decay scheme individually. Although there is not a general rule of thumb, it is obvious from inspection of the decay chain that both the parent and the daughters are effectively extinct.

Step 11. Employ detailed decay scheme information to identify those short-lived isotopes with no ongoing sources that will decay to a longer lived isotope that is separately tracked. Once this decay has happened, the short-lived parent isotope is no longer of interest.

Step 12. Employ detailed decay scheme information and an assumed period of institutional control (100 years) to identify those isotopes with no ongoing sources that will decay to a stable isotope during the period of institutional control.

Step 13. Employ detailed decay scheme information and an assumed period of institutional control (100 years) to identify those isotopes with no ongoing sources that will decay to a longer lived isotope that is separately tracked during the period of

institutional control. Once this decay has happened, the parent isotope is no longer of interest.

The isotopes remaining on the list which have not been identified for either inclusion or exclusion can now be examined. Many of the isotopes on the list were not created in the SRS reactors. This is because the initial list of isotopes for evaluation was pulled from a variety of sources and includes isotopes of interest for many different reasons due to other SRS activities other than just reactor operations.

Step 14. The remaining isotopes are now identified as those isotopes which require further analysis (i.e., pathway and/or inventory specific screening).

The results of the screening process yielded 159 remaining radionuclides for evaluation presented in Table A.0-1

## **APPENDIX B EVALUATION OF REMAINING RADIONUCLIDES**

From Table A.0-1, 90 isotopes are screened out for the initial inventory for the reasons described in Table B.0-1. There are radionuclides that are removed from the initial inventory although they are known to exist due to decay behavior. Justification for removing the in-growth from the initial inventories is discussed below.

The in-growth of radionuclides within a decay series is insignificant. For the short lived isotopes, the in-growth occurs quickly such that they are at equilibrium within the institutional control period (100 years). For the longer lived isotopes, the in-growth would be insignificant due to the length of the evaluation period (10,000 years). For example, assuming no in-growth within the initial inventory, the Th-299 in-growth from U-233 decay would be 62.2% of the initial U-233 inventory at 10,000 years. If in-growth is included, the Th-229 in-growth would be 62.5% of the U-233 initial inventory.

Although these radionuclides are not included in the initial inventories, they are included in the modeling software and are grown in as a function of their parent's inventory and time.

**Table B.0-1: Continued Evaluation of Radionuclides**

Radionuclide	Half-life*	Reason for Elimination from Initial Inventory	Decay Chain
Ac-225	10 days	Generated by Np-237 decay in modeling; short half-life	Neptunium Series
Ac-228	6.15 hours	Generated by Th-232 decay in modeling; short half-life	Thorium Series
Ag-108m	438 years	No decay source	Ag-108m → Ag-108 → Cd-108 (stable) and Pd-108 (stable)
Am-242	16 hours	Decay from Am-242m in modeling	Am-242m → Am-242 → Cm-242 → Pu-238 → U-234 (in Uranium Series)
Am-246	39 minutes	Ancestors not present, decays to U-238 series	Cm-250 → Pu-246 → Am-246 → Cm-246 → Pu-242 → U-238 (in Uranium Series)
At-217	<1 second	Generated by Np-237 decay in modeling; short half-life	Neptunium Series
At-218	1.5 seconds	Generated by U-238 decay in modeling; short half-life	Decay mode less than 1% of Po-218 decay.
Be-10	1,510,000 years	No decay source	Be-10 → Ba-10 (stable) Long-lived naturally occurring isotope
Bi-207	32.9 years	Ancestors not present	At-207 → Po-207 → Bi-207 → Pb-207 (stable)
Bi-210	5 days	Generated by U-238 decay in modeling; short half-life	Uranium Series
Bi-210m	3,040,000 years	No decay source	Bi-210m → Tl-206 → Pb-206 (stable)
Bi-211	2.14 seconds	Generated by U-235 decay in modeling; short half-life	Actinium Series
Bi-212	60.55 minutes	Generated by Th-232 decay in modeling; short half-life	Thorium Series

**Table B.0-1: Continued Evaluation of Radionuclides (Continued)**

Radionuclide	Half-life*	Reason for Elimination from Initial Inventory	Decay Chain
Bi-213	45.6 minutes	Generated by Np-237 decay in modeling; short half-life	Neptunium Series
Bi-214	20 minutes	Generated by U-238 decay in modeling; short half-life	Uranium Series
Bk-247	1,380 years	Ancestors not present, decays to U-235 series	Cf-247 → Bk-247 → Am-243 → Np-239 → Pu-239 → U-235 (in Actinium Series)
Bk-250	3.2 hours	Ancestors not present, decays to U-238 series	Md-258 → Es-254 → Bk-250 → Cf-250 → Cm-246 → Pu-242 → U-238 (in Uranium Series); Cm-250 → Bk-250 → Cf-250 → Cm-246 → Pu-242 → U-238 (in Uranium Series)
Ca-41	102,000 years	No decay source	Ca-41 → K-41 (stable)
Cf-250	13.1 years	Ancestors not present, decays to U-238 series	Md-258 → Es-254 → Bk-250 → Cf-250 → Cm-246 → Pu-242 → U-238 (in Uranium Series) Cm-250 → Bk-250 → Cf-250 → Cm-246 → Pu-242 → U-238
Cm-246	4760 years	Ancestors not present, decays to U-238 series	Cf-250 → Cm-246 → Pu-242 → U-238 (in Uranium Series); Es-250m → Cf-250 and Bk-246 → Cm-246 → Pu-242 → U-238 (in Uranium Series) Cm-250 → Pu-246 → Am-246 → Cm-246 → Pu-242 → U-238 (in Uranium Series)
Cm-250	8,300 years	No decay source	Cm-250 → Pu-246 → Am-246 → Cm-246 → Pu-242 → U-238 (in Uranium Series)
Co-60m	10.5 seconds	Ancestors not present	Fe-60 → Co-60m → Co-60 → Ni-60 (stable)
Eu-150	36.9 years	No decay source	Eu-150 → Sm-150 (stable)

**Table B.0-1: Continued Evaluation of Radionuclides (Continued)**

Radionuclide	Half-life*	Reason for Elimination from Initial Inventory	Decay Chain
Fe-60	1,500,000 years	No decay source	Fe-60 → Co-60m → Co-60 → Ni-60 (stable)
Fr-221	5 minutes	Generated by Np-237 decay in modeling; short half-life	Neptunium Series
Fr-223	22 minutes	Generated by U-235 decay in modeling; short half-life	Actinium Series
Gd-148	70.9 years	No decay source	Gd-148 → Sm-144 (stable)
Hf-178m	31 years	No decay source	Hf-178m → Hf-178 (stable)
Hf-182	8,900,000 years	Ancestors not present	Hf-182m → Hf-182 → Ta-182 → W-182 (stable)
Hg-194	444 years	Ancestors not present	[Ti-194 and Ti-194m] → Hg-194 → Au-194 → Pt-194 (stable)
Ho-166m	1200 years	No decay source	Ho-166m → Er-166 (stable)
Ir-192	74 days	Ancestors not present	Ir-192m → Ir-192 → Pt-192 (stable) or Os-192 (stable)
Ir-192m	241 years	No decay source	Ir-192m → Ir-192 → Pt-192 (stable) or Os-192 (stable)
La-137	60,000 years	Ancestors not present	Ce-137m → Ce-137 → La-137 → Ba-137 (stable); Pr-137 → Ce-137 → La-137 → Ba-137 (stable)
La-138	1.02E+11 years	No decay source	La-138 → Ce-138 (stable) Long-lived naturally occurring isotope
Lu-176	3.76E+10 years	No decay source	Lu-176 → Hf-176 (stable) Long-lived naturally occurring isotope
Mn-53	374,000 years	No decay source	Mn-53 → Cr-53 (stable)
Mo-93	4,000 years	Ancestors not present	[Mo-93m and Tc-93 and Tc-93m] → Mo-93 → Nb-93m → Nb-93 (stable)

**Table B.0-1: Continued Evaluation of Radionuclides (Continued)**

Radionuclide	Half-life*	Reason for Elimination from Initial Inventory	Decay Chain
Np-236	1,540 years	No decay source	Np-236 → U-236 → Th-232 (in Thorium Series); Np-236 → Pu-236 Np-236a → U-232 to Th-228 (in Thorium Series)
Np-239	2.4 days	Decay from Am-243 in modeling; short half-life	Cf-247 → Bk-247 → Am-243 → Np-239 → Pu-239 → U-235 (in Actinium Series); Es-255 → Bk-251 or Fm-255 → Cf-251 → Cm-247 → Pu-243 → Am-243 → Np-239 → Pu-239 → U-235 (in Actinium Series)
Np-240	62 minutes	Decay from Pu-244 in modeling; short half-life	Cf-252 → Cm-248 → Pu-244 → U-240 → Np-240 → Pu-240 → U-236 → Th-232 in Thorium Series
Pa-233	27 days	Generated by Np-237 decay in modeling; short half-life	Neptunium Series
Pa-234	6.7 hours	Generated by U-238 decay in modeling; short half-life	Uranium Series
Pb-202	52,500 years	Ancestors not present	Po-202 → Bi-202 → Pb-202 → [Tl-202 and Hg-198 (stable)]; Tl-202 → Hg-202 (stable)
Pb-205	1.73E+07 years	Ancestors not present	Po-205 → Bi-205 → Pb-205 → Tl-205 (stable)
Pb-209	3.3 hours	Generated by Np-237 decay in modeling; short half-life	Neptunium Series
Pb-210	22 years	Generated by U-238 decay in modeling	Uranium Series
Pb-211	36 minutes	Generated by U-235 decay in modeling; short half-life	Actinium Series
Pb-212	10.6 hours	Generated by Th-232 decay in modeling; short half-life	Thorium Series
Pb-214	27 minutes	Generated by U-238 decay in modeling; short half-life	Uranium Series

**Table B.0-1: Continued Evaluation of Radionuclides (Continued)**

Radionuclide	Half-life*	Reason for Elimination from Initial Inventory	Decay Chain
Pm-145	18 years	Ancestors not present	Gd-145 → Eu-145 → Sm-145 → Pm-145 → Nd-145 (stable)
Po-210	138 days	Generated by U-238 decay in modeling	Uranium Series
Po-211	<1 second	Generated by U-235 decay in modeling; short half-life	Decay mode less than 1% of Bi-211 decay.
Po-212	<1 second	Generated by Th-232 decay in modeling; short half-life	Thorium Series
Po-213	<1 second	Generated by Np-237 decay in modeling; short half-life	Neptunium Series
Po-214	<1 second	Generated by U-238 decay in modeling; short half-life	Uranium Series
Po-215	<1 second	Generated by U-235 decay in modeling; short half-life	Actinium Series
Po-216	<1 second	Generated by Th-232 decay in modeling; short half-life	Thorium Series
Po-218	3 minutes	Generated by U-238 decay in modeling; short half-life	Uranium Series
Pu-236	3 years	Ancestors not present, decays to Th-228 series	Cf-244 → Cm-240 → Pu-236 → U-232 → Th-228 (in Thorium Series)
Pu-243	5 hours	Decay from Cf-251 in modeling	Cf-251 → Cm-247 → Pu-243 → Am-243 → Np-239 → Pu-239 → U-235 (in Actinium Series)
Pu-246	11 days	Ancestors not present	Cm-250 → Pu-246 → Am-246 → Cm-245 Pu-241 (in Neptunium Series);

**Table B.0-1: Continued Evaluation of Radionuclides (Continued)**

Radionuclide	Half-life*	Reason for Elimination from Initial Inventory	Decay Chain
Ra-223	11 days	Generated by U-235 decay in modeling; short half-life	Actinium Series
Ra-224	3.6 days	Generated by Th-232 decay in modeling; short half-life	Thorium Series
Ra-225	15 days	Generated by Np-237 decay in modeling; short half-life	Neptunium Series
Rb-87	4.97E+10 years	Ancestors not present	[Kr-87 and Sr-87m] → Rb-87 → Sr-87 (stable)
Re-186m	200,000 years	No decay source	Re-186m → Re-186 → Os-186 → W-182 (stable)
Rn-219	4 seconds	Generated by U-235 decay in modeling; short half-life	Actinium Series
Rn-220	56 seconds	Generated by Th-232 decay in modeling; short half-life	Thorium Series
Rn-222	4 days	Generated by U-238 decay in modeling; short half-life	Uranium Series
Si-32	132 years	No decay source	Si-32 → P-32 → S-32 (stable)
Sm-146	1.03E+08 years	Ancestors not present	[Gd-146 and Tb-150] → Eu-146 → Sm-146 → Nd-142 (stable); Eu-150m → Gd-150 → Sm-146 → Nd-142 (stable)
Sm-147	1.06E+11 years	Decay from Pm-147 in modeling	Pr-147 → Nd-147 → Pm-147 → Sm-147 → Nd-143 (stable); Tb-147 → Gd-147 → Eu-147 → Sm-147 → Nd-143 (stable)
Sn-121m	44 years	No decay source	Sn-121m → Sn-121 → Sb-121 (stable)
Ta-182	114 days	Ancestors not present	Hf-182m → Hf-182 → Ta-182 → W-182 (stable)
Tb-157	71 years	Ancestors not present	Ho-157 → Dy-157 → Tb-157 → Gd-157 (stable)
Tb-158	180 years	No decay source	Tb-158 → Gd-158 (stable)

**Table B.0-1: Continued Evaluation of Radionuclides (Continued)**

Radionuclide	Half-life*	Reason for Elimination from Initial Inventory	Decay Chain
Tc-97	4,210,000 years	Ancestors not present	[Ru-97 and Tc-97m] → Tc-97 → Mo-97 (stable)
Tc-98	4,200,000 years	No decay source	Tc-98 → Ru-98 (stable)
Th-227	19 days	Generated by U-235 decay in modeling; short half-life	Actinium Series
Th-228	1.9 years	Generated by Th-232 decay in modeling; short half-life	Thorium Series
Th-231	25.5 hours	Generated by U-235 decay in modeling; short half-life	Actinium Series
Th-234	24 days	Generated by U-238 decay in modeling; short half-life	Uranium Series
Ti-44	60 years	No decay source	Ti-44 → Sc-44 → Ca-44 (stable)
Tl-207	5 minutes	Generated by U-235 decay in modeling; short half-life	Actinium Series
Tl-208	3 minutes	Generated by Th-232 decay in modeling; short half-life	Thorium Series
Tl-209	2.2 minutes	Generated by Np-237 decay in modeling; short half-life	Neptunium Series
Tl-210	1.3 minutes	Generated by U-238 decay in modeling; short half-life	Decay mode less than 1% of Bi-214 decay.
U-240	14 hours	Decay from Cf-252 in modeling; short half-life	Cf-252 → Cm-248 → Pu-244 → U-240 → Np-240 → Pu-240 → U-236 → Th-232 (in Thorium Series)

\*Half-life years obtained from the April 2005 Nuclear Wallet Cards.
