I. INTRODUCTION

This report presents the data collected during the second year of investigations conducted for the Southern California Edison Company to monitor environmental effects resulting from construction and dredging operations associated with placement of offshore water conduits for the San Onofre Nuclear Generating Station (SONGS) Units 2 and 3. The data presented are the results of biological and sediment investigations conducted from January 1978 through December 1978.

A. Purpose of the Study

The purpose of the study was to quantitatively assess environmental effects of sand dispersal during construction and dredging operations associated with the addition of SONGS Units 2 and 3 to the existing facility. The monitoring program was designed to meet all requirements specified by the California Regional Water Quality Control Board - San Diego Region in Order No. 71-6, as amended by Technical Change No. 2, and as a special study of the Nuclear Regulatory Commission (NRC) pre-operational monitoring program.

Included in the studies were the intertidal, subtidal-infauna, and kelp bed areas adjacent to SONGS. The kelp canopy and bottom topography from San Mateo Point to the mouth of the Santa Margarita River was mapped concurrently.

B. Study Site Location

The construction site for SONGS Units 2 and 3 is located on the coast of southern California at approximately 30° 22.5' North latitude and 117° 32.5' West longitude. San Clemente, the closest city to SONGS, is on the coast approximately 4 km to the northwest, while the nearest municipality to the southeast is Oceanside some 19 km downcoast from the station. The primary study area extended 3.7 km northwest and southwest of SONGS and approximately 2.1 km offshore. In addition, kelp bed areas located approximately 4.2 km northeast and 10.9 km southeast of SONGS were investigated.

C. Background

The SONGS construction monitoring program was initiated in December 1976 to investigate the effects of Units 2 and 3 construction and dredging operations on the marine biota in the vicinity. The first report was submitted in April 1978 (Marine Biological Consultants, Inc., [MBC] 1978). The report presented interpretations and discussions of results of physical and biological investigations conducted during the two preconstruction dredging surveys (December 1976 and March 1977), and the first three construction period surveys (June, September, and November 1977) of the construction monitoring program.

D. Scope and Organization

This document presents the raw and summarized biological data together with the corresponding physical and sediment data collected in 1978. This submittal, Volume IV, is in compliance with reporting requirements of the California Regional Water Quality Control Board, San Diego Region, and the Nuclear Regulatory Commission; 1 April, 1979. Field observations, which may be of importance in interpretation of the results, have been compiled into a separate document which is on file. Specific observations or comments which may be necessary for the interpretation or explanation of data, are presented in a task comment section.

The document is divided into Intertidal, Subtidal Infauna, Kelp Bed Macrofauna, Kelp Bed Biology. All raw data pertaining to the individual tasks are found in the corresponding sections.

A biological and sedimentological Data Analysis Report-1978, will be submitted to the appropriate regulatory agencies by 1 July 1979 as Volume IV of the SONGS 2 and 3 Construction Monitoring Program Annual Report.

II. INTERTIDAL STUDY

Intertidal investigations were established to determine if construction or dredge-induced changes in the sandy intertidal habitat would have a detrimental effect on the invertebrate community inhabiting the area.

A. Sampling Methods

A detailed description of station location, field, and laboratory procedures were presented in the 1978 SONGS Construction Monitoring Program for Units 2 and 3 (MBC, 1978). A general review is presented below.

Five fixed sandy intertidal transects were occupied quarterly during 1978.

1. Biological Sampling. Along each transect, seven biological sampling stations were established at +1 ft tidal elevation increments between 0 ft and the +6 ft tidal elevation using a modified surveyor's transect. At each station, five replicate 15.24 cm x 30 cm deep cores were collected and their contents screened through a 1.0 mm screen. All retained organisms were preserved in 10% buffered Formalin-seawater. All taxa collected were returned to the laboratory where they were identified to the lowest possible taxonomic level and enumerated.

2. Physical Measurements and Grain Size Determination. At each transect an accurate beach profile was constructed from the 0 ft tidal elevation to the maximum tidal excursion of the survey day, using a self-leveling surveyor's transect. Surf temperatures were recorded at each transect.

Core samples for grain size analyses were collected along each transect from the 0, +2, +4, and +6 ft tidal elevations. Grain size analyses were accomplished in the laboratory by sieving the sample through a graded series of American Society for Testing Materials (ASTM) sieves and weighing the retained fraction to the nearest 0.01 gm. Silt-clay fractions were analyzed using standard hydrometric techniques.

B. Results

Intertidal investigations were conducted on February 23-23, May 25-26, August 16-17, and November 15-16, 1978 at the permanent transects. The following tables present: 1) a summary of biological data by survey during 1978; 2) the abundance of intertidal taxa by transect, level, and replicate during the four quarterly surveys; 3) grain size characteristics of individual transects during the four quarterly surveys; 4) upper and lower beach slope of individual transects during the four quarterly surveys and 5) surf zone water temperatures at each transect during the four quarterly surveys.

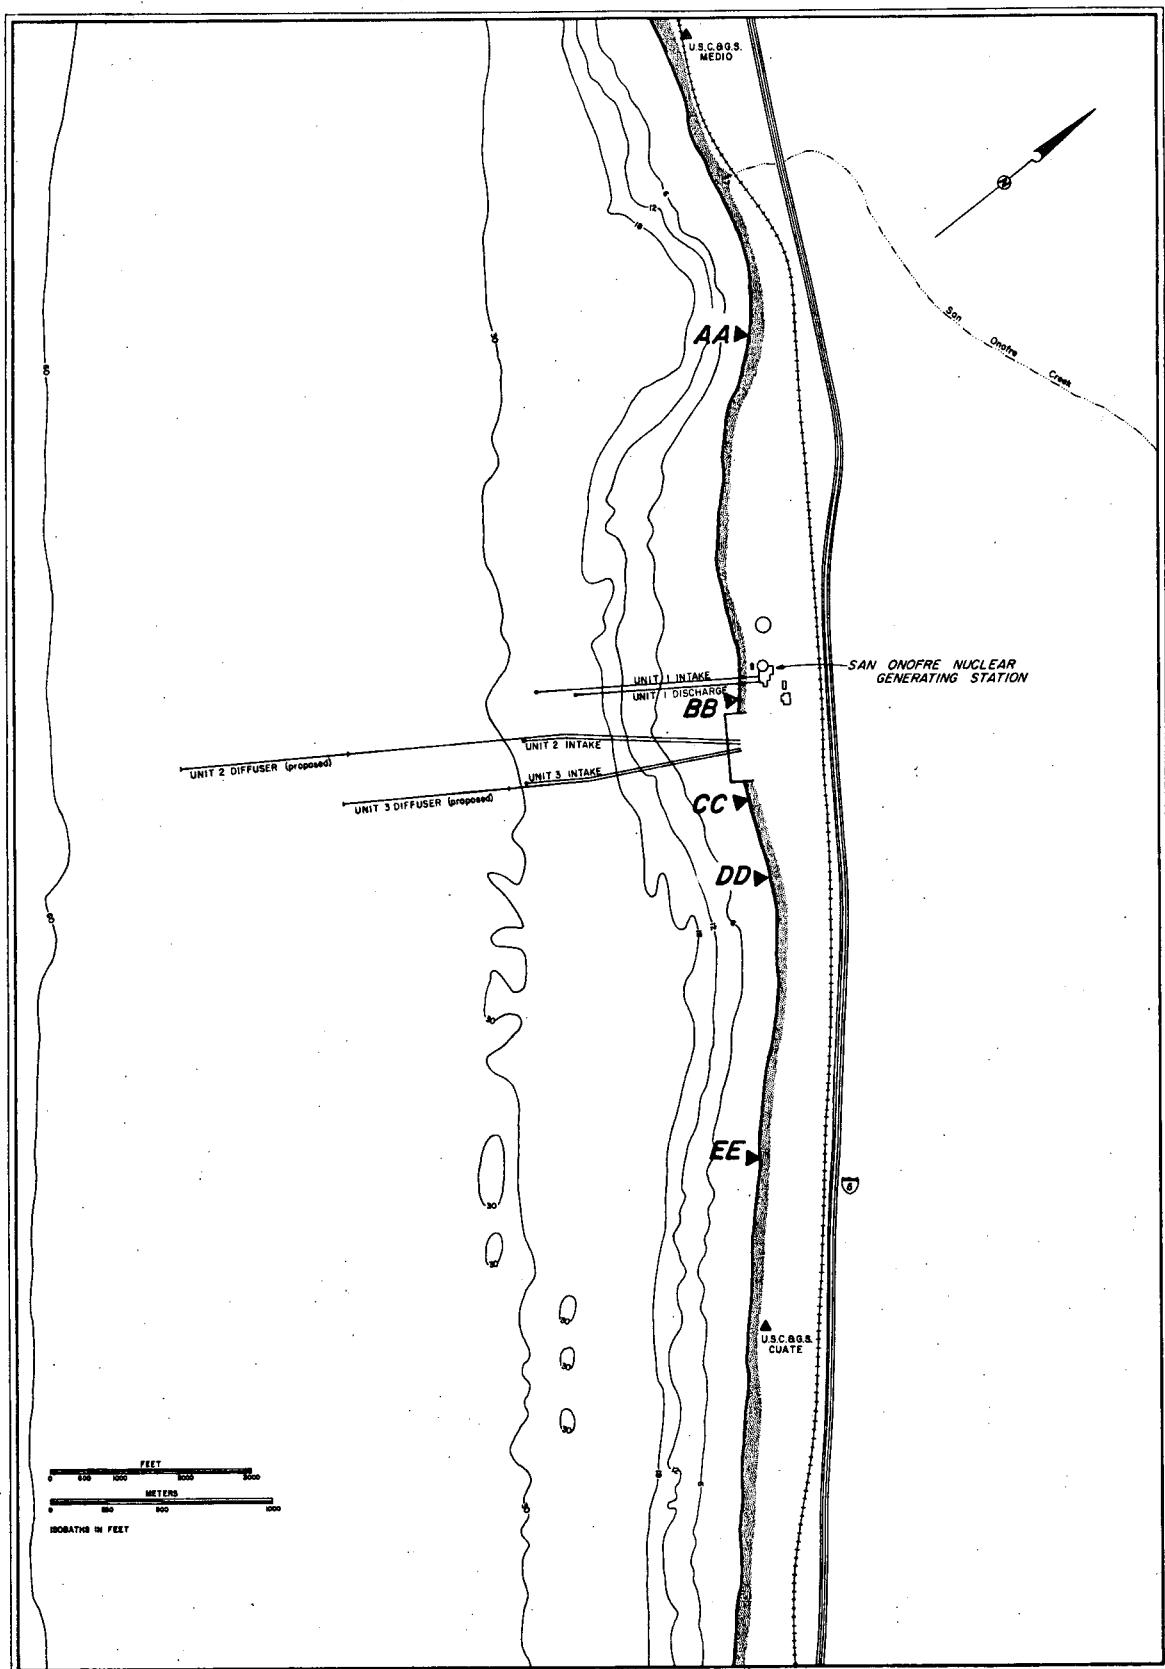

Survey dates of individual tasks.

E	15.5	17.5	16.4	17.2

III. INFAUNAL SURVEYS

Subtidal infaunal investigations were established to investigate effects of dredge-induced sedimentation on the infaunal invertebrate community adjacent to SONGS.

A. Sampling Methods

A detailed description of station location, field, and laboratory procedures was presented in the 1978 SONGS Construction Monitoring Program for Units 2 and 3 (MBC, 1978). A general review is presented below.

Six transects, composed of three permanent stations each, were occupied quarterly during 1978.

1. Biological Sampling

At each station, biological samples were collected for the identification and enumeration of taxa present. At stations located along the 6 m isobath (A1, B1, C1, D1, E1, and F1) five 1* replicate samples were collected quarterly, while 12 replicate 1* samples were collected at the remaining stations. Each sample was screened through a 0.5 mm mesh screen in the field, and the retained fraction preserved in 10% Formalin-seawater.

2. Physical Measurements and Sediment Characteristic Determination

At each station, sediment heights, which are used to determine changes in sediment height between surveys, were measured using a permanent monument. Sediment traps, located on top of the monuments, were collected, and the contents weighed (dry weight) to determine sediment deposition rates.

Sediment samples for total organic carbon determinations and grain size measurements were collected at each station concurrently with the collection of biological samples. Total organic carbon content was determined for each sample using a LECO gasometric carbon analyzer. Grain size analysis was accomplished by sieving the samples through a graded series of ASTM sieves and weighing the retained fraction to the nearest 0.01 gm. Silt-clay fractions were analyzed using standard hydrometric techniques.

Bottom water temperatures and Secchi disc readings were collected at all stations during each quarterly survey.

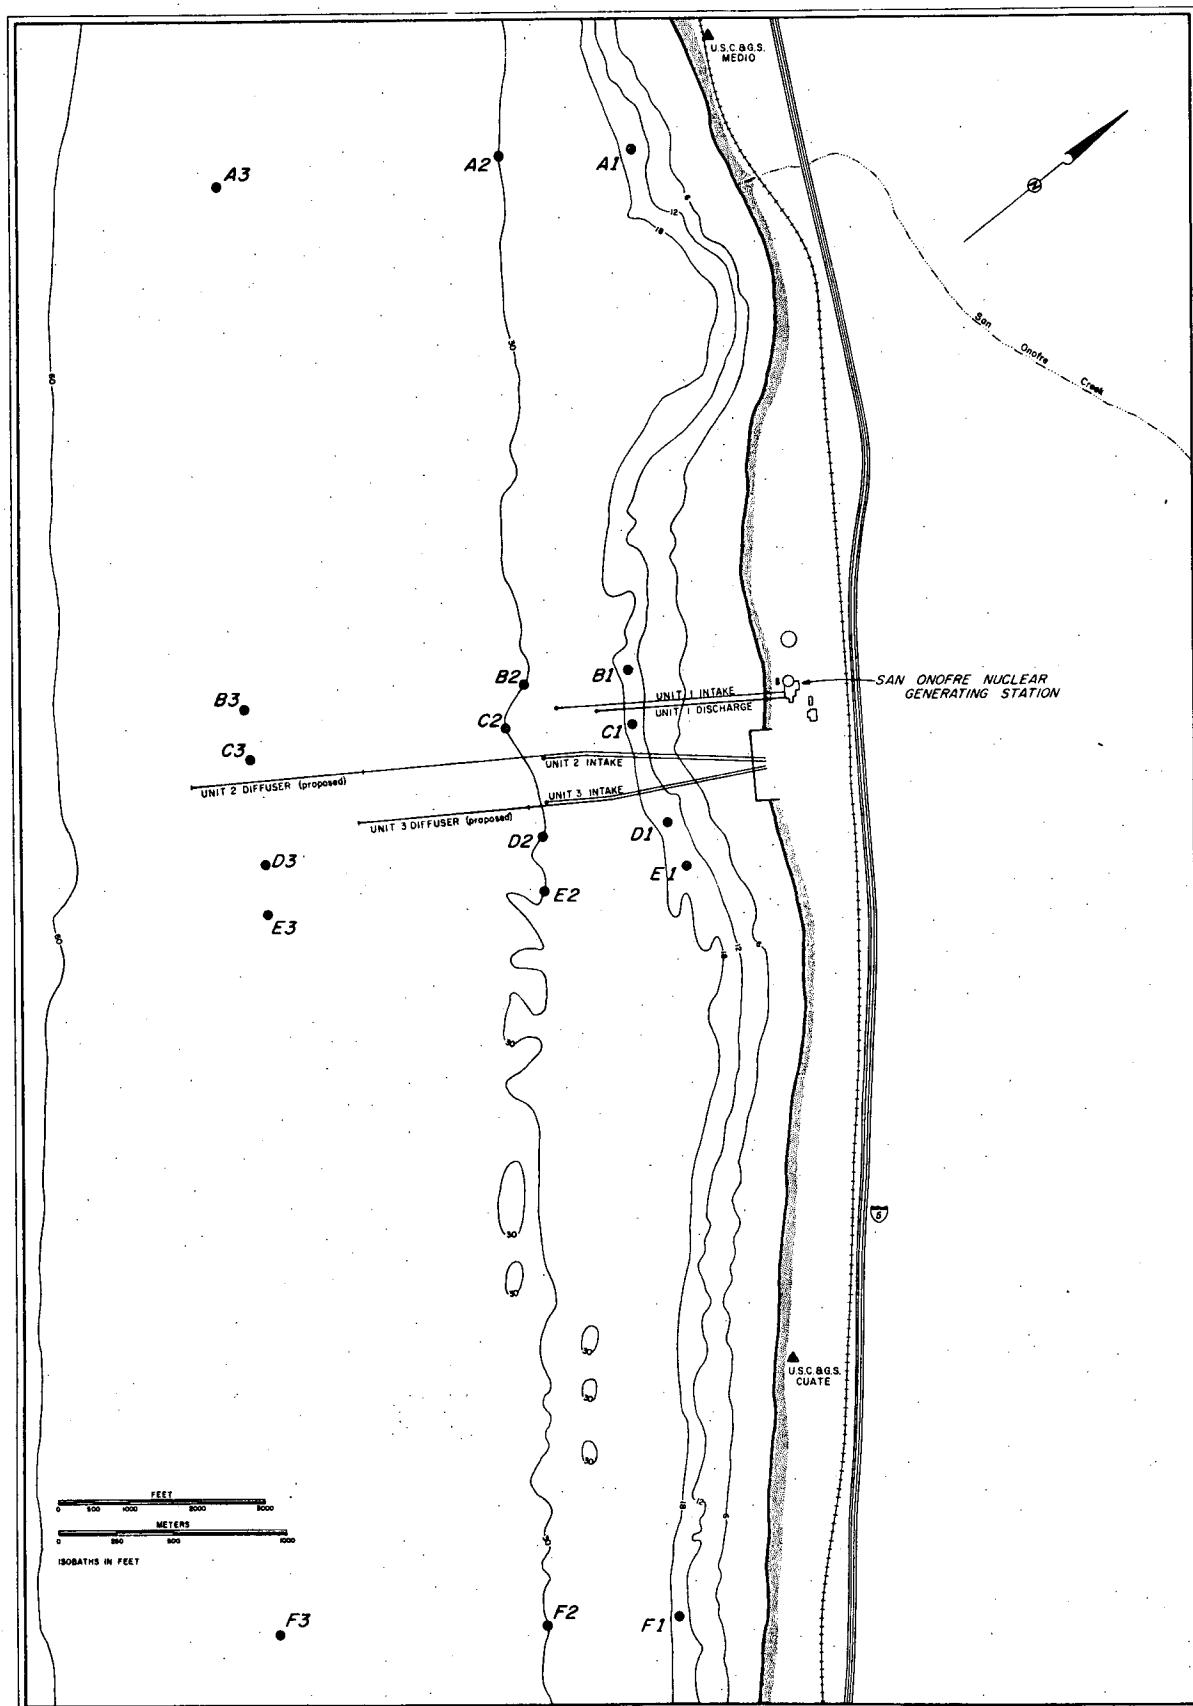

Monthly dredge volumes of disposed sand were supplied by the Southern California Edison Company.

B. Results

Subtidal infaunal investigations were conducted on March 20-24, June 5-7, September 18-20, and November 20-22, 1978 at 18 permanent stations. The following tables present a summary of biological data by survey during 1978 and the quarterly: 1) abundance of infaunal taxa by station and replicate; 2) total organic carbon content of the sediments at each station; 3) grain size sediment characteristics at each station; 4) sediment height by station; 5) sediment trap data by station; 6) bottom water temperatures by station; 7) Secchi disc reading by station; and 8) monthly dredge volumes of disposed sands.

C. Comments

Between January and March 1978, major storm conditions were continuously present in the southern California region. In addition to obviating sampling during this period, the associated sea conditions destroyed all the sediment traps and several monuments. Further, monuments were occasionally destroyed by boat anchors or sea conditions resulting in the loss of sediment traps.

Subtidal infaunal station locations.

IV. KELP BED MACROBIOTA SURVEYS

Kelp bed macrobiota investigations were initiated to examine the effects of dredge induced sedimentation on the benthic biotic community associated with the San Onofre kelp bed.

A. Sampling Methods

At each of two stations located within the San Onofre kelp bed (Figure 5), 10 permanent 1 m² quadrats were examined quarterly. The density of all macro-organisms within each permanent quadrat was estimated and recorded as either percent composition or total count. In addition, the percent sand cover in each quadrat was recorded.

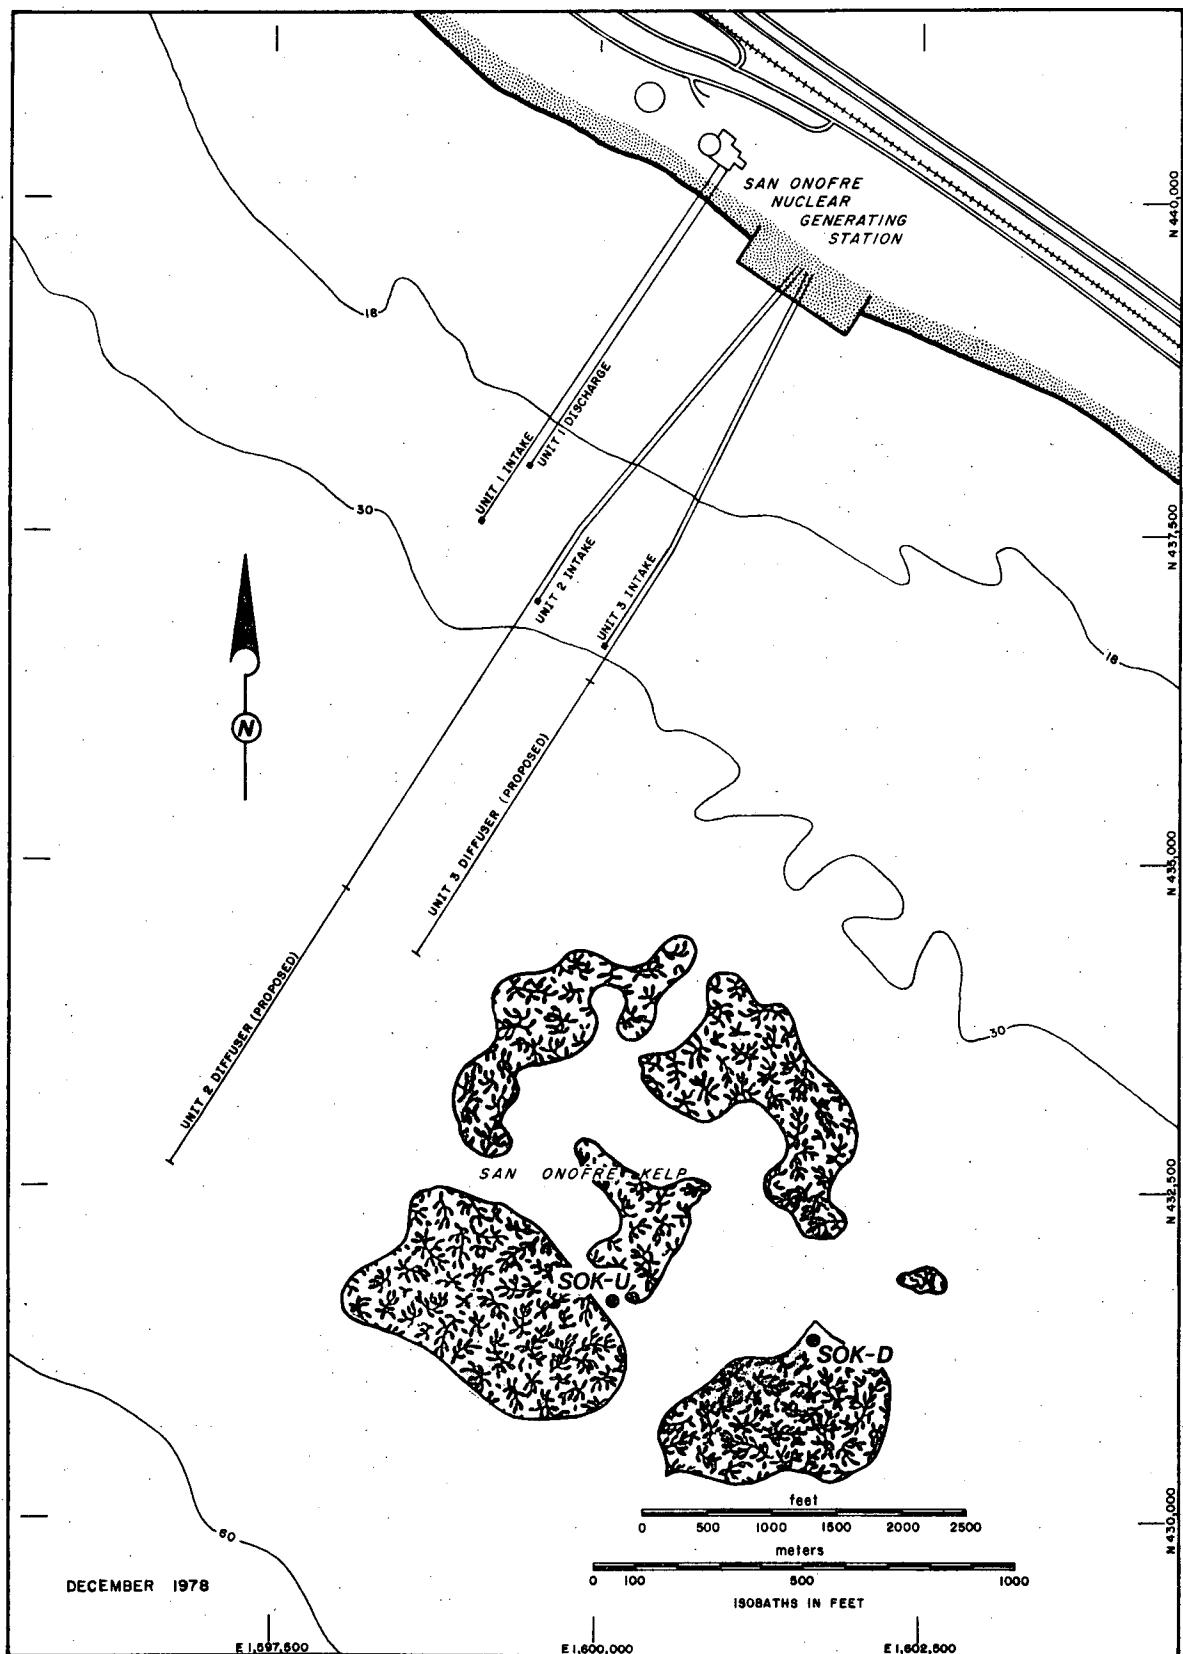

Bottom water temperatures were recorded at each station during the quarterly surveys.

B. Results

Kelp macrobiota surveys were conducted on April 11, June 8, September 22, and November 17, 1978. The following tables present: 1) a summary of biological data collected by survey during 1978; 2) the density of taxa by quadrat, station, and survey during 1978; and 3) bottom water temperatures by station and survey during 1978.

C. Comments

Due to weather conditions and the decreased water column visibility, the first macrobiota survey was deferred until April 11, 1978.

Kelp bed macrobiota station locations.

V. KELP BED BIOLOGY SURVEY

The kelp bed biology investigations were initiated to monitor the health of the kelp beds in the San Onofre region during the construction phase of SONGS Units 2 and 3.

A. Sampling Methods

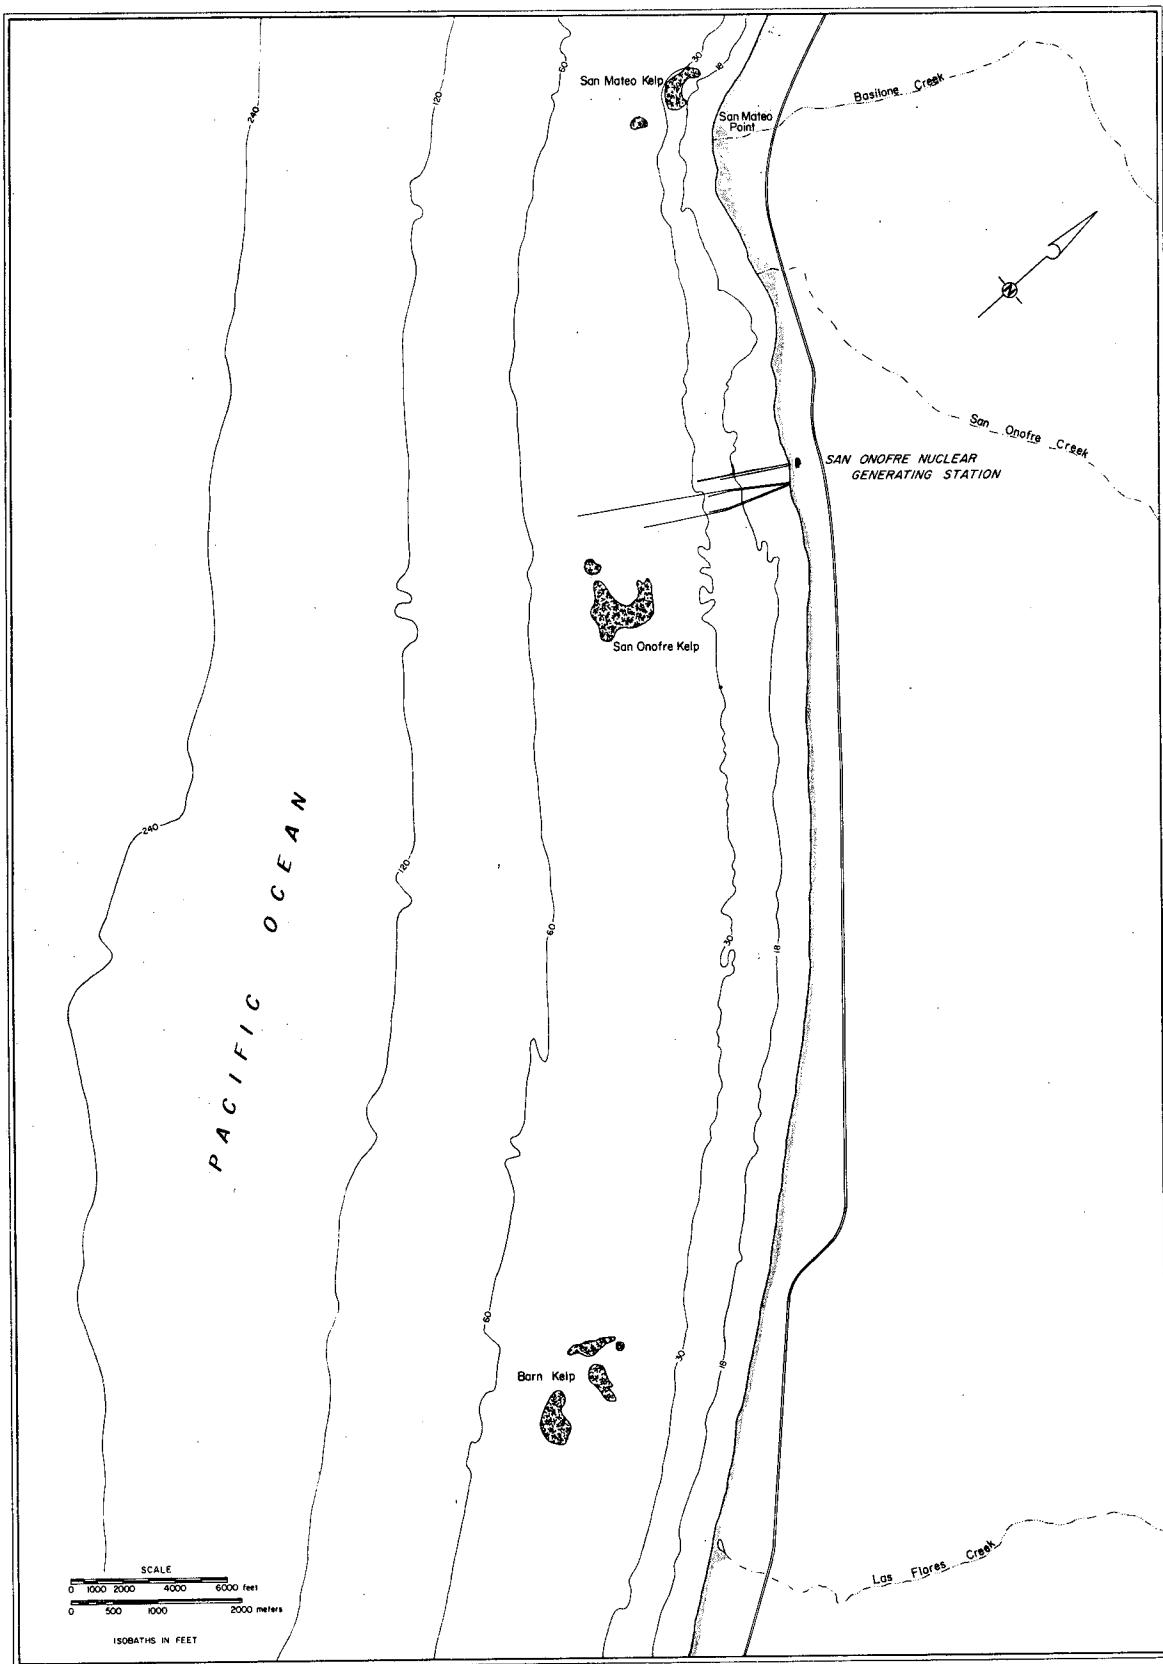

A detailed description of station location, field, and laboratory procedures for each task undertaken was presented in the 1978 SONGS Construction Monitoring Program for Units 2 and 3 (Marine Biological Consultants, Inc., 1978). A general review, by task, is presented below.

1. Kelp Bed Areal Mapping Methods. The areal extent of the San Mateo, San Onofre, and Barn kelp beds were mapped quarterly using a Miniranger III electronic positioning device and a side-scanning sonar system. Data was presented in the form of a map of the kelp canopies present. Areal extent of the individual canopies was estimated utilizing a planimeter.

In conjunction with the electronic mapping surveys, areal infrared photographs of individual canopies were taken quarterly to supplement the electronic mapping data. The infrared photographs are on file at Marine Biological Consultants, Inc.

2. Water Column Nutrients. Nutrient concentrations of phosphate (PO_4), nitrogen (NO_2+NO_3), and ammonia (NH_4) were determined monthly in the surface and bottom waters at the middle and directly outside the San Mateo, San Onofre, and Barn kelp beds. In addition, the concentrations of the three nutrients were determined at depths of surface, 16, 32, and 48 m at a station approximately 3.5 km offshore of the San Onofre kelp bed. The program design provided for an examination of nutrient conditions in and adjacent to the kelp beds under investigations, and a station to monitor upwelling conditions offshore of the study area.

3. Kelp Leave Nutrients. Nitrogen contents of the kelp leaves in the San Mateo, San Onofre, and Barn kelp beds were determined monthly. The nitrogen content of sporophylls and kelp fronds from each kelp bed was determined by Kjeldahl analysis.

Kelp bed biology station locations.

Estimated areal extent (m^2)
of the San Mateo, San Onofre,
and Barn kelp beds in 1978.
