**PROBABILISTIC RISK ASSESSMENT OF
PROPOSED SONGS 1 CCW HEAT EXCHANGER ALLOWED OUTAGE TIMES
SAN ONOFRE NUCLEAR GENERATING STATION UNIT 1**

1.0 INTRODUCTION

This study assesses the risk of proposed allowed outage times for the Component Cooling Water (CCW) Heat Exchangers at San Onofre Nuclear Generating Station Unit 1 (SONGS 1). The analysis contains a comparison of core damage frequencies for various CCW Heat Exchanger allowed outage times (AOTs) to determine an acceptable allowed outage time.

The guidance in the existing Technical Specifications is not clear regarding the limiting conditions for operation (LCO) of the CCW Heat Exchangers. At the request of the NRC, SCE has been asked to propose specifications for CCW Heat Exchanger operation.

The Standard Westinghouse Technical Specifications indicate a 72 hour AOT for a CCW loop. Due to the unique design features of SONGS 1 (e.g., train cross-connects), a probabilistic based evaluation was undertaken to determine an optimal AOT considering maintenance constraints and risk of core damage. The maintenance requirements of the CCW Heat Exchangers and associated motor-operated outlet valves are such that some repairs may not be achievable within 72 hours. A 72 hour AOT could result in a forced plant shutdown once every several years. Thus, the maintenance constraints require an AOT longer than 72 hours.

2.0 FUNCTION OF THE CCW SYSTEM

The Component Cooling Water (CCW) System is a closed loop system which provides cooling water for plant components that potentially contain radioactive material. The CCW System is cooled by the Salt Water Cooling System. The CCW System provides a barrier between the plant systems containing radioactive material and the environment. A simplified diagram of the CCW System is provided in Figure 1.

The CCW System contains parallel heat exchangers that can be selected by motor-operated outlet valves MOV-720A and B. The outlet of the heat exchangers enters a common outlet pipe and provides cooling to the following plant equipment:

- Recirculation Heat Exchanger
- Charging Pump Oil Coolers
- Seal Water Heat Exchangers
- Reactor Coolant Pumps (RCPs)
- Letdown Heat Exchangers
- Residual Heat Exchangers
- Residual Heat Removal Pumps
- Reactor Shield Cooling Coils

Flow from the components is returned to the common CCW pump suction piping.

A DC Thermal Barrier Pump provides non-safety related cooling to the RCP seals in the event of loss of the CCW pumps or a station blackout event. The pump takes suction from the component cooling water supply to the RCP seals and delivers this water to the thermal barrier of the RCPs downstream of the CCW inlet check valve to the thermal barrier. After flowing through the thermal barrier, this emergency flow resumes the normal component cooling water flow path.

3.0 EVALUATION OF RISK

The analysis of core damage includes probabilistic risk assessment (PRA) initiating events that would be significantly impacted by the loss of both CCW heat exchangers. These events include:

- Large LOCA (3" diameter or larger breaks)
- Small LOCA (3/4" to 3" diameter breaks)
- Small-Small LOCA (up to 3/4" diameter breaks)
- Loss of CCW (only from failure of the heat exchangers)

Event trees have been developed and analyzed to determine the core damage risk associated with each of these initiating events. Core damage is estimated for various AOTs of the CCW Heat Exchangers by analyzing these events. The analysis assumptions are presented in Section 3.1 below. The results of the analysis are provided in Section 3.2, and a discussion of the uncertainty of the results is given in Section 3.3.

3.1 ASSUMPTIONS

The following assumptions were utilized in the analysis:

1. The accident sequences analyzed include LOCA and loss of CCW Heat Exchanger initiating events. The core damage risk from the loss of the CCW Heat Exchangers in other events (e.g., main steam line break, main feedwater line break, steam generator tube rupture, etc.) are on the order of $10^{-9}/\text{year}$ or less which is small compared to the analyzed events. The requirements of the CCW System in the other unanalyzed events are no greater than for the LOCA events. The impact of CCW Heat Exchanger inoperability on core damage risk during shutdown events was not analyzed due to the unavailability of shutdown risk models and an assumption that the shutdown risk is low due to the longer time available for recovery actions prior to core uncovering.
2. The CCW Heat Exchangers are assumed to fail (predominately due to marine debris fouling) at a rate of approximately once per 3 years based upon actual SONGS 1 operating data.

3. The probability of failing to restore an out of service CCW Heat Exchanger given the operable CCW Heat Exchanger begins to evidence fouling is estimated to be 0.05 per demand, assuming low radiation levels around the CCW Heat Exchangers. This estimate is based on 1) a history of CCW heat exchanger fouling at a very slow and gradual rate over a matter of weeks, 2) the standard practice of operators checking one heat exchanger prior to removing the second from service, and 3) judgement that restoration of a heat exchanger or its associated MOV could be accomplished relatively quickly (Reference 1).

If the Recirculation System is in operation, radiation levels at the CCW Heat Exchangers could be too high for restoration of the CCW Heat Exchanger in maintenance. Therefore, following a Small or Large LOCA, the probability of failing to restore an out of service CCW heat exchanger is assumed to be 1.0. Post-LOCA Recirculation cooling is not assumed to be required following a small-small LOCA.

4. The loss of CCW System operability due to loss of both CCW Heat Exchangers is assumed to impact heat removal from the following heat loads in the probabilistic risk assessment:

Reactor Coolant Pump seals
Charging Pump lube oil
Recirculation Heat Exchanger

5. In the event of loss of both CCW Heat Exchangers during normal operation, the probability of non-recovery of the CCW System prior to the loss of RCP seal cooling is assumed to be 0.9. The basis for this non-recovery probability is a loss of CCW recovery evaluation in the Oconee PRA (Reference 2), which used a non-recovery probability of 0.13. The non-recovery probability used in this study is set to 0.9 for conservatism since a SONGS 1 specific evaluation has not yet been performed.

The probability of non-recovery of the CCW System after the loss of seal cooling and prior to increased leakage through the RCP seals is conservatively assumed to be 0.99. This is based upon Westinghouse studies which indicate that seal degradation is not instantaneous upon a loss of seal cooling and may take several hours before failure resulting in additional available recovery time (Reference 3).

6. Failure of RCP seal cooling (via the thermal barrier cooler) and charging seal injection is assumed to result in seal degradation leading to a seal leak of approximately 21 gpm per pump based on a Westinghouse Owners Group Report (Reference 3). A seal LOCA in all three RCPs would result in a 63 gpm RCS leak. This leak is assumed to conservatively occur

immediately upon loss of seal cooling for purposes of determining the time to loss of natural circulation cooling from RCS leakage. The operability of the Safety Injection System to makeup the RCS coolant lost through the failed RCP seals is assumed to be required immediately. This is a conservative assumption since significant time is available (approx. 1 3/4 hours) prior to the loss of natural circulation cooling. Most of the dominant potential failure modes of the Safety Injection System (e.g., failures of the Feedwater Pump suction and discharge valves to operate) could be recovered within an hour.

7. The event trees and supporting fault trees used in the analysis are based upon the SONGS 1 Probabilistic Safety Assessment, Revision 5 (Reference 4).
8. The failure rate for motor-operated or manual valves failing to remain open is assumed to be 5.0E-08/hr (Reference 5).
9. It is assumed that one CCW Heat Exchanger outage of the entire AOT duration would be entered once per year based upon actual plant maintenance data for the past four years.
10. Loss of CCW System operability would result in a loss of normal cooling of the Charging Pump lube oil. Backup lube oil cooling by an AC powered Lube Oil Cooling Fan is not available unless a SIS/LOP is present. In the event the Lube Oil Cooling Fan fails to operate or an SI signal does not occur, a calculation indicates that the Charging Pump lube oil temperature stabilizes at a steady state temperature of approximately 225 deg F after approximately two hours of operation (Reference 7). The Charging Pump thrust bearings and babbitt material have shown a capability in other applications to withstand temperatures of 345 deg F for up to 300 hours without seizure (Reference 8). Therefore, it is assumed that the Charging Pump can operate without lube oil cooling for at least 24 hours. Restoration of a CCW Heat Exchanger or repair of a Charging Pump Lube Oil Fan is assumed achievable within 24 hours.

The loss of CCW cooling to the Charging Pumps in the recirculation mode of operation was assumed to result in failure of the Charging Pumps. However, this assumption is inconsequential since the Recirculation Heat Exchangers would have also lost CCW cooling resulting in a failure of recirculation cooling.

The use of Chemical and Volume Control System Test Pump G-42 for providing RCP seal flow in the event of loss of both Charging Pumps is also included in the analysis. The Test Pump has the capability to provide RCP seal injection flow at the normal flow rate. Abnormal Operating Procedure S01-2.1-10

specifies the use of the Test Pump in the event of a Component Cooling Water System malfunction resulting in failure of the Charging Pumps.

3.2 Core Damage Analysis

The event trees analyzed for this study are provided in Figures 2 through 5. The supporting fault trees were taken from the SONGS 1 Partial PRA (Reference 4). The Loss of CCW Heat Exchanger initiating event frequency was determined as indicated below. The event trees were solved for the 31 day AOT case using the REBECA PRA software. The event trees for the 72 hour and 7 day AOT cases were solved by manipulating cut sets containing failures of the CCW Heat Exchangers in the 31 day AOT case.

The fault trees supporting event tree nodes were solved using a truncation limit of 1E-6 and the event trees were solved using a truncation limit of 1E-9. The choice of truncation limits assured that any core damage sequence cutsets containing failures of the CCW Heat Exchangers with a probability greater than 1E-9 per year were found and included in the quantification. Note that the maintenance for both the CCW Heat Exchangers is lumped into the B Train Heat Exchanger since the A Train Heat Exchanger is assumed to be normally running. The basic event probabilities used for CCW Heat Exchanger E-20B in maintenance for each case were:

PROBABILITY IN MAINTENANCE

EVENT	72 Hour AOT	7 Day AOT	31 Day AOT
E-HSE20B---M (CCW Heat Exchanger E-20B in maintenance)	8.22E-03	1.92E-02	8.49E-02

3.2.1 Loss of CCW Heat Exchanger Initiating Event

A loss of CCW Heat Exchanger event tree was created for this analysis to model the impact of loss of the CCW Heat Exchangers during normal operation (non-transient condition). A fault tree was created to determine the initiating event frequency for loss of both CCW Heat Exchangers. The fault tree is provided in Figure 6. Failures of the associated CCW Heat Exchanger discharge valves to remain open were neglected based upon their low probability of occurrence (5.0E-8 per hour, Reference 5). The only parameter which changes in the fault tree for various AOTs evaluated is the basic event for the probability of failure of the operating CCW Heat Exchanger while the other CCW Heat Exchanger is in maintenance (basic event E-HSE20A-7C). The values used for this basic event are as follows:

AOT	Basic Event Probability	Basis
72 hours	2.71E-03	(0.33/yr / 8760 hrs/yr * 72 hr)
7 days	6.33E-03	(0.33/yr / 365 day/yr * 7 day)
31 days	2.80E-02	(0.33/yr / 365 day/yr * 31 day)

The solution for the fault tree is given below for each AOT evaluated:

AOT	Initiating Event Frequency
72 hours	1.4E-04/yr
7 days	3.2E-04/yr
31 days	1.4E-03/yr

These values were used in the solution of the loss of CCW Heat Exchanger event tree for each AOT case.

3.2.2 Core Damage Results

The results of the event tree quantification for each of the AOTs evaluated are provided in Table 1. Only contributions to core damage from loss of the CCW Heat Exchangers are provided. The 72 hour AOT results are considered a base case, since this AOT is used in the standardized Westinghouse Technical Specifications. The increase in core damage frequency above the 72 hour case is considered the incremental risk impact of the 7 and 31 day AOTs.

The quantified event trees for each AOT evaluated are provided in Appendix A. The dominant cutsets resulting from the quantification of the 31 day AOT case are provided in Appendix B. Sequence cutset results are provided only for those sequences involving the failure of systems dependent on CCW operation (i.e., Charging and Recirculation). Cutsets containing failures of the CCW Heat Exchangers in the LOCA event tree solutions are identified by arrows in the left margin. Note that all the cutsets in the loss of CCW Heat Exchanger event tree sequence solutions contain failures of the CCW Heat Exchangers and are thus not identified in any special manner.

The dominant sequences involving loss of both CCW Heat Exchangers leading to core damage result from solution of the small and large LOCA, and loss of CCW Heat Exchanger event trees. The dominant cutsets involve the following failures:

- occurrence of a small or large LOCA
- one CCW Heat Exchanger in maintenance
- the second CCW Heat Exchanger plugs

or

- loss of offsite power during normal operation
- failure of the emergency diesel generators to operate
- failure to connect the DSD diesel to Charging Pump G-8A

As indicated in the assumptions, recovery of a CCW Heat Exchanger in maintenance is not assumed possible following a large or small LOCA due to the assumed high radiation at the CCW Heat Exchangers during Recirculation System operation.

3.3 Uncertainty in the Analysis

The sequences associated with the LOCA trees are based upon best estimate fault tree analysis with some conservative assumptions of the CCW System unavailability.

Standard uncertainty values for fault tree solutions are on the order of a factor of 10 (i.e., an error factor of 10) based on the failure data analysis. The total risk contribution from unanalyzed events, including main steam line break, steam generator tube rupture, shutdown modes, etc. is not assumed to be larger than the contribution from the LOCAs and loss of CCW Heat Exchanger events. However, the uncertainty in this assumption is assumed to be bounded by another factor of 10. For conservatism, the risk contribution from each incremental AOT change is increased by a factor of 10 as indicated below to account for these uncertainties:

Increase in AOT	Adjusted Incremental Increase in Core Damage Risk
72 hours to 7 days	2.9E-07 per year
72 hours to 31 days	2.0E-06 per year

4.0 CONCLUSIONS

The increased risk of core damage from a 72 hour to 7 day AOT for the CCW Heat Exchangers, after a conservative adjustment for uncertainties, is very low at 2.9E-7 per year. This increase in the risk of core damage represents an insignificant contribution of one tenth of one percent to the overall SONGS 1 core damage frequency (estimated to be 2E-4 per year).

The increased risk of core damage from a 72 hour to 31 day AOT for the CCW Heat Exchangers, after a conservative adjustment for uncertainties, is moderately low at 2.0E-6 per year. This increase in the risk of core damage represents a small, but potentially more significant contribution of one percent to the overall SONGS 1 core damage frequency.

Thus, conservatively considering the uncertainties in the analysis,

the 7 day AOT for the CCW Heat Exchangers is recommended as the optimal AOT given maintenance constraints and the low increase in core damage risk.
