PURPOSE

10 CFR 50.63¹ requires that SCE demonstrate the ability of SONGS Unit 1 to cope with a Loss of all AC power (Station Blackout). Regulatory Guide 1.155 provides NRC guidance for addressing this situation². This guide states that the NUMARC (<u>NU</u>clear <u>Management And Resource Council</u>) published guidelines³ to demonstrate ability to cope with a station blackout (NUMARC 87-00) is compatible with the Reg. Guide. The basic NUMARC/REG. GUIDE criteria are as follows:

- (i) procedures and equipment relied upon in station blackout should ensure that satisfactory performance of necessary decay heat removal systems is maintained for the required station blackout coping duration,
- (ii) the core must be kept covered for the coping duration, and
- (iii) appropriate containment integrity should be provided in a blackout to the extent that isolation valves perform their intended function without AC power.

The purpose of this calculation is to determine whether adequate RCS water inventory exists to perform the decay heat removal function and keep the core covered during a station blackout for the NUMARC defined coping duration.

II. RESULTS/CONCLUSIONS AND RECOMMENDATIONS

A. <u>RESULTS/CONCLUSIONS</u>

The significant events occurring during a station blackout including operator actions are shown on Table II-1. A trend of some of the important parameters during the critical times of the coping duration are shown in Table II-2.

On initiation of the blackout, the Pressurizer begins to empty rapidly due to the RCS leakage (171 gpm (cold) for the first 2 minutes and 101 gpm (cold) thereafter) and coolant shrinkage. In 21 minutes the pressurizer has emptied. Thereafter, the Reactor vessel upper head begins to drain resulting in a steam bubble in the upper head of the vessel. In 45 minutes the vessel upper head is completely voided. The outlet plenum then begins to drain causing the steam bubble to expand into the outlet plenum. The mixture level in the outlet plenum drops to just above the top of the hot leg at the end of one hour. During this one hour period natural circulation removes the core decay heat and keeps the core covered.

At one hour after the initiation of the blackout the charging pumps when powered by the DSD will provide makeup flow to the RCS. Thereafter the RCS inventory will be maintained (or will increase) for the remaining three hours of the coping duration. Again the core decay heat continues to be removed and the core remains covered for this period.

B. RECOMMENDATIONS

1. The Technical Specification leakage allowance of 6 gpm (total identified & unidentified) remains valid for Station Blackout. No changes to the Technical Specifications are thus required.

2. The allowable letdown isolation valve leakage of 20 gpm remains acceptable.

III. ASSUMPTIONS

A) NUMARC² BASED

- 1. The reactor is operating at 100% power for 100 days and at normal operating conditions at the time of the blackout.
- 2. All reactor support systems are within normal operating ranges.
- 3. The blackout does not occur during a design basis event.
- 4. Single failure criteria are not considered since SBO is not considered a design basis event.
- 5. The RCS pump seal leakage (cold) will not be greater than 25 gpm/pump.
- 6. The coping duration is four (4) hours⁶.
- 7. The initiating event is a loss of offsite power.

B) OPERATIONS BASED

- The Nominal pressurizer level at 100% power is 37.5%. This is the expected Pressurizer level at 551.5 F (i.e. based on the reduced Tavg program - see assumption B.2)²² (confirmed by E-mail from Operations -- see Appendix B). NUMARC permits use of the nominal pressurizer level as the initial condition of the blackout (see assumption A.1 & A.2).
- 2. The plant is using a Reduced Tavg program (due to the steam generator tube corrosion and plugging)²⁰.
- 3. The total unidentified and identified leakage is less than 6 gpm (requirement from Section 3.1.4 of the tech. specs.⁷).

C) EOI^{4,5} BASED

1. Steam generator level will be maintained between 50% and 70% NR during the blackout.

\square	V. F. Nazareth	6/21/91	W. Alhassani	6/21/91	$\left \right\rangle$				·	EV
\bigcirc		-			\land					I I

- 2. Auxiliary feedwater flow will be provided to the steam generators to maintain the steam generator level between the above limits. Auxiliary feedwater flow is provided through the turbine driven pump (G-10). The operator can throttle flow to the steam generators to maintain the Steam generators within these limits¹⁴.
- 3. The DSD can be powered up to restore charging capacity within one hour after the initiation of the blackout⁶.
- 4. The number of steam generator tubes plugged will be less than 20%²⁰. The safety analysis for Unit 1 cycle 11 assumes S.G. tube plugging of 20%. Therefore this assumption is used here.
- 5. The atmospheric dump valves are placed in manual mode to maintain plant subcooling conditions 3 minutes after initiation of the event. This is an expected operator action. However, this assumption will not compromise the conservatism of this calculation. If the manual operation of the ADV's were not credited, decay heat removal will still occur through automatic control of the ADV's and also through the Main Steam Safety Valves (MSSV).
- 6. The letdown leakage for the first two minutes after the blackout will be less than 90 gpm (i.e. 70 gpm greater than the leakage after blackout initiation). The 90 gpm value is the normal maximum letdown leakage (Section 9.3.4 of Reference 10). The letdown valve closure time is expected to be less than 30 seconds⁸. Therefore the assumption of a 90 gpm letdown leakage for 2 minutes since the initiation of the SBO is conservative.
- The total letdown system leakage (cold) after the first two minutes is less than 20 gpm. This is the maximum expected leakage from the letdown orifice isolation valves after the letdown system is isolated¹⁸.
- 8. Control rods are fully inserted within 3 seconds after initiation of the blackout¹².
- 9. No other leakage resulting in RCS water inventory drain exists.
- 10. The reactor trip is caused by the instantaneous loss of all AC. This produces the

> loss of the turbine bypass system which causes the initial opening of the ADV's. The ADV's are air operated and have Nitrogen backup. Therefore they will

continue to be operable during a blackout.

11. Control room adequacy and battery are assured to function during the entire coping duration¹⁹.

The minimum Auxiliary Feedwater flow delivered to all three steam 12. generators at a secondary side pressure of approximately 923 psia, when driven by pump G-10 will be at least 270 gpm. The actual minimum deliverable flow is expected to be between 288 gpm and 300 gpm. Therefore, it is conservative to assume a minimum deliverable flow of 270 gpm.

IV. DESIGN INPUT

Table IV-1 shows the design inputs used to determine the RCS inventory during the station blackout. The auxiliary feedwater flow that will be automatically delivered to each S.G. by means of the steam driven auxiliary feedwater pump (G10) is shown in Table IV-2. Some of the significant external inputs that require further explanation are described as follows:

- (i) <u>RCS Leakage</u> -- NUMARC 87-00 suggests using the assumption of leakage rates of 25 gpm per pump seal (i.e. total seal leakage of 75 gpm). The Unit 1 technical specification 3.1.4 permits a maximum allowable unidentified and identified leakage of 6 gpm. The letdown leakage limit is assumed to be 90 gpm until the letdown isolation valves are closed (i.e. for the first 2 minutes of the blackout) and subsequently 20 gpm for the remaining duration of the transient. Therefore the total leakage assumed is <u>171 gpm</u> for the first 2 minutes of the blackout and <u>101 gpm</u> for the rest of the coping duration. On a loss of all ac power, the letdown system is automatically isolated. This occurs by closure of valves CV-202, CV-203 & CV-204 along with CV-525 and CV-526 (See note in letdown system drawing²¹). The closure time for the letdown isolation valves is less than 30 seconds⁸. For conservatism the closure time of 2 minutes is used in this calculation.
- (ii) <u>Auxiliary Feedwater</u> -- After initiation of the blackout, main feedwater is not available as a decay heat removal system. Auxiliary feedwater however is available since it is driven by the steam driven auxiliary feedwater pump (G-10). AFW flow is automatically initiated when the SG level reaches a setpoint value of <u>5% NR</u> (Table 5.5-3 of Reference 10). It is then assumed that the delay time for the pump to be available to deliver flow into the S.G.'s is <u>3 minutes</u> (Section 6.5.2.2.3 of Reference 10). Thereafter once the S.G. level has reached between <u>50% and 70% NR</u>, the operator manually throttles the AFW flow to maintain this level in the

	$ \land $		6/21/91	W. Alhassani	6/21/91	\square					EV
	\wedge					\square					Ļ

S.G.'s⁴. The philosophy employed here is to maintain temperature and Pressure control in the Secondary side and consequently in the primary side and thus continue to have this system available for decay heat removal.

(iii) <u>Charging Flow</u> -- After one hour the charging pump when powered by the DSD restores charging flow to the Reactor. From Table II-2, the RCS pressure at this time will be 1067 psia. The charging flow capable of being delivered at this pressure will be at least 198.5 gpm⁹. However for this calculation a conservative value of 150 gpm charging flow is used^{*}. This minimum charging flow will be maintained from 1 hour to the end of the coping duration (i.e. 4 hours).

* Note that in this analysis it is only important that the charging flow delivered be greater than 101 gpm so that the RCS water that is lost due to the leakage can be made up.

The AFW flow shown in this table was derived from Figure 2-1 of Reference 16 and used in the RETRAN case. However, the actual flow expected to be delivered to <u>each</u> S.G. through the steam driven AFW pump G-10 will be at least 90 gpm. This will not significantly affect the results of this calculation since reduced AFW flow has a negligible effect on RCS water inventory change and the reduced flow remains sufficient to meet decay heat removal requirements. The lower initial AFW flow will slightly delay the recovery of S.G. secondary side level relative to the RETRAN results. However, once the S.G. level has reached 50% NR, the operator will throttle the AFW flow to maintain S.G. level. The secondary side results will then be consistent with the RETRAN values. For these reasons the lower AFW flow will not impact the RCS water inventory level nor will it significantly impact the ability of the system to remove core decay heat. AFW flows used are best estimate values and should not be considered design basis values.

V. METHODOLOGY

A. <u>GENERAL</u>

The RCS Inventory Analysis is performed based on the expected operator actions during a blackout as enumerated in EOI S01-1.0-60 and the expected Plant responses described in the Background Document for this EOI⁵. The simulation of the blackout and consequent plant actions and response is modeled using the RETRAN computer code. The results of the computer code will then be verified by a simplified hand calculation.

B. RETRAN CODE MODEL

The basic RETRAN model for Station Blackout was developed for the analysis performed to demonstrate the adequacy of the leakage technical specification (T.S. 3.1.4) and in response to LER 90-004¹⁸. A complete description of the input model used for this LER analysis is documented in Reference 12. The RETRAN nodal diagram describing the control volumes and junctions used in this analysis is shown in figure V-1. The code control systems for auxiliary feedwater flow and steam bypass are described in Figures V-2 and V-3.

The modifications made to the basic model¹² for this analysis are shown on Table V-1. The primary modifications along with the reasons for the changes are described as follows:

1. <u>RCS Leakage</u> -- The base model had the total RCS leakage only from one loop (i.e. volume 18). This approach is acceptable until such a time as the Pressurizer is drained. Thereafter the imbalance in the leakage appears to affect the convergence of the code. Therefore, a new junction (junction 51) was added for leakage from the other loops (i.e. volume 36). The amount of leakage through junction 50 will thus be reduced to one third of the total leakage and through junction 51 will be two thirds of the total leakage (since loops A & C are modeled

\square					\square					1

together as one loop). The HOT leakage is determined as follows:

 $L_{hot} = L_{cold} \star (d_{cold}/d_{hot})$

where,

 $L_{hot} = Hot leakage (gpm)$

 L_{cold} = Cold leakage (gpm)

 d_{hot} = density of water at 535 F

 $= 47.7 \text{ lbm/ft}^3$

 d_{cold} = density of water at 80 F

 $= 62.6 \text{ lbm/ft}^{3}$

The HOT leakage per RCS loop thus becomes 74.67 gpm (171*1.31/3) for the first 2 minutes of the SBO and 44.1 gpm (101*1.31/3) thereafter for the coping duration of 4 hours.

2. <u>Charging</u> -- The base model does not account for charging flow into the RCS system one hour after the SBO initiation. Therefore two extra junctions were added to provide this function (junctions 48 and 49). The amount of charging through these junctions will be one third through junction 48 and two thirds through junction 49. The hot charging flow per RCS loop will thus be 65.5 gpm (150*1.31/3) to be initiated one hour after the initiation of the SBO for the remaining 3 hours of the coping duration. In addition a charging initialization card was included to permit the initiation of charging flow.

3. <u>RCS Flow Rates & Temperatures</u> -- The base model flow rates were recalculated here based on the values from Table 4.4-1 of the FSAR¹⁰. Table V-2 shows the vessel flow rate, core flow rate and the calculation of the vessel inlet and outlet temperatures with the caveat that the Tavg will be maintained at 551.5 F (i.e. the Reduced Tavg program).

<u>Bubble Rise Models</u> -- The base model was developed for a RCS leakage of only
 27 gpm. The criteria used was Pressurizer drain. Since the criteria here is core

uncovery and the outlet plenum and upper head drain, a bubble rise model is included for the outlet plenum volume 6 (a bubble model in the upper head was in the original model). The model parameters are the same as for the upper head (i.e. Volume 7).

- <u>Volume overlaps</u> -- Due to the occurrence of bubbles in Volumes 6 & 7, RETRAN was not converging at the time that volume 7 was drained. Therefore, the volume height of volume 6 was adjusted to 9.6 inches to produce an overlap of 0.1 inches (old value was 9.5 inches). For the same reason the volume height of volumes 11, 16, 29 & 34 were also adjusted to 8.605 inches to produce an overlap of 0.1 inches (old value was 8.505 inches).
- 6. <u>Steam Generator Adjustments</u> -- The mass of water in the secondary side of each S.G. is 43,000 lbm. However, the code model is set up to accept only volumes. Therefore, the volume of the S.G.'s are adjusted to result in this S.G. water mass (i.e. Volume 50 = 1395, Volume 60 = 2906). In addition the initial S.G. liquid level and gain are adjusted to 22.2938 and 0.1044 to obtain an initial S.G. liquid level of 30% NR.
- 7. <u>AFW control block</u> -- The automatic AFW flow injection is modeled to inject water into the S.G.'s when the S.G. low level reaches 5% NR with a time delay of 3 minutes to account for valve stroking, transit time and time for the pump to get to full speed. The base model erroneously set the trip function for AFW initiation on a parameter for ADV control. This error was conservative in Reference 12 since the AFW would be actuated later than if it was correct. However, for this analysis this error is corrected (Card # 040030).
- 8. <u>Time step</u> -- In order to reduce the unnecessary time steps and consequently the code execution time, the time steps after the first hour of the transient are changed from 0.05 sec to 0.10 sec.. This will not compromise any of the results or conclusions of the code.

Problem Run Time -- The NUMARC guideline coping duration is 4 hours. 9. However, the charging flow powered by the DSD diesel is restored after one hour. Therefore, the simulation need be performed only for one hour. This simulation is performed for 30 minutes more (i.e. 90 minutes) to simulate some of the recovery process once the charging is restored.

VIII. CALCULATIONS

A. HAND VERIFICATION

In order to verify the accuracy of the RETRAN code results a simplified hand calculation will be performed. The purpose of this calculation is strictly to verify that the results are in the realm of reasonableness. The RCS inventory calculated during the station blackout is described in Table VIII-1. As shown on this Table the results of the hand verification calculation compare quite favorably with the results of RETRAN. Therefore it is concluded that the RETRAN results are acceptable.

[205] From: JOHN CUSTER at WEST3 6/20/91 1:41PM (859 bytes: 14 ln) To: MIKE MCDEVITT at NESL3 Subject: Pressurizer Program level

----- Message Contents ------

Mike -

Although Pressurizer program level is not specifically addressed in Operations procedures, this information is common operator required knowledge. It is addressed in our training and system description and is set by I&C as required by engineering. Presently the program level for our lower Tave program (level is prgrammed to Tave) is 25% level from 0 to 15% power and ramps linearly from 25% to 37.5% level from 15% power to 100% power.

At our present normal full Rx power level of 92% PZR program level is approximately 36.5%.

John Custer 89271 6/20/91

Each battery charger shall have adequate ampere capacity to restore the battery to a fully charged condition within 8 hours following ac recovery from a station blackout event.

ensure at least 105 volts is maintained at the inverter

terminals throughout the 4-hour SBO duration.

Since no design basis accidents or other events are assumed to occur immediately prior to or during station blackout, this calculation supplement is limited only to the verification of battery capability to provide for the SBO load requirements as well as the charger's ability to restore the battery in its fully charged state within the specified recharging time.

Credit is taken for manual dc load shedding operations during the SBO duration.

2.0 RESULTS/CONCLUSIONS and RECOMMENDATIONS

2.1 RESULTS/CONCLUSIONS

Battery Capacity 2.1.1

> The results of the calculations shown in Table 8.1 indicate the battery can cope with the 4-hour station blackout, as well as support Emergency Diesel Generator (EDG) No.1 manual random restart attempts throughout the 4-hour SBO duration, provided manual shedding of dc loads are performed in the sequence of operations identified in Sections 2.2.1 and 4.8.

Battery Terminal Voltage 2.1.2

The results of the calculations shown in Table 8.2 indicate a minimum battery voltage of 107.59 volts, thereby ensuring at least 105 volts at the inverter input terminals during the SBO duration.

2.1.3

Battery Charger Capacity

The results of the battery charger sizing calculation in Section 8.3 indicate a required charger ampacity of 555.35 amperes.

Each battery charger is rated 1000 amperes. Therefore, each charger has the capacity and capability to restore the battery to a fully charged state within 8 hours following ac power restoration.

2.1.4 Battery System Surveillance Requirements

Battery Service Test

The new SBO-based load profile is more severe than the SISLOP-based accident load profile. However, there is no present requirement for battery service testing to the SBO profile.

Should a service test to the SBO load profile be required in the future, station maintenance procedures, which presently use a service test profile based on the accident load profile shown in calculation Supplement T, shall be revised accordingly as recommended in Section 2.2.2.

Battery Charger Capability Verification

The 555.35 amperes charger ampacity required to recharge the battery following SBO recovery is well within the surveillance requirements of Technical Specification 4.4.D.2.c(4) and Station Maintenance Procedures SO123-I-2.5 and SO123-I-2.6, which specify verification of battery charger capability to supply at least 800 amperes for at least 8 hours.

Therefore, no change to Technical Specification 4.4.D.2.c(4) or Station Maintenance Procedures SO123-I-2.5 and SO123-I-2.6 is required.

2.2 RECOMMENDATIONS

Based on the above results and conclusions, the following actions are recommended:

4.7 The proposed replacement for the Train B battery bank (Battery No. 2) will be adequate to support the station blackout requirements.

Control Room instrumentation and controls supplied from Train A Inverters 1 and 3, and Train B Inverter 5 will be sufficient to satisfy the minimum control room instrumentation during station blackout (Reference 6.12). As such, loads noted in Table 4.8, including Train A Inverters 2 and 4, can then be manually tripped in order to reduce loading on Battery No. 1.

- The resultant load profile shown in Table 4.8 developed 4.8 based on:
 - The SISLOP-based loading tables of Table 5.1.142 of Supplement T, Revision 3 (DC-1604 Revision 9), considering those loads associated with a LOP only. The random load (EDG restart) value for this calculation (Supplement V) is developed from the 0-1 minute loading of Supplement T Table 5.1.142.
 - Cycle XI load changes (the 10 amperes contingency load is used instead of the actual net load added since the service test was performed based on the load profile which included this 10 amperes contingency load).
 - Cycle XII contingencies (10 amperes).
 - Manual load stripping of selected dc loads to reduce battery loading.

5.0 METHODOLOGY

Using the resultant load profile shown in Table 4.6, battery capacity and terminal voltages, as well as battery charger capacity are calculated as follows:

5.1 Battery Capacity Calculation

The end-of-discharge voltage is first determined by adding the worst case battery-bus and bus-inverter voltage drops to the minimum inverter terminal input voltage. The voltage drops are calculated using the following formula:

$VD = 2 \times I \times R \times L$

where: I = load in amperes R = conductor resistance in ohms/1000 ftat $75^{\circ}C$

L = circuit length in feet

With the end-of-discharge voltage established, the required battery capacity is then calculated using the GNB NCX-2550 discharge characteristics curves per IEEE Std 485 guidelines.

5.2 Battery Terminal Voltage Calculation

The battery terminal voltages calculated for each period of the battery duty cycle are calculated as follows:

Load Amps is the load amperes for the period.

Adjusted Load Amps is the Load Amperes multiplied by the Aging Factor and the Temperature Correction Factor.

Adjusted Load Amps per Positive Plate is the Adjusted Load Amperes divided by the number of positive plates.

REV	ORIGINATOR		DATE	IRE	DATE	REV	ORIGINATOR	DATE	IRE	DATE
0	A. S. MATIONG	adm	6/21/91	SCK	6/21/91					
				-		,	•			

Expended Amp-Hours per Positive Plate is the Adjusted Load Amperes per positive plate multiplied by the period duration.

For succeeding periods, it is the Expended Amp-Hours per Positive Plate of the period plus the Expended Amp-Hours per Positive Plate of the preceding period.

<u>Cell Volts</u> is the cell voltage read directly from the battery discharge characteristics curves corresponding to the specific Amps per Positive Plate and Expended Amp-Hours per Positive Plate. The <u>Begin</u> voltage corresponds to the specific period Amps per Positive Plate and Expended Amp-Hours at the beginning of the period. The <u>End</u> voltage corresponds to the specific period Amps per Positive Plate and Expended Amp-Hours at the end of the period.

<u>Battery Volts</u> is the Cell Volts multiplied by the number of cells.

5.3 Battery Charger Capacity

The ampere capacity of the charger is calculated using the following formula:

A = L + 1.1 (C/H)

where: A = required capacity charger in amperes

- L = continuous load amperes
- H = number of hours for recharging
- C = ampere hours removed from the battery

- 8.0 <u>COMPUTATIONS</u>
 - 8.1 Battery Capacity

The minimum end-of-discharge voltage for the 58-cell battery bank ($V_{battery}$) is the sum of the minimum inverter input voltage ($V_{inverter}$), the worst case battery-bus voltage drop ($VD_{battery-bus}$) and bus-inverter voltage drop ($VD_{bus-inverter}$).

From References 6.7, 6.8 and 6.9:

Battery-Bus feeder : 3-1/C#500 MCM per pole 47.5 ft circuit length 0.0265 ohm/1000 ft @ 75°C

Bus-Inverter feeder: 1/C#4/0 MCM per pole 132 ft circuit length 0.0626 ohm/1000 ft @ 75⁰C

The worst case voltage drop on the battery-bus feeder occurs during the initial minute of the duty cycle when battery load is at maximum (1195 amperes).

 $VD_{battery-bus} = 2(1195)(0.0265/3)(47.5/1000)$ = 1.0028 volts

The Inverter 4 supply feeder voltage drop represents the worst case bus-inverter voltage drop. Inverter 4 draws the most current (54.7 amperes) and is located farthest from the dc bus. Inverter 4 is located at the 4KV Switchgear Room while Inverters 1, 2 and 3 as well as the dc bus are all located in the DC Switchgear Room.

 $VD_{bus-inverter} = 2(54.7)(0.0626)(132/1000)$ = 0.9040 volt

The minimum required inverter input voltage is:

V_{inverter} = 105 volts

Justification for Removal of Loads From Battery No. 1 During a Station Blackout

<u>Justification For Removal of Loads</u> From Battery No. 1 During a Station Blackout

The Control Room must remain functional for the four hour coping duration of the SBO. Plant coping during the SBO is performed utilizing the DSD diesel. The DC loads on battery No. 1 listed below are removed during the station blackout and are not required for the Control Room to remain functional. The justification for removing loads at the indicated times during a blackout are provided. It should be noted that the plant configuration after removing the DC loads listed below is no different than the plant configuration when using the DSD diesel for plant shutdown after an Appendix R fire.

1) DC Breaker No. 72-120 - Emergency RCP Thermal Barrier Pump

The Emergency RCP Thermal Barrier Pump can provide alternate cooling to the RCP seals. However, during an SBO event, the thermal barrier pump is not credited. Seal cooling is provided along with RCS inventory makeup by the North Charging pump powered by the DSD diesel.

The SBO RCS inventory calculation assumes seal leakage consistent with NUMARC 87-00 guidelines for RCS inventory loss until charging is established utilizing the DSD diesel. This load can be shed at any time.

2)

DC Breaker No. 72-139 - Emergency Bearing Seal Oil Pump.

The Turbine Bearing Emergency Oil Pump can be shed after the turbine comes to rest. Westinghouse estimates that the standard time frame for the turbine to come to rest is 30 to 40 minutes. The pump can be manually tripped after this occurs which can be assumed to be 45 minutes.

3)

DC Breaker No. 72-138 - Emergency Hydrogen Seal Oil Pump.

The Emergency Seal Oil Pump is used to prevent hydrogen leakage from the generator. After the DSD diesel has been started and loaded, operators will be available to remove hydrogen from the generator. This process includes depressurizing, degassing and CO_2 flushing. Assuming one hour to start and load the DSD diesel and two hours to degas and partially flush the generator, this pump can be manually tripped after three hours.

4)

DC Breaker No. 72-102 - Turbine Plant Annunciator DC Breaker No. 72-104 - Reactor Plant Annunciator DC Breaker No. 72-109 - Hydrogen Control Panel Annunciator DC Breaker No. 72-127 - HVAC Control Board Annunciator DC Breaker No. 72-129 - Radwaste Control Board Annunciator

These annunciators do not provide an instrument or control function and can be removed at any time.

5) DC Breaker No. 72-110 - Digital Fault Recorder

This provides a diagnostic tool to monitor pre-fault and post fault conditions in breakers and power supplies. This is not required to cope with a SBO and can be removed at any time.

6) DC Breaker No. 72-111 - Turbine Controls

After the turbine has tripped, these controls are no longer required and can be removed at any time.

7) DC Breaker No. 72-121 - Chemical Control Board

This provides the capability to obtain a Steam Generator Blowdown sample. This load is not required to cope with a SBO and can be removed at any time.

8) DC Breaker No. 72-124 - Sequencer No. 1

The EDG has failed to start as part of the SBO scenerio and auto sequencing of the EDG is not required. This load can be removed at any time.

9) DC Breaker No. 72-140 - Emergency Lighting Switchboard

This provides DC control power to the incoming normal and standby supply breakers for the AC lighting switchboard. This load can be removed at any time.

10) DC Breaker No. 72-141 - Control Rods

Once the reactor has tripped this load is no longer required to cope with a SBO and can be removed at any time.

11) DC Breaker No. 72-122 - Containment Spray System DC Breaker No. 72-134 - NIS Coincidentor Cabinets A and B

Accidents are not assumed to occur concurrent with the SBO event. Therefore these loads are not required to cope with an SBO and can be removed at any time.

12) DC Breaker No. 72-123 - Sphere Isolation Valves

This breaker powers the isolation valves for the sphere sample, sump discharge, and RCS drain tank discharge lines. They all fail closed on loss of DC power. Closure of these valves meets the SBO position on establishing containment integrity. This load can be removed at any time.

13) DC Breaker No. 72-131 - Inverter No. 4 DC Breaker No. 72-136 - Inverter No. 2

> Inverters 1 and 3 will provide the minimum instrumentation required for the Control Room to remain functional during a SBO. Inverters 2 and 4 provide instrumentation that is redundant to that provided by Inverters 1 and 3.

> Additionally, with the shedding of these breakers, the control valves powered by Inverters 2 and 4 are left in the same configuration as when the breakers are shed during a plant shutdown after an Appendix R fire which utilizes the DSD diesel.
