

### **3.0 Fiber Analysis**

There were two different types of fiber beds used during test; (1) blender-processed debris beds and (2) NEI-processed debris beds. The NEI-processed debris bed was used for the duration of the 30-day test followed by the insertion of the blender-processed debris bed exposed to solution for 2 days. At the end of the test, the beds were analyzed by the naked eye to spot any noticeable features (particles, debris, etc.). Sections of the fiber bed with particulate were extracted and sent for SEM analysis. The following images depict samples taken from Test 1 post-test fiber beds. The name of the sample includes which bed it came from (NEI or Blender) and the approximate description of the visual appearance of the particle being examined is noted in the figure captions. If EDX of a particle was acquired, the location of the particle examined is indicated on the figure by an "X".

## **4.0 Baseline Fiber**

The method of preparation of fiber debris samples for SEM analysis was examined to determine if the procedure contributed to the formation of particulates or attributes that may be of interest. Two batches of NEI-processed fiber were prepared and soaked for 24 hours in solution of interest. One batch of fiber was allowed to soak in borated-TSP solution, while the other batch was soaked in deionized (DI) water. Three types of samples were taken from the two batches. One sample was taken from the fiber soaked in the DI water and, a second sample was taken from the borated-TSP solution, and a third sample was taken from the borated TSP solution and quickly rinsed with DI water. All samples were allowed to dry in a desiccator before they were sputter coated. The results of the samples taken are below. A description of the images is given by the caption. If EDX of a particle was acquired, the location of the particle examined is indicated on the figure by an "X".

## 5.0 Aluminum SEM

Aluminum used in the test was taken from aluminum scaffolding obtained from STP. This scaffolding was a non-homogenous sample with unknown constituents from years of use which remained after cleaning and the alloy of aluminum is not known. The samples which were to be submerged were from the side of the scaffolding and had a different texture and appearance than the samples cut for the vapor space. Three types of aluminum samples for submerged and vapor samples were examined using SEM and are as follows: (1) examination of test samples, (2) analysis of pre-test samples (3) examination of test samples after scale removal. Post-test samples were labeled "used", while base line pre-test samples were labeled as "not used". Samples which had scale removed were labeled as "acid washed". Those that did not have scaled removed were labeled as "not washed". The SEM results of all aluminum samples are shown below. A description of the images is given by the caption. If EDX of a particle was acquired, the location of the particle examined is indicated on the figure by an "X".
