Safety Analysis Report for the Model 8-120B Type B Shipping Packaging,
Consolidated Revision 8, May 2014, Public Version
(1 paper copy)

SAFETY ANALYSIS REPORT

For

MODEL 8-120B TYPE B SHIPPING PACKAGING

CONSOLIDATED REVISION 8

May 2014

TABLE OF CONTENTS

1.0	GENERAL INFORMATION	1-1
1.1	Introduction	1-1
1.2	Package Description.....	1-1
1.2.1	Packaging.....	1-1
1.2.2	Contents of Packaging	1-5
1.2.3	Special Requirements For Plutonium	1-7
1.2.4	Operational Features	1-7
1.3	Appendix	1-9
2.0	STRUCTURAL EVALUATION.....	2-1
2.1	Description of Structural Design.....	2-1
2.1.1	Discussion.....	2-1
2.1.2	Design Criteria.....	2-2
2.1.3	Weight and Center of Gravity.....	2-4
2.1.4	Identification of Codes and Standards for Package Design.....	2-4
2.2	Materials.....	2-4
2.2.1	Material Properties and Specifications	2-4
2.2.2	Chemical Galvanic and Other Reactions	2-5
2.2.3	Effects of Radiation on Materials	2-6
2.3	Fabrication and Examination	2-6
2.3.1	Fabrication	2-6
2.3.2	Examination.....	2-6
2.4	General Requirements for All Packages	2-7
2.4.1	Minimum Packaging Size	2-7
2.4.2	Tamper-Indicating Features	2-7
2.4.3	Positive Closures.....	2-7
2.5	Lifting and Tie-Down Standards for All Packages	2-7
2.5.1	Lifting Devices.....	2-8
2.5.2	Tie-Down Devices	2-17
2.6	Normal Conditions of Transport	2-22
2.6.1	Heat.....	2-23
2.6.2	Cold.....	2-24
2.6.3	Reduced External Pressure	2-25
2.6.4	Increased External Pressure	2-26

2.6.5	Vibration	2-26
2.6.6	Water Spray	2-26
2.6.7	Free Drop	2-26
2.6.8	Corner Drop	2-28
2.6.9	Compression	2-28
2.6.10	Penetration	2-28
2.7	Hypothetical Accident Conditions	2-29
2.7.1	Free Drop	2-29
2.7.2	Crush.....	2-49
2.7.3	Puncture	2-49
2.7.4	Thermal.....	2-55
2.7.5	Immersion – Fissile material.....	2-56
2.7.6	Immersion – All packages	2-56
2.7.7	Deep Water Immersion Test	2-56
2.7.8	Summary of Damage	2-56
2.8	Accident Conditions for Air Transport of Plutonium	2-57
2.9	Accident Conditions for Fissile Material Packages for Air Transport.....	2-57
2.10	Special Form.....	2-57
2.11	Fuel Rods.....	2-57
2.12	Appendix	2-58
2.12.1	List of References	2-58
3.0	THERMAL EVALUATION.....	3-1
3.1	Description of Thermal design.....	3-1
3.1.1	Design Features.....	3-1
3.1.2	Content’s Decay Heat	3-1
3.1.3	Summary Tables of Temperatures.....	3-1
3.1.4	Summary Table of Maximum Pressures.....	3-2
3.2	Material properties and component specifications.....	3-2
3.2.1	Material Properties.....	3-2
3.2.2	Component Specifications	3-2
3.3	Thermal Evaluation for Normal Conditions of Transport.....	3-2
3.3.1	Heat and Cold	3-3
3.3.2	Maximum Normal Operating Pressure	3-4
3.3.3	Thermal Stresses	3-6
3.4	Hypothetical Accident Thermal Evaluation.....	3-6

3.4.1	Initial Conditions	3-7
3.4.2	Fire Test Conditions.....	3-7
3.4.3	Maximum Temperatures and Pressure.....	3-8
3.4.4	Maximum Thermal Stresses	3-9
3.4.5	Accident Conditions for Fissile Packages for Air Transport	3-9
3.5	Appendix	3-9
3.5.1	List of References	3-9
3.5.2	Attachment.....	3-11
4.0	CONTAINMENT.....	4-1
4.1	Description of Containment System	4-1
4.1.1	Containment Vessel	4-1
4.1.2	Containment Penetration.....	4-1
4.1.3	Welds and Seals	4-1
4.1.4	Closure.....	4-1
4.2	Containment Under Normal Conditions of Transport.....	4-2
4.2.1	Maximum Permitted Leak Rate	4-2
4.2.2	Containment Under Normal Conditions of Transport (Powdered Solids).....	4-3
4.2.3	Containment Under Normal Conditions of Transport (Irradiated Hardware)	4-6
4.3	Containment Under Hypothetical Accident Conditions (Type B Packages)	4-7
4.3.1	Containment Under Hypothetical Accident Conditions (Powdered Solids).....	4-8
4.3.2	Containment Under Hypothetical Accident Conditions (Irradiated Hardware)	4-9
4.4	Reference Air Leakage Rate	4-11
4.5	Determination of Equivalent Reference Leakage Rate for R-134a Gas	4-11
4.6	Determination of Equivalent Reference Leakage Rate for Helium Gas	4-15
4.7	Determining Time for Pre-Shipment Leak Test Using Air or Nitrogen	4-19
4.7.1	Minimum Hold Time for Closure Lid	4-19
4.7.2	Minimum Hold Time for Vent Port.....	4-21
4.8	Leakage Rate Tests for Type B Packages	4-22
4.9	Periodic Verification Leak Rate Determination for Leaktight Status	4-24
4.9.1	Introduction.....	4-24
4.9.2	Test Conditions	4-24
4.10	References	4-25
5.0	SHIELDING EVALUATION.....	5-1
5.1	Description of Shielding Design	5-1

5.1.1	Shielding Design Features	5-2
5.1.2	Maximum Radiation Levels.....	5-2
5.2	Source Specification.....	5-4
5.2.1	Gamma Source.....	5-4
5.2.2	Neutron Source	5-4
5.2.3	Beta Source	5-4
5.3	Model Specification	5-5
5.3.1	Description of Radial and Axial Shielding Configuration.....	5-5
5.3.2	Material Properties.....	5-7
5.4	Shielding Evaluation	5-8
5.4.1	Methods.....	5-8
5.4.2	Input and Output Data.....	5-8
5.4.3	Flux-to-Dose-Rate Conversion	5-8
5.4.4	External Radiation Levels and Source Strength Limits.....	5-8
5.5	Payload Qualification.....	5-10
5.6	References	5-10
5.7	Loading Specification 8-120B-1 (General Sources)	5-11
5.7.1	Loading Specification 8-120B-1 Description	5-11
5.7.2	8-120B-1 Sources.....	5-11
5.7.3	Loading Specification 8-120B-1 Model Specification	5-12
5.7.4	8-120B-1 Shielding Evaluation.....	5-12
5.7.5	8-120B-1 Payload Qualification	5-20
5.8	Loading Specification 8-120B-2 (Activated Steel).....	5-36

REVISION CONTROL SHEET		
TITLE: Safety Analysis Report for Model 8-120B Type B Shipping Packaging		
AFFECTED PAGE(S)	REVISION AND DATE	REMARKS
As indicated	Consolidated Revision 3 July 2012	Approved version, Certificate of Compliance Revision 19.
As indicated	Consolidated Revision 4 May 2013	Submitted to NRC May, 2013 with initial amendment request. Revision marks indicate changes since Consolidated Revision 3.
As indicated	Consolidated Revision 5 August 2013	Submitted to NRC August, 2013 in response to RAIs. Revision marks indicate changes since Consolidated Revision 3.
As indicated	Consolidated Revision 6 September 2013	Submitted to NRC September, 2013 in response to second RAI. Revision marks indicate changes since Consolidated Revision 3.
1-5, 7-1, 7-4, 7-5, and 8-6 through 8-9.	Consolidated Revision 7 November 2013	Submitted to NRC October, 2013 to support issuance of Certificate of Compliance Revision 20. Revision marks indicate changes since Consolidated Revision 3.
As indicated	Consolidated Revision 8 May 2014	Added Loading Specifications 8-120B-1 through -4. Submitted to NRC May, 2014 with initial amendment request.

1.0 GENERAL INFORMATION

1.1 INTRODUCTION

This Safety Analysis Report describes a reusable shipping package designed to protect radioactive material from both normal conditions of transport and hypothetical accident conditions. The package is designated the Model8-120B package.

1.2 PACKAGE DESCRIPTION

1.2.1 PACKAGING

The package consists of a steel and lead cylindrical shipping cask with a pair of cylindrical foam-filled impact limiters installed on each end. The package configuration is shown in Figure 1-1. The internal cavity dimensions are $61\frac{13}{16}$ inches in diameter and $74\frac{7}{8}$ inches high. The cylindrical cask body is comprised of a $1\frac{1}{2}$ inch thick external steel shell and a $\frac{3}{4}$ inch internal steel shell. The annular space between the shells is filled with 3.35 inch thick lead. The base of the cask consists of two $3\frac{1}{4}$ inch thick flat circular steel plates. The cask lid consists of two $3\frac{1}{4}$ inch thick flat circular steel plates. The lid is fastened to the cask body with twenty 2-8 UN bolts. There is a secondary lid in the middle of the primary lid. This secondary lid is attached to the primary lid with twelve 2-8 UN bolts. A thermal shield protects the secondary lid. The thermal-shield consists of two polished stainless-steel plates that are separated by a thin air gap with stand-offs which provide an additional air gap above the secondary lid. The thermal-shield assembly is attached to the secondary lid lifting lugs with hitch-pins.

The impact limiters are 102 inches in outside diameter and extend 22 inches beyond each end of the cask. There is a 50.0 inch diameter void at each end. Each impact limiter has an external shell, fabricated from ductile low carbon steel, which allows it to withstand large plastic deformations without fracturing. The volume inside the shell is filled with a crushable shock and thermal insulating polyurethane foam. The polyurethane is sprayed into the shell and allowed to expand until the void is completely filled. The foam bonds to the shell, which creates a unitized construction for the impact limiters. The impact limiters' skin is 12 gage steel, including the upper impact limiter's weather cover. The lower impact limiter has a $\frac{1}{2}$ -inch thick steel cover plate.

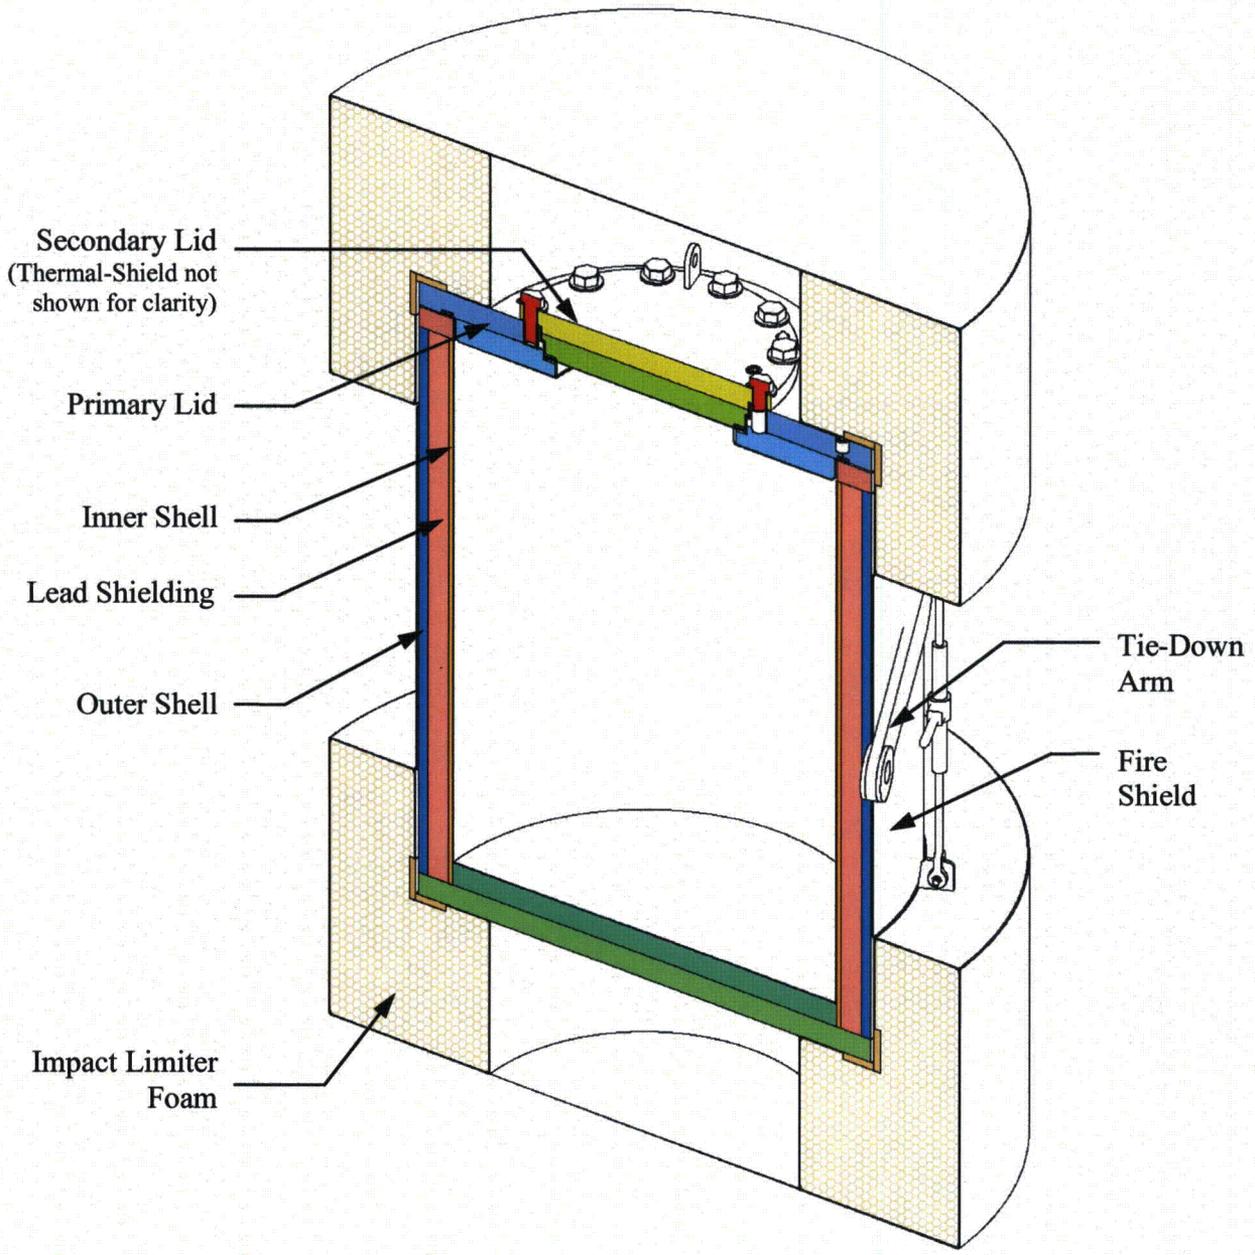

Figure 1-1 - Features of the 8-120B Cask

The properties of the foam are further described in Section 2.2. The top and bottom impact limiters are connected together by eight one-inch diameter ratchet binders. This serves to hold the impact limiters in place on the cask during shipment, while allowing easy removal of the impact limiters for loading and unloading operations.

A general arrangement drawing of the package is included in Appendix 1.3. It shows the package dimensions as well as all materials of construction.

1.2.1.1 Containment Vessel

The containment vessel is defined as the inner steel shell of the cask body together with closure features comprised of the lower surface of the cask primary lid and 20 equally spaced 2-8 UN closure bolts and the lower surfaces of the cask secondary lid and the 12 equally spaced 2-8 UN closure bolts.

1.2.1.2 Neutron Absorbers

There are no materials used as neutron absorbers or moderators in the package.

1.2.1.3 Package Weight

Maximum gross weight for the package is 74,000 lbs. including a maximum payload weight of 14,150 lbs.

1.2.1.4 Receptacles

There are no receptacles on this package.

1.2.1.5 Vent and Test Ports

Pressure test ports with manual venting features exist between the twin o-ring seals for both the primary and secondary lids. This facilitates leak testing the package in accordance with ANSI N14.5.

The vent port is provided with the same venting features for venting pressures within the containment cavity, which may be generated during transport, prior to lid removal. Each port is sealed with an elastomer gasket. Specification information for all seals and gaskets is contained in Chapter 4.

1.2.1.6 Lifting Devices

Lifting devices are a structural part of the package. From the General Arrangement Drawing shown in Appendix 1.3, it can be seen that two removable lifting ears are provided, which attach to the cylindrical cask body. Three lifting lugs are also provided for removal and handling of the lid. Similarly, three lugs are provided for removal and handling of the secondary lid. Refer to Section 2.5.1 for a detailed analysis of the structural integrity of the lifting devices.

1.2.1.7 Tie-downs

From the General Arrangement Drawing, shown in Appendix 1.3, it can be seen that the tie-down arms are an integral part of the external cask shell. Consequently, tie-down arms are considered a structural part of the package. Refer to Section 2.5.2 for a detailed analysis of the structural integrity of the tie-down arms.

1.2.1.8 Heat Dissipation

There are no special devices used for the transfer or dissipation of heat.

1.2.1.9 Coolants

There are no coolants involved.

1.2.1.10 Protrusions

There are no outer or inner protrusions except for the tie-down arms described above. Lifting lugs are removed prior to transport.

1.2.1.11 Shielding

Cask walls provide a shield thickness of 3.35 inches of lead and 2¼ inches of steel. Cask ends provide a minimum of 6½ inches of steel. The contents will be limited such that the radiological shielding provided (4½ inches lead equivalent) will assure compliance with DOT and IAEA regulatory requirements.

1.2.1.12 Configurations

There are three physical configurations of the 8-120B cask body and impact limiters.

- Configurations 1 and 2 were fabricated per the previously approved drawing Rev. 13 and differ mainly in the inclusion (Configuration 1) or lack (Configuration 2) of the optional drain port. Configuration 1 now includes sealing the drain port with the insertion and welding of a rod in the drain port. Acceptance Testing of Configurations 1 and 2 are described in Section 8.1. Fabrication of Configurations 1 or 2 after April 1, 1999 are not permitted.
- Configuration 3 does not have a drain port and the base plate is fabricated differently than Configurations 1 and 2. Acceptance Testing of Configuration 3 is described in Section 8.2.
- Configurations 1, 2 and 3 have the same Operations and Maintenance requirements and are described in Sections 7.0 and 8.3 respectively

All configurations have the same structural, thermal, containment, shielding, and criticality evaluations.

In order to provide operational flexibility, shipments in the 8-120B cask are made under the provisions of Loading Specifications. Loading Specifications provide a standardized way to add

to or refine definitions of acceptable 8-120B contents within the overall contents restrictions described in the Certificate of Compliance. Loading Specifications include a description of the payload, any required secondary containers, the allowable radiological source terms, and any other restrictions or notes applicable to the Specification. Payloads meeting the requirements of a particular Loading Specification may have radiological source terms up to the limits described in the appendices to Chapter 5 for the Loading Specification. In some cases, payloads may be qualified by using a sum-of-fractions method encompassing more than one Loading Specification. Table 1-1 lists the currently defined 8-120B Loading Specifications and where their radiological source limits are defined. Table 1-2 defines the requirements for each Loading Specification.

Table 1-1 - 8-120B Loading Specifications

Loading Specification	Qualified Sources	Notes
8-120B-1 General Sources	Section 5.7.4.4	8-120B-1 is the general-purpose Loading Specification covering a wide range of payload shapes, source energies, and materials. Any contents allowed by the Certificate of Compliance may be shipped using this Loading Specification. It is the most conservative Loading Specification so it may be desirable to qualify payloads using another Loading Specification, if applicable.
8-120B-2 Activated Steel	Section 5.8.4.4	8-120B-2 applies to shipments of activated steel using a steel shipping liner meeting the requirements of the 8-120B-2 liner drawing in Section 1.3.
8-120B-3 Reformed Residue	Section 5.9.4.4	8-120B-3 applies to shipments of reformed residue (RR) generated using the THOR™ process that are made in a typical high-integrity container (HIC).
8-120B-4 Resins	Section 5.10.4.4	8-120B-4 applies to shipments of ion-exchange resins, charcoal, and zeolite, made in a secondary container (liner or HIC).

1.2.2 CONTENTS OF PACKAGING

1.2.2.1 Type form of material:

- Byproduct, source, or special nuclear material, in the form of dewatered resins, solids, including powdered or dispersible solids, or solidified material, contained within secondary container(s); or
- Radioactive material in the form of neutron activated metals or metal oxides in solid form contained within secondary container(s).

1.2.2.2 Maximum quantity of material per package:

Type B quantity of radioactive material not to exceed 3000A₂, 200 thermal watts, and 14,150 pounds including weight of the contents, secondary container(s) and shoring. The contents may include fissile materials provided at least one of the paragraphs (a) through (f) of 10 CFR 71.15 is met. Materials producing more than 1×10^5 neutrons/sec in the total contents, other than fissile materials as allowed in the preceding sentence, are not authorized.

The activity of beta and gamma emitting radionuclides shall not exceed the limits determined per the Loading Specification sections in Chapter 5.

Powdered or dispersible solid radioactive materials must have a mass of at least 60 grams or a specific activity of 50 A₂/g or less.

1.2.2.3 Loading Restrictions

Contents shall be packaged in secondary containers. Except for close fitting contents, shoring must be placed between the secondary containers or activated components and the cask cavity to prevent movement during accident conditions of transport.

Explosives, non-radioactive pyrophorics, and corrosives (pH less than 2 or greater than 12.5), are prohibited. Pyrophoric radionuclides may be present only in residual amounts less than 1 weight percent. Materials that may auto-ignite or change phase (i.e., change from solid to liquid or gas) at temperatures less than 350°F, not including water, shall not be included in the contents. In addition, as required by 10 CFR 71.43 (d), the contents shall not include any materials that may cause any significant chemical, galvanic, or other reaction.

Powdered solids shipments shall be performed only when the most recent periodic leak test meets the requirements of Chapter 4, Section 4.9. Powdered solid radioactive material shall not include radioactive forms of combustible metal hydrides, combustible elemental metals, i.e., magnesium, titanium, sodium, potassium, lithium, zirconium, hafnium, calcium, zinc, plutonium, uranium, and thorium, or combustible non-metals, i.e., phosphorus.

For any package containing water and/or organic substances which could radiolytically generate combustible gases, a determination must be made that, over a period of time that is twice the expected shipping time, the hydrogen generated must be limited to a molar quantity that would be no more than 5% by volume (or equivalent limits for other inflammable gases) of the secondary container gas void if present at STP (i.e., no more than 0.063 g-moles/ft³ at 14.7 psia and 70°F).

The determination of hydrogen generation will be made using the methods in NUREG/CR-6673, *Hydrogen Generation in TRU Waste Transportation Packages*. NUREG/CR-6673 has equations that allow prediction of the hydrogen concentration as a function of time for simple nested enclosures and for packages containing multiple contents packaged within multiple nested confinement layers. The inputs to these equations include the bounding effective G(H₂)-value for the contents, the G(H₂)-values for the packaging material(s), the void volume in the containment vessel and in the confinement layers (when applicable), the temperature when the package was sealed, the temperature of the package during transport, and the contents decay heat.

For any package delivered to a carrier for transport, the secondary container must be prepared for shipment in the same manner in which the determination for gas generation is made. Shipment period begins when the package is prepared (sealed) and must be completed within twice the expected shipping time.

For any package containing materials with radioactivity concentration not exceeding that for LSA and shipped within 10 days of preparation, or within 10 days of venting the secondary container, the gas generation determination above need not be made and the shipping time restriction does not apply.

8-120B Loading Specifications include unique loading restrictions wherever the safety analyses credit particular restrictions on contents properties, secondary containers, or other parameters. Table 1-2 lists the unique requirements for Loading Specifications.

1.2.3 SPECIAL REQUIREMENTS FOR PLUTONIUM

Any contents that contain more than 0.74 TBq (20 Ci) of plutonium must be in solid form.

1.2.4 OPERATIONAL FEATURES

Refer to the General Arrangement Drawing of the package in Appendix 1.3. There are no complex operational requirements associated with the package

Table 1-2 - 8-120B Loading Specification-Unique Requirements

Loading Specification	Payload	Secondary Container	Other
8-120B-1 General Sources	<ul style="list-style-type: none"> Volumetric sources (Table 5-5, columns 2, 4, or 5) valid for mass densities less than 9.0 g/cc. 	<ul style="list-style-type: none"> No unique requirements 	
8-120B-2 Activated Steel	<ul style="list-style-type: none"> Activated steel in the form of rod, tube, plate, sheet, dross or fines (e.g., reactor decommissioning waste). ⁶⁰Co-dominated sources. Other items may be added via sum-of-fractions using Loading Specification 8-120B-1. 	<ul style="list-style-type: none"> Steel shipping liner meeting the requirements of the 8-120B-2 liner drawing in Section 1.3. Allowable sources (Section 5.8) depend on liner thickness. 	<ul style="list-style-type: none"> The limits on ⁶⁰Co specific activity apply to the most activated portion of the waste material. Specified source includes CRUD allowance. Greater CRUD levels require reduction in allowed sources per Section 5.8.
8-120B-3 Reformed Residue	<ul style="list-style-type: none"> Reformed residue (RR) formed using the THOR™ process. Use Loading Specification 8-120B-1 for partial fills where RR volume is ≥94 cubic feet. 	<ul style="list-style-type: none"> Polymer high-integrity container (HIC) with wall thickness of 1 inch or less. 	<ul style="list-style-type: none"> Bases for radiological qualification include analysis and pre-shipment measurements per requirements in Section 5.9.
8-120B-4 Resins	<ul style="list-style-type: none"> Any combination of ion-exchange resins, charcoal, and/or zeolite filter media. Other items may be added via sum-of-fractions using Loading Specification 8-120B-1. 	<ul style="list-style-type: none"> Steel or polymer.

2.0 STRUCTURAL EVALUATION

This Section identifies, describes, discusses and analyzes the structural design of the 8-120B packaging components, and safety systems for compliance with performance requirements of 10 CFR 71 (Reference 2-1).

2.1 DESCRIPTION OF STRUCTURAL DESIGN

The package has been designed to provide a shielded containment vessel that can withstand the loading due to the Normal Conditions of Transport, as well as those associated with the Hypothetical Accident Conditions.

The 8-120B package is designed to protect the payload from the following conditions: Transport environment, 30-foot drop test, 40-inch puncture test, 1475°F thermal exposure, and transfer or dissipation of any internally generated heat. The design of the package satisfies these requirements.

Principal elements of the system consist of:

- Containment Boundary
- Lead Shielding
- Impact Limiters

These components are identified in the drawings of Appendix 1.3. The design and function of these components in meeting the requirements of 10 CFR 71 is discussed below.

Figure 2-1 shows the nomenclature of the components of the cask used throughout this SAR.

2.1.1 DISCUSSION

Containment Boundary

The containment boundary of the package is made up of the cask body and the lid. They are fabricated of ASTM A516, Grade 70 steel. The cask body consists of two shells, which envelop a lead shield. The top end of the cask body consists of a bolting ring that provides sealing and bolting surfaces for the lid. The bottom end of the cask body consists of two baseplates. A removable primary lid is attached to the cask body with twenty (20) equally spaced 2"–8UN bolts. A secondary lid is centered and attached to the primary lid with twelve (12) equally spaced 2"–8UN bolts. The lid-to-cask body and lid-to-lid joints are each sealed by pairs of solid elastomeric O-rings. The cask containment boundary consists of the inner shell, the outer baseplate, the bolting ring, the inner O-ring, and the lids. This boundary is penetrated by the vent port. Thus, the parts of this port up to the stat-o-seal are also considered to be on the containment boundary. Figure 2-2 shows the containment boundary of the package.

Shielding

The space between the two shells, discussed above, is filled with lead. This lead shielding is subjected to a gamma scan inspection to assure lead integrity. The designed thickness assures that no biological hazard is presented by the package and all shielding requirements of 10 CFR 71 are met.

Impact Limiters

The impact limiters are designed to protect the package from damage during the HAC drop test and to provide thermal protection during the hypothetical fire accident condition.

They are constructed of fully welded steel shells filled with foamed-in-place closed-cell rigid polyurethane foam. The impact limiter shells and internal foam cores deform and absorb energy during free drop impacts. Eight circumferentially located attachment points are provided to interconnect the two impact limiters. The steel plates that cover the central hollow regions of the upper and lower impact limiters are designed to remain intact and attached to the impact limiters during NCT. However, these cover plates have no significant effect on the energy-absorption characteristics of the impact limiters during the NCT and HAC free drop tests, and therefore they are not considered in the NCT and HAC free drop analyses.

Detailed discussions of all components and materials utilized in the 8-120B Package including stress, thermal, and pressure calculations are contained in the applicable sections of this SAR.

2.1.2 DESIGN CRITERIA

The package is designed to satisfy the requirements of 10 CFR 71.71 under the normal conditions of transport (NCT) and hypothetical accident conditions (HAC). Compliance with the "General Standards for All Packages" specified in 10 CFR 71.43 and the "Lifting and Tie-Down Standards" specified in 10 CFR 71.45 are discussed in Section 2.4 and 2.5 respectively. Table 2-1 summarizes the NCT and HAC loading and their combination with various initial conditions, used for the design assessment of the 8-120B package. Table 2-1 has been developed from the recommendations of Regulatory Guide 7.8 (Reference 2-2).

The allowable stresses in the package containment boundary (other than bolting) are based on the criteria of Regulatory Guide 7.6 (Reference 2-3).

The allowable stresses under normal conditions (RG 7.6, Regulatory Position 2) are:

$$\begin{aligned} \text{Primary membrane stresses} &< S_m \\ \text{Primary membrane + bending stresses} &< 1.5 S_m \end{aligned}$$

Where, S_m = design stress intensity

Based on ASME Code (Reference 2-4), Section II, Appendix 1, Article 1-100, the design stress intensity is defined to be:

$$S_m = \text{smaller of } (2/3 S_y \text{ or } S_u/3.5)$$

Where, S_y = material yield stress

S_u = material ultimate strength

The allowable stresses under hypothetical accident conditions (RG 7.6, Regulatory Position 5), are:

Primary membrane stresses < smaller of (2.4 S_m or 0.7 S_u)

Primary membrane + bending stresses < smaller of (3.6 S_m or S_u)

Regulatory Guide 7.6 does not provide guidance for the bolting allowable stress limits. The allowable stress in the bolting for the NCT loading is established to be similar to that for the non-bolting components. For the HAC conditions it is established based on the requirements of ASME B&PV Code, Section III, Appendix F, Article F-1335.

For HAC loading, average tensile stress in the bolts shall not exceed smaller of 0.7 S_u or S_y . The direct tension plus bending, excluding stress concentration shall not exceed S_u . The average bolt shear stress shall not exceed the smaller of 0.42 S_u or 0.6 S_y . The combined tensile and shear stress to corresponding allowable stress ratio shall satisfy the following equation:

$$\left(\frac{f_t}{F_{tb}}\right)^2 + \left(\frac{f_v}{F_{vb}}\right)^2 \leq 1.0$$

Where, f_t = computed tensile stress

f_v = computed shear stress

F_{tb} = allowable tensile stress

F_{vb} = allowable shear stress

Table 2-2 lists the allowable stresses for various stress components under NCT and HAC loading conditions. Allowable values for all the materials that are used for the construction of the structural components of the cask are listed in this table. It should be noted that the allowable stress values listed in this table are applicable to elastically calculated stresses only.

Table 2-3 lists the definition of the regulatory and/or the ASME code definition of stress components. This table also explains how these definitions have been incorporated into the 8-120B Cask analyses documented in this SAR.

The acceptance criterion for prevention of buckling is based on the criteria detailed in Section 2.7.1.7. Factors of safety of 2.0 for the normal conditions of transport and 1.34 for hypothetical accident conditions have been used in the buckling evaluation of the cask.

The primary structural components of the package are fabricated with ASTM A516, Grade 70 with supplemental nil ductility temperature (NDT) requirements. Fracture toughness requirements specified in Regulatory Guide 7.11 (Reference 2-6), "Fracture Toughness Criteria for Ferritic Steel Shipping Casks Containment Vessels with a Maximum Wall Thickness of Four Inches", (June 1991) and NUREG/CR-1815, "Recommendations for Protecting Against Failure by Brittle Fracture in Ferritic Steel Shipping Containers up to Four Inches Thick" (August 1981)

(Reference 2-18) are both complied with. Section 2.6.2 evaluates the critical components of the cask.

The design criteria, used for the evaluation of the impact limiters, is based on a proprietary methodology developed by EnergySolutions and is fully documented in EnergySolutions proprietary document ST-551 (Reference 2-5).

2.1.3 WEIGHT AND CENTER OF GRAVITY

The following is a nominal estimate of the weight of various components of the 8-120B package.

Cask Body.....	=	42,220 lb	
Lid.....	=	7,080 lb	
Payload.....	=	14,150 lb	
Impact Limiters (2).....	=	4,860 lb	(each)
Misc.....	=	830 lb	
Package.....	=	74,000 lb	

The C.G. of the package is located at approximately the same location as the geometric center of the package. The maximum possible axial shift of the package center of gravity due to eccentric payload configurations is small (i.e., approximately 6 inches, or 5% of the package length, if the payload is conservatively modeled as a solid steel cylinder at one end of the cask cavity), and therefore, will not significantly affect the package structural response.

2.1.4 IDENTIFICATION OF CODES AND STANDARDS FOR PACKAGE DESIGN

The 8-120B package is designed as a Type-B, Category II package per U.S. NRC Regulatory Guide 7.11 (Reference 2-6). Based on the recommendations of NUREG/CR-3854 (Reference 2-7), the fabrication, examination, and inspection of the containment boundary components of a Category II package should be per ASME B&PV Code Section III, Subsection ND.

2.2 MATERIALS

The material properties of the cask components used in the analysis of the 8-120B package are provided in Table 2-4. This table provides the temperature dependent yield stress, ultimate tensile strength, allowable membrane stress, Young's modulus, and mean coefficient of thermal expansion for stainless steel, carbon steel and lead. The thermal properties of these materials that were used for the evaluation of temperature distribution in the cask are provided in Section 3.2.1.

2.2.1 MATERIAL PROPERTIES AND SPECIFICATIONS

All the components of the cask body are specified to be ASTM A516 Grade 70 steel, except for the seal rings that are specified to be ASTM A-240 Type 304L stainless steel. These materials are approved for the construction of the ASME Section III, Subsection ND vessels. The material properties for these materials have been obtained from the ASME Code.

The bolting used for connecting the primary lid to the cask body and the secondary lid to primary lid has been specified to be ASTM A-354 Gr. BD material. This material is approved for use in

the ASME Section III, Subsection ND vessels. The material properties for this material have been obtained from the ASME Code.

The poured in place lead shielding is specified to be ASTM B-29 lead. This material has been used in numerous radioactive shipping casks over the last 30 years. The material properties for lead are obtained from NUREG/CR-0481 (Reference 2-8).

Various seals, used in the cask for maintaining the internal pressure, are specified to be elastomer O-rings. The lid and vent o-ring seals are an elastomer, have a durometer of 50-70, and have a usable temperature range that meets or exceeds the range required to meet the Normal Conditions of Transport (elastomer long-term temperature criterion: minimum = -40°F, maximum = +250°F) and meets or exceeds the temperature required to meet the Hypothetical Accident Conditions (elastomer temperature criterion: +350°F for 1 hour). Elastomers that have been evaluated and meet the criteria listed above are butyl rubber, ethylene propylene rubber, and silicone rubber. Seals with these specifications have been successfully used in similar packages over the last 30 years.

The impact limiters are filled with closed-cell rigid polyurethane foam. The foam is procured based on *EnergySolutions* specification ES-M-175 (Reference 8.4.1), which specifies, among other things, the mechanical properties, flame retardant characteristics, and the test requirements for the foam material. The type of foam specified by the specification is General Plastics Manufacturing Company's Type FR-3700 or FR-6700, or equivalent. The General Plastics Technical Manual (Reference 2-9) provides the stress-strain properties of various density foams. The ES specification uses the 25 lb/ft³ nominal density foam's stress-strain properties perpendicular-to-rise direction as the required property. However, in the analyses of the impact limiters both parallel-to-rise and perpendicular-to-rise direction properties have been used, as appropriate. These properties are shown in Figures 2-3 and 2-4.

2.2.2 CHEMICAL GALVANIC AND OTHER REACTIONS

The 8-120B cask is fabricated from carbon steel, stainless steel and lead and has impact limiters containing polyurethane foam. These materials will not cause chemical, galvanic, or other reactions in air or water environments. These materials are commonly used in radioactive material (RAM) packages for transport of radioactive wastes and have been so used for many years without incident. The materials of construction were specifically selected to ensure the integrity of the package will not be compromised by any chemical, galvanic or other reactions.

2.2.2.1 Materials of Construction

The 8-120B package is primarily constructed of ASTM A516 Grade 70 steel with the tie-down arms and lifting ears made from ASTM A514 or A517 steel. This material is painted and is corrosion-resistant to most environments. The weld material and processes have been selected in accordance with the ASME Boiler and Pressure Vessel Code to provide as good or better material properties than the base material. The polyurethane foam in the impact limiters is closed-cell foam that is very low in free halogens. The foam material is sealed inside a dry cavity in each impact limiter, to prevent exposure to the elements. Even if moisture were available for leaching trace chlorides from the foam, very little chloride would be available, since the material

is closed-cell foam and water does not penetrate the material to allow significant leaching. The solid elastomeric O-ring seals contain no corrosive material that would adversely affect the packaging.

2.2.2.2 Materials of Construction and Payload Compatibility

The typical contents of the 8-120B will be similar to the primary materials of construction, i.e., carbon steel, contained in a secondary container typically made of carbon steel. Corrosive materials are prohibited from the payloads. The steel contents of the cask will not react with the cask materials of construction. Water will not react with the painted steel cask body.

2.2.3 EFFECTS OF RADIATION ON MATERIALS

The material from which the package is fabricated (carbon steel, stainless steel, lead, solid elastomeric O-ring and foam) along with the contents exhibit no measurable degradation of their mechanical properties under a radiation field produced by the contained radioactivity. Polyurethane and silicone can absorb more than 10^8 rads without damage (see Reference 2-9). The maximum dose to the silicone seal is less than 4×10^5 rad/yr and to the impact limiter is less than 3×10^3 rad/yr. Over the lifetime of these components, the absorbed dose will not result in damage.

2.3 FABRICATION AND EXAMINATION

As discussed in Section 2.1.4, the 8-120B packaging is designed as a Category II container. To assure the fabrication and examination processes used for the package (e.g. material procurement and control, fitting, welding, lead pouring, foaming, examining, testing, personnel qualification, etc.) are appropriately controlled, EnergySolutions will apply its USNRC approved 10 CFR 71 Subpart H Quality Assurance Program, which implements a graded approach to quality based on a component's or material's importance to safety consistent with the guidance provided in NUREG/CR-6407 (Reference 2-22), NUREG/CR-3854 (Reference 2-7), NUREG/CR-3019 (Reference 2-10) and Industry practice.

2.3.1 FABRICATION

As specified in the above referenced documents, fabrication of the 8-120B containment components will be based on ASME B&PV Code, Section III, Subsection ND and that of the non-containment components will be based on ASME B&PV Code, Section III, Subsection NF.

2.3.2 EXAMINATION

As specified in the above referenced documents, examination of the 8-120B containment components will be based on ASME B&PV Code, Section III, Subsection ND-5000 and that of the non-containment components will be based on ASME B&PV Code, Section III, Subsection ND-5000 or NF-5000.

Section 8.0 provides additional information on examination and acceptance criteria for the packaging.

2.4 GENERAL REQUIREMENTS FOR ALL PACKAGES

10 CFR 71.43 establishes the general standards for packages. This section identifies these standards and provides the bases that demonstrate compliance.

2.4.1 MINIMUM PACKAGING SIZE

10 CFR 71.43(a) requires that:

“The smallest overall dimension of a package must not be less than 10 cm (4”).”

The smallest overall dimension of the package is the diameter of the cask (73.20”), which is larger than 4”. Therefore, the minimum package size requirement is satisfied.

2.4.2 TAMPER-INDICATING FEATURES

10 CFR 71.43(b) requires that:

“The outside of a package must incorporate a feature, such as a seal, which is not readily breakable, and which, while intact, would be evidence that the package has not been opened by unauthorized persons.”

The 8-120B package incorporates a tamper resistant seal that is installed between the cask body and each of the two impact limiters after the package has been closed. Breach of these seals would indicate that the package has been tampered with by unauthorized persons.

2.4.3 POSITIVE CLOSURES

10 CFR 71.43(c) requires that:

“Each package must include a containment system securely closed by a positive fastening device that cannot be opened unintentionally or by a pressure that may arise within the package,”

The 8-120B package uses 20 bolts that fasten the primary lid to the cask body and 12 bolts to attach the secondary lid to the primary lid. Additionally, the vent port is closed with the help of threaded attachment. These closure components are encompassed within the two impact limiters when the package is prepared for the shipment. They cannot be opened unintentionally. Also, it has been shown that the MNOP produces very small bolt loads. These loads are much smaller than the bolt pre-tension and are not capable of loosening them.

2.5 LIFTING AND TIE-DOWN STANDARDS FOR ALL PACKAGES

10 CFR 71.45 specifies the requirements for the lifting and tie-down devices that are “structural parts of the package”. The 8-120B package is designed to be lifted with two removable lifting ears that are attached to the side of the cask. The primary and secondary lids are each furnished with three lifting lugs by which the lids may be removed from the cask. The cask is also equipped with four tie-down arms that are used for the tie-down of the 8-120B cask during transportation.

2.5.1 LIFTING DEVICES

According to 10 CFR 71.45(a), “any lifting device, that is a structural part of the package must be designed with a minimum safety factor of three against yield when used to lift the package in the intended manner and it must be designed so that failure of any lifting device under excessive load would not impair the ability of the package to meet other requirements of this subpart.”

The 8-120B Cask is designed to be lifted with the help of a pair of lifting lugs. Depending on the crane characteristics, a dynamic load amplification may result due to such lifting. The dynamic load factor for a typical crane is between 1.0 and 1.1. For conservatism a dynamic load factor of 1.3 is used for the evaluation of the lifting assembly. It should be noted that the users of this cask shall perform an evaluation based on their crane characteristics to obtain the dynamic load factor and ensure that it is less than 1.30 in order to use this cask.

2.5.1.1 Cask Lifting Ears

(1) Cask Lifting Ear Eye Tear-out Stresses

The cask lifting ears can be used only with the impact limiters removed. Therefore, the total lifted weight is:

$$74,000 - 2 \times 4,860 = 64,280 \text{ lbs}$$

With the dynamic amplification of 1.3 the load is:

$$W = 1.3 \times 64,280 = 83,564 \text{ lbs} \quad \text{say } 84,000 \text{ lbs}$$

For three times the weight of the cask, the vertical ear load is:

$$P_v = \frac{3W}{2 \text{ ears}} = \frac{3 \times 84,000}{2} = 126,000 \text{ lb/ear}$$

The critical tear-out area for the cask lifting ear is determined from Figure 2-6 as:

$$A_{\text{tear-out}} = 2 \times t \times d$$

Where:

t = section thickness = 1.0 in.

d = tear-out distance = 1.6 in.

$$A_{\text{tear-out}} = 3.20 \text{ in}^2$$

As previously determined, the vertical force applied to the cask lifting ear is 126,000 lbs. This results in a nominal tear-out stress of:

$$\tau = \frac{P}{A_{\text{tear-out}}} = \frac{126,000}{3.20} = 39,375 \text{ psi}$$

The allowable shear stress is $0.6 \times \text{Allowable Normal Stress} = 0.6 \times S_y$

The tie-down arms and lifting ears are fabricated from ASTM A514 or ASTM A517 material with minimum yield stress of 90,000 psi. Therefore,

$$\tau_{\text{allowable}} = 0.6 \times 90,000 = 54,000 \text{ psi}$$

This corresponds to a factor of safety of:

$$F.S. = \frac{\tau_{\text{allowable}}}{\tau} = \frac{54,000}{39,375} = 1.37$$

(2) Lifting, Ear Mounting Plate Weld Stresses

The stresses in the welds attaching the lifting ear mounting plate to the cask outer shell are found by applying the bolt shear and tensile forces to the weld around the perimeter of the plate. The shear stress in the weld due to the shear force is given by,

$$\tau_1 = \frac{V}{A_w}$$

Where:

A_w = effective weld area

$$= 2 \times (b + L) \times t \times 1.0 = 2 \times 19.5 \times 1.375 \times 1.0 = 53.625 \text{ in}^2$$

b = plate width = 7.5 in.

L = plate length = 12 in.

t = weld leg dimension = 1.375 in.

V = shear force = 126,000 lb

$$\tau_1 = 2,350 \text{ psi}$$

The shear stress in the weld due to the tensile force is given by:

$$\tau_2 = \frac{F}{A_w}$$

Where:

A_w = weld area as defined above = 53.625 in²

F = tensile force = 7,298 lb. [Calculated in Section 2.5.1.1(4)]

$$\tau_2 = 136 \text{ psi}$$

The maximum shear stress is given by:

$$\tau_{\text{max}} = \sqrt{\tau_1^2 + \tau_2^2} = 2,354 \text{ psi}$$

This corresponds to a factor of safety for the welds of:

$$F.S. = \frac{\tau_{\text{allowable}}}{\tau_{\text{max}}} = \frac{22,800}{2,354} = 9.69$$

(3) Outstanding Lifting Ear Plate Weld Stresses

The outstanding lifting ear plate is attached to the lower flush plate with a vertical double vee weld, as shown in Figure 2-6.

The shear stress in the weld due to the shear force is given by:

$$\tau_3 = \frac{V}{A_w}$$

Where:

A_w = effective weld area = $2 \times t \times L$

t = Weld leg dimension = 0.5 in

L = Plate length = 12.0 in

V = shear force = 126,000 lb

$$\tau_3 = 10,500 \text{ psi}$$

The shear stress in the weld due to the tensile force is found from:

$$\tau_4 = \frac{F}{A_w}$$

Where:

A_w = effective weld area as defined above

F = tensile force = 7,298 lb. [Calculated in Section 2.5.1.1(4)]

$$\tau_4 = 608 \text{ psi}$$

The maximum shear stress is given by:

$$\tau_{\text{max}} = \sqrt{\tau_3^2 + \tau_4^2} = 10,518 \text{ psi}$$

This corresponds to a factor of safety for the welds of:

$$F.S. = \frac{\tau_{\text{allowable}}}{\tau_{\text{max}}} = \frac{22,800}{10,518} = 2.17$$

(4) Bolt Stresses

The equations of equilibrium for the lifting ear shown in Figure 2-5 are:

Summation of Forces:

$$\begin{aligned} \text{Horizontal:} & \quad F + P_H - R_T = 0 \\ \text{Vertical:} & \quad P_v - V = 0 \end{aligned}$$

Summation of Moments about point O:

$$25 \times F + 2.688 \times P_H - 5 \times P_v + 2 \times V = 0$$

Given:

$$P_v = 126,000 \text{ lbs}$$

$$P_H = \frac{P_v}{\tan 60} = 72,746 \text{ lbs} \quad P_H \frac{P_v}{\tan 60} = 57591 \text{ lb.}$$

Then:

$$V = 126,000 \text{ lb.}$$

$$\begin{aligned} F &= (1/25)(5 \times P_v - 2.688 \times P_H - 2 \times V) \\ &= 7,298 \text{ lb.} \end{aligned}$$

$$R_T = 80,044 \text{ lb.}$$

Each lifting ear is attached to the cask, as shown in Figure 2-6, using four 1-1/4 – 7 UNC-2A, 2-3/4 inch long ASTM A354 Grade BD hex head bolts. The stress area for each bolt is 0.969 in².

The shear force, V, will be carried by four bolts, so the shear stress in the bolts is:

$$\tau = \frac{126,000}{4 \times 0.969} = 32,508 \text{ psi}$$

The tensile force, F, will be carried by the four bolts. The resulting tensile stress will be:

$$\sigma_t = \frac{F}{4 \times 0.969} = 1,883 \text{ psi}$$

The maximum principal stresses in the bolt are found by:

$$\sigma_p = \frac{\sigma_t}{2} \pm \sqrt{\left(\frac{\sigma_t}{2}\right)^2 + \tau^2} = \frac{1,883}{2} \pm \sqrt{\left(\frac{1,883}{2}\right)^2 + (32,508)^2}$$

Thus:

$$\sigma_{p1} = 33,463 \text{ psi}$$

$$\sigma_{p2} = -31,580 \text{ psi}$$

The maximum shear stress is given by:

$$\tau_{\text{maximum}} = \frac{\sigma_{p1} - \sigma_{p2}}{2} = 32,522 \text{ psi}$$

The yield stress for ASTM A354, Grade BD material bolts is 130,000 psi. Therefore, the allowable shear stress is:

$$\tau_{\text{allowable}} = 0.6 \times \text{Allowable Normal Stress} = 0.6 \times S_y$$

The factor of safety for the bolts is:

$$F.S. = \frac{\tau_{\text{allowable}}}{\tau_{\text{maximum}}} = \frac{0.6 \times 130,000}{32,522} = \frac{78,000}{32,522} = 2.40$$

(5) Threads - Cask Metal

Because the cask material is weaker than the bolt material, failure will occur at the root of the cask material threads. From Reference 2-19, the equation for the length of thread engagement required to develop full strength of the threads is:

$$L_e = \frac{S_{st} \times 2 \times A_s}{S_{nt} \times \pi \times n \times D_{\min} \left[\left(\frac{1}{2 \times n} \right) + 0.57735 \times (D_{\min} - E_{n\max}) \right]}$$

Where:

$$D_{\min} = \text{Min. O.D. of bolt, in.} \\ = 1.2314 \text{ in.}$$

$$E_{n\max} = \text{Max. P.D. of cask threads, in.} \\ = 1.167 \text{ in.}$$

$$S_{st} = \text{Tensile Strength of bolt material, psi} \\ = 150,000 \text{ psi}$$

$$n = \text{Threads per inch} \\ = 7.0 \text{ threads/in.}$$

$$A_s = \text{Stress area of bolt threads, in}^2 \\ = 0.969 \text{ in}^2$$

$$S_{nt} = \text{Tensile strength of cask material, psi} \\ = 70,000 \text{ psi}$$

$$L_e = \text{Length of thread engagement required to develop full strength, in.}$$

$$L_e = \frac{150,000 \times 2 \times 0.969}{\pi \times 70,000 \times 7 \times 1.2314 \times \left[\left(\frac{1}{2 \times 7} \right) + 0.57735 \times (1.2314 - 1.167) \right]} = 1.41 \text{ in Deep}$$

The bolt engagement provided in the design is $2.75 - 1 = 1.75$ inch, which is larger than 1.41 inch required.

(6) Cask Lifting Ear Stress Summary

The results of the cask lifting ear stress analyses are summarized below from Sections 2.5.1.1 (1) to 2.5.1.1 (5):

<u>Location</u>	<u>Max. Shear Stress Memb.+Bending (psi)</u>	<u>Factor of Safety</u>
Lifting ear tear-out	39,375	1.37
Lifting ear mounting plate (weld)	2,354	9.69
Outstanding lifting ear plate (weld)	10,518	2.17
Bolt	32,522	2.40

(7) Failure of the Cask Lifting Ears under Excessive Loads

From the stress summary presented above it is observed that the lifting ear design has the minimum margin of safety against the tear-out. Therefore, under excessive loading the failure of the lifting ear will occur by tear-out at the hole. This will not impair the ability of the package to meet other regulatory requirements.

2.5.1.2 Primary and Secondary Lid Lifting Lugs

The primary and secondary lid lifting lugs have the same design and are illustrated in Figures 2-7 and 2-8. They are sized such that the combined weight of the primary and secondary lids may be lifted from either the secondary lift lugs or the primary lift lugs. These lugs are made of ASTM A516 Gr70 material.

(1) Weight Analysis

Weights of the primary and secondary lids are as follows:

Primary lid (including bolts)	5,180 lbs
Secondary lid	2,140 lbs
Total lid weight	7,320 lbs.

The effective weight to be lifted by each lug, P_v with the dynamic load factor of 1.3, is therefore determined as:

$$P_v = \frac{3 \times 1.3 \times 7,320}{3 \text{ lugs}} = 9,516 \text{ lbs.}$$

Considering a 45° lift angle, the total load per lug (see Figure 2-8) is determined as:

$$P = \frac{P_v}{\cos 45} = \frac{9,516}{0.707} = 13,460 \text{ lbs}$$

This results in a shear force of:

$$P_H = P \cos 45 = 13,560 \times 0.707 = 9,516 \text{ lbs}$$

(2) Lifting Lug Tear-out Stress Analysis

The critical section for lifting lug tear-out was determined to be as shown in Figure 2-9. Numerically, this area is:

$$A_{shear} = 2 \times L \times t$$

Where:

L = length of tear-out section = 1.1875 in.

t = Section thickness = 0.75 in.

$$A_{shear} = 1.78 \text{ in}^2$$

As previously determined in Section 2.5.1.2 (1), the total cable force is 13,460 lbs. This results in a shear stress due to tear-out of:

$$\tau = \frac{P}{A_{shear}} = \frac{13,460}{1.78} = 7,562 \text{ psi}$$

These lugs are fabricated from ASTM A516 Grade 70 material with minimum yield stress of 38,000 psi. Therefore the allowable shear stress is:

$$\tau_{allowable} = 0.6S_y = 0.6 \times 38,000 = 22,800 \text{ psi}$$

This translates into a factor of safety of:

$$F.S. = \frac{\tau_{allowable}}{\tau} = \frac{22,800}{7,562} = 3.02$$

(3) Base Stresses

The tensile stress at the bottom of the lifting lug as shown on Figure 2-8 is:

$$\sigma_{tensile} = \frac{P_v}{A_b}$$

Where:

$$\begin{aligned} A_b &= \text{base area} = w \times t \text{ in}^2 \\ w &= \text{lug width} = 4 \text{ in.} \\ t &= \text{lug thickness} = 0.75 \text{ in.} \\ P_v &= \text{vertical reaction} = 9,516 \text{ lbs.} \end{aligned}$$

$$\sigma_{tensile} = \frac{9,516}{3} = 3,172 \text{ psi}$$

The bending stress, maximum at the bottom outer edge of each lug, is:

$$\sigma_{bending} = \frac{M \times c}{I}$$

Where:

$$\begin{aligned} M &= \text{bending moment} = 3 \times P_H = 3 \times 9,516 = 28,548 \text{ in-lbs} \\ c &= \text{distance to neutral axis} = 2 \text{ in.} \end{aligned}$$

$$I = \text{moment of inertia} = \frac{b \times h^3}{12}$$

$$\begin{aligned} b &= \text{lug thickness} = 0.75 \text{ in.} \\ h &= \text{lug height} = 4 \text{ in.} \end{aligned}$$

$$\sigma_{bending} = \frac{(28,548 \times 2)}{\frac{0.75 \times 4^3}{12}} = 14,274 \text{ psi}$$

At the outer edge of the lift ear, the bending stress will add to the tensile stress to produce a total tensile stress of:

$$\sigma_{total} = \sigma_{bending} + \sigma_{tensile} = 14,274 + 3,172 = 17,446 \text{ psi}$$

The shear stress at the bottom of the lift ear is:

$$\tau = \frac{P_H}{A_{bs}}$$

Where:

$$\begin{aligned} P_H &= \text{shear force} = 9,516 \text{ lb.} \\ A_{bs} &= \text{base area} = 3 \text{ in}^2 \\ \tau &= 3,172 \text{ psi} \end{aligned}$$

The effects of the shear and total tensile stresses are combined to form the principal stresses for the lifting ears as follows:

$$\sigma_{p1}, \sigma_{p2} = \frac{\sigma_{total}}{2} \pm \left[\left(\frac{\sigma_{total}}{2} \right)^2 + (\tau)^2 \right]^{1/2}$$

Thus,

$$\sigma_{p1} = 18,005 \text{ psi}$$

$$\sigma_{p2} = -559 \text{ psi}$$

The maximum shear stress will be:

$$\tau_{maximum} = \frac{\sigma_{p1} - \sigma_{p2}}{2} = 9,282 \text{ psi}$$

Using an allowable shear = 0.6 × S_y and a yield stress of 38,000 psi, therefore the allowable shear stress is:

$$\tau_{allowable} = 0.6 \times 38,000 = 22,800 \text{ psi}$$

The factor of safety will be:

$$F.S. = \frac{\tau_{allowable}}{\tau_{maximum}} = \frac{22,800}{9,282} = 2.46$$

(4) Lifting Lug Stress Analysis at Pin Hole

The maximum tensile stress in the lifting lug occurs in the section of least cross-sectional area, as shown in Figure 2-10. Numerically, this area is found to be:

$$A = (W - D) \times t$$

Where:

W = width of lifting lug at hole centerline = 4.0 in.

D = diameter of hole = 1.63 in.

t = plate thickness = 0.75 in.

A = 1.78 in²

From Section 2.5.1.2(1), the shear and tensile forces were determined as:

$$P_H = P_V = 9,516 \text{ lbs.}$$

This translates into a nominal shear and tensile stress of:

$$\tau = \sigma_t = \frac{P_H}{A} = \frac{P_v}{A} = \frac{9,516}{1.78} = 5,346 \text{ psi}$$

Combining the effects of the shear and tensile stresses to form the principal stresses yields:

$$\sigma_{p1}, \sigma_{p2} = \frac{\sigma_t}{2} \pm \left[\left(\frac{\sigma_t}{2} \right)^2 + \tau^2 \right]^{1/2} = \frac{5,346}{2} \pm \left[\left(\frac{5,346}{2} \right)^2 + 5,346^2 \right]^{1/2}$$

Thus,

$$\sigma_{p1} = 8,650 \text{ psi}$$

$$\sigma_{p2} = -3,304 \text{ psi}$$

The maximum shear stress is found to be:

$$\tau_{\text{maximum}} = \frac{\sigma_{p1} - \sigma_{p2}}{2} = 5,977 \text{ psi}$$

These lugs are fabricated from ASTM A516 Grade 70 material with minimum yield stress of 38,000 psi. Therefore the allowable shear stress is:

$$\tau_{\text{allowable}} = 0.6S_y = 0.6 \times 38,000 = 22,800 \text{ psi}$$

This translates into a factor of safety of:

$$F.S. = \frac{\tau_{\text{allowable}}}{\tau_{\text{maximum}}} = \frac{22,800}{5,977} = 3.81$$

(5) Primary and Secondary Lid Lifting Lug Stress Summary

The results of the lifting lug stress analyses are summarized as follows:

<u>Location</u>	<u>Max. Shear Stress</u>	
	<u>Memb. + Bending (psi)</u>	<u>Factor of Safety</u>
Lug tear-out	7,562	3.02
Base	9,282	2.46
At pin hole	5,977	3.81

2.5.2 TIE-DOWN DEVICES

The cask is equipped with four tie-down arms that are used for the tie-down of the 8-120B cask during transportation (Figure 2-11). The transportation of the packages in the United States is

controlled under the provisions of 49 CFR 393 (Reference 2-12). Loadings are specified by 49 CFR 393.102 for minimum performance criteria for cargo securement devices and systems. However, 10 CFR 71.45(b) requires that:

“If there is a system of tie-down devices that is a structural part of the package, the system must be capable of withstanding, without generating stress in any material of the package in excess of its yield strength, a static force applied to the center of gravity of the package having a vertical component 2 times the weight of the package with its contents, a horizontal component along the direction in which the vehicle travels of 10 times weight of the package with contents, and a horizontal component in the transverse direction of 5 times the weight of the package with its contents.”

Since the 10 CFR 71 loading on the tie-down system is much more severe than the 49 CFR 393 loading, it is used for the evaluation of the 8-120B package for the transportation conditions.

Description of the Tie-Down Device

The package has been provided with two 1-1/2” thick steel plates (tie-down arms) which are welded to the external shell of the cask body. The steel plates are used for tying the package down. They project outward from the cask in four directions so as to allow specially designed rigging components to be connected to the ends of the tie-down arms. Four shear blocks prevent movement of the base of the package.

The geometric configuration of the tie-down system was selected such that:

- (1) The resultant tie-down arm tensile loads are tangent to the cask surface in order to minimize the effects of out-of-plane stresses in the cask shell. (See Figure 2-12 for determination of the tie-down geometry).
- (2) The shear block loads are transferred to the cask surface via compression in the lower overpack.

Tie-Down Forces

The analytical model for determining the loads required preventing rotation and translation of the package due to the applied loads is shown in Figure 2-13. The shear block forces at the bottom of the package are represented by the orthogonal components of a single force vector, S , making an angle of θ with the global y-axis.

The six equations of equilibrium for the free body diagrams of Figure 2-13 yield the following for the six unknowns:

$$\sum F_x = 0$$

$$\frac{-59}{102.34} \times T_1 + \frac{59}{102.34} \times T_2 + \frac{59}{102.34} \times T_3 - S \times \sin\theta = 5(74) = 370$$

$$\sum F_y = 0$$

$$\frac{72.3}{102.34} \times T_1 + \frac{72.3}{102.34} \times T_2 - \frac{72.3}{102.34} \times T_3 + S \times \cos\theta = 10(74) = 740$$

$$\sum F_z = 0$$

$$\frac{42}{102.34} \times T_1 + \frac{42}{102.34} \times T_2 + \frac{42}{102.34} \times T_3 - V = 2(74) = 148$$

$$\sum M_x = 0$$

$$\left[\frac{42}{102.34} \times 23.73 + \frac{72.3}{102.34} \times 79 \right] \times T_1 + \left[\frac{42}{102.34} \times 23.73 + \frac{72.3}{102.34} \times 79 \right] \times T_2 - \left[\frac{42}{102.34} \times 23.73 + \frac{72.3}{102.34} \times 79 \right] \times T_3 + 24 \times S \times \cos\theta = 10 \times 74 \times 62.5 = 46,250$$

$$\sum M_y = 0$$

$$\left[\frac{42}{102.34} \times 29.04 - \frac{59}{102.34} \times 79 \right] \times T_1 + \left[\frac{59}{102.34} \times 79 - \frac{42}{102.34} \times 29.04 \right] \times T_2 + \left[\frac{59}{102.34} \times 79 - \frac{42}{102.34} \times 29.04 \right] \times T_3 - 24 \times S \times \sin\theta = 5 \times 74 \times 62.5 = 23,125$$

$$\sum M_z = 0$$

$$\left[\frac{(59^2 + 72.3^2)^{0.5}}{102.34} \times 37.5 \right] \times T_1 - \left[\frac{(59^2 + 72.3^2)^{0.5}}{102.34} \times 37.5 \right] \times T_2 + \left[\frac{(59^2 + 72.3^2)^{0.5}}{102.34} \times 37.5 \right] \times T_3 = 0$$

In matrix notation the equations appear as:

$$\begin{bmatrix} -0.577 & 0.577 & 0.577 & -1 & 0 & 0 \\ 0.706 & 0.706 & -0.706 & 0 & 1 & 0 \\ 0.410 & 0.410 & 0.410 & 0 & 0 & -1 \\ 65.550 & 65.550 & -65.550 & 0 & 24 & 0 \\ -33.626 & 33.626 & 33.626 & -24 & 0 & 0 \\ 34.194 & -34.194 & 34.194 & 0 & 0 & 0 \end{bmatrix} \times \begin{bmatrix} T_1 \\ T_2 \\ T_3 \\ S\sin\theta \\ S\cos\theta \\ V \end{bmatrix} = \begin{bmatrix} 370 \\ 740 \\ 148 \\ 46,250 \\ 23,125 \\ 0 \end{bmatrix}$$

Simultaneous solution of the six equations yields the following:

$$\begin{aligned} T_1 &= 293 \text{ kips} \\ T_2 &= 653 \text{ kips} \\ T_3 &= 360 \text{ kips} \\ S\sin\theta &= 46 \text{ kips} \\ S\cos\theta &= 326 \text{ kips} \\ V &= 388 \text{ kips} \end{aligned}$$

Tie-Down Arm

The tie-down arm is detailed as shown in Figure 2-14. The maximum tie-down arm load of 653 kips = 653,000 lbs. was determined in Section 2.5.2 above.

Stresses for the tie-down arm and its connection to the exterior cask shell are determined as follows:

Tension on Net Section at Hole

$$A_{\text{net}} = (6.5 - 2.875) \times 2.75 = 9.97 \text{ in}^2$$

$$\sigma_t = \frac{653,000}{9.97} = 65,497 \text{ psi}$$

$$\sigma_{\text{allow}} = \sigma_y = 90,000 \text{ psi}$$

Therefore:

$$F.S. = \frac{\sigma_{\text{allow}}}{\sigma_t} = \frac{90,000}{65,497} = 1.37$$

Contact Bearing at Lifting Hole

$$A_{\text{brg}} = 2.75 \times 2.75 = 7.56 \text{ in}^2$$

$$\sigma = \frac{653,000}{7.56} = 86,376 \text{ psi}$$

$$\sigma_{allow} = 1.35 \times 90,000 = 121,500 \text{ psi} \quad (\text{See ST-635, Reference 2-25})$$

Therefore:

$$F.S. = \frac{\sigma_{allow}}{\sigma} = \frac{121,500}{86,376} = 1.41$$

Arm Tension

$$A_{arm} = 1.5 \times 6.5 = 9.75 \text{ in}^2$$

$$\sigma_t = \frac{653,000}{9.75} = 66,974 \text{ psi}$$

$$\sigma_{allow} = \sigma_y = 90,000 \text{ psi}$$

Therefore:

$$F.S. = \frac{\sigma_{allow}}{\sigma} = \frac{90,000}{66,974} = 1.34$$

Edge Tear out

$$A = (3.25 + 0.75 - 0.5 \times 2.875) \times 2.75 \times 2 = 14.09 \text{ in}^2$$

$$\tau = \frac{653,000}{14.09} = 46,345 \text{ psi}$$

$$\tau_{allow} = 54,000 \text{ psi}$$

Therefore:

$$F.S. = \frac{\tau_{allow}}{\tau} = \frac{54,000}{46,345} = 1.17$$

Weld Stresses

Welds connecting each tie-down arm to the cask outside shell are evaluated in *EnergySolutions* Document ST-635 (Reference 2-25).

Outer Shell Stresses

To evaluate the cask outer shell, conservatively assuming the maximum tensile load of 653 kips is applied at each tie-down arm (symmetrical loading) and therefore a one-quarter finite element model of the 8-120B cask can be utilized. The model of the outer shell and one tie-down arm is made of all solid elements as detailed in *EnergySolutions* Document ST-635 (Reference 2-25). The cask outside shell is made of 20-node solid element (ANSYS SOLID186) and that of the tie-down arm is made of 10-node solid element (ANSYS SOLID187). Each tie-down arm is welded onto the cask outer shell with groove and fillet welds, as shown in *EnergySolutions* Document ST-635 (Reference 2-25). The groove welds are included in the FEM and the fillet welds are conservatively ignored. Since the objective of the modeling is to obtain stresses at the tie-down arm and the cask outer-shell interface, the doubler-plates near the tie-down arm holes have been neglected. The stresses in the vicinity of the hole have been evaluated in Section 2.5.2 above. (Tie-Down Arm section above).

The interface between the unwelded portion of the tie-down arm and the outer shell of the cask has been modeled by pairs of 3-dimensional 8-node contact (CONTA 174) and 3-dimensional target segments (TARGE 170) elements. The tie-down arm load is applied at the hole-surface as a distributed load.

Figure 2-15 shows the finite element model of the outer shell and the tie-down arm. Figure 2-16 gives the maximum principal stress (tensile) for the outer shell. The maximum principal stress (tensile) of 36,653 psi obtained from the analysis is less than the yield stress of the material (38,000 psi) and is considered acceptable.

Figure 2-17 provides the maximum stress intensities in the entire finite element model. It shows that under the applied loading of 653,000 lbs, the maximum stresses are developed in the tie-down arm near the hole and in the welds. These stresses are much higher than those in the cask outer shell. Therefore, it is concluded that the failure of the tie-down arm under excessive loading will not impair the cask from meeting other requirements of the regulations.

Any other part of the package that could be used for the tie-down (e.g. impact limiter lifting lugs) will be rendered inoperable during the transportation of the package.

2.6 NORMAL CONDITIONS OF TRANSPORT

This Section demonstrates that the package is structurally adequate to meet the performance requirements of Subpart E of 10 CFR 71 when subjected to NCT as defined in 10 CFR 71.71. Compliance with these requirements is demonstrated by analyses in lieu of testing as allowed by 10 CFR 71.41(a) and Regulatory Guide 7.6 (Reference 2-3).

The structural analyses of the 8-120B Cask under NCT events have been performed through the use of finite element models. ANSYS finite element analysis code (Reference 2-11) has been employed to perform the analyses. The cask assembly has at least one plane of symmetry, so a one-half model of the cask has been utilized for the analyses.

The model of the cask is made using 3-dimensional 8-node structural solid elements (ANSYS SOLID185) to represent the major components of the cask, the bolting ring, the lid, and the bolts.

The shell components of the cask - the inner and outer shells, and the baseplates have been represented in the finite element model by SOLSH190 elements.

The fire shield does not provide any structural strength to the cask. Therefore, it is not included in the model.

The poured lead in the body is not bonded to the steel. It is free to slide over the steel surface. Therefore, the interface between the lead and the steel is modeled by pairs of 3-d 8 node contact element (CONTA174) and 3-d target (TARGE170) elements. These elements allow the lead to slide over the steel at the same time prevent it from penetrating the steel surface. The interface between the two plates that form the lid is also modeled by the contact-target pairs. The transition from a coarser mesh to a finer mesh, as well as bondage between various parts of the model, is also modeled using these elements.

Figure 2-18 shows the finite element model used in the analyses of various load cases. The model has node-to-node and element-to-element correspondence with the thermal finite element model used for the thermal analysis of the package, described in Section 3.3. The nodal temperatures during various NCT events are obtained from the analyses in Section 3.

The details of the finite element model, including the assumptions, modeling details, boundary conditions, and input and output data are included in the *EnergySolutions* document ST-626 (Reference 2-13).

2.6.1 HEAT

The thermal evaluation of the 8-120B package is described in Section 3.3. Results from the thermal analyses are used in performing the evaluation in this section.

2.6.1.1 Summary of Pressure and Temperatures

Based on the requirements of 10 CFR 71.71(c)(1), the thermal finite element model described in Section 3.3 computes the nodal temperature of the cask body. Figure 2-19 (reproduced from Figure 3-4) shows the temperature distribution in the structural components of the package. The maximum temperatures in various components of the package are summarized as follows (Reference Table 3-1 and Figure 2-19):

Fire Shield	=	160.6°F
Outer Shell	=	161.3°F
Inner Shell	=	161.5°F
Lead	=	161.4°F
Seal	=	161.7°F
Lid/Baseplate	=	162.6°F

The maximum temperature of the cask cavity is under normal conditions is 162.6° which is conservatively assumed to be the average cask cavity temperature. The gas mixture in the cavity is conservatively assumed to be 180° F. This temperature has been used for calculating the Maximum Normal Operating Pressure (MNOP) in Section 3.3.2. The MNOP of 35.0 psig is used for the evaluation of the hot and cold environment load conditions.

2.6.1.2 Differential Thermal Expansion

The structural finite element model used for the analyses of the 8-120B package under various loading conditions, described in Section 2.6, uses temperature dependent material properties of the cask components. The differential thermal expansion of various components of the cask is included in the stress calculation of the package.

2.6.1.3 Stress Calculations

The stresses in the package under the hot environment loading conditions have been performed in *EnergySolutions* Document ST-626 (Reference 2-13). The loading combination is listed in Table 2-1. Table 2-5 presents the maximum stresses in various components of the package. Figure 2-20 shows the plot of stress intensity contour in the cask body.

2.6.1.4 Comparison with Allowable Stresses

The stresses in the package under the hot environment loading conditions are compared with their allowable values in Table 2-5. The allowable values in various components of the package are listed in Table 2-2. It is noticed from the comparison with the allowable values that all the components of the package experience stresses well below their allowable values. Of all components, a minimum factor of safety of 1.22 occurs in the bolting ring.

2.6.2 COLD

The thermal evaluation of the 8-120B package under cold conditions is described in Section 3.3. Results from the thermal analyses are used in performing the evaluation in this section.

Based on the requirements of 10 CFR 71.71(c)(2), the thermal finite element model described in Section 3.3 computes the nodal temperature of the cask body. Figure 2-21 (reproduced from Figure 3-5) shows the temperature distribution in the structural components of the package.

The structural finite element model used for the analyses of the 8-120B package under various loading conditions, described in Section 2.6, uses temperature dependent material properties of the cask components. The lead shrinkage, caused due to the differential thermal expansion of the lead and cask shells, is included in the stress calculation of the package.

The stresses in the package under the cold environment loading conditions have been performed in *EnergySolutions* Document ST-626 (Reference 2-13). The loading combination is listed in Table 2-1. Table 2-6 presents the maximum stresses in various component of the package. Figure 2-22 shows the plot of stress intensity contour in the cask body.

The stresses in the package under the cold environment loading conditions are compared with their allowable values in Table 2-6. It is noticed from the comparison with the allowable values that all the components of the package experience stresses well below their allowable values. Of all components, a minimum factor of safety of 3.94 occurs in the inner shell.

For the evaluation of the cold environment the ambient temperature of -40°F has been specified by the regulation. However, for the initial conditions for the other load combinations the ambient

temperature of -20°F has been specified in 10 CFR 71.73(b). In the load combinations described in Regulatory Guide 7.8 (Reference 2-2), this condition is associated with the minimum decay heat load. It is not intuitively obvious that the minimum decay heat load in the cold conditions will result in a conservative estimate of thermal stresses in the package. Therefore, the cold condition's load combinations listed in Table 2-1 have been performed two ways - one with the maximum decay heat load and another with no decay heat load. The combinations that result in larger stresses have been reported in this SAR as the cold combination.

Per regulatory Guide 7.8 (Reference 2-2), the cask must be able to resist brittle fracture failure under normal conditions of transport and hypothetical accident conditions at temperature as low as -20°F. Fracture critical parts of the cask are shown in Figure 2-23. For compliance with Category II fracture toughness requirements of NUREG/CR-1815, the nil ductility transition temperature (T_{NDT}) of this steel with which these parts are fabricated must be less than the value determined by the equation:

$$T_{NDT} = LST - A$$

Where:

LST = Lowest service temperature (-20°F)

A = Value from Figure 7 of NUREG/CR 1815 (Reference 2-18) also shown in Figure 2-24

Table 2-7 tabulates the T_{NDT} required for the fracture critical components of the 8-120B cask except bolting.

For the bolting NUREG/CR-1815 does not provide any guidance. ASME Section III Subsection ND is used to specify the toughness requirements of the fracture-critical bolts. The lid bolts and the bolts attaching the lifting lugs with the cask body are considered to be fracture-critical. The toughness requirements for these bolts, based on article ND-2333 of the code are:

- Energy required – 30 ft-lb
- Lateral expansion = 15 mils

The Charpy V-Notch test must be performed at -20°F using ASTM A-370 standard.

2.6.3 REDUCED EXTERNAL PRESSURE

10 CFR 71.71 (c)(3) requires that package be evaluated for a reduced external pressure of 3.5 psi. The MNOP of the 8-120B package is 35.0 psig (14.7 psi atmospheric pressure). With the external pressure reduced to 3.5 psi, the inside pressure of the package will be:

$$P_{\text{reduced external}} = 35.0 + 14.7 - 3.5 = 46.2 \text{ psi (conservatively use 50.0 psi)}$$

The load combination for the reduced external pressure is listed in Table 2-1 under "Minimum External Pressure". Please note that this nomenclature is retained to be consistent with Regulatory Guide 7.8.

The stresses in the package under the reduced external pressure loading conditions have been performed in *EnergySolutions* Document ST-626 (Reference 2-13). Table 2-8 presents the

maximum stresses in various components of the package. Figure 2-25 shows the plot of stress intensity contour in the cask body.

The stresses in the package under the reduced external pressure loading conditions are compared with their allowable values in Table 2-8. It is noticed from the comparison with the allowable values that all the components of the package experience stresses well below their allowable values. A minimum factor of safety of 2.43 occurs in the bolting ring.

2.6.4 INCREASED EXTERNAL PRESSURE

10 CFR 71.71 (c)(4) requires that package be evaluated for an increased external pressure of 20 psi. The MNOP of the 8-120B package is 35 psig (14.7 psi atmospheric pressure). To be conservative for this loading the package internal pressure is assumed to be the minimum (i.e., 0 psi) and the external pressure has been increased to 25 psi. The load combination for the increased external pressure is listed in Table 2-1

The stresses in the package under the increased external pressure loading conditions have been performed in *EnergySolutions* Document ST-626 (Reference 2-13). Table 2-9 presents the maximum stresses in various component of the package. Figure 2-26 shows the plot of stress intensity contour in the cask body.

The stresses in the package under the increased external pressure loading conditions are compared with their allowable values in Table 2-9. It is noticed from the comparison with the allowable values that all the components of the package experience stresses well below their allowable values. Of all components, a minimum factor of safety of 4.10 occurs in the inner shell.

2.6.5 VIBRATION

10 CFR 71.71 (c)(5) requires that “vibration normally incident to transport” be evaluated.

The 8-120B package consists of thick section materials that will be unaffected by vibration normally incident to transport, such as over the road vibrations.

2.6.6 WATER SPRAY

Not applicable, since the package exterior is constructed of steel.

2.6.7 FREE DROP

As described in Section 2.7.1 the analyses of the free drop of the package under NCT is performed in two steps. First the dynamic analyses of the package are performed using an *EnergySolutions* proprietary methodology outlined in document ST-551 (Reference 2-5) that utilizes the ANSYS/LS-DYNA computer code (Reference 2-11). The methodology was developed after a considerable amount of research and parametric studies for the accuracy of results. These studies included the choice of elements, mesh density, material damping, hourglass control, and, solution parameters and controls, etc. It was successfully validated against test results and is fully documented in an *EnergySolutions* proprietary document ST-551 (Reference 2-5). The sensitivity study of the modeling technique is documented in the

EnergySolutions document ST-596 (Reference 2-29). A discourse on the use of foam properties in the LS-DYNA analyses of the casks is documented in the EnergySolutions document ST-618 (Reference 2-30). The methodology has also been used in a recently approved NRC cask package (3-60B).

Next, the detailed FEM analyses of the cask are performed using ANSYS. The analyses are performed in the three customary orientations – end, side and corner. All the load combinations listed in Table 2-1 are analyzed. The details of the package dynamic analyses are documented in EnergySolutions Document ST-625 (Reference 2-14). The documentation of the detailed FEM analyses of the package is provided in EnergySolutions Document ST-627 (Reference 2-15).

The summary of the results from the package dynamic analyses of the NCT free drop are presented in Table 2-10. The stresses in the cask under the load combinations involving the NCT free drop are described below.

2.6.7.1 End Drop

The following impact limiter reactions are obtained from EnergySolutions Document ST-625 (Reference 2-14).

Cold Conditions = 1.556×10^6 lb (Table 2 and Figure 13 of Reference 2-14)

Hot Conditions = 1.286×10^6 lb (Table 2 and Figure 16 of Reference 2-14)

For the NCT test in the end drop orientation, the maximum of the two reactions are used in the analyses.

The distribution of reactions and inertia loads used in the FEM analyses are identical to those described in Section 2.7.1.1 for the HAC loading, except that they have been linearly proportioned in the ratio of corresponding impact limiter reactions. The results obtained from the detailed FEM analysis of the cask are presented in Tables 2-11 and 2-12 for the hot and cold combinations, respectively.

Of all components, a minimum safety factor of 1.18 is computed for the loading combinations involving end drop.

2.6.7.2 Side Drop

The following impact limiter reactions are obtained from EnergySolutions Document ST-625 (Reference 2-14).

Cold Conditions = 859,600 lb (Table 2 and Figure 19 of Reference 2-14)

Hot Conditions = 710,400 lb (Table 2 and Figure 22 of Reference 2-14)

For the NCT test in the side drop orientation, the maximum of the two reactions are used in the analyses.

The distribution of reactions and inertia loads used in the FEM analyses are identical to those described in Section 2.7.1.2 for the HAC loading, except that they have been linearly

proportioned in the ratio of corresponding accelerations. The results obtained from the detailed FEM analysis of the cask are presented in Tables 2-13 and 2-14 for the hot and cold combinations, respectively.

Of all components, a minimum safety factor of 1.21 is computed for the loading combinations involving side drop.

2.6.7.3 Corner Drop

The following impact limiter reactions are obtained from EnergySolutions Document ST-625 (Reference 2-14).

Cold Conditions = 318,800 lb (Table 2 and Figure 25 of Reference 2-14)

Hot Conditions = 278,500 lb (Table 2 and Figure 28 of Reference 2-14)

For the NCT test in the corner drop orientation, the maximum of the two reactions are used in the analyses.

The distribution of reactions and inertia loads used in the FEM analyses are identical to those described in Section 2.7.1.3 for the HAC loading, except that they have been linearly proportioned in the ratio of corresponding accelerations. The results obtained from the detailed FEM analysis of the cask are presented in Tables 2-15 and 2-16 for the hot and cold combinations, respectively.

Of all components, a minimum safety factor of 1.64 is computed for the loading combinations involving corner drop.

2.6.8 CORNER DROP

Not applicable; the 8-120B package is not a fiberboard, wood, or fissile material package.

2.6.9 COMPRESSION

Not applicable; the 8-120B package weighs more than 11,000 lbs.

2.6.10 PENETRATION

The package is evaluated for the impact of the hemispherical end of a vertical steel cylinder of 1¼" diameter and 13 lb mass, dropped from a height of 40" on to the exposed surface of the package.

The penetration depth of the 13 lb 1¼" diameter rod dropped from a height of 40" is calculated from the Ballistic Research Laboratories (BRL) formula cited in Reference 2-17. For a steel target, the penetration depth is given by the formula:

$$\left(\frac{e}{d}\right)^{3/2} = \frac{DV_0^2}{1.12 \times 10^6 \times K_s^2}$$

Where,

$$\begin{aligned}
 e &= \text{penetration depth, inch} \\
 d &= \text{effective projectile diameter, inch} = 1.25'' \\
 W &= \text{missile weight, lb} = 13 \text{ lb} \\
 D &= \text{caliber density of the missile, lb/in}^3 = W/d^3 \\
 V_0 &= \text{striking velocity of the missile, ft/sec} \\
 K_s &= \text{steel penetrability constant} = 1.0
 \end{aligned}$$

For a 40" drop of the rod, the striking velocity,

$$\begin{aligned}
 V_0 &= (2 \times 32.2 \times 40 / 12)^{0.5} = 14.65 \text{ ft/sec} \\
 D &= 13 / 1.25^3 = 6.656 \text{ lb/in}^3
 \end{aligned}$$

Solving the penetration equation, we get,

$$e = 1.25 \times \left(\frac{6.656 \times 14.65^2}{1.12 \times 10^6 \times 1^2} \right)^{2/3} = 0.0147''$$

The thickness of the 8-120B outer shell is 1½", the lid is ¾" (min.), the outer baseplate is ¾" the impact limiter skins and weather cover are 12 gauge = 0.105", and the lower impact limiter cover plate is ½". All these thickness are greater than 0.0147" required for penetration.

Therefore, the penetration test will not cause any damage to the package. It should be noted that in the penetration evaluation, no credit for the lead shielding and the inner shell has been taken.

2.7 HYPOTHETICAL ACCIDENT CONDITIONS

2.7.1 FREE DROP

The 8-120B package is shown to comply with the hypothetical accident conditions (HAC) test requirements by analytical methods in lieu of the physical tests. Advanced finite element methods have been employed in the analyses. A major assumption that is made in performing these analyses is that the dynamic behavior of the 8-120B package, which consists of the cask body and the impact limiters, can be decoupled into a dynamic behavior of the impact limiters and a pseudo-static behavior of the cask body. The rationale for this assumption is based on the relative stiffness of the impact limiters and the cask body. The impact limiters are made of a shock absorbing polyurethane material, which is very low in density compared to the cask body which is primarily made from steel and lead, with stainless steel used for the seal rings. The fundamental periods of the two components are, therefore, sufficiently far apart that little or no interaction takes place between their dynamic responses during the drop loading. The overall dynamic analyses of the package, in various drop orientations, are performed separately and the reactions of the impact limiter on the cask body, obtained from these analyses are used in detailed finite element analyses of the cask body.

Dynamic Analyses of the Package

Proprietary modeling techniques, developed by EnergySolutions, using an explicit dynamic finite element code, ANSYS/LS-DYNA (Reference 2-11), for the drop analysis of packages that use closed-cell cellular polyurethane foam impact limiters, have been employed to perform the drop

analyses of the 8-120B package. The validation of the modeling techniques have been performed with the actual drop test data of a cask of similar size to the 8-120B. The details of the modeling techniques and the verification and validation with the test results are documented in an *EnergySolutions* proprietary document ST-551 (Reference 2-5). The *EnergySolutions* modeling techniques predict the acceleration results conservatively and the time-history trace of the analyses and test data are reasonably close to each other to validate the analysis.

The finite element model used for the analyses of the 8-120B package is described in details in *EnergySolutions* document ST-625 (Reference 2-14). Figures 2-27 and 2-28 show the finite element model. It is made of 8-node solid elements, 4-node shell elements, and 3-node spar elements.

Analyses of the 8-120B package have been performed in three customary drop orientations. The analyzed orientations are:

End Drop – The cask axis parallel to the drop direction (see Figure 2-29)

Side Drop – The cask axis perpendicular to the drop direction (see Figure 2-30)

Corner Drop – The C.G. of the cask directly over the impact point. The cask axis makes an angle of 38° with the vertical plane (see Figure 2-31).

The finite element transient analyses are performed for sufficiently large duration so that the primary as well as secondary impacts, if any, are included. The time-history data of the reaction forces between the package and the rigid contact surface are obtained for each load case (see Figure 2-32 for a typical plot). The time-history of the results are examined for various quantities such as the kinetic energy, internal energy, total energy, hourglass energy, and the external work (see Figure 2-33 for a typical plot). The time-history data of the maximum impact limiter crush are also obtained for each load case. The impact limiter attachment load time-histories are also obtained for each drop orientation.

The HAC drop tests, according to 10 CFR 71.73(b), must be performed at a constant temperature between -20°F and 100°F, which is most unfavorable for the feature under consideration. To envelop the entire spectrum of the temperature range, the dynamic analyses of the package are performed for two initial conditions – the cold condition (Ambient temperature -20°F) and the hot condition (ambient temperature 100°F). To be conservative, the larger of the two results are used for the detailed analyses of the cask body.

The details of the dynamic analyses of the 8-120B package, including the finite element model details, assumptions, boundary conditions, and the input and output data are included in the *EnergySolutions* document ST-627 (Reference 2-15).

The summary of the results from these analyses are presented in Table 2-17.

Detailed Analyses of the Cask

The detailed analyses of the cask under various drop test conditions have been performed using advanced finite element modeling techniques. ANSYS finite element analysis code (Reference 2-11) has been employed to perform the analyses. Since for all the drop orientations (end, side,

corner), at least one plane of symmetry exists, a one-half model has been employed in all the analyses.

The model of the cask is made using 3-dimensional 8-node structural solid elements (ANSYS SOLID185) to represent the major components of the cask, the bolting ring, the lid, and the bolts. The shell components of the cask - the inner and outer shells, and the baseplates have been represented in the finite element model by SOLSH190 elements.

Since the fire shield does not provide any structural strength to the cask, it is not included in the model.

The poured lead in the body is not bonded to the steel. It is free to slide over the steel surface. Therefore, the interface between the lead and the steel is modeled by pairs of 3-d 8 node contact element (CONTA174) and 3-d target (TARGE170) elements. These elements allow the lead to slide over the steel and at the same time prevent it from penetrating the steel surface. The interface between the two plates that form the lid is also modeled by the contact-target pairs. The transition from a coarser mesh to a finer mesh, as well as bondage between various parts of the model, is also modeled using these elements.

Figure 2-34 shows the outline of the model depicting the material numbering. Figure 2-35 shows the finite element grid of the lid, seal plate, bolts, and the cask. Figure 2-36 shows the finite element grid of the cask body without the lead.

To incorporate the loading combinations of Table 2-1 for various drop conditions, the analyses have been performed for three thermal conditions. The loading combinations in hot conditions have been performed per Regulatory Guide 7.8, which requires an ambient temperature of 100°F and the maximum internal decay heat load. The loading combination for the cold conditions, per Regulatory Guide 7.8, requires an ambient temperature of -20°F and the minimum internal decay heat load. It is not intuitively obvious that the minimum decay heat load in the cold conditions will result in a conservative estimate of thermal stresses in the package. Therefore, the cold condition's load combinations listed in Table 2-1 have been performed two ways - one with the maximum decay heat load and another with the minimum decay heat load. The combinations that result in larger stresses have been reported in this SAR as the cold combination. The nodal temperatures for all the thermal conditions are obtained from the analyses in Section 3 and are applied to the structural models to get the appropriate load combinations.

The documentation of the detailed analyses of the cask, including the finite element model details, assumptions, boundary conditions, and the input and output data are included in the *EnergySolutions* document ST-627 (Reference 2-15). ANSYS finite element model grid convergence study has been performed in *EnergySolutions* document ST-608 (Reference 2-16). This document also provides the validation of the major modeling techniques used in the finite element analyses.

2.7.1.1 End Drop

The following impact limiter reactions are obtained from *EnergySolutions* Document ST-625 (Reference 2-14).

$$\text{Cold Conditions} = 5.359 \times 10^6 \text{ lb} \quad (\text{Table 3 and Figure 31 of Reference 2-14})$$

$$\text{Hot Conditions} = 4.427 \times 10^6 \text{ lb} \quad (\text{Table 3 and Figure 35 of Reference 2-14})$$

The maximum of the two reactions is conservatively used for the analyses of all environmental conditions. The impact limiter reaction is converted to the rigid body acceleration by dividing the reaction by that portion of the mass of the package which causes this reaction. During the end drop test the impact limiter reaction is caused by the total mass of the package less the mass of one impact limiter, i.e. $49,300 + 14,680 + 4,860 = 68,840 \text{ lb}$ (SAR Section 2.1.3). Since the FEM represents only $\frac{1}{2}$ of the package, the total mass is divided by 2 in the calculation of the rigid body acceleration.

$$\text{Rigid body acceleration} = 2 \times 5.359 \times 10^6 / 68,840 = 155.7 \gg \text{Use } 160\text{g}$$

The value used for rigid body acceleration is conservatively set at 160g. The distribution of reactions and inertia loads used in the quasi-static FEM analyses are shown in Figure 2-37. The plot of the maximum stress intensities in the cask are shown in Figures 2-38 for the hot condition, in Figure 2-39 for the cold condition (maximum decay heat), and in Figure 2-40 for the cold condition (no decay heat). The results obtained from the detailed FEM analysis of the cask are presented in Tables 2-18 and 2-19 for the hot and cold combinations, respectively.

Of all components, a minimum safety factor of 1.02 is computed for the loading combinations involving end drop.

2.7.1.2 Side Drop

The following impact limiter reactions are obtained from *EnergySolutions* Document ST-625 (Reference 2-14).

$$\text{Cold Conditions} = 3.937 \times 10^6 \text{ lb} \quad (\text{Table 3 and Figure 39 of Reference 2-14})$$

$$\text{Hot Conditions} = 3.403 \times 10^6 \text{ lb} \quad (\text{Table 3 and Figure 43 of Reference 2-14})$$

Conservatively use the maximum of the two reactions for the analyses of all environmental conditions. The impact limiter reaction is converted to the rigid body acceleration by dividing the reaction by that portion of the mass of the package which causes this reaction. During the side drop test the impact limiter reaction is caused by the total mass of the package less the mass of the two impact limiters, i.e. $74,000 - 2 \times 4,860 = 64,280 \text{ lb}$ (Section 2.1.3). Since the FEM represents only $\frac{1}{2}$ of the package the total mass is divided by 2 in the calculation of the rigid body acceleration.

$$\text{Rigid body acceleration} = 2 \times 3.927 \times 10^6 / 64,280 = 122.2\text{g} \gg \text{Use } 150\text{g}$$

The value used for the rigid body acceleration is conservatively set at 150g. The distribution of reactions and inertia loads used in the quasi-static FEM analyses are shown in Figure 2-41. The plot of the maximum stress intensities in the cask are shown in Figures 2-42 for the hot condition, in Figure 2-43 for the cold condition (maximum decay heat), and in Figure 2-44 for the cold condition (no decay heat). The results obtained from the detailed FEM analysis of the cask are presented in Tables 2-20 and 2-21 for the hot and cold combinations, respectively.

The minimum safety factor of 1.05 is computed for the loading combinations involving side drop. This minimum safety factor occurs in the lid bolts. Of all components, a minimum factor of safety on the containment boundary components is 1.05.

2.7.1.3 Corner Drop

The following impact limiter reactions are obtained from EnergySolutions Document ST-625 (Reference 2-14).

$$\text{Cold Conditions} = 2.103 \times 10^6 \text{ lb} \quad (\text{Table 3 and Figure 47 of Reference 2-14})$$

$$\text{Hot Conditions} = 2.000 \times 10^6 \text{ lb} \quad (\text{Table 3 and Figure 51 of Reference 2-14})$$

Conservatively use the maximum of the two reactions for the analyses of all environmental conditions. The impact limiter reaction is converted to the rigid body acceleration by dividing the reaction by that portion of the mass of the package which causes this reaction. During the corner drop test the impact limiter reaction is caused by the total mass of the package less the mass of one impact limiter, i.e. $49,300 + 14,680 + 4,860 = 68,840 \text{ lb}$ (Section 2.1.3). Since the FEM represents only $\frac{1}{2}$ of the package, the total mass is divided by 2 in the calculation of the rigid body acceleration.

$$\text{Rigid body acceleration} = 2 \times 2.103 \times 10^6 / 68,840 = 61.1 \gg \text{Use } 75\text{g}$$

The value used for rigid body acceleration is conservatively set at 75g. The distribution of reactions and inertia loads used in the quasi-static FEM analyses are shown in Figure 2-45. The plot of the maximum stress intensities in the cask are shown in Figures 2-46 for the hot condition, in Figure 2-47 for the cold condition (maximum decay heat), and in Figure 2-48 for the cold condition (no decay heat). The results obtained from the detailed FEM analysis of the cask are presented in Tables 2-22 and 2-23 for the hot and cold combinations, respectively.

Of all components, a minimum safety factor of 1.01 is computed for the loading combinations involving corner drop.

2.7.1.4 Oblique Drop

The diameter of the 8-120B package impact limiter is 102 inches and the overall package height is 132 inches. The following analysis indicates that for the 8-120B package with the diameter approximately equal to its length, there is no slapdown effect. That is, the impact is not more severe than a side drop.

This section represents an analysis demonstrating that oblique impacts are not worst-case for casks having length-to-diameter ratios less than 1.37. Figure 2-49 illustrates a cask of length (l), and weight (W), dropped at an angle (α) measured from the horizontal plane. No energy absorption is initially assumed from the impact limiter of cask during primary impact (first contact of the lower end of the cask with the impact surface). This assumption results in the worst case (greatest) impact velocity of the higher end of the cask.

The angular momentum before and after impact can be estimated based on the following assumptions:

- The impact point does not slide along the horizontal impact surface.
- The rotational inertia of the cask can be approximated assuming a uniform density

$$I_{CG} = \frac{1}{4} \times M \times \left(r^2 + \frac{l^2}{3} \right)$$

solid cylinder, i.e. :

- The gravitational acceleration of the cask is neglected after the initial impact.

Then, before impact,

$$L_1 = M \times v_1 \times \left(\frac{1}{2} \times l - r \times \tan a \right) \times \cos a$$

And, after impact:

$$L_2 = I_i \times \omega_2$$

Where:

L_1 = angular momentum before impact

M = mass of cask

v_1 = impact velocity

I_i = rotational inertia of cask about impact point

$$= I_{CG} + M \times R^2$$

$$= M \times \left(\frac{1}{4} \times r^2 + \frac{1}{12} \times l^2 + R^2 \right)$$

ω_2 = angular velocity of cask following impact

Since no moments are applied to the cask, angular momentum is conserved, and $L_1 = L_2$:

$$M \times v_1 \times \left(\frac{1}{2} \times l - r \times \tan a \right) \times \cos a = M \times \left(\frac{1}{4} \times r^2 + \frac{1}{12} \times l^2 + R^2 \right) \times \omega_2$$

Solving for angular velocity:

$$\omega_2 = v_1 \times \frac{\left(\frac{1}{2} \times l - r \times \tan a \right) \times \cos a}{\frac{1}{4} \times r^2 + \frac{1}{12} \times l^2 + R^2}$$

In general, maximum angular velocity occurs when the impact angle equals zero.

The velocity of the secondary impact is given by:

$$v_s = l \times \omega_2$$

Then:

$$v_s = l \times v_1 \times \frac{\left(\frac{1}{2} \times l - r \times \tan a\right) \times \cos a}{\frac{1}{4} \times r^2 + \frac{1}{12} \times l^2 + R^2}$$

The limiting case can be taken as that for which the secondary impact velocity equals the initial impact velocity for the worst case angular velocity. Then,

$$v_s = v_1 \text{ at } a = 0$$

And:

$$\frac{\frac{1}{2} \times l^2}{\frac{1}{4} \times r^2 + \frac{1}{12} \times l^2 + R^2} = 1$$

From Figure 2-49,

$$R^2 = \frac{1}{4} \times l^2 + r^2$$

Therefore,

$$\frac{1}{2} \times l^2 = \frac{1}{4} \times r^2 + \frac{1}{12} \times l^2 + \frac{1}{4} \times l^2 + r^2$$

$$\frac{l^2}{r^2} = 7.50 \quad \text{and,} \quad \frac{l}{r} = 2.74$$

Implying that:

$$\frac{l}{d} = \frac{l}{2 \times r} = 1.37$$

Thus, for length-to-diameter ratios greater than 1.37, slapdown impacts may be more severe than a normal side drop. Since this analysis very conservatively neglects any energy absorption of the initial impact, this ratio may be taken as a lower bound, below which one may safely assume that secondary impact will be less severe than side drop impacts. Since the 8-120B cask has a length-to-diameter ratio of 1.29, the oblique drop is less severe than the side drop. Cask stresses in an oblique drop will be less than those experienced during a side drop.

2.7.1.5 Lead Slump Evaluation

The 8-120B package experiences the largest acceleration during the end drop orientation. Analyses of the 8-120B package under various environmental conditions in this drop orientation have been performed in Section 2.7.1.1. The most severe environmental condition for the lead slump is the cold condition with no decay heat load. From the finite element model analysis the relative displacement at the lead-steel interface is obtained. Figure 2-50 shows the exaggerated displacement plot under this drop condition. The total relative displacement of the lead column

(0.141 inch) is reported as the lead-slump. However, it should be noted that in considering this value to be the lead slump, the elastic recovery of the lead and steel has been conservatively neglected.

2.7.1.6 Impact Limiter Attachment Evaluation

The impact limiter attachment loads for each drop condition are obtained from the FEM analyses described in Section 2.7.1. These loads are presented in Table 2-24. The maximum load in an individual attachment under any of the HAC events is 35,350lb (EnergySolutions document ST-625, Reference 2-14). The following evaluation shows that the impact limiter attachments are capable of withstanding this load. Each impact limiter attachment point is fabricated from ASTM A516 Grade 70 material.

Considering failure for an equivalent state of stress which produces a maximum shear stress of:

$$\tau_{failure} = \frac{F_u}{\sqrt{3}} = \frac{70,000}{\sqrt{3}} = 40,415 \text{ psi}$$

The impact limiter attachment eye tear-out stress is:

$$\tau = \frac{35,350}{2 \times 0.5 \times (2 - 0.5 \times 0.9375)} = 23,086 \text{ psi} < 40,415 \text{ psi} \quad \text{O.K.}$$

Each impact limiter attachment is welded on to the 1" thick inner ring of impact limiter with 6" long 1/2" fillet weld on each side and to the impact limiter skin with smaller size fillet weld. Ignoring any contribution from the impact limiter skin welds, the weld shear stress is:

$$\tau = \left[\left(\frac{35,350 \times (2.875 - 1)}{\frac{6^2}{3} \times 0.707 \times 0.5} \right)^2 + \left(\frac{35,350}{2 \times 6 \times 0.707 \times 0.5} \right)^2 \right]^{0.5} = 17,708 \text{ psi} < 40,415 \text{ psi} \quad \text{O.K.}$$

The top and bottom impact limiters are interconnected at eight attachment points with 1" diameter shank ratchet binders. The ratchet binder has a working load limit of 9,000 lbs with ultimate load equal to 5 times the working load limit = 9,000 × 5 = 45,000 lbs

Maximum attachment point load = 35,350 lbs < 45,000 lbs O.K.

Therefore, the impact limiter attachments can withstand the maximum applied load under any of the HAC events.

2.7.1.7 Shell Buckling

Buckling, per Regulatory Guide 7.6 (Reference 2-3), is an unacceptable failure mode for the containment vessel. The intent of this guideline is to make large deformations unacceptable because they would compromise the validity of linear assumptions and quasi-linear allowable stresses as given in Paragraph C.6 of NRC Regulatory Guide 7.6.

The remainder of this subsection defines techniques and criteria used in subsequent sections of this Safety Analysis Report to demonstrate that containment vessel buckling does not occur.

Euler Column Buckling

From Reference 2-23, p. 104, the critical axial buckling load for a self-weight load combined with an added axial force is:

$$P_{cr} = \frac{m \times E \times I}{l^2}$$

Where:

m = tabulated function of n

$$n = \frac{4 \times q \times l^3}{\pi^2 \times E \times I}$$

q = distributed axial load intensity

$$= 2 \times \pi \times R \times w \times a \times t$$

l = half length of cylinder

E = Young's modulus = 27.8×10^6 psi

$$I = \pi \times R^3 \times t$$

R = cylinder radius

t = cylinder thickness

w = weight density = 0.283 lb/in³

a = acceleration in g's

This mode of buckling applies to the outer shell of the cask, composed of a $1\frac{1}{2}$ -inch thick plate.

$$l = 39.25 \text{ in.}$$

$$R = 35.5 \text{ in.}$$

$$t = 1.5 \text{ in.}$$

$$I = 210,827 \text{ in}^2$$

$$q = 94.69a \text{ lb/in.}$$

And:

$$n = 3.96 \times 10^{-7} \times a$$

For:

$$a = 169$$

$$n = 0$$

Therefore:

$$m = \frac{\pi^2}{4}$$

And:

$$P_{cr} = 9.4 \times 10^9 \text{ lb.}$$

Axial Stress Limits

According to Reference 2-24, p. 230, a thin-wall cylinder is considered “moderately long” if

$$c \times Z > \frac{\pi^2 \times K_{co}}{2\sqrt{3}}$$

Where:

c = correlation factor dependent on R/t

$$Z = \frac{L^2}{R \times t} \times \sqrt{1 - m^2}$$

$K_{co} = 1$ for simply supported edges (conservative)

L = length of cylinder

R = mean radius of cylinder

t = wall thickness

m = Poisson's ratio

The following two sets of properties correspond to the inner and outer shells of the cask sidewall.

	<u>Inner Shell</u>	<u>Outer Shell</u>
t_i	= 0.75 in	t_o = 1.5 in
R_i	= 31.375 in	R_o = 35.5 in
L_i	= 76 in	L_o = 79.5 in
m	= 0.3	m = 0.3

For both shells,

$$\frac{\pi^2 \times K_{co}}{2\sqrt{3}} = 2.849$$

Then:

$$R_i/t_i = 41.83$$

$$R_o/t_o = 23.67$$

$$Z_i = 234$$

$$Z_o = 113$$

From Reference 2-24, Fig. 10-9, p. 230.

$$c_i = 0.70$$

$$c_o = 0.55$$

For both shells,

$$c \times Z > \frac{\pi^2 K_{co}}{2\sqrt{3}}$$

Therefore, both will be treated as moderately long cylinders.

From Reference 2-24, p. 229:

$$\sigma_c = \frac{\pi^2 \times K_c \times E}{12 \times (1 - m^2)} \times \left(\frac{t}{L}\right)^2$$

σ_c = elastic buckling stress

E = Young's modulus

$$= 27.8 \times 10^6 \text{ psi}$$

$$\sigma_c = \frac{4\sqrt{3}}{\pi^2} \times c \times Z$$

$$\sigma_{ci} = 281,353 \text{ psi}$$

$$\sigma_{co} = 390,240 \text{ psi}$$

Hoop Stress Limits

From Reference 2-24, p. 236:

$$\sigma_c = \frac{\pi^2 \times K_p \times E}{12 \times (1 - m^2)} \times (t/L)^2$$

Where:

K_p = function of Z (Reference 2-24, Fig. 10-15, p. 237)

Then:

$$K_{pi} = 13$$

$$K_{po} = 9$$

$$\sigma_{ci} = 31,810 \text{ psi}$$

$$\sigma_{co} = 80,503 \text{ psi}$$

Critical Buckling Stress

σ_{cr} for the above cases can be found by solving the following equation (from Reference 2-24, p. 265):

$$\sigma_{cr} - \eta \times \sigma_c = 0$$

Where:

η = plasticity coefficient

The plasticity coefficient, η , is defined by the following equations for each of the various loading conditions:

For axial stresses, from Reference 2-24, p. 266:

$$\eta = \frac{\sqrt{E_s \times E_t}}{E}$$

For external pressure stress, from Reference 2-24, p. 236:

$$\eta = \frac{E_s}{E_t} \sqrt{\left(\frac{E_t}{E_s}\right)^{1/2} \times \left(\frac{1}{4} + \frac{3}{4} \times \frac{E_t}{E_s}\right)}$$

Where:

E_t = tangent modulus = $d\sigma/d\varepsilon$

E_s = secant modulus = σ / ε

σ = stress

ε = strain

For stresses below the proportional limit, conservatively assumed to be $0.7 \times S_y$:

$$E = E_t = E_s$$

and $\eta = 1$

For stresses above the proportional limit, stress is assumed to be a parabolic function of strain that is tangent to the elastic line at the proportional limit and has zero slope at the yield stress.

For:

$$S_y = 38,000 \text{ psi}$$

and:

$$E = 27.8 \times 10^6 \text{ psi}$$

Then, for:

$$0.7 \times S_y < \sigma < S_y$$

$$\sigma = A \times \varepsilon^2 + B \times \varepsilon + C$$

Where:

$$A = -1.6948 \times 10^{10}$$

$$B = 6.0233 \times 10^7$$

$$C = -1.5517 \times 10^4$$

Using this expression for stress, the critical buckling stress equation is solved:

$$A^2 \times \varepsilon_{cr}^5 + 2AB \times \varepsilon_{cr}^4 + \left[2AC + B^2 - 2A^2 \left(\frac{\sigma_e}{E} \right)^2 \right] \times \varepsilon_{cr}^3 + \left[2BC - 3AB \left(\frac{\sigma_e}{E} \right)^2 \right] \times \varepsilon_{cr}^2 + \left[C^2 - \left(\frac{\sigma_e}{E} \right)^2 (2AC + B^2) \right] \times \varepsilon_{cr} - BC \left(\frac{\sigma_e}{E} \right)^2 = 0$$

	<u>Axial:</u>	
	<u>Inner</u>	<u>Outer</u>
ε_{cr}	1.7578 x 10 ⁻³	1.7670 x 10 ⁻³
η	0.13504	9.73727
σ_{cr}	37,994 psi	37,999 psi
	<u>Hoop:</u>	
ε_{cr}	1.0678 x 10 ⁻³	1.5710 x 10 ⁻³
η	0.91158	0.43138
σ_{cr}	28,997 psi	34,727 psi

The buckling stress limits are summarized in the following table

	<u>Inner Shell</u>	<u>Outer Shell</u>
Axial Membrane	37,994 psi	37,999 psi
Hoop Membrane	28,997 psi	34,727 psi

Evaluation of buckling of the cylindrical shells, for combined loading, is done using the technique described in Reference 2-24, p. 275:

$$\sigma_{cr} - \eta \times \sigma_i = 0$$

Where:

σ_{cr} = combined load critical buckling stress intensity

$$\eta = \text{plasticity correction factor} = \frac{\sqrt{E_t \times E_s}}{E}$$

$$\sigma_i = \text{elastic buckling stress intensity} = \sqrt{\sigma_a^2 + \sigma_h^2 - \sigma_a \sigma_h}$$

σ_a = elastic axial buckling stress limit

σ_h = elastic hoop buckling stress limit

Values for the inner and outer shells are as follows:

	<u>Inner</u>	<u>Outer</u>
σ_a , psi	281,353	390,240
σ_h , psi	31,810	80,503

σ_i , psi	266,874	356,865
η	0.14236	0.10648
σ_{cr} (combined load)	37,993	37,998

In evaluating stress conditions for buckling of the shells, the individual stress components are compared to the allowable buckling stresses in the hoop and axial directions. The stress intensities are compared to the values of σ_{cr} above for combined loading.

Evaluation

Evaluation of the 8-120B Cask body is performed for buckling under the NCT and HAC events. The two components that have the highest susceptibility to buckling are the inner and outer shells of the cask. Both the shells are subjected to axial compressive stresses under the 1-ft and 30-ft drop tests. In addition, the inner shell undergoes compressive hoop stress under the cold conditions. The coefficient of thermal expansion of the lead is much larger than that of the steel. The lead is poured in the cask body at the room temperature (70°F). At a temperature lower than 70°F, the lead shrinks more than the steel which causes an interference stress in the inner shell.

Stresses are calculated for the NCT and HAC conditions and compared with the buckling stresses calculated above. The axial stresses are calculated for the 1-ft drop test for the NCT conditions and 30-ft drop for the HAC conditions. The hoop stress in the inner shell is calculated at -40°F and is conservatively used for both NCT and HAC conditions.

Axial Stress Calculation

The axial stresses in inner and outer shells are calculated with the conservative assumption that the entire reaction load under a particular end drop test is reacted entirely by these shells.

$$\text{Inner shell outside radius} = 31.75 \text{ in}$$

$$\text{Inner shell inside radius} = 31 \text{ in}$$

$$\text{Outer shell outside radius} = 36.6 \text{ in}$$

$$\text{Outer shell inside radius} = 35.1 \text{ in}$$

Area of the two shells,

$$\text{Area} = \pi \times [(31.75^2 - 31^2) + (36.6^2 - 35.1^2)] = 485.7 \text{ in}^2$$

Largest reaction under the 1-ft drop test on the half model is 1.556×10^6 lb (see Section 2.6.7.1). Therefore the axial stress in the shells under this loading is:

$$\sigma_{\text{axial}} = 2 \times 1.556 \times 10^6 / 485.7 = 6,407 \text{ psi}$$

Largest reaction under the 30-ft drop test on the half model is 5.359×10^6 lb (see Section 2.7.1.1). Therefore the axial stress in the shells under this loading is:

$$\sigma_{\text{axial}} = 2 \times 5.359 \times 10^6 / 485.7 = 22,067 \text{ psi}$$

Using a safety factor of 2 for NCT and 1.34 for the HAC tests, the factored axial stresses are as follows:

$$\begin{aligned} \text{NCT F.S.} \times \sigma_{\text{axial}} &= 2 \times 6,407 = 12,814 \text{ psi} \\ \text{HAC F.S.} \times \sigma_{\text{axial}} &= 1.34 \times 22,067 = 29,570 \text{ psi} \end{aligned}$$

Hoop Stress Calculation

Hoop stresses are calculated in the inner shell using the closed-form solutions from Roark and Young (Reference 2-26).

$$\begin{aligned} \text{Inner shell mean radius} &= 31.375 \text{ in} \\ \text{Inner shell thickness} &= 0.75 \text{ in} \\ \text{Lead column mean radius} &= 33.425 \text{ in} \\ \text{Lead column thickness} &= 3.35 \text{ in} \\ \text{Shell-lead interface radius} &= 31.75 \text{ in} \\ \text{Coefficient of thermal expansion of lead at } -40^\circ\text{F} &= 15.65 \times 10^{-6} \text{ in/in-}^\circ\text{F} \\ \text{Coefficient of thermal expansion of steel at } -40^\circ\text{F} &= 6.4 \times 10^{-6} \text{ in/in-}^\circ\text{F} \\ \text{Elastic Modulus of lead at } -40^\circ\text{F} &= 2.46 \times 10^6 \text{ psi} \\ \text{Elastic Modulus of steel at } -40^\circ\text{F} &= 30 \times 10^6 \text{ psi} \end{aligned}$$

Differential thermal expansion at the steel-lead interface,

$$\Delta_{\text{diff}} = 31.75 \times (15.65 - 6.4) \times 10^{-6} \times (70 + 40) = 0.0323 \text{ in}$$

Assuming that the interface pressure is q , the radial deformation of the steel shell and lead column is calculated based on the formulas from Reference 2-26 as follows:

$$\begin{aligned} \Delta_{\text{steel}} &= q \times 31.375^2 / (30 \times 10^6 \times 0.75) \\ \Delta_{\text{lead}} &= q \times 33.425^2 / (2.46 \times 10^6 \times 3.35) \end{aligned}$$

Equating the sum of these deformations with the differential thermal expansion, we get

$$q \times [31.375^2 / (30 \times 10^6 \times 0.75) + 33.425^2 / (2.46 \times 10^6 \times 3.35)] = 0.0323$$

or, $q = 180.12 \text{ psi}$

The hoop stress in the inner shell under this pressure is:

$$\sigma_{\text{hoop}} = 180.12 \times 31.375 / 0.75 = 7,535 \text{ psi}$$

Using a safety factor of 2 for NCT and 1.34 for the HAC tests, the factored hoop stresses are as follows:

$$\begin{aligned} \text{NCT F.S.} \times \sigma_{\text{hoop}} &= 2 \times 7,535 = 15,070 \text{ psi} \\ \text{HAC F.S.} \times \sigma_{\text{hoop}} &= 1.34 \times 7,535 = 10,097 \text{ psi} \end{aligned}$$

Since the maximum of above inner shell stresses (15,070 psi) is less than the combined load critical buckling stress intensity (37,993 psi) calculated earlier in this Section, and the thinner

inner shell (0.75 inches) stresses envelope that of the outer shell (1.50 inches thick), therefore the 8-120B cask buckling will not occur.

2.7.1.8 Vent Port Evaluation

The 8-1200B package has one penetration through the containment boundary that is closed with a bolt. This is the vent port. The vent port is recessed into the cask lid. The vent port is completely covered by the foam of the impact limiter. Therefore, during the HAC drop tests the vent port does not make contact with the impact surface.

2.7.1.9 Closure Bolt Evaluation

The primary and secondary lid bolt stresses under various loading combinations that were obtained from the FEM analyses have been provided in the appropriate sections of the SAR. They have been compared with the corresponding design allowable values and typically show that a large factor of safety exists in the design of the bolts under all loading combinations. For the 30-ft side and corner drop loadings the primary lid bolt stresses were calculated using the approach shown in Section 7.3 of *EnergySolutions* document ST-627 (Reference 2-15) presented below.

The individual loads for the primary lid bolts are given in Tables 19 through 30 of *EnergySolutions* document ST-627 (Reference 2-15). Loads are calculated at two locations where the highest stresses occur; the root of the bolt shank and the lid interfaces.

Locations of bolts on the primary lid are identified by angle according to *EnergySolutions* document ST-627 (Reference 2-15). Maximum stresses in the bolts by location during the corner and side drops are shown in Figures 48 and 49 of *EnergySolutions* document ST-627 (Reference 2-15).

Below is a sample calculation for the bolt stresses from the tabulated FEM data. A sample of bolt load data from the FEM as given in Tables 19 through 30 of *EnergySolutions* document ST-627 (Reference 2-15) is below:

Load	FX	FY	FZ	MX	MY	MZ
	lbs	lbs	lbs	in-lbs	in-lbs	in-lbs
bolt4	-114,222	-4,322	-70,317	-3,492	-92,463	-2,618

$$F_{\text{Axial}} = FZ = 70,317\text{lbs}$$

$$V_{\text{Shear}} = \sqrt{(FX)^2 + (FY)^2} = \sqrt{114,222^2 + 4,322^2} = 114,304\text{lbs}$$

$$M = \sqrt{(MX)^2 + (MY)^2} = \sqrt{3,492^2 + 92,463^2} = 92,529 \text{ in-lbs}$$

$$T = MZ = -2,618 \text{ in-lbs (Neglected)}$$

The bolts are 2" - 8 UN:

$$\text{Bolt diameter} = d_{\text{bolt}} = 2.0 \text{ in}$$

$$\text{Bolt area} = A_{\text{stress area}} = 2.7665 \text{ in}^2$$

$$\sigma_{\text{axial}} = \frac{F_{\text{axial}}}{A_{\text{stress area}}} = \frac{F_{\text{axial}}}{2.7665} = \frac{70,317}{2.7665} = 25,417 \text{ psi}$$

Allowable bolt axial (average) stress = Allowable membrane stress = 105,000 psi

(per Table 2-2)

$$\sigma_{\text{axial}} = \sigma_{\text{average}} = 25,417 \text{ psi} < 105,000 \text{ psi} \quad \text{O.K.}$$

$$\sigma_{\text{bending}} = \frac{M}{S} = \frac{M}{\frac{\pi \times d_{\text{bolt}}^3}{32}} = \frac{32 \times 92,529}{\pi \times 2^3} = 117,812 \text{ psi}$$

$$\tau = \frac{V_{\text{shear}}}{A_{\text{stress area}}} = \frac{114,304}{2.7665} = 41,317 \text{ psi}$$

Allowable bolt shear stress = Smaller of (0.42S_u and 0.6S_y) = 63,000 psi

$$\tau = 41,317 \text{ psi} < 63,000 \text{ psi} \quad \text{O.K.}$$

$$\sigma_{\text{axial+bending}} = \sigma_{\text{axial}} + \sigma_{\text{bending}} = 25,417 + 117,812 = 143,229 \text{ psi}$$

Allowable membrane + bending stress = 150,000 psi (per Table 2-2)

$$\sigma_{\text{axial+bending}} = 143,229 \text{ psi} < 150,000 \text{ psi} \quad \text{O.K.}$$

Bolt axial-shear interaction (I.C.) is:

$$\text{I.C.} = \left(\frac{\sigma_{\text{axial}}}{105,000} \right)^2 + \left(\frac{\tau}{63,000} \right)^2 = \left(\frac{25,417}{105,000} \right)^2 + \left(\frac{41,317}{63,000} \right)^2 = 0.4887 < 1.0 \quad \text{O.K.}$$

Therefore, bolt design meets the design criteria established in Section 2.1.2.

Additionally, it is shown that under NCT loading conditions, the bolt torque provides sufficient preload in the bolts to overcome the loading arising from the thermal and pressure loadings. It is also shown that the minimum engagement length requirement for the specified bolts and the bolting ring material is also satisfied.

Lid Bolt Torque Evaluation

In order to maintain the seal during the NCT, the 8-120B package primary and secondary lid bolts are tightened to a torque value of 500 ± 50 ft-lbs (lubricated). Under the NCT loading combinations listed in Table 2-1, the largest bolt loads are experienced due the loading of minimum external pressure, under which the package is subject to an internal pressure of 50 psig. The lid and bolting ring (ASTM A516 Grade 70) and bolt (ASTM A354 Grade BD) are fabricated from different material that have the same coefficient of thermal expansion (Table 2-4). The seal plate is made from ASTM A240 Type 304L with a higher coefficient of thermal expansion (Table 2-4). These components expand different amounts during the hot and cold environments. Therefore, in the cold environment the seal plate contracts more and as a result the bolts experience a loss of tension due to this relative expansion. The amount of loss of tension is conservatively calculated as follows:

Assume that the joint temperature is -40°F . Coefficient of thermal expansion of the seal plate material from Table 2-4 at 70°F is 8.5×10^{-6} in/(in $^{\circ}\text{F}$) and for bolt and lid materials is 6.4×10^{-6} in/(in $^{\circ}\text{F}$).

Primary Lid Bolts

Required Torque Calculation:

The effective length of the bolt for this relative expansion is the distance between the bolt-head to the top of the bolting ring (L) is:

$$L = 1.625'' \text{ Primary lid} + 0.25'' \text{ washer} + 0.25'' \text{ seal plate} = 2.125 \text{ in}$$

The relative expansion of the bolt and seal ring is:

$$\delta = 0.25 \times (8.5 - 6.4) \times 10^{-6} \times (-40 - 70) = -5.775 \times 10^{-5} \text{ in}$$

Young's Modulus for the bolting material at 70°F is 29.2×10^6 psi. Therefore, the loss of bolt stress due to relative thermal expansion is:

$$\sigma_{thermal} = 29.2 \times 10^6 \times 5.775 \times 10^{-5} / 2.125 = 794 \text{ psi}$$

For 2" diameter bolts, the preload lost is:

$$F_{thermal} = \pi / 4 \times 2^2 \times 794 = 2,495 \text{ lb}$$

The Maximum internal pressure of the package is 50 psi, which occurs under minimum external pressure load combinations (see Table 2-1). For the total 20 primary lid bolts, the average bolt load under this pressure is:

$$F_{p-avg} = \pi \times \left(31 \frac{7}{16}\right)^2 \times 50 / 20 \quad \left(31 \frac{15}{16} - \frac{1}{2} = 31 \frac{7}{16}'' \text{ is the radius of inner seal}\right)$$

$$= 7,762 \text{ lb}$$

The total required preload is:

$$F_{preload} = 2,495 + 7,762 = 10,257 \text{ lb}$$

Using the customary torque equation,

$$T = K \times D \times F$$

Where, T = torque

K = nut factor = 0.1 for lubricated condition

D = nominal diameter of the bolt = 2.0"

F = preload

The required torque is:

$$T = 0.1 \times 2.0 \times 10,257 = 2,052 \text{ in-lb} = 171 \text{ ft-lb}$$

Therefore, the specified torque of $500 \pm 50 \text{ ft-lb}$ (lubricated) is sufficient to maintain the needed bolt preload for the NCT loading.

Bolt Engagement:

The 2"-8UN, Class 2A bolts are installed though 2" long threaded inserts which develop strengths equal or greater than that of the bolt.

Secondary Lid Bolts

Required Torque Calculation:

The effective length of the bolt for this relative expansion is the distance between the bolt-head to the top of the primary lid (L') is:

$$L' = 2.1875" \text{ Secondary lid} + 0.25" \text{ washer} = 2.4375"$$

For a 3/8" thick seal plate, the relative expansion of the bolt and seal ring is:

$$\delta = (0.375 \times (8.5 - 6.4) \times 10^{-6}) \times (-40 - 70) = -8.6625 \times 10^{-5}"$$

Young's Modulus for the bolting material at 70°F is $29.2 \times 10^6 \text{ psi}$. Therefore, the loss of bolt stress due to relative thermal expansion is:

$$\sigma_{thermal} = 29.2 \times 10^6 \times 8.6625 \times 10^{-5} / 2.4375 = 1,038 \text{ psi}$$

For 2" diameter bolts, the preload lost is:

$$F_{thermal} = \pi/4 \times 2^2 \times 1,038 = 3,261 \text{ lb}$$

The Maximum internal pressure of the package is 50 psi, which occurs under minimum external pressure load combinations (see Table 2-1). For the total 12 secondary lid bolts, the average bolt load under this pressure is:

$$F_{p-avg} = \pi \times \left(14 \frac{13}{16}\right)^2 \times 50 / 12 \quad \left(0.5 \times 28 \frac{3}{4} + 0.5 \times 1 \frac{7}{8} - \frac{1}{2} = 14 \frac{13}{16}'' \text{ is the radius of inner seal}\right)$$

$$= 2,872 \text{ lb}$$

The total required preload is:

$$F_{preload} = 3,261 + 2,872 = 6,133 \text{ lb}$$

Using the customary torque equation,

$$T = K \times D \times F$$

Where, T = torque

K = nut factor = 0.1 for lubricated condition

D = nominal diameter of the bolt = 2.0"

F = preload

The required torque is:

$$T = 0.1 \times 2.0 \times 6,133 = 1,227 \text{ in-lb} = 102 \text{ ft-lb}$$

Therefore, the specified torque of 500 ± 50 ft-lb (lubricated) is sufficient to maintain the needed bolt preload for the NCT loading.

Bolt Engagement:

The 2"-8UN, Class 2A bolts are installed through 2" long threaded inserts which develop strengths equal or greater than that of the bolt.

2.7.1.10 Thermal-Shield Attachment Evaluation

The thermal-shield is attached to the secondary lid lifting lugs by three hitch pins. These pins have ½" diameter and are made of ASTM A-276 Gr. 304 stainless steel. In this section an evaluation is performed to show that the pins will provide enough strength to support the inertia of the thermal-shield during all the postulated hypothetical free drop tests.

The mass of the thermal-shield is calculated as follows (Reference: *EnergySolutions* drawing DWG-CSK-12CV01-EG-001-01, included in Section 1.0).

Mass of Item #1	= $0.28 \times \pi/4 \times 492 \times 0.25$	= 132 lb
Mass of Item #2	= $0.28 \times \pi/4 \times 492 \times 0.12$	= 63 lb
Mass of Item #3	= $7 \times 0.28 \times 5.58 \times 2.9375$	= 32 lb
<u>Misc (10% of above)</u>		<u>= 23 lb</u>
Total		= 250 lb

The ultimate tensile strength of ASTM A-276 Gr. 304 stainless steel is specified to be 75,000 psi. Taking 60% of this value as the shear strength, the shear strength of the pin material is $0.6 \times 75,000 = 45,000$ psi. The total pin shear area is:

$$A = 3 \times 2 \times (\pi/4) \times 0.5^2 = 1.178 \text{ in}^2$$

Total shear load that can be resisted by the pins is:

$$V = 1.178 \times 45,000 = 53,010 \text{ lb}$$

Deceleration acceptable = $53,010/250 = 212 \text{ g's}$

The largest deceleration is experienced by the package is 160 g's during the end drop test (see Section 2.7.1.1). Therefore, it is concluded that the thermal-shield will remain attached to the secondary lid during all the postulated free drop tests.

2.7.2 CRUSH

Not applicable; the package weighs more than 1,100 lb, and its density is larger than 62.4 lb/ft³.

2.7.3 PUNCTURE

The Nelms puncture relation (Reference 2-20, Page 18) is given as:

$$t = (W/S)^{0.71}$$

Where:

t = shell thickness = 1 1/2 inches

W = cask weight, lbs.

S_u = ultimate tensile strength of outer shell
= 70,000 psi

The package weight causing puncture is:

$$W = S \times t^{1.4}$$

The corresponding weight to cause puncture of the 1-1/2 inch outer shell is:

$$W_s = 70,000 \times 1.5^{1.4} = 123,488 \text{ lbs.}$$

The actual package weight is 74,000 lbs; therefore, the factor of safety for puncture resistance on an energy basis is:

$$F.S. = \frac{123,488}{74,000} = 1.67$$

When the package impacts the puncture pin, the force imposed upon the package is estimated as:

$$F_l = K_s \times A_l$$

K_s = Dynamic flow pressure of steel = 45,000 psi (Reference 2-20, Page 64)

R_c = Pin diameter = 6.0 inches

$$A_l = \frac{\pi}{4} \times (R_c)^2 = \frac{\pi}{4} \times (6.0)^2 = 28.27 \text{ in.}^2$$

$$F_l = (45,000) \times (28.27)$$

$$= 1.272 \times 10^6 \text{ lbs.}$$

This force induces a moment at the midsection of the package. The moment is estimated as:

$$M = \frac{F \times l}{8} = \frac{(1.272 \times 10^6) \times (88)}{8} = 13.99 \times 10^6 \text{ in-lb}$$

Calculating the section properties of the outer shell at the midsection:

$$I = \frac{\pi(d_o^4 - d_i^4)}{64}$$

$$= \frac{\pi(73.2^4 - 70.2^4)}{64} = 2.172 \times 10^5 \text{ in}^4$$

Using these section properties gives a bending stress of:

$$S_b = \frac{M \times c}{I} = \frac{(13.99 \times 10^6) \times (36.6)}{2.172 \times 10^5} = \pm 2,357 \text{ psi}$$

Conservatively assuming that the compressive and tensile stresses occur at the same location, the stress intensity is 4,714 psi and the factor of safety is:

$$F.S. = \frac{70,000}{4,714} = 14.8$$

To evaluate the ability of the cask to withstand puncture from a 40-inch end drop onto a 6-inch diameter pin, the end of the cask will be treated as two simply supported plates with a central load. Since the end is comprised of two 3.25-inch thick plates which must have identical deflections, the energy of the drop will be divided evenly between the two plates.

Reference 2-27, p. 415, gives the following equation for the deflection of a centrally loaded circular plate:

$$\frac{w_o}{h} + A \times \left(\frac{w_o}{h}\right)^3 = B \times \left(\frac{P \times a^2}{E \times h^4}\right)$$

Where:

w_o = deflection at center of plate, in.

h = plate thickness, in.

P = central load, lb.

E = Young's modulus, psi

a = plate radius, in.

$A = 0.272$ (simply supported plate, Ref. 2-29, p. 416)

$B = 0.552$ (simply supported plate, Ref. 2-29, p. 416)

The deformation energy can be found from:

$$u = \int_0^{\delta} P dw_o$$

$$= \frac{E \times h^4}{B \times a^2} \left[\frac{\delta^2}{2h} + \frac{A \times \delta^4}{4h^3} \right]$$

This can be equated to the drop energy, $\frac{W \times H}{2}$ to find the central deflection:

$$EhA\delta^4 + 2Eh^3\delta^2 - 2Ba^2WH = 0$$

$$\delta^2 = \frac{-2Eh^3 + \sqrt{(4E^2h^6 + 4EhA \times 2Ba^2WH)}}{2EhA}$$

$$\delta^2 = \frac{-2 + \sqrt{\left(4 + \frac{8ABa^2WH}{Eh^5}\right)}}{\frac{2A}{h^2}}$$

For:

$$h = 3.25 \text{ in.}$$

$$E = 29 \times 10^6 \text{ psi}$$

$$a = 31 \text{ in.}$$

$$W = 74,000 \text{ lb.}$$

$$H = 40 \text{ in.}$$

$$\delta^2 = \frac{-2 + \sqrt{\left(4 + \frac{8 \times 0.272 \times 0.552 \times 31^2 \times 74,000 \times 40}{29 \times 10^6 \times 3.25^5}\right)}}{\frac{2 \times 0.272}{3.25^2}} = 1.547 \text{ in}^2$$

Then:

$$\delta = 1.244 \text{ in.}$$

Solving for the force required to produce this deflection yields a value:

$$\frac{1.244}{3.25} + 0.272 \times \left(\frac{1.244}{3.25}\right)^3 = 0.552 \times \left(\frac{P \times 31^2}{29 \times 10^6 \times 3.25^4}\right)$$

$$P = 2.43 \times 10^6 \text{ lb}$$

However, using the dynamic flow pressure of the steel pin, the maximum force that can be exerted by the pin is given by:

$$F_{\max} = A_p \times K_s$$

$$= \frac{\pi(\delta^2)}{4} \times 45,000$$

$$= 1.27 \times 10^6 \text{ lb.}$$

This force will produce the maximum deflection of the plates

$$\delta = 0.669 \text{ in.}$$

Reference 2-27, p. 415, gives the following equations for the maximum membrane and membrane plus bending stresses:

Membrane:

$$\sigma_1 = \frac{\alpha \times E \times \delta^2}{a^2}$$

Membrane-plus-bending:

$$\sigma_2 = \frac{\beta \times E \times \delta \times h}{a^2}$$

For:

$$\alpha = 0.407 \quad (\text{Ref. 2-29, p. 416})$$

$$\beta = 0.606$$

Then:

$$\sigma_1 = \frac{0.407 \times 29 \times 10^6 \times 0.669^2}{31^2}$$

$$\sigma_1 = 5,497 \text{ psi.}$$

$$\sigma_2 = \frac{0.606 \times 29 \times 10^6 \times 0.669 \times 3.25}{31^2}$$

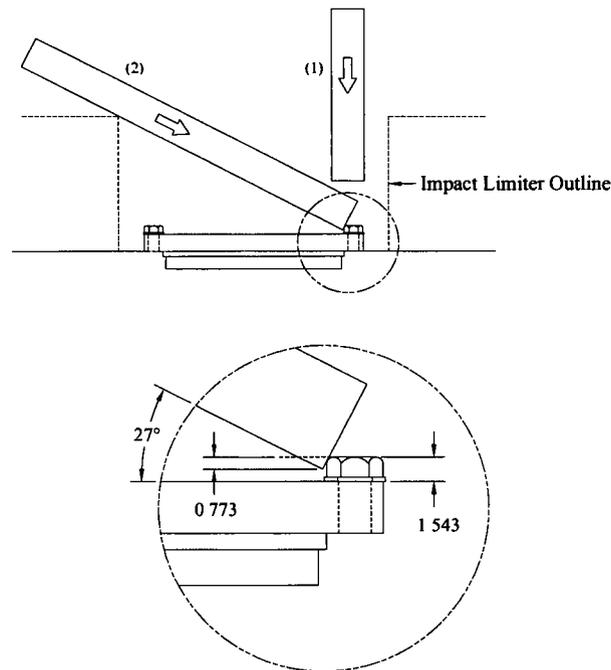

$$\sigma_2 = 39,761 \text{ psi.}$$

The minimum factor of safety is:

$$F.S. = \frac{70,000}{39,761} = 1.76$$

In the scenario of the puncture bar piercing through the top hollow portion of the impact limiter sheet-metal cover, it is also postulated that the puncture bar may contact the thermal shield and possibly the secondary lid bolts. Structural evaluation of the thermal-shield has been performed in Reference 2-31. Evaluate the deformation and/or damage to the thermal-shield in this scenario has been performed using a 3-dimensional ANSYS inelastic finite element model. It has been shown that the puncture bar may cause a minor damage to the shield near the central portion. Near the edge of the assembly the puncture bar may cause the shield-plates to deform all the way to the lid with only minor damages. The two stainless-steel plates will remain intact over most of the area, providing thermal resistance during the fire test.

The secondary lid bolts will remain covered by the thermal-shield in this scenario. However, a conservative evaluation of the bolts has been performed here with the assumption that the thermal-shield does not provide any cover to the bolts. Under this assumption, the rod impact on the bolthead is envisioned as shown in the following sketch.

In the two extreme cases, the rod may strike the bolthead as shown in the above sketch. If the rod strikes the bolthead as shown in (1) above, the bolt undergoes compression. The secondary lid comes in contact with the primary lid, and the rod can cause no damage to the lid as shown in the lid puncture evaluation provided above. If the rod strikes the bolthead as shown in (2) above, the shear-out of the bolthead is of concern. An evaluation is performed below to show that the shear-out of the bolthead is not possible in the scenario postulated here.

Based on the geometry of the impact limiter hollow section, the rod will have to be inclined at an angle of 27° from the lid surface to make contact with the bolthead in an orientation that may cause the maximum shear load on the bolthead. The bolts are specified to be 2" heavy head cap screws with flat washers.

$$\text{Maximum head thickness of 2" heavy head cap screws} = 1.263''$$

$$\text{Maximum thickness of 2" washers} = 0.28''$$

$$\text{Maximum projection above the lid surface} = 1.263 + 0.28 = 1.543''$$

Assuming that the rod makes contact at approximately the mid-height of the projection, the height of the shear-plane on the rod is located at 0.77'' as shown in the sketch.

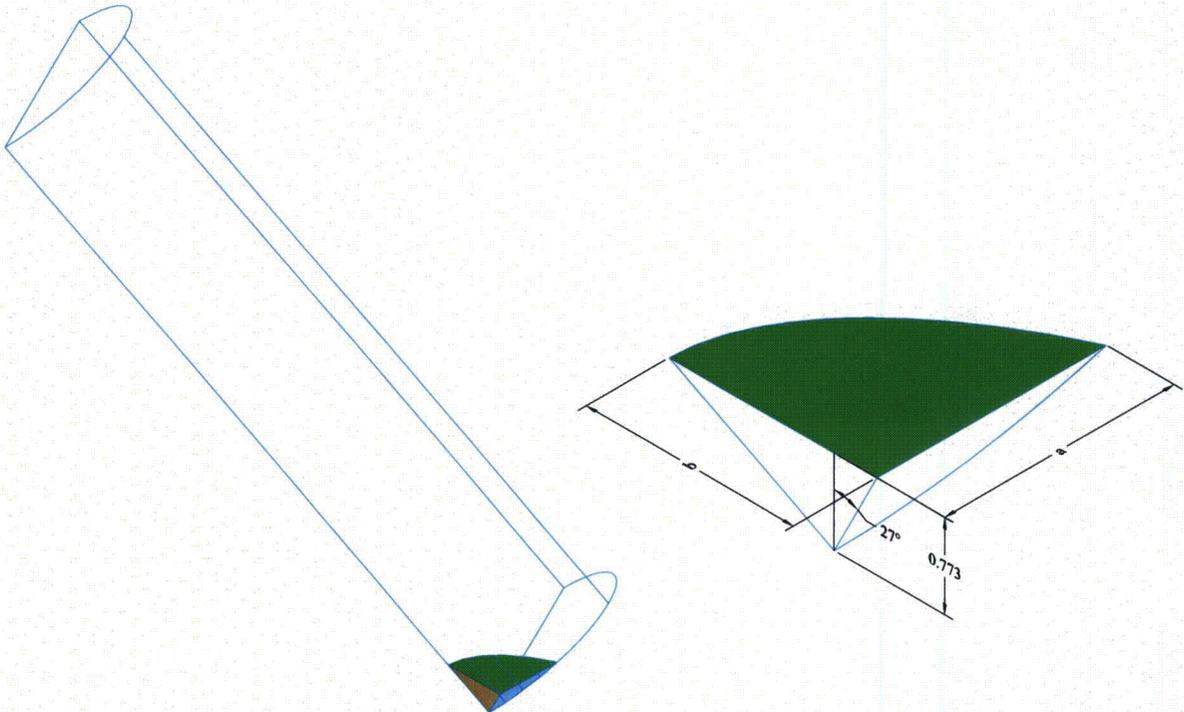

The rod, according to the regulations (Reference 2-1) is specified to be mild steel. Typical value of the ultimate tensile strength of mild steel is 45,000 to 55,000 psi (e.g. A-675 Gr. 45). The bolt has been specified as ASTM-354 Gr. BD for which the ultimate tensile strength is 150,000 psi. Taking 60% of the ultimate tensile strength as the shear stress at failure, the shear strengths of the two materials are as follows:

$$\text{Rod material shear strength} = 0.6 \times 55,000 = 33,000 \text{ psi}$$

$$\text{Bolt material shear strength} = 0.6 \times 150,000 = 90,000 \text{ psi}$$

The bolt shear area is $(\pi/4) \times 2^2 = 3.14 \text{ in}^2$. The rod shear area is calculated as follows.

Consider the following sketch that shows half of the rod:

The shear area of the rod is a parabola which has a base $2a$ and height b as shown in the sketch. The rod has a radius of 3'' as specified in Reference 2-1. From the geometry above;

$$a = \sqrt{3^2 - (3 - 0.773 / \cos 27^\circ)^2} = 2.11''$$

$$b = 0.773 \times (\tan 27^\circ + \cot 27^\circ) = 1.911''$$

Area of the parabola:

$$A = (2/3) \times 2a \times b = (2/3) \times 2 \times 2.11 \times 1.911 = 5.38 \text{ in}^2$$

Thus,

$$\text{Rod shear strength} = 5.38 \times 33,000 = 177,540 \text{ lb}$$

$$\text{Bolt shear strength} = 3.14 \times 90,000 = 282,600 \text{ lb}$$

Since the bolt shear strength is much greater than that of the rod, it is concluded that the puncture bar will not cause any damage to the bolts in the scenario postulated here.

Lead Shielding Deformation

After the puncture drop test the 8-120B cask may experience denting of the sidewall. The lead shielding behind the dent may experience a slight flattening which may result in a shielding loss in this region. A conservative evaluation of the maximum amount of lead deformation under puncture drop test of 8-120B cask has been performed in Reference 2-15. It has been shown that the lead shielding deformation is limited to 0.458 inch. This deformation is used in Section 5 for the shielding calculations.

2.7.4 THERMAL

The thermal evaluation of the 8-120B package for the HAC fire test specified in 10 CFR 71.73(c)(4) has been performed in Section 3.4. It has been shown in the free drop analyses that the rupture of the impact limiter skin near the point of impact is possible. The polyurethane foam is self-extinguishing and produces intumescent char when thermally degraded. The two impact limiters are assumed to provide thermal insulation.

Using the results of the thermal analysis of Section 3.4, structural evaluation of the package has been performed in this section. The finite element model described in Section 2.6 has been employed in the analyses. The details of the model, including the assumptions, modeling details, boundary conditions, and input and output data are included in the *EnergySolutions* document ST-637 (Reference 2-21).

2.7.4.1 Summary of Pressure and Temperatures

Based on the thermal analysis of the package during the HAC fire test, presented in Section 3.4, the maximum temperatures in various parts of the package are presented in Table 3-2 and plotted in Figure 3-12. These temperatures are summarized here as follows:

Fire Shield	= 1,392°F
Outer Shell	= 464.4°F
Inner Shell	= 295.5°F
Lead	= 295.8°F
Primary Lid Seal	= 212.4°F
Secondary Lid Seal	= 266.0°F

It should be noted that the maximum temperature in various components of the package occur at different time instants. The maximum temperature of the cask cavity during the entire HAC fires

test and subsequent cool-down is 320.5°F as shown in Figure 17 of *EnergySolutions* document TH-028 (Reference 2-28). Conservatively 325°F temperature is used in Section 3.4.3 for calculating the maximum internal pressure of the package during the HAC fire test. The calculated internal pressure of the package during the HAC fire test is 155.0 psig.

2.7.4.2 Differential Thermal Expansion

The structural finite element model used for the analyses of the 8-120B package under HAC fire test uses temperature dependent material properties of the cask components. The differential thermal expansion of various components of the cask is automatically included in the stress evaluation of the package.

2.7.4.3 Stress Calculations

The stresses in the package under the HAC fire test have been calculated in *EnergySolutions* document ST-637 (Reference 2-21). The loading combination used for the HAC fire test is listed in Table 2-1. Table 2-25 presents the maximum stresses in various component of the package.

2.7.4.4 Comparison with Allowable Stresses

The stresses in the package under the HAC fire test are compared with their allowable values in Table 2-25. The allowable values in various components of the package are listed in Table 2-2. It is noticed from the comparison with the allowable values that all the components of the package experience stresses well below their allowable values. A minimum factor of safety of 1.73 occurs in the bolting ring.

2.7.5 IMMERSION – FISSILE MATERIAL

Not applicable for 8-120B package; since it does not contain fissile material.

2.7.6 IMMERSION – ALL PACKAGES

All the Type-B packages are required to meet the water immersion test specified in 10 CFR 71.73(c)(6). According to which, an undamaged package must be subjected to a pressure of 21.7 psig.

The package has been analyzed for an increased external pressure of 25 psig in Section 2.6.4. Therefore, the stresses presented in that section envelope those that will arise due to the immersion test.

2.7.7 DEEP WATER IMMERSION TEST

Not applicable; 8-120B package does not contain irradiated nuclear fuel.

2.7.8 SUMMARY OF DAMAGE

It has been demonstrated by several analyses performed in Section 2.7 that the 8-120B package can withstand the HAC test, specified in 10 CFR 71.73, including the free drop, puncture and

fire. During these drop tests the protective impact limiters may undergo some damage, which is summarized as follows:

- During the HAC drop tests, the impact limiter skin may buckle and/or rupture in the vicinity of impact. The rupture may expose a portion of the polyurethane foam that is contained inside the steel skin.
- During the puncture drop test on the sidewall of the package, the fire-shield which is designed to have a separation from the outer shell, may come in contact with the outer shell due to deformation of the helically wound wire. The loss of separation will only be in the close vicinity of the puncture bar end. This will decrease the thermal resistance in that local area. The temperature there may increase slightly from those calculated for the intact package. In the area of the outer shell surface, the temperatures are well within the acceptable value. No unacceptable stress increase is expected because of slight increase in the local temperature.
- During the puncture drop test on the impact limiters, the outer steel skin will deform significantly due to large compression of polyurethane foam at the impact point. This may expose a portion of the polyurethane foam that is contained inside the steel skin. In addition, the steel plates that cover the central hollow regions of the upper and lower impact limiters may be penetrated or completely dislodged by the puncture drop test, resulting in direct exposure of the secondary lid thermal shield and the cask bottom plate in these regions to the subsequent fire. The seating surface of the impact limiters, which includes the impact limiter attachments, will remain intact as shown in the analysis. Therefore, during the HAC fire test, the impact limiters will provide thermal insulation with a reduced efficiency. The temperature in the critical components of the cask will not vary significantly.
- Puncture drop test will not cause a direct impact with any of the port closure plates.

Based on the assessment of the above damage it is concluded that the 8-120B package can safely withstand the HAC free drop, puncture, and fire tests performed in sequence. The package structural components under these drop tests have been shown to meet the design criteria set forth in Section 2.1.2.

2.8 ACCIDENT CONDITIONS FOR AIR TRANSPORT OF PLUTONIUM

Not applicable for 8-120B package since it is not transported by air.

2.9 ACCIDENT CONDITIONS FOR FISSILE MATERIAL PACKAGES FOR AIR TRANSPORT

Not applicable for 8-120B package since it is not transported by air.

2.10 SPECIAL FORM

Not applicable for 8-120B package since the package contents are not limited to special form.

2.11 FUEL RODS

Not applicable for 8-120B package; since the contents do not include fuel rods.

Table 2-1 - Summary of Load Combinations for Normal and Accident Condition Loading

Loading Conditions	Ambient Temperature (°F)	Insolation	Heat Load (Watt)	Pressure (psi)		Stress Table ⁽²⁾ or Reference
				Internal	External	
NORMAL CONDITIONS⁽¹⁾						
Hot Environment	100	✓	200	35		2-5
Cold Environment	-40		200	35		2-6
Increased External Pressure	-20		0		25	2-8
Minimum External Pressure	100	✓	200	50		2-7
Free Drop + Max. Internal Pressure	100	✓	200	35		2-10, 2-12 & 2-14
Free Drop + Min. Internal Pressure	-20		0		0	2-11, 2-13 & 2-15
ACCIDENT CONDITIONS⁽¹⁾						
Free Drop + Max. Internal Pressure	100	✓	200	35		2-17, 2-19 & 2-21
Free Drop + Min. Internal Pressure	-20		0		0	2-18, 2-20 & 2-22
Puncture						Section 2.7.3
Fire	1475		200	155		2-24

Notes:

- (1) These loading combinations have been derived from the NRC Regulatory Guide 7.8 (Reference 2-2).
- (2) See these tables for the stress analysis results of the corresponding loading combinations

Table 2-2 - Allowable Stresses

Material →		ASTM A240 Type 304L	ASTM A516 Gr. 70	ASTM A354 Gr. BD
Yield Stress, S_y	(psi)	25,000 ⁽¹⁾	38,000 ⁽¹⁾	130,000 ⁽¹⁾
Ultimate Stress, S_u	(psi)	70,000 ⁽¹⁾	70,000 ⁽¹⁾	150,000 ⁽¹⁾
Design Stress Intensity, S_m	(psi)	16,700 ⁽¹⁾	20,000 ⁽¹⁾	30,000 ⁽¹⁾
Normal Conditions	Membrane Stress	16,700 ⁽²⁾	20,000 ⁽²⁾	60,000 ⁽³⁾
	Mem. + Bending Stress	25,050 ⁽²⁾	30,000 ⁽²⁾	90,000 ⁽³⁾
Hypothetical Accident Conditions	Membrane Stress	40,080 ⁽⁴⁾	48,000 ⁽⁴⁾	105,000 ⁽⁵⁾
	Mem. + Bending Stress	60,120 ⁽⁴⁾	70,000 ⁽⁴⁾	150,000 ⁽⁵⁾

Notes:

- (1) From ASME B&PV Code 2001, Section II, Part D (Reference 2-4).
- (2) Established from Regulatory Guide 7.6 (Reference 2-3), Position 2.
- (3) Regulatory Guide 7.6 (Reference 2-3) does not provide any criteria. ASME B&PV Code, Section III, Subsection ND has been used to establish these criteria.
- (4) Established from Regulatory Guide 7.6 (Reference 2-3), Position 6.
- (5) Regulatory Guide 7.6 (Reference 2-3) does not provide any criteria. ASME B&PV Code, Section III, Appendix F has been used to establish these criteria.

Table 2-3 - Stress Component Definition

	ASME Definition	8-120B Cask Incorporation
Primary (General) Membrane, P_m [RG 7.6, B-2 & B-4 WB-3213.6 & WB-3213.8]	Average primary stress across solid section. Excludes discontinuities and concentrations. Produced by pressure and mechanical loads.	The stresses caused by thermal expansion (contraction) are also included besides those caused by pressure and mechanical loading. The total stress over a section, <i>if meeting the allowable of membrane stress</i> , has been categorized as primary membrane. Otherwise, the stresses obtained from the FEA have been linearized to obtain the membrane component.
Primary Bending, P_b [RG 7.6, B-2 & B-4 WB-3213.7 & WB-3213.8]	Component of primary stress proportional to distance from centroid of solid section. Excluding discontinuities and concentrations. Produced by pressure and mechanical load.	The stresses caused by thermal expansion (contraction) are also included besides those caused by pressure and mechanical loading. The total stress over a section, <i>if meeting the allowable of membrane plus bending stress</i> , has been categorized as primary membrane plus bending stress. Otherwise, the stresses obtained from the FEA have been linearized to obtain the membrane plus bending component.
Secondary Membrane Plus Bending, Q [RG 7.6, B-3 WB-3213.9]	Self-equilibrating stress necessary to satisfy continuity of structure. Occurs at structural discontinuities. Can be caused by mechanical loads or by thermal expansion. Excludes local stress concentration.	The total stress over a section, <i>if meeting the allowable of membrane plus bending stress</i> , has been categorized as secondary membrane plus bending stress. Otherwise, the stresses obtained from the FEA have been linearized to obtain the membrane plus bending component.

Table 2-4 - Material Properties

Material	Temp. (°F)	Strength (ksi)			Young's Modulus (10 ⁶ psi)	Coefficient of Thermal Expansion (10 ⁻⁶ in/in °F)
		Yield (S _y)	Ultimate (S _u)	Membrane Allowable (S _m)		
ASTM A240 Type 304L		(1)	(1)	(1)	(1)	(1)
	-20	25.0	70.0	16.7	28.8	-
	70	25.0	70.0	16.7	28.3	8.5

- (2) From NUREG/CR 0481 (Reference 2-8)

Table 2-5 - Stress Intensities in 8-120B Cask under Hot Environment Loading

Component	Stress Category	Allowable S.I. (psi)	Calculated S.I. (psi) ⁽¹⁾	F.S. ⁽²⁾
Primary Lid	P _m	20,000	3,989	5.01
	P _m + P _b	30,000	3,989	7.52
Secondary Lid	P _m	20,000	2,255	8.87
	P _m + P _b	30,000	2,255	13.30
Bolting Ring	P _m	20,000	16,385	1.22
	P _m + P _b	30,000	16,385	1.83
Inner Shell	P _m	20,000	13,872	1.44
	P _m + P _b	30,000	13,872	2.16
Outer Shell	P _m	20,000	14,314	1.40
	P _m + P _b	30,000	14,314	2.10
Baseplate	P _m	20,000	9,919	2.02
	P _m + P _b	30,000	9,919	3.02
Primary Lid Bolts	P _m	60,000	12,516	4.79
	P _m + P _b	90,000	12,516	7.19
Secondary Lid Bolts	P _m	60,000	4,189	14.32
	P _m + P _b	90,000	4,189	21.48

Notes:

- (1) Unless otherwise indicated in this column, the maximum stress intensity values have been conservatively reported as P_m and P_m + P_b stress intensities.
- (2) Factor of Safety, F.S. = (Allowable S.I.) / (Calculated S.I.)
- (3) The stress values presented here are obtained from EnergySolutions Document ST-626 (Reference 2-13)

Table 2-6 - Stress Intensities in 8-120B Cask under Cold Environment Loading

Component	Stress Category	Allowable S.I. (psi)	Calculated S.I. (psi) ⁽¹⁾	F.S. ⁽²⁾
Primary Lid	P _m	20,000	3,695	5.41
	P _m + P _b	30,000	3,695	8.12
Secondary Lid	P _m	20,000	2,102	9.51
	P _m + P _b	30,000	2,102	14.27
Bolting Ring	P _m	20,000	4,177	4.79
	P _m + P _b	30,000	4,177	7.18
Inner Shell	P _m	20,000	5,075	3.94
	P _m + P _b	30,000	5,075	5.91
Outer Shell	P _m	20,000	4,778	4.19
	P _m + P _b	30,000	4,778	6.28
Baseplate	P _m	20,000	2,312	8.65
	P _m + P _b	30,000	2,312	12.98
Primary Lid Bolts	P _m	60,000	6,197	9.68
	P _m + P _b	90,000	6,197	14.52
Secondary Lid Bolts	P _m	60,000	3,904	15.37
	P _m + P _b	90,000	3,904	23.05

Notes:

- (1) Unless otherwise indicated in this column, the maximum stress intensity values have been conservatively reported as P_m and P_m + P_b stress intensities.
- (2) Factor of Safety, F.S. = (Allowable S.I.) / (Calculated S.I.)
- (3) The stress values presented here are obtained from EnergySolutions Document ST-626 (Reference 2-13)

**Table 2-7 - Nil Ductility Temperature Requirements for
Fracture Critical Components of the 8-120B Cask**

Component	Thickness (in)	A ⁽¹⁾ (°F)	T _{NDT} Req ⁽²⁾ (°F)
Bottom End Plate (Outside)	3.25	1	-21
Bottom End Plate (Inside)	3.25	1	-21
Inner Wall	0.75	-20	0
Outer Wall	1.5	-20	0
Primary Lid (Inside)	3.25	1	-21
Primary Lid (Outside)	3.25	1	-21
Secondary Lid (Inside)	3.25	1	-21
Secondary Lid (Outside)	3.25	1	-21
Bolting Ring	3.0	-2	-18

Notes:

- (1) Obtained from Figure 2-24.
- (2) T_{NDT} determined according to ASTM Standard E208-81.

Table 2-8 - Stress Intensities in 8-120B Cask under Reduced External Pressure

Component	Stress Category	Allowable S.I. (psi)	Calculated S.I. (psi) ⁽¹⁾	F.S. ⁽²⁾
Primary Lid	P_m	20,000	4,488	4.46
	$P_m + P_b$	30,000	4,488	6.68
Secondary Lid	P_m	20,000	2,612	7.66
	$P_m + P_b$	30,000	2,612	11.49

	P _m + P _b	30,000	2,554	11.75
Baseplate	P _m	20,000	2,812	7.11
	P _m + P _b	30,000	2,812	10.67
Primary Lid Bolts	P _m	60,000	6,466	9.28
	P _m + P _b	90,000	6,466	13.92
Secondary Lid Bolts	P _m	60,000	1,018	58.94
	P _m + P _b	90,000	1,018	88.41

Notes:

- (1) Unless otherwise indicated in this column, the maximum stress intensity values have been conservatively reported as P_m and P_m + P_b stress intensities.
- (2) Factor of Safety, F.S. = (Allowable S.I.) / (Calculated S.I.)
- (3) The stress values presented here are obtained from EnergySolutions Document ST-626 (Reference 2-13)

Table 2-10 - Normal Condition Drop Test Summary

Drop Orientation	Thermal Environment	Maximum Impact Limiter Reaction ⁽¹⁾ (lb)	Approximate Pulse Duration (msec)	Maximum Crush ⁽²⁾ (in)
End	Cold	1.556×10^6	20	0.471
	Hot	1.286×10^6	20	0.556
Side	Cold	8.596×10^5	30	1.043
	Hot	7.104×10^5	30	1.249
Corner	Cold	3.188×10^5	125	4.0
	Hot	2.785×10^5	125	4.8

Notes:

- (1) See Figures 13, 16, 19, 22, 25 and 28 of *EnergySolutions* Document ST-625 (Reference 2-14) for the time-history plots of the impact limiter reactions during various drop tests.
- (2) See Figures 15, 18, 21, 24, 27, and 30 of *EnergySolutions* Document ST-625 (Reference 2-14) for the time-history plots of the impact limiter crush during various drop tests.

Table 2-11 - Stress Intensities in 8-120B Cask under 1-ft End Drop – Hot Condition

Component	Stress Category	Allowable S.I. (psi)	Calculated S.I. (psi) ⁽¹⁾	F.S. ⁽²⁾
Primary Lid	P _m	20,000	15,086	1.33
	P _m + P _b	30,000	15,086	1.99
Secondary Lid	P _m	20,000	12,890	1.55
	P _m + P _b	30,000	12,890	2.33
Bolting Ring	P _m	20,000	12,994	1.54
	P _m + P _b	30,000	12,994	2.31
Inner Shell	P _m	20,000	16,983	1.18
	P _m + P _b	30,000	16,983	1.77
Outer Shell	P _m	20,000	6,837	2.93
	P _m + P _b	30,000	6,837	4.39
Baseplate	P _m	20,000	8,980	2.23
	P _m + P _b	30,000	8,980	3.34
Primary Lid Bolts	P _m	60,000	6,209	9.66
	P _m + P _b	90,000	6,209	14.50
Secondary Lid Bolts	P _m	60,000	15,983	3.75
	P _m + P _b	90,000	15,983	5.63

Notes:

- (1) Unless otherwise indicated in this column, the maximum stress intensity values have been conservatively reported as P_m and P_m + P_b stress intensities.
- (2) Factor of Safety, F.S. = (Allowable S.I.) / (Calculated S.I.)

Table 2-12 - Stress Intensities in 8-120B Cask under 1-ft End Drop – Cold Condition

Component	Stress Category	Allowable S.I. (psi)	Calculated S.I. (psi) ⁽¹⁾	F.S. ⁽²⁾
Primary Lid	P _m	20,000	14,529	1.38
	P _m + P _b	30,000	14,529	2.06
Secondary Lid	P _m	20,000	11,767	1.70
	P _m + P _b	30,000	11,767	2.55
Bolting Ring	P _m	20,000	9,959	2.01
	P _m + P _b	30,000	9,959	3.01
Inner Shell	P _m	20,000	15,787 ⁽³⁾	1.27
	P _m + P _b	30,000	15,787 ⁽³⁾	1.90
Outer Shell	P _m	20,000	6,655	3.01
	P _m + P _b	30,000	6,655	4.51
Baseplate	P _m	20,000	15,550	1.29
	P _m + P _b	30,000	15,550	1.93
Primary Lid Bolts	P _m	60,000	4,115	14.58
	P _m + P _b	90,000	4,115	21.87
Secondary Lid Bolts	P _m	60,000	13,075	4.59
	P _m + P _b	90,000	13,075	6.88

Notes:

- (1) Unless otherwise indicated in this column, the maximum stress intensity values have been conservatively reported as P_m and P_m + P_b stress intensities.
- (2) Factor of Safety, F.S. = (Allowable S.I.) / (Calculated S.I.)
- (3) The stress intensity values reported here have been obtained by averaging the values in the vicinity of the highest local stress. The high local stresses resulted from the modeling constraint in this area. See Figures 50, 51 and Appendix 2 of *EnergySolutions* Document ST-627 (Reference 2-15).

Table 2-13 - Stress Intensities in 8-120B Cask under 1-ft Side Drop – Hot Condition

Component	Stress Category	Allowable S.I. (psi)	Calculated S.I. (psi) ⁽¹⁾	F.S. ⁽²⁾
Primary Lid	P _m	20,000	12,159 ⁽³⁾	1.64
	P _m + P _b	30,000	12,159 ⁽³⁾	2.47
Secondary Lid	P _m	20,000	6,058	3.30
	P _m + P _b	30,000	6,058	4.95
Bolting Ring	P _m	20,000	13,360	1.50
	P _m + P _b	30,000	13,360	2.25
Inner Shell	P _m	20,000	14,098	1.42
	P _m + P _b	30,000	14,098	2.13
Outer Shell	P _m	20,000	10,564	1.89
	P _m + P _b	30,000	10,564	2.84
Baseplate	P _m	20,000	10,536	1.90
	P _m + P _b	30,000	10,536	2.85
Primary Lid Bolts	P _m	60,000	34,995	1.71
	P _m + P _b	90,000	34,995	2.57
Secondary Lid Bolts	P _m	60,000	10,982	5.46
	P _m + P _b	90,000	10,982	8.20

Notes:

- (1) Unless otherwise indicated in this column, the maximum stress intensity values have been conservatively reported as P_m and P_m + P_b stress intensities.
- (2) Factor of Safety, F.S. = (Allowable S.I.) / (Calculated S.I.)
- (3) Obtained from the model after removing the elements in the bolt hole vicinity. See Appendix 2 of EnergySolutions Document ST-627 (Reference 2-15).

Table 2-14 - Stress Intensities in 8-120B Cask under 1-ft Side Drop – Cold Condition

Component	Stress Category	Allowable S.I. (psi)	Calculated S.I. (psi) ⁽¹⁾	F.S. ⁽²⁾
Primary Lid	P _m	20,000	12,720 ⁽³⁾	1.57
	P _m + P _b	30,000	12,720 ⁽³⁾	2.36

	P _m + P _b	70,000	40,893	1.71
Baseplate	P _m	48,000	26,335	1.82
	P _m + P _b	70,000	26,335	2.66
Primary Lid Bolts	P _m	105,000	20,456	5.13
	P _m + P _b	150,000	90,545	1.66
Secondary Lid Bolts	P _m	105,000	51,222	2.05
	P _m + P _b	150,000	51,222	2.93

Notes:

- (1) Obtained from the stress linearization over the cross-section. See Appendix 2 of EnergySolutions Document ST-627 (Reference 2-15).
- (2) Obtained from the model after removing the elements in the bolt hole vicinity. See Appendix 2 of EnergySolutions Document ST-627 (Reference 2-15).
- (3) Factor of Safety, F.S. = (Allowable S.I.) / (Calculated S.I.)
- (4) Unless otherwise indicated in this column, the maximum stress intensity values have been conservatively reported as P_m and P_m + P_b stress intensities.
- (5) Bolt stresses reported here have been obtained from the bolt section evaluation using the loading obtained from the FEM analyses. See Section 7.3 and Tables 26 and 29 of EnergySolutions Document ST-627 (Reference 2-15).

Table 2-24 - Maximum Impact Limiter Attachment Force during Various HAC Drop Tests

Drop Orientation	Thermal Environment	Maximum Attachment Force ⁽¹⁾ (lb)
End	Cold	12,796
	Hot	10,826
Side	Cold	35,350
	Hot	29,943
Corner	Cold	31,296
	Hot	30,986

Notes:

- (1) See Figures 33, 37, 41, 45, 49, and 53 of ST-625 (Reference 2-14) for the time-history plots of the maximum attachment forces during various drop tests.

Table 2-25 - Maximum Stress Intensities in 8-120B Cask HAC Fire

Component	Stress Category	Allowable S.I. (psi)	Calculated S.I. ^{(1), (2)} (psi)	F.S. ⁽³⁾
Primary Lid	$P_m + P_b$	70,000	20,391	3.43
Secondary Lid	$P_m + P_b$	70,000	8,781	7.97
Bolting Ring	$P_m + P_b$	70,000	40,535	1.73
Inner Shell	$P_m + P_b$	70,000	26,802	2.61
Outer Shell	$P_m + P_b$	70,000	36,692	1.91
Baseplate	$P_m + P_b$	70,000	18,332	3.82
Primary Lid Bolts	$P_m + P_b$	150,000	45,904	3.27
Secondary Lid Bolts	$P_m + P_b$	150,000	16,357	9.17

Notes:

- (1) Unless otherwise indicated in the column, the maximum stress intensity values, obtained from the finite element model, have been conservatively reported as $P_m + P_b$ stress intensities.
- (2) EnergySolutions Document ST-637 (Reference 2-21) presents the plot of temperature distribution and stresses in the cask at various time instants. The stress values presented here are the maximum stress in a particular component during the entire HAC fire.
- (3) Factor of Safety, F.S. = (Allowable S.I.) / (Calculated S.I.)

3.0 THERMAL EVALUATION

This Section identifies, describes, discusses, and analyzes the principal thermal engineering design of the 8-120B package. Compliance with the performance requirements of 10 CFR 71 (Reference 3-1) is demonstrated.

3.1 DESCRIPTION OF THERMAL DESIGN

Two components contribute to the thermal protection of the cask body. These components are the impact limiters which provide thermal protection to the ends of the cask and the fire shield which protects the side walls between the impact limiters.

3.1.1 DESIGN FEATURES

Figure 3-1 shows the design features of the components contributing to the thermal protection of the cask. These components are identified in the figure with solid red color.

The fire shield is made of 3/16" steel sheet metal. In order to provide an air gap between the cask outer shell and the fire shield, 5/32" diameter wires are helically wrapped around the cask outer shell. The fire shield is welded to the cask body at the two ends. Cut-outs are provided in the fire shield in order to wrap around the tie down lugs and lifting ear pads.

The impact limiters are sheet metal enclosures filled with polyurethane foam which acts as insulation barrier to heat flow. The impact limiters are attached together with the help of turnbuckles on the ends of the cask as shown in Figure 3-1. The impact limiters remain attached to the cask body during the HAC drop tests (See Section 2.7). Therefore they provide thermal insulation to the cask during the NCT events and the fire test. The central portion of both, the top and the bottom, impact limiters contain a hollow region that is covered by sheet-metal (upper) or steel plate (lower). In the puncture drop test, which precedes the fire test, these covers may rupture and provide a direct path to the secondary lid and the baseplate. In order to protect the seals a thermal-shield is externally attached to the secondary lid.

3.1.2 CONTENT'S DECAY HEAT

The maximum decay heat of the waste component is 200 watt. The minimum decay heat of zero Watt is used in the evaluation of other limiting case.

3.1.3 SUMMARY TABLES OF TEMPERATURES

The maximum temperatures in various important components of the cask during the NCT events are summarized in Table 3-1. Table 3-2 summarizes the maximum temperature in these components during the HAC fire test. The time at which these components achieve the maximum temperature is also identified in Table 3-2. The results summarized in Table 3-1 and 3-2 are discussed in detail in Sections 3.3 and 3.4.

3.1.4 SUMMARY TABLE OF MAXIMUM PRESSURES

The summary of maximum pressures during the NCT and HAC fire test are provided in Table 3-3. The details of these pressure calculations are provided in Sections 3.3.2 and 3.4.3 for NCT and HAC fire test, respectively.

3.2 MATERIAL PROPERTIES AND COMPONENT SPECIFICATIONS

3.2.1 MATERIAL PROPERTIES

The material properties of the cask components used in the analysis of the 8-120B package are provided in Tables 3-4 through 3-6. Table 3-4 provides the temperature independent properties of the steel and lead components. Table 3-5 provides the temperature dependent specific heat and thermal conductivity of stainless steel, carbon steel and lead. Table 3-6 provides the temperature dependent density, specific heat and conductivity of air. Material properties have been obtained from standard references (References 3-2 through 3-6) and are identified in Tables 3-4 through 3-6.

3.2.2 COMPONENT SPECIFICATIONS

The metallic components that are important for the thermal performance of the package are made of steel. The non-metallic components are specified as follows:

- The seals used in the package are specified to be elastomer, 50-70 Shore A Durometer, usable temperature range that meets or exceeds the range required to meet the Normal Conditions of Transport (minimum= -40°F, maximum= +180°F) and meets or exceeds the temperature required to meet the Hypothetical Accident Conditions (+340°F) as specified by ES-C-038 (Reference 8.4.2).
- Lead is specified to be ASTM B-29 commercial grade. The melting temperature is 622°F.
- Polyurethane foam used in the impact limiters are specified by ES-M-175 (Reference 8.4.1). All the pertinent thermal properties are included in this specification.

3.3 THERMAL EVALUATION FOR NORMAL CONDITIONS OF TRANSPORT

The thermal analyses of the 8-120B package under various loading conditions have been performed using finite element modeling techniques. ANSYS finite element analysis code (Reference 3-7) has been employed to perform the analyses. Two finite element models have been employed in performing the NCT thermal analyses. A three-dimensional solid model and a 2-dimensional axisymmetric model were used in the analyses. For the load cases in which the mechanical loading on the cask are non-uniform, a three dimensional finite element model was used. To obtain the temperature distribution in the cask where the bolt loadings have no effect on the results, a two-dimensional axisymmetric finite element model has been used.

The cask geometry is symmetrical about a vertical plane, so a one-half model of the cask is represented in the 3-dimensional model. The impact limiters are not explicitly included in the finite element model. For NCT the impact limiters are conservatively represented by fully-

isolated boundary conditions, and only the exposed portions of the fire shield and cask body are used for the heat rejection to the ambient.

Figure 3-2 shows the three-dimensional finite element model used in various thermal load analyses. Figure 3-3 shows the material property modeling of various components of the cask.

The internal heat load has been modeled in the FEM in two different ways - implicitly (in 3-d model) and explicitly (in 2-d model). In the implicit model the heat load is applied as a uniform flux over the cavity of the cask. This results in a conservative cask body temperature. However, the cavity temperature predicted is not conservative. To get a conservative prediction of the cask cavity temperature, the internal contents of the cask is explicitly represented in the 2-d model. The cask body structural evaluation has been performed with the implicit model results and the cask cavity temperature needed for the calculation of internal pressure has been obtained from the explicit model.

The cask body structural evaluation has been performed in Section 2 with the temperature results obtained in this section.

The details of the analyses, including the assumptions, modeling details, boundary conditions, and input and output data are included in *EnergySolutions* document TH-027 (Reference 3-8).

3.3.1 HEAT AND COLD

The finite element model described in Section 3.3 is analyzed for the following loading conditions:

- Hot Environment – This load case is based on the requirements of 10 CFR 71.71 (c) (1). The loading includes a 100° F ambient temperature, solar insolation, and maximum internal heat load. This loading is used as one of the extreme initial conditions for the normal conditions of transport (NCT) and hypothetical accident condition (HAC) test evaluation. The temperature distribution in the cask body under this loading condition is shown in Figure 3-4.
- Cold Environment – This load case is based on the requirements of 10 CFR 71.71 (c) (2). The loading includes a -40° F ambient temperature, no solar insolation, and maximum internal heat load. This loading is used as one of the extreme initial conditions for the normal conditions of transport (NCT) and hypothetical accident condition (HAC) test evaluation. The temperature distribution in the cask body under this loading condition is shown in Figure 3-5.
- Normal Hot - This load case is based on the requirements of 10 CFR 71.71 (b). The loading includes a 100° F ambient temperature, no solar insolation, and maximum internal heat load. The temperature distribution in the cask body under this loading condition is shown in Figure 3-6.
- Normal Cold - This load case is based on the requirements of 10 CFR 71.71 (b). The loading includes a -20° F ambient temperature, no solar insolation, and maximum internal heat load. The temperature distribution in the cask body under this loading condition is shown in Figure 3-7.

The 2-d axisymmetric model, with the explicit heat loading, has been analyzed for the hot environment conditions. The temperatures results from this model have been used to report the waste and cavity temperatures. Figure 3-8 shows the temperature distribution in the cask and its internal contents.

The temperature distributions in the 8-120B cask under various conditions analyzed in this section are used in the structural analyses presented in Section 2. Under the cold conditions with minimum (zero) heat loading the body temperature of the cask reaches the ambient temperature in steady state. Therefore, no thermal analyses for this case are needed. On the other hand, with any amount of heat load, there exist temperature gradients in various parts of the cask. To capture these two effects, the evaluation of the cask in Section 2 has been performed for the two cold conditions one with the maximum internal heat load and another with minimum (zero) heat load. These two load cases envelope the conditions of maximum and minimum temperature gradient through the cask body.

The thermal analysis shows that under the normal conditions of transport there is no reduction in packaging effectiveness. The heat transfer capability of the components is not reduced under NCT, nor are there changes in material properties that affect structural performance, containment, or shielding. It has also been demonstrated that the maximum temperature of the accessible portion of the package is 160.6°F which is less than 185°F, required by 10 CFR 71.43(g), for an exclusive use shipment.

3.3.2 MAXIMUM NORMAL OPERATING PRESSURE

The maximum internal pressure of the cask is calculated assuming that the gas within the cask, a mixture of air, water vapor, oxygen, and hydrogen, behaves as an ideal gas. To determine the maximum internal pressure under normal conditions in the cask (MNOP) the temperature of the gas mixture within the cask was evaluated. The maximum temperature of the cask cavity under normal conditions is 197.87°F, (see Table 3-1). The gas mixture in the cavity is conservatively assumed to be 200°F.

The maximum pressure is the sum of three components:

1. The pressure due to the increased temperature of the gas in the cavity;
2. The pressure due to water in the cask (vapor pressure of water); and
3. The pressure due to generation of gas (hydrogen and oxygen) by radiolysis.

1. The cask on loading has an internal pressure equal to ambient, assumed to be 1 atm absolute (14.7 psia) at 70 °F (21.1 °C, 294.3 K) and defined as P_1 in the equation below. Per the ideal gas law, the increased partial pressure of the air initially sealed in the fixed volume of the cask at the ambient temperature as it is heated to 200 °F (93.3 °C, 366.5°K) is:

$$P_2 = P_1 \times \frac{T_2}{T_1} = (14.7 \text{ psia}) \times \frac{366.5 \text{ K}}{294.3 \text{ K}} = 18.31 \text{ psia}$$

2. Since the cask cavity is assumed to also contain water, the vapor pressure of water must be added to the pressure in the cavity. The vapor pressure contributed by water (P_{H_2O}) in the cavity at 200°F (93.3 °C) is 11.52 psia (interpolated from the table Vapor Pressure of Water from 0 °C to 370 °C, page 6-15, from Reference 3-4, a copy of the table is attached as Attachment 3A). Adding the water vapor pressure at 200 °F to the partial pressure of the initially-sealed air at this temperature gives:

$$P_3 = P_2 + P_{H_2O} = 18.31 \text{ psia} + 11.52 \text{ psia} = 29.83 \text{ psia}$$

3. Further, the cask atmosphere is assumed to contain five volume percent (5 vol%) hydrogen (H_2) gas due to radiolysis of the water. By stoichiometry of the water molecule (H_2O), the cask atmosphere will also contain 2.5 vol% oxygen (O_2) gas generated by radiolysis. Noting that partial pressures in an ideal gas mixture are additive and behave the same as ideal gas volume fractions or mole fractions, the partial pressure of hydrogen is described by the following equation:

$$P_{H_2} = 0.05 \times (P_{air} + P_{H_2O} + P_{H_2} + P_{O_2})$$

Combining P_{air} and P_{H_2O} into P_3 per item 2 above, and noting that $P_{O_2} = 0.5 \times P_{H_2}$, gives:

$$P_{H_2} = 0.05 \times (P_3 + 1.5P_{H_2})$$

Solving this equation explicitly for P_{H_2} gives:

$$P_{H_2} = \frac{(0.05)P_3}{1 - (0.05)(1.5)} = \frac{(0.05)(29.83 \text{ psia})}{1 - (0.05)(1.5)} = 1.61 \text{ psia}$$

Recalling the stoichiometric relationship between hydrogen and oxygen liberated by radiolysis of water, and again combining the pressures of the initially sealed air and water vapor as P_3 , the total pressure in the cask at 200 °F is:

$$P_{Total} = P_3 + 1.5P_{H_2} = 32.25 \text{ psia}$$

Therefore, the MNOP in gage pressure is calculated as:

$$MNOP = P_{Total} - P_1 = 32.25 \text{ psia} - 14.7 \text{ psia} = 17.6 \text{ psig}$$

The MNOP value is conservatively set at 35.0 psig for use in the cask structural analysis under normal conditions of transport (NCT).

3.3.3 THERMAL STRESSES

The structural evaluation of the package under the normal conditions of transport loading is performed in Reference (2-13). All the stresses are within the design allowable values established for 8-120B package.

3.4 HYPOTHETICAL ACCIDENT THERMAL EVALUATION

The thermal analyses of the 8-120B package under HAC fire conditions have been performed using finite element model, described in Section 3.3. A nonlinear thermal transient analysis is performed to obtain the time-history of the temperature in package.

The temperature results from the thermal analyses have been used for performing the structural evaluation of the 8-120B Cask under HAC fire. The maximum temperature of the cavity during the entire transient has been used for calculating the cask pressure during the HAC fire.

The impact limiters of the 8-120B package have been shown to remain attached to the cask body during the free drop tests. The effect of these drop tests is a local crushing of the foam, and possible rupture of the impact limiter skin. The puncture drop on the impact limiters will crush the foam and may also rupture the skin in the vicinity of the impact location. The rupture of the impact limiter skin after the drop and puncture tests may expose the polyurethane foam material to the fire. However, the polyurethane fire retardant characteristics will mitigate the effect of the direct exposure to fire due to formation of intumescent char. The intumescent char has the ability to seal large voids which could be caused by the impact damage. The char also provides a secondary thermal barrier which breaks down very slowly at 2000 to 2200°F.

The 5-gallon bucket tests performed by General Plastics where the open face of the bucket is exposed to direct fire show the formation of the char that prevents the fire from extending into the underlying foam. These tests also indicate that for the 11¾" foam thickness in the test, the effect of 30-minute fire has a minimal effect on the end opposite the exposed end. These tests were performed for various density foams and it was shown that the effectiveness of the foam is enhanced with the increasing foam density. With 25 lb/ft³ foam density and a minimum foam thickness of 11" in the 8-120B cask package, the effect of exposure of a small portion of foam due to rupture during the drop and puncture test will not have a significant effect on the impact limiter performance during the fire. Therefore, the same boundary conditions at the interface between the cask and the impact limiter as those under the NCT (total thermal insulation) have been used for the HAC fire test analyses. However, the puncture drop test may result in failure of the steel covers on the central hollow region of the upper and lower impact limiters, which could result in the regions of the cask located underneath these covers being exposed directly to the fire. Therefore, the central hollow regions of the upper and lower impact limiters are conservatively modeled fully exposed for the HAC fire test.

The direct impact of the puncture bar on the sidewall of the cask will remove the air gap provided between the fire-shield and the cask body. The fire shield may come in contact with the cask body near the impact location. During the HAC fire test extra amount of heat will be input to the cask body locally near the impact point. Analyses have also been performed to evaluate the conditions in which the fire-shield is damaged during the puncture drop test. The fire is

assumed to hit the area directly where the puncture bar damages the fire shield. It has been shown that under these conditions the cask experiences locally high temperatures but they are within the acceptable limit for the materials. See Reference 3-10 for the details of this analysis.

The details of the analyses, including the assumptions, modeling details, boundary conditions, and input and output data are included in EnergySolutions document TH-028 (Reference 3-10).

3.4.1 INITIAL CONDITIONS

The initial temperature condition, used for the HAC fire test analysis is obtained by running the finite element model with the following boundary conditions:

- Internal heat load – 200 W
- Solar insolation - yes
- Heat Transfer to the ambient by radiation – yes
- Heat transfer to the ambient by natural convection – yes
- Ambient air temperature - 100°F

3.4.2 FIRE TEST CONDITIONS

The fire transient is run with the body temperature resulting from the above initial conditions. The fire transient is run for 30 minutes (1,800 sec) with the following boundary conditions:

- Internal heat load – 200 W
- Solar insolation - no
- Heat Transfer to the ambient by radiation – yes
- Heat transfer to the ambient by forced convection – yes
- Ambient air temperature - 1475°F

The end of fire analysis of the model is performed with the body temperature resulting from the above fire transient to 1801 sec with the following boundary conditions:

- Internal heat load – 200 W
- Solar insolation - no
- Heat Transfer to the ambient by radiation – yes
- Heat transfer to the ambient by natural convection – yes
- Ambient air temperature - 100°F

The cool-down analysis of the model is performed with the body temperature resulting from the above fire transient to 22,500 sec with the following boundary conditions:

- Internal heat load – 200 W
- Solar insolation - yes

- Heat Transfer to the ambient by radiation – yes
- Heat transfer to the ambient by natural convection – yes
- Ambient air temperature - 100°F

Figure 3-9 shows the boundary conditions used during the fire transient analysis.

3.4.3 MAXIMUM TEMPERATURES AND PRESSURE

From the analyses of the finite element model, a time-history data of the temperature in various components of the cask is obtained. The fire shield, outer shell, inner shell, lead, and seal were considered as the critical components of the cask. The temperatures at representative locations in these components are monitored during the entire fire and cool down transient analysis. The nodes that are monitored at these critical components are shown in Figure 3-10.

Figure 3-11 gives the plot of the time-history data at the representative nodes of the cask components. Figure 3-12 gives the same data in cask components that are not directly exposed to the fire. The maximum temperature of various components of the cask during the entire transient analysis is presented in Table 3-2. The temperature profile in the cask during the cool-down period is shown in Figure 3-13. The temperature profile of the cask cavity at the time when its internal contents attain the maximum temperature is shown in Figure 3-14. Figure 3-15 shows the temperature profile in the cask body with the damage to the fire shield caused during the puncture drop.

The scenario in which the hollow central portion of the impact limiters is breached during the puncture drop test that precedes the fire test has been analyzed in *EnergySolutions* document TH-0002 (Reference 3-11). In Reference 3-11 a finite element model of the secondary lid with the thermal shield is analyzed for the HAC fire test. The finite element model is reproduced in Figure 3-13. The temperature time-history plot of the representative seal locations is shown in Figure 3-14. Figure 3-15 shows the temperature contour plot of the secondary lid with the thermal-shield at the time when the seal temperature attains the maximum value.

The scenario in which the thermal-shield is also damaged during the puncture drop test is also addressed in Reference 3-11. An axisymmetric finite element model has been used to evaluate the maximum seal temperatures in the damaged condition. The finite element model is reproduced in Figure 3-16. The temperature time-history plot of the representative seal locations is shown in Figure 3-17. Figure 3-18 shows the temperature contour plot of the secondary lid with the damaged thermal-shield at 5,400 seconds after the fire initiation of the fire.

The maximum internal pressure of the cask is calculated assuming that the gas within the cask, a mixture of air, water vapor, oxygen, and hydrogen, behaves as an ideal gas. The average temperature of the air inside the cask is obtained from *EnergySolutions* document TH-0001 (Reference 3-12). In this document the HAC fire analysis of the 8-120B Cask is performed with the assumption that the lower hollow portion of the impact limiter has been breached during the puncture drop test that precedes the HAC fire test. Consequently, a portion of the baseplate is directly exposed to the fire, which results in the highest temperature of the cask cavity. The average cask air temperature calculated in Reference 3-11 is 266°F.

The gas mixture temperature in the cavity is conservatively assumed to be 275°F. Assuming 32.3 psia (see Section 3.3.2) exists inside the cask at 200°F, the pressure in the cask at 275°F, P_2 , may be calculated by the ideal gas relationship:

$$P_2 = \frac{T_2}{T_1} \cdot P_1, \text{ where T is in degrees absolute}$$

$$P_2 = 35.9 \text{ psia}$$

The vapor pressure contributed by water in the cavity at 275°F is 45.4 psia (interpolated from the table Vapor Pressure of Water from 0 to 370 °C , page 6-15, from Reference 3-4, a copy of the table is attached as Attachment 3A).

Therefore, the maximum pressure during the HAC fire,

$$P_{\max} = 35.9 + 45.4 - 14.7 = 66.62 \text{ psig}$$

The value used for P_{\max} is conservatively set at 155 psig.

3.4.4 MAXIMUM THERMAL STRESSES

The structural evaluation of the package under the HAC fire test conditions is performed in Section 2.7.4 of this SAR. The maximum thermal stresses in the package with the corresponding allowable stresses are compared in Table 2-23. All the stresses are within the design limits established for the 8-120B package.

3.4.5 ACCIDENT CONDITIONS FOR FISSILE PACKAGES FOR AIR TRANSPORT

Not applicable.

4.0 CONTAINMENT

This chapter describes the containment configuration of the Model 8-120B Package for Normal Transport and Hypothetical Accident Conditions.

4.1 DESCRIPTION OF CONTAINMENT SYSTEM

4.1.1 CONTAINMENT VESSEL

The package containment vessel is defined as the inner shell of the shielded transport cask, together with the associated lid, o-ring seals and lid closure bolts. The inner shell of the cask or containment vessel consists of a right circular cylinder of 62 inches inner diameter and 75 inches inside height. The shell is fabricated of 3/4" thick carbon steel plate, ASTM A516-70. At the base, the cylindrical shell is attached to a circular end plate with full penetration welds. The primary lid is attached to the cask body with twenty (20) equally spaced 2-8 UN bolts. A secondary lid covers an opening in the primary lid and is attached to the primary lid using twelve (12) equally spaced 2-8 UN bolts. See Section 4.1.4 for closure details.

4.1.2 CONTAINMENT PENETRATION

There are three penetrations of the containment vessel. These are: (1) the primary lid with the containment boundary of the primary lid's inner o-ring, (2) the secondary lid with the containment boundary of the secondary lid's inner o-ring, and (3) the cask vent port located in the primary lid. A vent port penetrates the primary lid into the main cask cavity. The vent penetration is sealed with a Parker Stat-O-Seal. The primary and secondary lids are sealed with elastomeric o-rings.

4.1.3 WELDS AND SEALS

The containment vessel is fabricated using full penetration groove welds. Seals (vent seal and o-rings) meet the requirements of ES Specification, ES-C-038 [Ref. 4.4].

4.1.4 CLOSURE

The primary lid closure consists of two 3-1/4" thick laminated plates, stepped to fit over and within the top edge of the cylindrical body. The lid is supported at the perimeter of the cylindrical body by a thick plate (bolt ring) welded to the top of the inner and outer cylindrical body walls. This plate contains a 14-gauge stainless steel ring at a location, which corresponds to the sealing surface for the o-rings mounted in the lid. The lid is attached to the cask body by twenty (20) equally spaced 2-8 UN bolts. These bolts are torqued to 500 ft-lbs \pm 10 % (lubricated). Two (2) solid elastomeric o-rings are retained in machined grooves at the lid perimeter. Groove dimensions prevent over-compression of the o-rings by the closure bolt pre-load forces and hypothetical accident impact forces. The cask is fitted with a secondary lid of similar construction attached to the primary lid with twelve (12) equally spaced identical bolts. The secondary lid is also sealed with two (2) solid, elastomeric o-rings in machined grooves.

The vent penetration is sealed with a Parker Stat-O-Seal, which is used beneath the heads of the hex head cap screws. Table 4-1 gives the torque values for the cap screws.

Table 4-1 - Bolt and Cap Screw Torque Requirements

Location	Size (in.)	Torque Values (ft-lbs, \pm 10% lubricated)
Vent Seal Bolt	1/2	20
Primary Lid	2-8UN	500
Secondary Lid	2-8UN	500

4.2 CONTAINMENT UNDER NORMAL CONDITIONS OF TRANSPORT

The 8-120B package is designed, fabricated, and leak tested to preclude release of radioactive materials in excess of the limits prescribed in 10CFR71.51(a)(1).

Of the permitted contents discussed in Section 1, two are considered in the following calculations as representative of the various types and forms permitted in the 8-120B; powdered solids and irradiated hardware. In this section and Section 4.2.1 below, the maximum permitted reference leakage rates (as defined in ANSI N14.5 – 1997 [Ref. 4.1]) for normal and hypothetical accident conditions are calculated for powdered solids and irradiated hardware waste forms, and the most restrictive of these (i.e., the smallest leakage rate permitted) is taken as the reference leakage rate for the 8-120B cask and the basis for the acceptance criteria for leak testing. It is shown that the reference leakage rate (L_R) for the 8-120B cask is 1.54×10^{-6} ref-cm³/sec, and that the release limits specified in 10CFR 71.51(a)(1) are met by limiting the release rate of the 8-120B to less than this value.

As discussed above, the most limiting type of radioactive waste contents permitted in the 8-120B is either powdered solids or irradiated hardware. The maximum permitted volumetric and reference leakage rates for Normal Conditions of Transport (NCT) are calculated for powdered solids and irradiated hardware ($L_{R_N_PS}$ and $L_{R_N_IH}$, respectively). Similar calculations are performed in Section 4.3 for Hypothetical Accident Conditions (HAC) ($L_{R_A_PS}$ and $L_{R_A_IH}$, respectively). The most restrictive of these four values is taken to be the maximum permitted reference leakage rate, L_R .

4.2.1 MAXIMUM PERMITTED LEAK RATE

In this section the maximum permitted leakage rate under Normal Conditions of Transport is calculated for the 8-120B package. 10CFR71.51(a)(1) states that the containment requirements for normal conditions of transport are:

...no loss or dispersal of radioactive contents, as demonstrated to a sensitivity of $10^{-6}A_2$ per hour, no significant increase in external radiation levels, and no substantial reduction in the effectiveness of the packaging.

ANSI N14.5-1997 (Ref 4.1) states that the permissible leak rate shall be determined by Equation 4-1 below:

$$L = \frac{R}{C} \text{ (cm}^3\text{/s) (Eqn. 4 - 1)}$$

Where:

L = permissible volumetric leak rate (cm³/sec)

R = package containment requirements (Ci/sec)

C = activity per unit volume of the medium that could escape from the containment system (Ci/cm³)

For normal conditions of transport:

$$R_N = A_2 \times 10^{-6} \frac{1}{\text{hr}} \Rightarrow R_N = 2.78 \times 10^{-10} \frac{A_2}{\text{sec}} \quad 10\text{CFR71}$$

Determine the volume of the 8-120B cavity using dimensions from SAR drawing (Ref. 4.2):

$$L_{\text{cavity}} = 75 \text{ in} \quad L_{\text{cavity}} = 190.5 \text{ cm}$$

$$D_{\text{cavity}} = 61.8 \text{ in} \quad D_{\text{cavity}} = 156.972 \text{ cm}$$

The void volume of a typical hardware shipment and a powdered solids shipment are, respectively, 68% and 37% of the cask cavity volume. For leak rate calculations, the void volume (V_{cavity}) is conservatively assumed to be 25% of the cavity volume. Therefore,

$$V_{\text{cavity}} = \frac{(.25)\pi \cdot D_{\text{cavity}}^2 \cdot L_{\text{cavity}}}{4} \Rightarrow V_{\text{cavity}} = 9.217 \times 10^5 \text{ cm}^3$$

In Sections 4.2.2 and 4.2.3 below, the maximum permitted volumetric leak rates under normal conditions of transport (L_N) are calculated for powdered solids and irradiated hardware respectively, and each is then converted into a reference leak rates (L_{R_N}).

4.2.2 CONTAINMENT UNDER NORMAL CONDITIONS OF TRANSPORT (POWDERED SOLIDS)

Note: The following calculation for L_{N_PS} follows the methodology in NUREG/CR-6487 (Ref. 4.3)

C_{NPS} = concentration of releasable material during normal conditions of transport, Ci/cm³

$$\rho = \text{density of powder aerosol, g/cm}^3$$

$$\rho = 1 \times 10^{-6} \text{ g/cm}^3 \text{ from NUREG/CR-6487 (Ref. 4.3)}$$

Assume the mass (M) of the powdered solid is 60 grams and the activity (A) is 3000 A₂.

$$S_A = \text{specific activity of the releasable material, A}_2/\text{g}; = A/M = 50 \text{ A}_2/\text{g}$$

$$C_{NPS} = S_A H \rho$$

Using Eqn. 4-1:

$$L_{N_PS} = \frac{R_N}{C_{NPS}}$$

Then,

$$L_{N_PS} = 5.556 \times 10^{-6} \text{ cm}^3/\text{sec} \quad \textbf{Maximum permitted volumetric leakage rate, normal conditions, powdered solids under the condition that the mass exceeds 60 grams or SA is less than 50.}$$

Next, determine the Reference Leakage Rate, $L_{R_N_PS}$, normal conditions, powdered solids, for a volumetric leak rate L_{N_PS} :

$$\mu_{\text{air}} = 0.0214 \text{ cP (Ref. 4.1)}$$

$$M_{\text{air}} = 29.0 \text{ gm/mole (Ref. 4.1)}$$

$$a = 0.6 \text{ cm, assumed length for hole leaking air (equals o-ring diameter)}$$

For normal conditions of transport:

$$T_N = 180^\circ\text{F (from Chapter 3)}$$

$$MNOP = P_{u_N} = 3.38 \text{ atm (from Chapter 3)}$$

$$P_{u_N} = 3.38 \text{ atm}$$

$$P_{d_N} = 1.0 \text{ atm}$$

$$P_{a_N} = \frac{P_{u_N} + P_{d_N}}{2} \Rightarrow P_{a_N} = 2.19 \text{ atm}$$

Use Eqn. B.3, B.4, and B.5 in ANSI N14.5 - 1997. Determine the diameter of a hole, D_{maxI} that would leak L_{N_PS} .

$$L_{N_PS} = 5.56 \times 10^{-6} \text{ cm}^3/\text{sec (from above)}$$

$$F_{mn}(D_{max}) = \frac{\left[3.8 \times 10^3 \cdot D_{max}^3 \cdot \sqrt{\frac{T_N}{M_{air}}} \right]}{a \cdot P_{a_N}} \text{ (cm}^3/\text{atm} \cdot \text{sec) (Eqn. B. 4 of ANSI N14.5 – 1997)}$$

Also,

$$F_{cn}(D_{max}) = \frac{2.49 \times 10^6 \cdot D_{max}^4}{a \cdot \mu_{air}} \text{ (cm}^3/\text{atm} \cdot \text{sec) (Eqn. B. 3 of ANSI N14.5 – 1997)}$$

Use Eqn. B.5 from ANSI N14.5 - 1997. Let D_{max1} represent the diameter of the hole that will leak L_{N_PS} :

Solve for D_{max1} :

$$L(D_{max1}) = \left[(F_{cn}(D_{max1}) + F_{mn}(D_{max1})) \cdot (P_{u_N} - P_{d_N}) \cdot \frac{P_{a_N}}{P_{u_N}} \right] - L_{N_PS}$$

$$D_{max1} = 3.57 \times 10^{-4} \text{ cm}$$

Now calculate $L_{R_N_PS}$ based on D_{max1} . At standard conditions:

$$P_{u_S} = 1.0 \text{ atm}$$

$$P_{d_S} = 0.1 \text{ atm}$$

$$P_{a_S} = 0.55 \text{ atm}$$

$$T_S = 298 \text{ K}$$

Eqns. B.3, B.4, and B.5 at standard conditions become:

$$F_{mstd}(D_{max}) = \frac{3.81 \times 10^3 \cdot (D_{max})^3 \cdot \sqrt{\frac{T_S}{M_{air}}}}{a \cdot P_{a_S}}$$

Simplify this equation:

$$F_{mstd}(D_{max}) \rightarrow 3.70 \times 10^4 \cdot D_{max}^3$$

$$F_{cstd}(D_{max}) = \frac{2.49 \times 10^6 \cdot (D_{max})^4}{a \cdot \mu_{air}}$$

Simplify this equation:

$$F_{cstd}(D_{max}) \rightarrow 2.24 \times 10^8 \cdot D_{max}^4$$

Therefore, Eqn. B.5 at standard conditions and a hole diameter D_{max1} is:

$$L_{R_N_PS}(D_{max1}) = (F_{cstd}(D_{max1}) + F_{mstd}(D_{max1})) \cdot (P_{u,S} - P_{d,S}) \cdot \frac{P_{a,S}}{P_{u,S}}$$

Thus,

$$L_{R_N_PS}(D_{max1}) = 2.64 \times 10^{-6} \text{ cm}^3/\text{sec} \quad \text{Standard leak rate, normal conditions, powdered solids.}$$

4.2.3 CONTAINMENT UNDER NORMAL CONDITIONS OF TRANSPORT (IRRADIATED HARDWARE)

Assume that the worst case source term for irradiated hardware is control rod blades having the same type and level of surface contamination as spent fuel, and that the potentially releasable contents from the control rod blades is entirely from this surface contamination. The surface contamination on the control rod blades that is equivalent to spent fuel is characterized in NUREG/CR-6487 (Ref. 4.3).

The following information was derived from Ref. 4.3, except as noted:

- bounding value for surface activity; worst case is for BWR fuel, $S_B = 1254 \times 10^{-6} \text{ Ci/cm}^2$
- surface area of control rod blade, $SA_B = 44,500 \text{ cm}^2$, cruciform shape has 4 blade surfaces, blade width = 9.8", length conservatively assumed to be 175", $A = 4 \times 9.8" \times 175"$, see Ref. 4.3
- A_2 for BWR fuel crud, normal transport conditions = 11.0 Ci
- fraction of surface activity that can spall off the surface of a blade and therefore is potentially releasable, normal transport conditions, $f_N = .15$

In addition, conservatively set the weight of control rod blade at 200 lbs, Ref. 4.3.

Given:

- assumed upper bound payload weight capacity of 8-120B cask = 14,680 lbs.
- number of control rod blades that can be transported in the 8-120B; assume 100% packing efficiency; N
- C_{NIH} = activity concentration in the cavity that could potentially escape during normal conditions of transport, irradiated hardware, Ci/cm^3
- total surface activity available for release on the surface of the control rod blades, normal transport conditions, RL_N :
- number of control rod blades in the cavity = N

$$N = \frac{14680}{200} \quad N = 73 \text{ blades}$$

$$f_N = .15$$

$$S_B = 1254 \times 10^{-6} \text{ Ci/cm}^2$$

$$SA_B = 44500 \text{ cm}^2$$

$$RL_N = N \cdot S_B \cdot SA_B \cdot f_N \rightarrow RL_N = 6.11 \times 10^2 \text{ Ci}$$

$$C_{NIH} = \frac{RL_N}{V_{\text{cavity}} \cdot (11.0)} \Rightarrow C_{NIH} = 6.027 \times 10^{-5} \cdot \text{cm}^{-3}$$

From Eqn. 1-1 above:

$$L_{N_IH} = R_N / C_{NIH} = 4.609 \times 10^{-6} \text{ cm}^3/\text{sec} \quad \text{Maximum permitted volumetric leakage rate, normal conditions of transport, for irradiated hardware.}$$

Next, determine the Reference Leakage Rate, $L_{R_N_IH}$, normal conditions, irradiated hardware, for a volumetric leak rate L_{N_IH} :

Follow the same steps used above. First, determine a $D_{\text{max}2}$ that would leak L_{N_IH} :

Use Eqn. 4-2:

$$L(D_{\text{max}2}) = \left[(F_{\text{cn}}(D_{\text{max}2}) + F_{\text{mn}}(D_{\text{max}2})) \cdot (P_{u_N} - P_{d_N}) \cdot \frac{P_{a_N}}{P_{u_N}} \right] - L_{N_IH}$$

Solve this equation for $D_{\text{max}2}$:

$$D_{\text{max}2} = 3.4 \times 10^{-4} \text{ cm}$$

Now substitute $D_{\text{max}2}$ into Eqn. B.5 and determine $L_{R_N_IH}$ at standard conditions:

$$L_{R_N_IH}(D_{\text{max}2}) = (F_{\text{cstd}}(D_{\text{max}2}) + F_{\text{mstd}}(D_{\text{max}2})) \cdot (P_{u_S} - P_{d_S}) \cdot \frac{P_{a_S}}{P_{u_S}}$$

$$L_{R_N_IH}(D_{\text{max}2}) = 2.20 \times 10^{-6} \text{ cm}^3/\text{sec} \quad \text{Standard leak rate, normal conditions, irradiated hardware.}$$

4.3 CONTAINMENT UNDER HYPOTHETICAL ACCIDENT CONDITIONS (TYPE B PACKAGES)

In this section the maximum permitted leakage rates under Hypothetical Accident Conditions are calculated for the 8-120B package. 10CFR71.51(a)(2) states that the containment requirements for Hypothetical Accident Conditions are:

...no escape of krypton-85 exceeding 10A₂ in 1 week, no escape of other radioactive material exceeding a total amount A₂ in 1 week, and no external radiation dose rate exceeding 10 mSv/h (1 rem/h) at 1 m (40 in) from the external surface of the package.

Following the methodology from Section 4.2 in Sections 4.3.1 and 4.3.2 below, the maximum permitted volumetric leakage rates under Hypothetical Accident Conditions are calculated for powdered solids and irradiated hardware, L_{A_PS} and L_{A_IH} respectively. In Section 4.3.1 the reference leakage rate corresponding to L_{A_PS} , $L_{R_A_PS}$, is calculated, and in Section 4.3.2 the reference leakage rate corresponding L_{A_IH} , $L_{R_A_IH}$, is calculated.

In Section 4.4, $L_{R_A_PS}$ and $L_{R_A_IH}$ are compared to the reference leakage rates for Normal Conditions of Transport calculated in Section 4.2.1 to determine the most restrictive, and thus the reference air leakage rate for the 8-120.

$$R_A = 1 \cdot \frac{A_2}{\text{week}} \quad R_A = 1.65 \times 10^{-6} \frac{A_2}{\text{sec}} \quad 10CFR71$$

4.3.1 CONTAINMENT UNDER HYPOTHETICAL ACCIDENT CONDITIONS (POWDERED SOLIDS)

Use the same parameters as Section 4.2.2:

C_{APS} = concentration of releasable materials during hypothetical accident conditions, C_i/cm^3

$$C_{APS} = C_{NPS}$$

Using Eqn. 1-1:

$$L_{A_PS} = R_A/C_{APS} = 0.033 \text{ cm}^3/\text{sec} \quad \text{Volumetric leakage rate, hypothetical accident conditions, powdered solids.}$$

Next, determine the reference leakage rate, $L_{R_A_PS}$, accident conditions, powdered solids, for a volumetric leak rate L_{A_PS} :

$$P_{d_A} = 1 \text{ atm} \quad (\text{Ref. 4.1})$$

$$\mu_{\text{air}} = 0.0185 \text{ cP} \quad (\text{Ref. 4.1})$$

$$M_{\text{air}} = 29.0 \text{ gm/mol} \quad (\text{Ref. 4.1})$$

$$A = 0.6 \text{ cm} \quad \text{assumed length of hole leaking air (equals o-ring diameter)}$$

For hypothetical accident conditions:

$$T_A = 325^\circ\text{F}$$

$$\text{HACP} = P_{u_A} = 155 \text{ psig}$$

$$P_{u_A} = 155 \text{ psig} \quad (\text{from Section 3})$$

$$P_{u_A}(x) = (x + 14.7) \text{ psi}$$

$$P_{u_A} = 11.6 \text{ atm}$$

$$P_{d_A} = 1 \text{ atm}$$

$$P_{a_A} = \frac{P_{u_A} + P_{d_A}}{2} = 6.28 \text{ atm}$$

Equations B.3 and B.4 at accident conditions are as follows:

$$F_{mA}(D_{\max}) = \frac{3.8 \times 10^3 \cdot D_{\max}^3 \cdot \sqrt{\frac{T_A}{M_{\text{air}}}}}{a \cdot P_{a_A}} \quad (\text{Eqn. B. 3, ANSI N14.5 - 1997})$$

$$F_{mA}(D_{\max}) = 3.91 \times 10^3 \cdot D_{\max}^3 \text{ cm}^3/\text{atm}\cdot\text{sec}$$

$$F_{cA}(D_{\max}) = \frac{2.49 \times 10^6 \cdot D_{\max}^4}{a \cdot \mu_{\text{air}}} \quad (\text{Eqn. B. 4, ANSI N14.5 - 1997})$$

$$F_{cA}(D_{\max}) = 1.85 \times 10^8 \cdot D_{\max}^4 \text{ cm}^3/\text{atm}\cdot\text{sec}$$

Let $D_{\max3}$ represent the diameter of the hole that will leak L_{A_PS} :

$$L_{A_PS} = 0.033 \text{ cm}^3/\text{sec}$$

$$L(D_{\max3}) = \left[(F_{cA}(D_{\max3}) + F_{mA}(D_{\max3})) \cdot (P_{u_A} - P_{d_A}) \cdot \frac{P_{a_A}}{P_{u_A}} \right] - L_{A_PS}$$

Solve this equation for $D_{\max3}$:

$$D_{\max3} = 2.4 \times 10^{-3} \text{ cm}$$

Substitute this value of $D_{\max3}$ into Eqn B.3 at standard conditions:

$$L_{R_A_PS}(D_{\max3}) = (F_{cstd}(D_{\max3}) + F_{mstd}(D_{\max3})) \cdot (P_{u_S} - P_{d_S}) \cdot \frac{P_{a_S}}{P_{u_S}}$$

$$L_{R_A_PS}(D_{\max3}) = 0.004 \text{ cm}^3/\text{sec} \quad \text{Standard leak rate, accident conditions, powdered solids.}$$

4.3.2 CONTAINMENT UNDER HYPOTHETICAL ACCIDENT CONDITIONS (IRRADIATED HARDWARE)

(See Section 4.4 for the basic assumptions regarding control rod blades and irradiated hardware.)

For accident conditions:

- A_2 for BWR fuel, accident conditions = 11.0 Ci (Ref. 4.3)
- $f_A = 1.0$ (Ref. 4.3) fraction of surface activity potentially that can spall off surface of a blade and therefore is potentially releasable under accident conditions,

C_{AIH} = activity concentration in the cavity that could potentially escape during accident conditions, irradiated hardware, C_i/cm^3

$$RL_A = N \cdot S_B \cdot SA_B \cdot f_A \Rightarrow RL_A = 4.07 \times 10^3 C_i$$

$$C_{AIH} = \frac{RL_A}{V_{cavity} \cdot (11.0)} \Rightarrow C_{AIH} = 4.02 \times 10^{-4} \cdot A_2 \cdot C_i/cm^3$$

$$L_{A_IH} = R_A/C_{AIH} = 4.12 \times 10^{-3} \text{ cm}^3/\text{sec} \quad \text{Volumetric leak rate, Hypothetical Accident Conditions, Irradiated hardware}$$

Next, determine the reference leakage rate, $L_{R_A_IH}$, accident conditions, irradiated hardware, for a volumetric leak rate L_{A_IH} :

Follow the same steps used in Section 4.3.1 above. First, determine a D_{max4} that would leak L_{A_IH} :

$$L_{A_IH} = 4.12 \times 10^{-3} \text{ cm}^3/\text{sec} \text{ (from above)}$$

$$L(D_{max4}) = \left[(F_{cA}(D_{max4}) + F_{mA}(D_{max4})) \cdot (P_{u,A} - P_{d,A}) \cdot \frac{P_{a,A}}{P_{u,A}} \right] - L_{A_IH}$$

Solve this equation for D_{max4}

$$D_{max4} = 1.40 \times 10^{-3} \text{ cm}$$

Now substitute D_{max4} into Eqn B.5 and determine $L_{R_A_IH}$ at standard conditions:

$$L_{R_A_IH}(D_{max4}) = (F_{cstd}(D_{max4}) + F_{mstd}(D_{max4})) \cdot (P_{u,S} - P_{d,S}) \cdot \frac{P_{a,S}}{P_{u,S}}$$

$$L_{R_A_IH}(D_{max4}) = 4.77 \times 10^{-4} \text{ cm}^3/\text{sec} \quad \text{Standard leak rate, accident conditions, irradiated hardware.}$$

4.4 REFERENCE AIR LEAKAGE RATE

The following table summarizes results in Sections 4.2 and 4.3 above:

	Max. Volumetric Leak Rate (cm ³ /sec)	Max. Hole Diameter (cm)	Reference Leak Rate (cm ³ /sec)
Normal Conditions of Transport, Powdered Solids	$L_{N_PS} = 5.56 \times 10^{-6}$	$D_{max1} = 3.57 \times 10^{-4}$	$L_{R_N_PS} = 2.64 \times 10^{-6}$
Normal Conditions of Transport, Irradiated Hardware	$L_{N_IH} = 4.61 \times 10^{-6}$	$D_{max2} = 3.4 \times 10^{-4}$	$L_{R_N_IH} = 2.20 \times 10^{-6}$
Hypothetical Accident Conditions, Powdered Solids	$L_{A_PS} = 0.033$	$D_{max3} = 2.4 \times 10^{-3}$	$L_{R_A_PS} = 0.004$
Hypothetical Accident Conditions, Irradiated Hardware	$L_{A_IH} = 4.12 \times 10^{-3}$	$D_{max4} = 1.40 \times 10^{-3}$	$L_{R_A_IH} = 4.77 \times 10^{-4}$

The reference leak rate for powdered solids was determined based on the assumption that the powdered solid source has a mass of at least 60 grams or the SA is less than 50. With these constraints, $L_{R_N_PS}$ is not the most restrictive leak rate. The most restrictive reference leak rate is $L_{R_N_IH}$, for normal conditions of transport, irradiated hardware, and will be the reference leak rate for the cask. Therefore, for the 8-120B cask:

$$L_R = 2.20 \times 10^{-6} \text{ ref-cm}^3/\text{sec} \quad \text{8-120B cask reference air leakage rate}$$

4.5 DETERMINATION OF EQUIVALENT REFERENCE LEAKAGE RATE FOR R-134A GAS

The purpose of this calculation is to determine the allowable leak rate using the R-134a halogen gas that may be used to perform the annual verification leak tests on the 8-120B cask. This halogen gas is now in widespread use as a replacement gas for R-12 in many industrial applications.

This calculation uses formulas presented in ANSI N14.5 - 1997.

$$L_R = 2.2 \times 10^{-6} \text{ cm}^3/\text{sec}$$

As calculated above, maximum diameter hole through the O-ring corresponding to this leakage rate is:

$$D_{MAX} = D_{max2} \text{ cm} \Rightarrow D_{MAX} = 3.4 \times 10^{-4} \text{ cm}$$

Determine the equivalent air/R134a mixture (L_{mix}) that would leak from D_{MAX} during a leak test. Assume the cask void is first evacuated to 20" Hg vacuum (9.92" Hg abs) and then pressurized to 25 psig (2.7 atm) with an air/R134a mixture.

$$P_{\text{mix}} = 2.701 \text{ atm}$$

$$P_{\text{air}} = 9.92 \text{ in. Hg} = 0.332 \text{ atm}$$

$$P_{\text{R134a}} = P_{\text{mix}} - P_{\text{air}} \Rightarrow P_{\text{R134a}} = 2.37 \text{ atm}$$

$$P_d = 1.0 \text{ atm}$$

$$P_a = \frac{P_{\text{mix}} + P_d}{2} \Rightarrow P_a = 1.85 \text{ atm}$$

The properties of R134a are:

$$M_{\text{R134a}} = 102 \text{ gm/mole}$$

$$\mu_{\text{R134a}} = 0.012 \text{ cP}$$

$$M_{\text{mix}} = \frac{M_{\text{R134a}} \cdot P_{\text{R134a}} + M_{\text{air}} \cdot P_{\text{air}}}{P_{\text{mix}}} = 93.04 \frac{\text{gm}}{\text{mole}} \quad (\text{Eqn. B7 of ANSI N14.5 - 1997})$$

$$\mu_{\text{mix}} = \frac{\mu_{\text{air}} \cdot P_{\text{air}} + \mu_{\text{R134a}} \cdot P_{\text{R134a}}}{P_{\text{mix}}} = 0.0128 \text{ cP} \quad (\text{Eqn. B. 8 of ANSI N14.5 - 1997})$$

Determine L_{mix} as a function of temperature. Assume the viscosities of air and R134a do not change significantly over the range of temperatures evaluated:

$$T = 273, 278, \dots, 328 \text{ K} \quad \text{Temperature range for test: } 32^\circ\text{F to } 130^\circ\text{F}$$

$$F_c = \frac{2.49 \times 10^6 \cdot D_{\text{MAX}}^4}{a \cdot \mu_{\text{mix}}} = 4.541 \times 10^{-6} \frac{\text{cm}^3}{\text{atm} \cdot \text{sec}}$$

$$F_m(T) = \frac{3.81 \times 10^6 \cdot D_{\text{MAX}}^3 \cdot \sqrt{\frac{T}{M_{\text{mix}}}}}{a \cdot P_a}$$

$$L_{\text{mix}}(T) = (F_c + F_m(T)) \cdot (P_{\text{mix}} - P_d) \cdot \frac{P_a}{P_{\text{mix}}}$$

$$T_F(T) = \left[(T - 273) \cdot \frac{9}{5} + 32 \right] ^\circ\text{F}$$

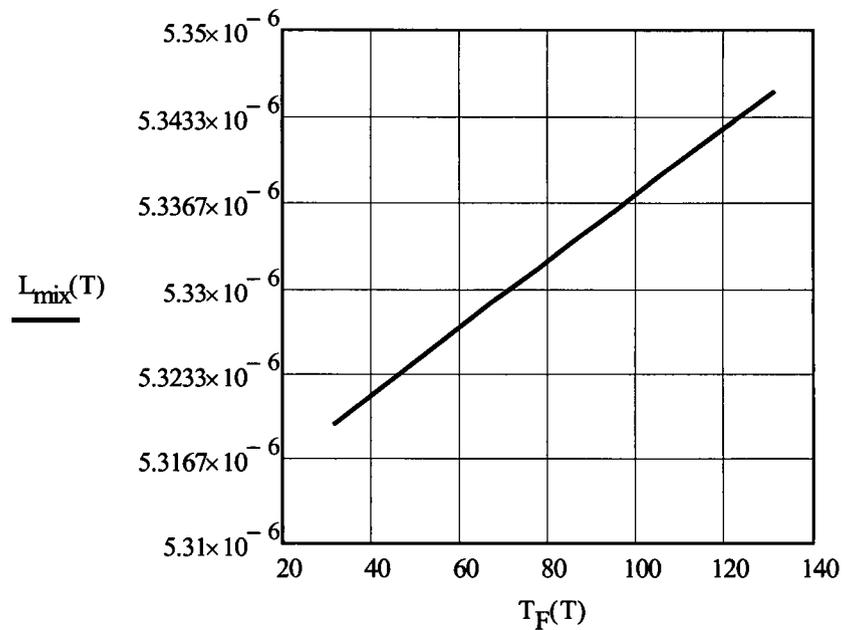

Figure 4-1 - Allowable He/Air Mixture Test Leakage, cm³/sec, versus test temperature, °F

The R-134a component of this leak rate can be determined by multiplying the leak rate of the mixture by the ratio of the R-134a partial pressure to the total pressure of the mix, as follows.

$$L_{R134a}(T) = L_{mix}(T) \cdot \frac{P_{R134a}}{P_{mix}}$$

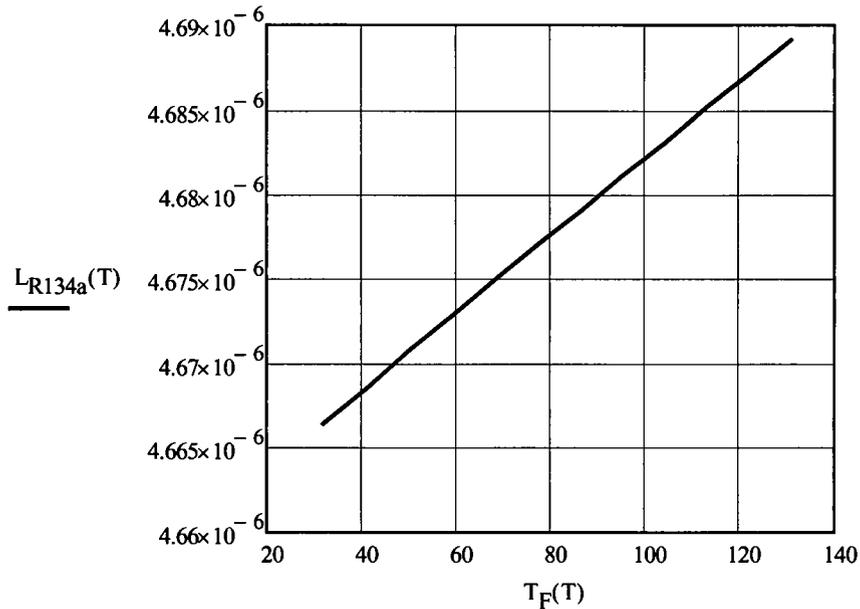

Figure 4-2 - Allowable R-134a Test Leakage, cm³/sec, versus Test Temperature, °F

Determine the equivalent mass flow rate for L_{R134a} in oz/yr:

$$N(T) = \frac{P_{R134a} \cdot V}{R_o \cdot T} \quad (\text{Ideal Gas Law})$$

Where,

$$R_o = 82.05 \frac{\text{cm}^3 \cdot \text{atm}}{\text{mol}}$$

$$V = 1 \text{ cm}^3$$

This data can then be used to convert the volumetric leak rate for R-134a calculated above to a mass leak rate. By dividing N by V , the number of moles per unit volume can be multiplied by the molecular weight of the gas and the maximum allowable volumetric leak rate to determine the maximum allowable mass leak rate, as a function of test temperature as shown in the graph below. The conversion from grams per second to ounces per year is also shown below.

$$1.0 \frac{\text{gm}}{\text{sec}} = 1.11 \times 10^6 \frac{\text{oz}}{\text{yr}} \quad (\text{Conversion of gm/sec to oz/year})$$

$$L(T) = L_{R134a}(T) \cdot \frac{N(T)}{V} \cdot M_{R134a}$$

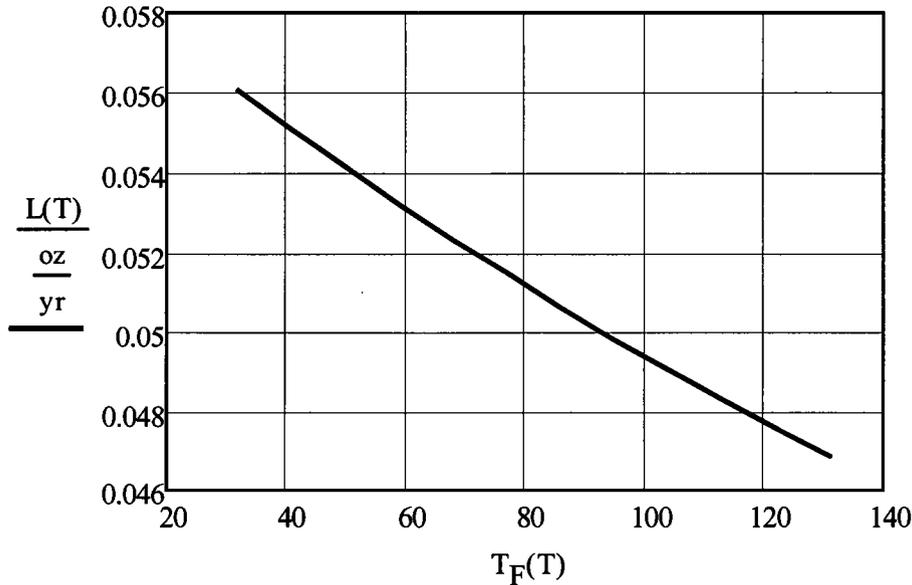

Figure 4-3 - Allowable R-134a Test Leakage, oz/yr, versus Test Temperature, °F

Figure 4-4 can be used to determine the allowable leak rate based on the temperature at the time of the test. A simplified version of the equation can be used to validate the curve:

$$L(T_F) = 4.872 \times 10^{-2} \cdot \left(\frac{5}{9} \cdot T_F + 255.2 \right)^{-0.5} + 15.28 \cdot \left(\frac{5}{9} \cdot T_F + 255.2 \right)^{-1}$$

According to ANSI N14.5 methodology, the maximum allowable leak rate must be divided by 2 to determine the minimum sensitivity for the test. A graph of the required sensitivity in oz/yr is presented below:

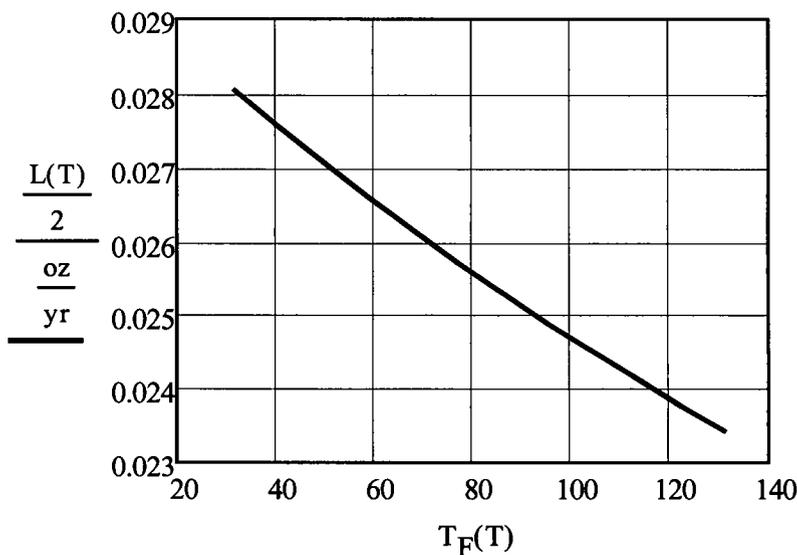

Figure 4-4 - Allowable R-134a test leakage sensitivity, oz/yr, versus test temperature, °F

A simplified version of the equation can be used to validate the sensitivity curve:

$$\frac{L(T_F)}{2} = 2.436 \times 10^{-2} \cdot \left(\frac{5}{9} \cdot T_F + 255.2 \right)^{-0.5} + 7.64 \cdot \left(\frac{5}{9} \cdot T_F + 255.2 \right)^{-1}$$

4.6 DETERMINATION OF EQUIVALENT REFERENCE LEAKAGE RATE FOR HELIUM GAS

The purpose of this calculation is to determine the allowable leak rate using the Helium gas that may be used to perform the annual verification leak tests on the 8-120B cask.

This calculation uses formulas presented in ANSI N14.5 - 1997.

$$L_R = 2.2 \times 10^{-6} \frac{\text{cm}^3}{\text{sec}}$$

As calculated above, maximum diameter hole through the O-ring corresponding to this leakage rate is:

$$D_{MAX} = D_{max2} \text{ cm} \Rightarrow D_{MAX} = 3.4 \times 10^{-4} \text{ cm}$$

Determine the equivalent air/helium mixture (L_{mix}) that would leak from D_{MAX} during a leak test. Assume the cask void is first evacuated to 20" Hg vacuum (9.92" Hg abs) and then pressurized to 1 psig (1.07 atm) with an air/helium mixture.

$$P_{air} = 0.33 \text{ atm} \quad P_d = 0.01 \text{ atm} \quad P_{mix} = 1.07 \text{ atm}$$

$$P_{He} = P_{mix} - P_{air}$$

$$P_a = \frac{P_{mix} + P_{air}}{2} = 0.54 \text{ atm}$$

$$M_{He} = 4.0 \cdot \frac{\text{g}}{\text{mol}} \text{ (ANSI N14.5 - 1997)}$$

$$\mu_{He} = 0.0198 \text{ cP (ANSI N14.5 - 1997)}$$

$$M_{mix} = \frac{M_{He} \cdot P_{He} + M_{air} \cdot P_{air}}{P_{mi}} = 11.75 \frac{\text{g}}{\text{mol}} \text{ (Eqn. B. 7 of ANSI N14.5 - 1997)}$$

$$\mu_{mix} = \frac{\mu_{air} \cdot P_{air} + \mu_{He} \cdot P_{He}}{P_{mi}} = 0.019 \text{ cP (Eqn. B. 8 of ANSI N14.5 - 1997)}$$

Determine L_{mix} as a function of temperature. Assume the viscosities of air and Helium do not change significantly over the range of temperatures evaluated:

$$T = 273, 278, \dots, 328 \text{ K} \quad \text{Temperature range for test: } 32^\circ\text{F to } 130^\circ\text{F}$$

$$F_c = \frac{2.49 \times 10^6 \cdot D_{MAX}^4}{a \cdot \mu_{mix}} \text{ (Eqn. B. 3 of ANSI N14.5 - 1997)}$$

$$F_m(T) = \frac{3.81 \times 10^6 \cdot D_{MAX}^3 \cdot \sqrt{\frac{T}{M_{mix}}}}{a \cdot P_a} \text{ (Eqn. B. 4 of ANSI N14.5 - 1997)}$$

$$L_{mix}(T) = (F_c + F_m(T)) \cdot (P_{mix} - P_d) \cdot \frac{P_a}{P_{mix}} \text{ (Eqn. B. 5 of ANSI N14.5 - 1997)}$$

$$T_F(T) = \left[(T - 273) \cdot \frac{9}{5} + 32 \right] ^\circ\text{F}$$

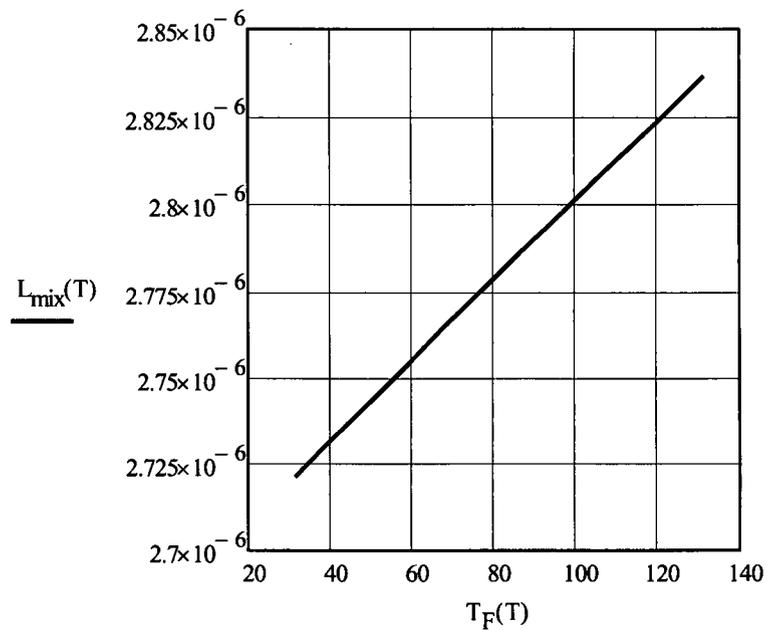

Figure 4-5 - Allowable R-134a/Air Mixture Test Leakage, cm^3/sec , versus test temperature, °F

The Helium component of this leak rate can be determined by multiplying the leak rate of the mixture by the ratio of the Helium partial pressure to the total pressure of the mix, as follows.

$$L_{\text{He}}(T) = L_{\text{mix}}(T) \cdot \frac{P_{\text{He}}}{P_{\text{mix}}}$$

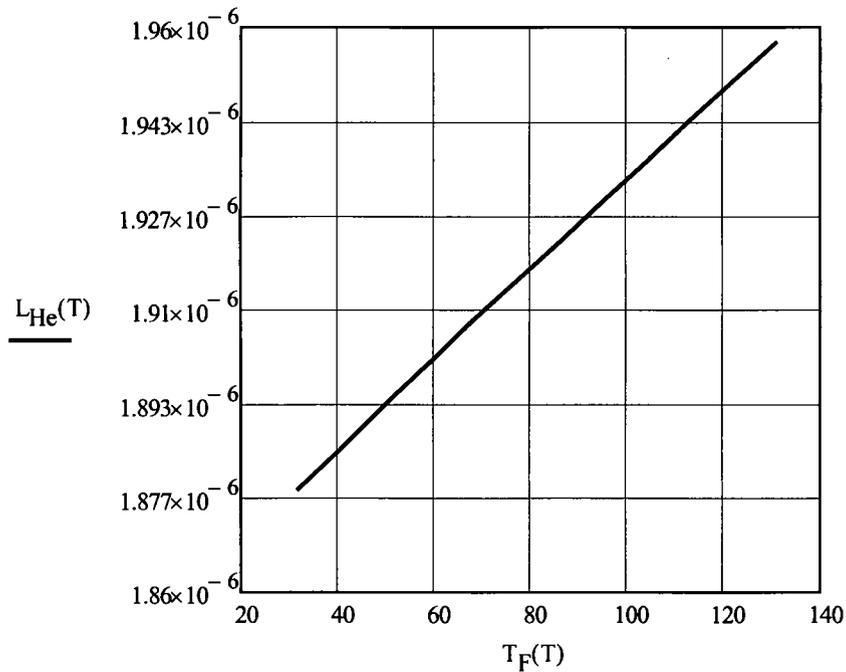

Figure 4-6 - Allowable He Test Leakage, cm^3/sec , versus test temperature, $^{\circ}F$

Figure 4-6 can be used to determine the allowable leak rate based on the temperature at the time of the test. A simplified version of the equation can be used to validate the curve:

$$L_{He}(T_F) = 2.114 \times 10^{-6} + 5.193 \times 10^{-8} \cdot \left(\frac{5}{9} \cdot T_F + 255.2 \right)^{0.5}$$

According to ANSI N14.1 methodology, the maximum allowable leak rate must be divided by 2 to determine the minimum sensitivity for the test. A graph of the required sensitivity is presented below.

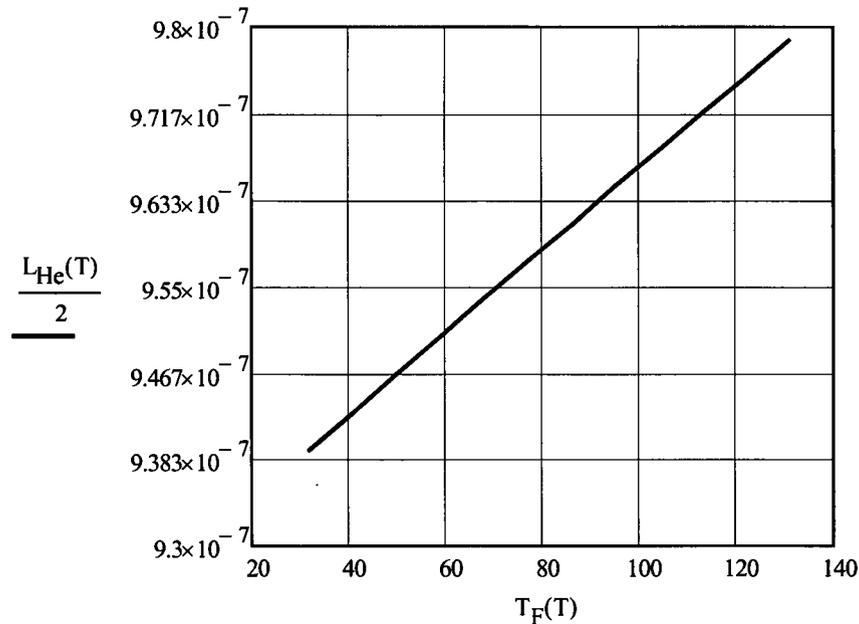

Figure 4-7 - Allowable helium test leakage sensitivity, cm³/sec, versus test temperature, °F

A simplified version of the equation can be used to validate the sensitivity curve:

$$\frac{L_{\text{He}}(T_F)}{2} = \frac{2.114 \times 10^{-6} + 5.193 \times 10^{-8} \cdot \left(\frac{5}{9} \cdot T_F + 255.2\right)^{0.5}}{2}$$

4.7 DETERMINING TIME FOR PRE-SHIPMENT LEAK TEST USING AIR OR NITROGEN

The pre-shipment leak test is to be performed by the pressure drop test method using air or nitrogen. The test will be performed on the closure lid and vent port. In this section the minimum hold time for each of the tests is determined.

4.7.1 MINIMUM HOLD TIME FOR CLOSURE LID

The pre-shipment leak test is performed by charging the annulus between the O-rings of the closure lid with air at 18 psig and holding the pressure for the prescribed time. The maximum volume of the test manifold is 10 cm³, which is added to the annulus volume.

The annulus between the O-rings is 1/8" deep and 1/8" wide with a center-line diameter (primary lid) of 63 7/8". The volume of the annulus is:

$$ID_{\text{ann}} = \left[(63.875) - \frac{1}{8} \right] \text{ in} \quad \Rightarrow \quad ID_{\text{ann}} = 63.75 \text{ in}$$

$$OD_{\text{ann}} = \left(63.875 + \frac{1}{8}\right) \text{ in} \quad \Rightarrow \quad OD_{\text{ann}} = 64.00 \text{ in}$$

$$V_{\text{ann}} = \frac{\pi}{4} \cdot (.125 \text{ in})(OD_{\text{ann}}^2 - ID_{\text{ann}}^2)$$

$$V_{\text{ann}} = 3.14 \text{ in}^3 \quad \Rightarrow \quad V_{\text{ann}} = 51.38 \text{ cm}^3$$

$$V_T = V_{\text{ann}} + 10 \text{ cm}^3 \quad \Rightarrow \quad V_T = 61.4 \text{ cm}^3$$

Use Equation B.14 from ANSI N14.5 to determine the required hold time given the maximum permitted leak rate, where:

L = atm-cm³/sec of air at standard conditions

V_{ann} = gas volume in the test annulus

T_s = reference absolute temperature, 298 K

H = test duration, hrs

P_s = standard pressure, 1 atm

P₁ = gas pressure in annulus at start of test, 1.232 atm (18.1 psig)

P₂ = gas pressure in annulus at end of test, 1.225 atm (18.0 psig)

T₁ = gas temperature in annulus at start of test, K

T₂ = gas temperature in annulus at end of test, K

$$T_s = 298 \text{ K} \quad T_1 = T_s \quad T_2 = T_s$$

$$P_s = 1 \text{ atm}$$

$$P_1 - P_2 = P_{\text{delta}} \quad \text{Maximum permitted } P_d = \text{sensitivity of pressure gage:}$$

$$P_{\text{delta}} = .1 \text{ psi} \quad P_{\text{delta}} = 0.007 \text{ atm}$$

$$L = \frac{V_T \cdot T_s}{3600 H \cdot P_s} \cdot \left(\frac{P_1}{T_1} - \frac{P_2}{T_2}\right) \frac{\text{cm}^3}{\text{sec}}$$

The maximum permitted sensitivity for the pre-shipment leak test as prescribed in ANSI N14.5 - 1997 is 10⁻³ ref-cm³/sec. From Equation B.17 in ANSI N14.5, the maximum permitted leak rate when the sensitivity is prescribed is:

$$L < \frac{S}{2}$$

therefore,

$$L = \frac{10^{-3} \text{ cm}^3}{2 \text{ sec}}$$

Rearranging Eqn. 4.7-1 to solve H:

$$H = \frac{V_T \cdot T_s \cdot P_{\text{delta}}}{3600 \frac{\text{sec}}{\text{hr}} \cdot L \cdot P_s \cdot T_s} \quad \text{Eqn. 4.7 - 2}$$

$$H = 13.92 \text{ min} \quad \text{For conservatism, the test will be conducted for 15 minutes.}$$

The smaller diameter secondary lid will be conservatively tested for the same time as the primary.

4.7.2 MINIMUM HOLD TIME FOR VENT PORT

Volume of vent port cavity:

$$V_{\text{vent}} = \frac{\pi}{4} (1.875 \text{ in})^2 \cdot 1.125 \text{ in}$$

Volume of seal plug head inside vent port cavity:

$$V_{\text{seal}} = \frac{\pi}{4} (1.5 \text{ in})^2 \cdot (1 \text{ in})$$

$$V_{\text{test}} = V_{\text{vent}} - V_{\text{seal}} \quad V_{\text{test}} = 21.945 \text{ cm}^3$$

$$V_T = V_{\text{test}} + 31.6 \text{ cm}^3$$

$$H = \frac{V_T \cdot T_s \cdot P_{\text{delta}}}{3600 \frac{\text{sec}}{\text{hr}} \cdot L \cdot P_s \cdot T_s} = 0.202 \text{ hr} = 12.145 \text{ min}$$

For conservatism, the test will be conducted for 15 minutes.

4.8 LEAKAGE RATE TESTS FOR TYPE B PACKAGES

The following leakage tests are conducted on the 8-120B package as required by ANSI N14.5:

Table 4-2 - Leakage Tests of the 8-120B Package

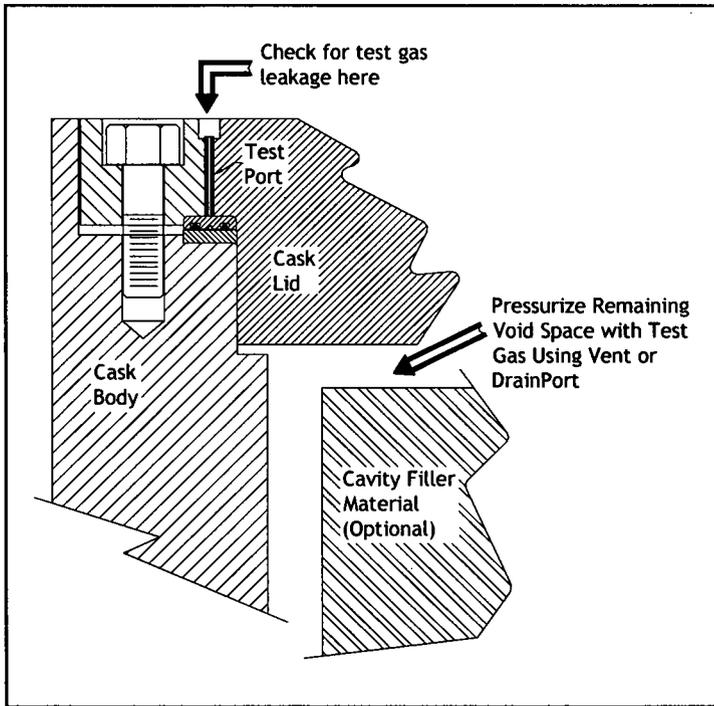

Test	Frequency	Test Gas	Acceptance Criteria	Procedure
Maintenance	After maintenance, repair (such as weld repair), or replacement of components of the containment system.	R-134a, or helium (optional)	< L_R^*	8.2.2.1
Fabrication	Prior to first use of the 8-120B.			8.1.4
Periodic	Within 12 months prior to each shipment.			8.2.2.1
Pre-Shipment	Before each shipment, after the contents are loaded and the package is closed.	nitrogen or air (optional)	sensitivity < 10^{-3} ref-cm ³ /sec	8.2.2.2

* Adjusted for the individual properties of the test gas; sensitivity is < $L_R/2$.

As shown in Table 4-2, the Maintenance, Fabrication, and Periodic leakage tests may be performed using R-134a, or helium as the tracer gas. The acceptance criterion for these tests is the reference air leakage rate, L_R , which is calculated in Section 4.4. An equivalent maximum permissible leakage rate to L_R has been calculated in Sections 4.5 and 4.6 for R-134a and He, respectively, adjusting for individual properties for the gas plus the test pressure and temperature. The equivalent leakage becomes the acceptance criteria for the particular gas being used to perform the test.

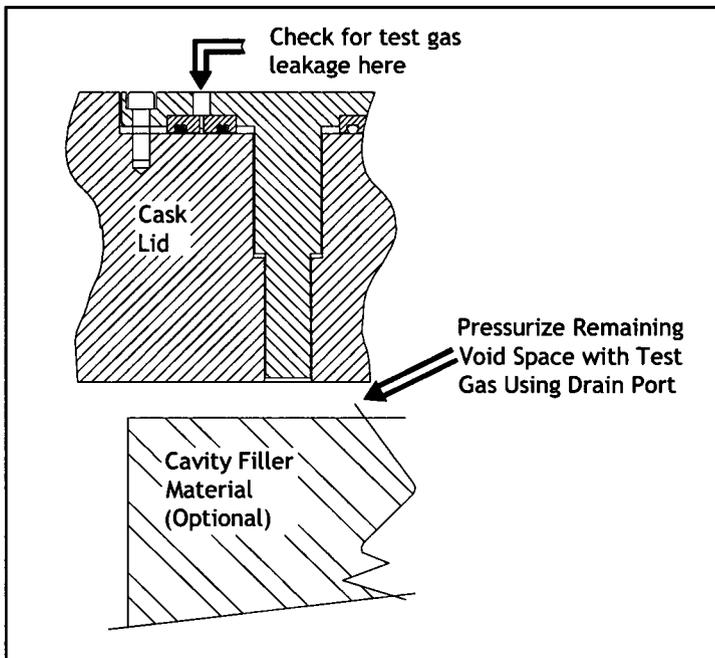

The Fabrication leakage tests are performed on the entire containment boundary including the closure lid, the vent port, the cask inner shell and base plate, and associated weldings. The procedure for performing the leakage tests is described in Section 8.1.4.

The Maintenance and Periodic leakage tests are performed on the closure lid and the vent port. The detailed procedure for performing these tests is given in 8.2.2.1, but generally they will be conducted as follows:

- Pressurize the void space in the cavity with a test gas using the vent port in the lid. Some of the volume of the cavity may be temporarily filled to reduce the volume of test gas required to conduct the test.
- Check for leaks of the inner (containment boundary) O-ring using the test port in the lid.

Figure 4-8 - Periodic Leak Test of Closure Lid

- Pressurize the void space in the cavity with a test gas using the drain port. Some of the volume of the cavity may be temporarily filled to reduce the volume of test gas required to conduct the test.
- Check for leaks of the inner (containment boundary) vent port cover plate O-ring.

Figure 4-9 - Periodic Leak Test of Vent Port

4.9 PERIODIC VERIFICATION LEAK RATE DETERMINATION FOR LEAKTIGHT STATUS

4.9.1 INTRODUCTION

The purpose of this section is to describe the method for performing a periodic leak test to demonstrate meeting the leaktight criterion per ANSI N14.5-1997. This test method is only applicable to a 8-120B cask with o-rings and seals that meet the helium permeability requirement of Seal Specification ES-C-038 [Ref. 4.4].

4.9.2 TEST CONDITIONS

The test is performed with a mass spectrometer leak detector. The test is conducted on the 8-120B by evacuating the cask cavity to at least 90% vacuum then pressurizing the cask cavity with helium (+1 psig, -0 psig). The annulus between the o-rings is evacuated until the vacuum is sufficient to operate the helium mass spectrometer leak detector and the helium concentration in the annulus is monitored. The acceptance criterion is 1.0×10^{-7} atm-cm³/sec of air (leaktight). The detector sensitivity must be less than or equal to 5.0×10^{-8} atm-cm³/sec. Similar tests are performed on the vent port.

5.0 SHIELDING EVALUATION

5.1 DESCRIPTION OF SHIELDING DESIGN

The Model 8-120B packaging is designed to meet the regulatory requirements of 10 CFR 71 for a non-fissile, exclusive-use packaging. This chapter provides the description of the package shielding design and the shielding evaluation (§71.31(a)(1), §71.31(a)(2), and §71.35(a)).

The package is designed, fabricated, assembled, tested, maintained, and used in accordance with the codes and standards described in Chapters 1, 7, and 8 to assure radiological safety (§71.31(c)).

The package is designed, constructed, and prepared for shipment so that, under the NCT tests specified in §71.71, there will be no loss or dispersal of radioactive contents (as demonstrated to a sensitivity of 10^{-6} A₂ per hour), no significant increase in external surface radiation levels, and no substantial reduction in the effectiveness of the packaging (§71.43(f)).

This Chapter shows that, under the NCT tests specified in §71.71, the external radiation levels meet the requirements of §71.47(b) for exclusive-use (§71.43(f)), and that, under the HAC tests specified in §71.73, the external radiation level does not exceed the requirement of §71.51(a)(2). Specifically, the packaging is designed to meet the following requirements.

- §71.47(b)(1) applies to all surfaces of the package except for the bottom, which is not accessible during routine operations. The 8-120B is shipped upright on a flat-bed style vehicle; thus the lower impact limiter bottom surface is closed from direct access, similar to a closed transport vehicle. The package is secured on the trailer bed so that its position remains fixed during transportation. There are no loading or unloading operations between the beginning and end of the transportation. Since the lower impact limiter bottom surface is inaccessible, radiation measurements made per §71.87(j) must be taken on the underside of the trailer deck; and, similarly, the underside of the trailer deck is considered the bottom external surface of the packaging consistent with §71.47(b)(1)(i) through (iii). The 8-120B top surface, radial surfaces, and underneath the trailer therefore must not exceed 2 mSv/h (200 mrem/hr) at any point. The bottom surface of the lower impact limiter must not exceed 10 mSv/h (1000 mrem/hr) at any point.
- Additionally per §71.47(b)(3), 0.1 mSv/h (10 mrem/hr) must not be exceeded at any point 2 meters (6.6 feet) from the vertical planes projected by the outer edges of the vehicle.
- Any normally occupied space (e.g., driver) must not exceed 0.02 mSv/h (2 mrem/h), per §71.47(b)(4), unless the shipment is performed by a private carrier, if exposed personnel under their control wear radiation dosimetry devices in accordance with 10 CFR 20.1502.
- Per §71.51(a)(1), there must be no significant increase in external surface radiation levels under the tests specified in §71.71 (normal conditions of transport, NCT).

- Per §71.51(a)(2), external radiation dose rates may not exceed 10 mSv/h (1 rem/h) at 1 m (40 in) from the external surface of the package under the tests specified in §71.73 (hypothetical accident conditions, HAC).

Because of the wide range of contents, the 8-120B shielding evaluations are divided into Loading Specifications. Each Loading Specification describes the payload material, any associated hardware (liners, shields, etc.), the shielding model, shielding evaluation, allowable source limits, plus any other descriptions, evaluations, or requirements pertaining to the shipments. The following Loading Specifications have been established:

- Section 5.7.....Loading Specification 8-120B-1 (General Sources)
- Section 5.8.....Loading Specification 8-120B-2 (Activated Steel)
- Section 5.9.....Loading Specification 8-120B-3 (Reformed Residue)
- Section 5.10.....Loading Specification 8-120B-4 (Resins and Filter Media)

5.1.1 SHIELDING DESIGN FEATURES

5.1.1.1 Cask Body and Impact Limiters

The cask side wall consists of an outer 1.5 inch thick steel shell surrounding 3.35 inches of lead and an inner containment shell wall of 0.75 inch thick steel and steel 12-gauge thick cladding. The radial thermal barrier is 3/16-inch thick steel.

The primary cask lid consists of two layers of 3.25 inch thick steel, giving a total material shield thickness of 6.5 inches of steel. This lid closure is made in a stepped configuration to eliminate radiation streaming at the lid/cask body interface.

A secondary lid is located at the center of the main lid, covering a 29.0 inch opening. The secondary lid is constructed of two 3.25 inch steel plates with multiple steps machined in the secondary lid. These match steps in the primary lid, eliminating radiation streaming pathways. A stainless steel thermal shield covers the secondary lid and is attached to the secondary lid lifting lugs. This axial thermal shield is conservatively ignored in the shielding evaluation.

The impact limiters and radial thermal barrier provide a small amount of additional shielding. The impact limiters have 12 gage steel skin; and the lower impact limiter has a ½-inch thick steel cover plate in the “hole.”

5.1.1.2 Cask Inserts

When cask inserts (secondary containers, liners, shields, etc.) are credited for one or more safety functions, they shall be described in the associated loading restrictions in Section 1.2.2.3 and/or packaging drawings in Section 1.3.

5.1.2 MAXIMUM RADIATION LEVELS

The 8-120B package carries a range of contents, from small concentrated sources to large volume homogeneous materials and combinations of these, and may include nearly every

radionuclide. In order to determine the maximum activity of any particular radionuclide or mixture of radionuclides, a series of evaluations of bounding source configurations over a range of gamma energies are performed. The resulting set of source limits ensure that any content meeting the source limit for the appropriate configuration and gamma energy will comply with the most restrictive of the dose rate limits from 10 CFR 71.47 and §71.51. These evaluations are presented in Section 5.4.

In order to provide a concise summary of the results, the point source results for only ^{60}Co and ^{137}Cs from Loading Specification 8-120B-1 are provided in Table 5-1. This table gives both normal and accident condition dose rates for the maximum ^{60}Co and ^{137}Cs point source in the cask.

Table 5-1 - Summary of Maximum Dose Rates (mrem/hr)

Condition	Package Surface		1 m from Surface		2m from 8' trailer
	Side	Top/Bottom	Side	Top/Bottom	Side
NCT					
Co-60 Source	190.0	75.1	NA	NA	3.1
Cs-137 Source	182.6	190.0	NA	NA	5.3
Allowable	200	200	NA	NA	10.0
HAC					
Co-60 Source	NA	NA	102.2	34.9	NA
Cs-137 Source	NA	NA	424.9	93.4	NA
Allowable	NA	NA	1000.0	1000.0	NA

The following assumptions were used to develop the values given in the table (typical maximum dose rates from Loading Specification 8-120B-1).

5.1.2.1 Normal Conditions

The source is modeled as a point source (1 cm dia x 1 cm high) at the location within the cask cavity that yields maximum peak cask exterior dose rates (i.e., at the top corner of the cavity, or on the side of the cask cavity at an elevation between the top and bottom impact limiters). Reference 5.6.2 includes a complete summary of the package response functions for all source configurations of interest.

5.1.2.2 Accident Conditions

1. Lead slump of 0.15" resulting from the accident drop analysis is incorporated in the model
2. Thinning of the lead shield layer due to the puncture drop is incorporated by reducing the lead thickness by 0.5"
3. The source is modeled as a point source (1 cm dia x 1 cm high) in the top corner of the cavity (partially up into the chamfer region at the bottom corner of the primary cask lid so that the bottom of the source is flush with the top of the lead). Reference 5.6.2 includes a

complete summary of the package response functions for all source configurations of interest.

5.1.2.3 Conclusion

For the ^{60}Co point source case, the maximum allowable payload gamma source is governed by the 200 mrem/hr dose rate limit that applies on the cask body side, under NCT. The results determine a maximum allowable source strength of 1.277×10^{11} γ/sec (1.73 Ci) for that isotope. At this source strength, the results show a dose rate of close to 200 mrem/hr on the package side surface, and dose rates that are well under their regulatory limits at all other locations. An administrative margin of 5% is then applied (to account for any uncertainties), which reduces the allowable ^{60}Co gamma source strength to 1.213×10^{11} γ/sec (1.64 Ci). Because of the 5% administrative margin, the actual peak dose rate is 190.0 mrem/hr, as shown in Table 5-1.

For the ^{137}Cs point source case, the maximum allowable payload gamma source strength is governed by the 200 mrem/hr dose rate limit that applies on the package top surface, under NCT. The results determine a maximum allowable source strength of 5.719×10^{12} γ/sec (77.3 Ci) for that isotope. At this source strength, the results show a dose rate of close to 200 mrem/hr on the package surface, and dose rates that are well under their regulatory limits at all other locations. An administrative margin of 5% is then applied (to account for any uncertainties), which reduces the allowable ^{137}Cs gamma source strength to 5.433×10^{12} γ/sec (73.4 Ci). Because of the 5% administrative margin, the actual peak dose rate is 190.0 mrem/hr, as shown in Table 5-1.

As the results do not exceed the allowable dose rates, the 8-120B cask meets the shielding requirements of 10 CFR Part 71.

5.2 SOURCE SPECIFICATION

5.2.1 GAMMA SOURCE

Gamma source specifications are discussed in the Loading Specifications appendices in this Chapter.

5.2.2 NEUTRON SOURCE

There are no significant sources of neutron radiation in the radioactive materials carried in the 8-120B cask that result in measureable neutron doses outside the cask. A shielding analysis (SAR Chapter 5) for a cask with a similar geometry and shield materials (Reference 5.6.4) shows that a $1.1 \text{ E}+08$ n/s neutron source produces a dose rate of 9.4 mrem/hr at 2m from the side of the trailer. Limiting the neutron emission rate from the 8-120B contents to less than $1 \text{ E}+05$ n/s will result in a dose rate less than 0.1 mrem/hr. Thus, setting the total neutron emission to less than $1 \text{ E}+05$ n/s will result in a neutron dose rate that is a small fraction of the transport limit.

5.2.3 BETA SOURCE

For payloads with significant beta contributors, the beta source specifications are discussed in the Loading Specification appendices in this Chapter.

5.3 MODEL SPECIFICATION

5.3.1 DESCRIPTION OF RADIAL AND AXIAL SHIELDING CONFIGURATION

This Section describes the basic cask model for NCT and HAC. Each Loading Specification appendix in this Chapter describes any differences or additions.

5.3.1.1 Normal Conditions of Transport (NCT)

The walls of the 8-120B cask, 0.75" inner wall, a 12-gauge inner steel cladding, and a 1.5" outer steel wall, with a 3.35" lead layer between, are modeled as cylindrical shells around the cavity cylinder. The base and lid of the cask are two 3.25" steel plates, for a total thickness of 6.5". Standard minimum sheet and plate tolerances are modeled, except for drawing items 4 and 9 which were modeled at maximum tolerance thickness as this positions the lid and point-source as high as possible with respect to the top of the lead. This geometry is shown in Figure 5-1. The cask is transported upright, i.e., with the axis of the cylinder vertical. Doses are evaluated at contact with the cask sidewall, the impact limiter surface, and at 2m from the 8' wide trailer. The impact limiter ends and side surfaces are modeled at reduced dimensions consistent with the maximum NCT impact limiter deformations in Table 2-10. Corner crush was not modeled because the peak dose rates do not occur at the corners.

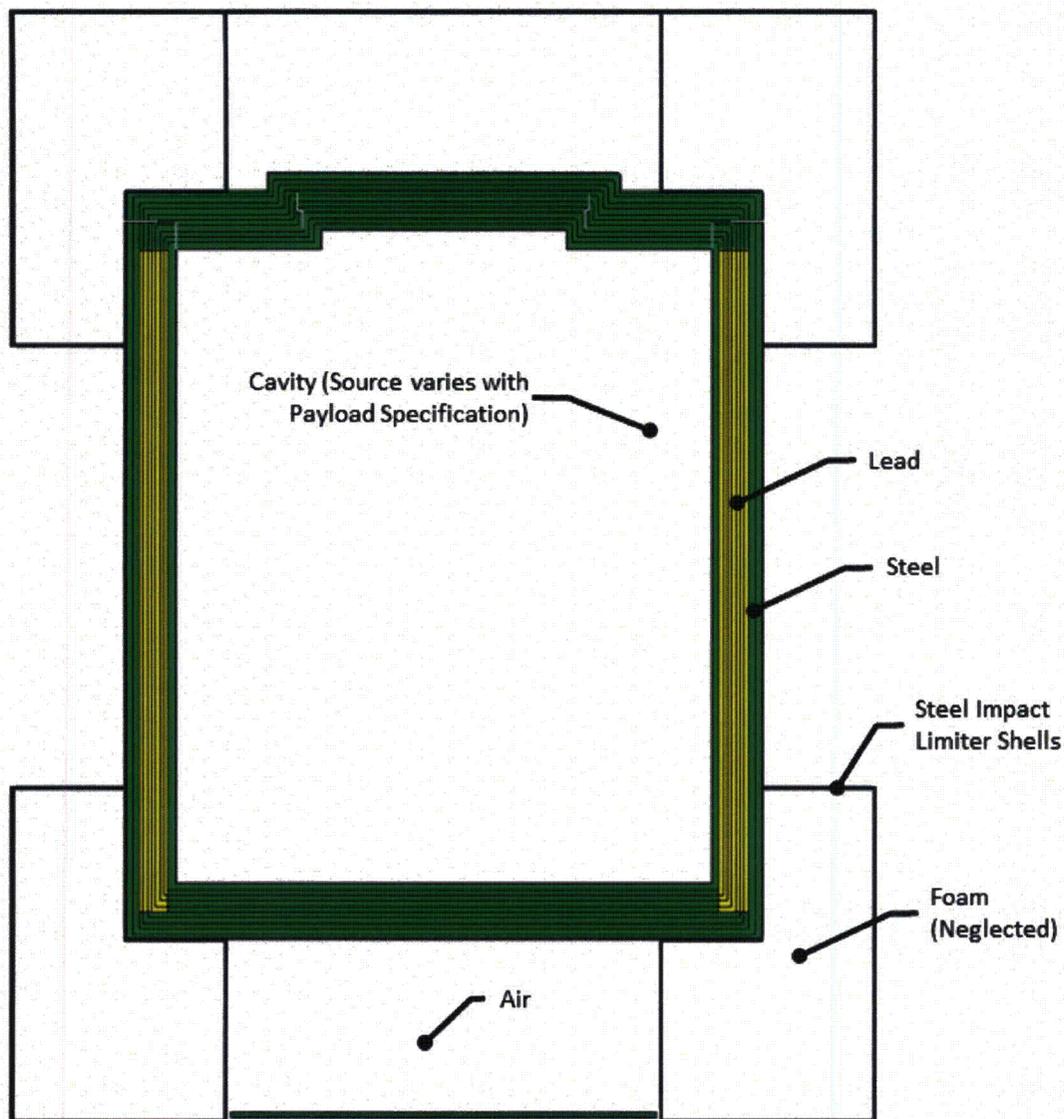

Figure 5-1 - Cask Model

5.3.1.2 Hypothetical Accident Conditions (HAC)

As discussed in Chapter 2, the hypothetical accident 30' drop results in a 0.15" lead slump and the puncture drop causes a local 1/2" thinning of the lead layer. The HAC model has a 0.15" air-filled void at the top of the lead shield layer. Also, to conservatively reflect the puncture drop thinning, the thickness of the radial lead shield is reduced by 1/2" in the HAC model. The impact limiters are conservatively ignored. The HAC model is shown in Figure 5-2. Doses are determined at 1 m from the sidewall and the lid.

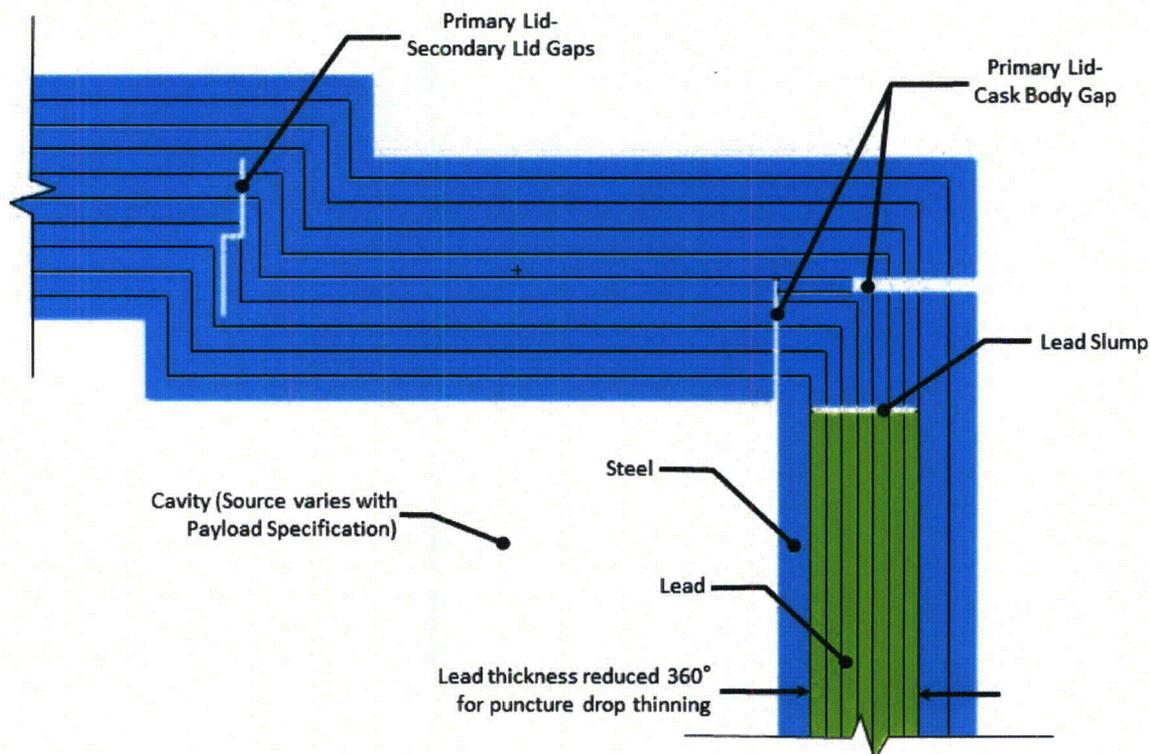

Figure 5-2 - HAC Cask Model

5.3.2 MATERIAL PROPERTIES

The compositions and densities of the materials modeled in the shielding analyses are described in Table 5-2 below. The table also lists the MCNP material/cross-section identifier (ZAID) for each modeled material. Each Loading Specification section in this Chapter describes any differences or additions.

Table 5-2- Material Composition and Density

Material	Total Density (g/cc)	Composition	MCNP ZAID
Carbon Steel	7.82	99% Fe 1% C	26000.84p 8000.84p
Lead	11.34	100% Pb	82000.84p
Air	0.001205	76.508% N 23.479% O 0.013% C	7000.84p 8000.84p 6000.84p

5.4 SHIELDING EVALUATION

5.4.1 METHODS

Each Loading Specification section in this Chapter describes the shielding methods.

5.4.2 INPUT AND OUTPUT DATA

Each Loading Specification section in this Chapter describes the input and output data.

5.4.3 FLUX-TO-DOSE-RATE CONVERSION

The flux to exposure rate conversion factors are listed in Table 5-3 (Reference 5.6.1).

5.4.4 EXTERNAL RADIATION LEVELS AND SOURCE STRENGTH LIMITS

Each Loading Specification section in this Chapter describes the source strength limits required to meet external radiation level limits.

Table 5-3- Gamma-Ray-Flux-To-Dose-Rate
Conversion Factors (ANSI/ANS-6.1.1 1977)

5.7 LOADING SPECIFICATION 8-120B-1 (GENERAL SOURCES)

5.7.1 LOADING SPECIFICATION 8-120B-1 DESCRIPTION

Loading Specification 8-120B-1 is a general-purpose specification for qualifying radioactive payloads ranging in physical size from point sources to full-cavity sources, for the full range of payload materials permitted by the Certificate of Compliance. The specifications for the payload, secondary containers, and other restrictions are summarized in Table 1-2. Allowable source terms are presented in Section 5.7.4.4, and the procedure for performing the payload radiological qualification is in Section 5.7.5.

5.7.2 8-120B-1 SOURCES

5.7.2.1 Gamma Source

Analyses are performed for idealized source configurations that bound any actual source configuration that may occur. These bounding configurations are: a point source at the center of the cask cavity in the NCT configuration, a point source at the side of the cask cavity in the NCT configuration, a point source at the top corner of the cask cavity in the NCT configuration, a point source in the top corner of the cask cavity in the HAC configuration, and a uniform mass of material within a defined source region, as described in Section 5.7.4, for both NCT and HAC configurations. Further details of the analyses are found in Reference 5.6.2.

All of the analyses described above are performed for several gamma energy levels, ranging from 0.5 MeV to 5.0 MeV. Two specific isotope cases, ^{60}Co and ^{137}Cs (and the corresponding specific gamma energies) are also analyzed. The ^{137}Cs source includes an equilibrium amount of $^{137\text{m}}\text{Ba}$. The gamma energy and abundance of ^{60}Co and ^{137}Cs are shown in Table 5-4.

Table 5-4 - Gamma Energy and Abundance

Radionuclide	Gamma Energy MeV	Abundance # of Gamma/decay
^{60}Co	1.176	1
	1.333	1
^{137}Cs	0.662	0.85

5.7.2.2 Neutron Source

Loading Specification 8-120B-1 does not allow shipment of significant neutron sources. Neutron sources in the 8-120B cask are discussed in Section 5.2.2.

5.7.2.3 Beta Source

Significant beta emitters may be qualified for shipment under Loading Specification 8-120B-1. Betas are treated as equivalent gammas as described in Section 5.7.4.4.3.

5.7.3 LOADING SPECIFICATION 8-120B-1 MODEL SPECIFICATION

5.7.3.1 Configuration of Source and Shielding

Section 5.3.1 describes the shielding model configuration for Loading Specification 8-120B-1.

5.7.3.2 Material Properties

Section 5.3.2 describes the material properties for Loading Specification 8-120B-1. In order to model a bounding mass attenuation factor, all source regions for volumetric source runs were modeled as zirconium.

5.7.4 8-120B-1 SHIELDING EVALUATION

The 8-120B package carries a range of contents, from small concentrated sources to large volume homogeneous materials and combinations of these, and may include nearly every radionuclide. In order to determine the maximum source strength of any particular radionuclide or mixture of radionuclides, a series of evaluations of bounding source configurations over a range of gamma energies are performed to determine the maximum source strength (γ/sec) or maximum source strength density ($\gamma/\text{sec}\cdot\text{g}$) for each combination of configuration and energy that results in the meeting the most restrictive of the dose rate limits from 10 CFR 71.47 and §71.51. The resulting set of source strength limits ensure that any content meeting the source strength limit for the appropriate configuration and gamma energy will comply with the §71.47 and §71.51 limits.

5.7.4.1 Methods

The gamma dose rates were calculated using MCNP Version 5, rev. 1.51.

In addition to the point source locations noted in Section 5.2, a uniformly-distributed gamma source is modeled within the source region. The uniform mass that fills the defined source region is zirconium, iron, or aluminum, whichever has the more conservative (smaller) attenuation coefficient at the gamma energy thus bounding other contents materials. The uniform mass is set at a density of 9.0 g/cc, which exceeds the density of nearly all expected payloads. Since the distributed source analyses determine limits in source strength density ($\gamma/\text{sec}\cdot\text{g}$), this density bounds all other lower density contents. Defined source regions include the entire cask interior cavity, a “55 gallon” source zone centered within the cavity and a 2.5 ft³ source zone centered within the cavity. All the above source zones are modeled for the NCT cask configuration. For the HAC cask configuration, only the full-cask-cavity source zone is modeled.

For the normal condition of transport (NCT) cases, dose rates are tallied on the vertical surface two meters from the package/transporter side (i.e., 322 cm from the cask centerline), and on the package surface which includes the impact limiter side and end surfaces as well as the cask body side cylindrical surface that lies between the impact limiters.

For the HAC point source cases, the dose rates are tallied at two locations on the surface one meter from the cask body. One location lies on the radial one meter surface, directly across from

the source point (viewing the source point through the lead slump gap). The second location lies on the top one meter surface, directly above the source point, viewing the source point through the gap between the radial cask body and the lower part of the primary cask lid.

For the HAC distributed source cases, the dose rates are tallied over the entire spans of the surfaces that lie one meter from the side, top and bottom of the cask body.

For each of the analyses, the peak dose rates (per source gamma) that occur on each of the (NCT or HAC) regulatory surfaces described above are determined.

From these peak dose rates, limits are calculated over the range of gamma energies 0.5-5.0 MeV and for the radionuclides ^{60}Co and ^{137}Cs . The limits are determined, in source strength (γ/sec) for the point source configurations and in source strength density ($\gamma/\text{sec}\cdot\text{g}$) for the distributed source cases. The regulatory dose rate limit for each surface is divided by the highest per-source-gamma dose rate for that surface, to yield a maximum source strength, in γ/sec . The lowest of the allowable source strengths is then selected as the limiting gamma source strength for that case. Then, for the distributed source cases (only), the allowable source strength is divided by the modeled source region mass to yield the allowable source strength density in $\gamma/\text{sec}\cdot\text{g}$.

Analysis Method Uncertainties and Conservatism

The MCNP-calculated dose rates are adjusted upwards to account for statistical uncertainty in the MCNP results before they are used to determine source limits. These statistical uncertainties (which are conservatively accounted for in the source limit calculations) are less than 5% for all MCNP results that govern payload source limits. Tallies with statistical uncertainties between 5% and 10 %, and those tallies that did not pass all 10 MCNP statistical checks, are evaluated to determine the suitability of the tally and rerun as necessary.

Uncertainties in the analyses performed to demonstrate that an upper-bound payload material density (of 9.0 g/cc) yields maximum cask exterior dose rates may result in an uncertainty of less than 1% in the final dose rate results. Uncertainties in evaluations performed to determine the most conservative payload material (element) to be modeled in the 0.5 MeV and 5.0 MeV gamma analyses may also result in an uncertainty of ~1% in the final dose rate results. Finally, cask exterior dose rate contributions from neglected beta sources (discussed below in Section 5.4.4) could increase the final dose rate results by as much as ~1%.

The above analytical uncertainties, which could yield as much as a 3% increase in cask exterior dose rates, will be more than offset by conservatism in the analysis method, for virtually all actual payloads. Conservatism includes modeling minimum steel plate thicknesses, neglecting all payload self shielding and concentrating the source into a point, in the worst possible cavity location, in the γ/sec limit calculations, modeling the entire cask cavity as being filled with the highest source strength density material (that occurs anywhere within the payload) in the $\gamma/\text{sec}\cdot\text{g}$ limit calculations, rounding gamma energies up (to the nearest evaluated value) when determining source strength limits, and modeling the lowest attenuation material within the payload to determine the $\gamma/\text{sec}\cdot\text{g}$ limit. Also, as discussed below in Section 5.4.4, the method used to treat beta sources is conservative by more than a factor of 100.

The sources of uncertainty and conservatism in the analyses are discussed in more detail in Reference 5.6.2.

Although the conservatisms in the analysis would more than offset any uncertainties, for virtually all actual payloads, all final payload source limits are reduced by an administrative margin of 5%, to account for uncertainties in the analysis.

5.7.4.2 Input and Output Data

The MCNP input and output files are found in Reference 5.6.2. The input file lists the inputs that define the source dimensions, shield dimensions, materials and density, and source spectrum.

5.7.4.3 Flux-to-Dose-Rate Conversion

ANSI/ANS-6.1.1 1977 flux-to-dose-rate conversion factors were used as described in Section 5.4.3.

5.7.4.4 External Radiation Levels and Source Strength Limits

5.7.4.4.1 *Gamma Source Strength Limits*

The results of the analyses of the bounding configurations are compared to the external radiation limits allowed for the various compliance locations identified in §71.47 and §71.51. The configuration, at each energy, that has the largest ratio of result to limit is set as the governing configuration from which the limits are established.

The final results of the shielding evaluation are the limits on payload gamma source strength (γ/sec) and payload gamma source strength density ($\gamma/\text{sec}\cdot\text{g}$), which vary as a function of gamma energy and payload configuration. These limits are presented, for all gamma energies and all analyzed source configurations, in Table 5-5 below. The limits are presented graphically in Figure 5-3 and Figure 5-4.

Detail of the calculations (and process) used to determine the payload source limits shown in Table 5-5 are found in Reference 5.6.2. Note a 5% administrative margin is applied which effectively reduces all the source strength limits presented above in Table 5-5 by 5%. Application of the margin (as part of the sum of fractions method) is discussed below in Section 5.7.5.

Section 5.7.5 describes the use of Table 5-5.

Table 5-5- Loading Specification 8-120B-1 Source Limits

Energy (MeV)	General Sources		Discrete Sources (shored at centroid)*		
	Source γ/sec	Source Density γ/sec-g	Source γ/sec	Source Density γ/sec-g	
				2.5 ft ³	55 gal
	①	②	③	④	⑤
5.00	7.678E+09	2.286E+05	1.754E+11	1.395E+06	9.070E+05
3.50	9.611E+09	4.093E+05	2.504E+11	2.724E+06	1.451E+06
2.75	1.285E+10	6.515E+05	3.293E+11	4.301E+06	2.281E+06
2.25	1.823E+10	1.065E+06	4.432E+11	6.800E+06	3.634E+06
1.83	3.040E+10	2.061E+06	6.404E+11	1.279E+07	6.869E+06
1.50	6.111E+10	4.938E+06	8.971E+11	2.920E+07	1.592E+07
1.17	2.142E+11	1.640E+07	1.528E+12	8.418E+07	6.173E+07
0.90	8.635E+11	5.539E+07	2.747E+12	2.796E+08	1.919E+08
0.70	2.131E+12	1.887E+08	5.088E+12	9.566E+08	6.366E+08
0.50	7.075E+12	1.255E+09	1.151E+13	6.344E+09	4.026E+09
Co-60	1.393E+11	1.182E+07	1.294E+12	6.169E+07	4.074E+07
Cs-137	2.580E+12	2.556E+08	5.768E+12	1.281E+09	8.536E+08

*For discrete source limits, use columns ③ and ④ when the payload object meets the 2.5 ft³ size criteria, or columns ③ and ⑤ when it meets the 55 gallon size criteria. When the size meets neither criteria use columns ① and ②.

Source Qualification by γ /sec

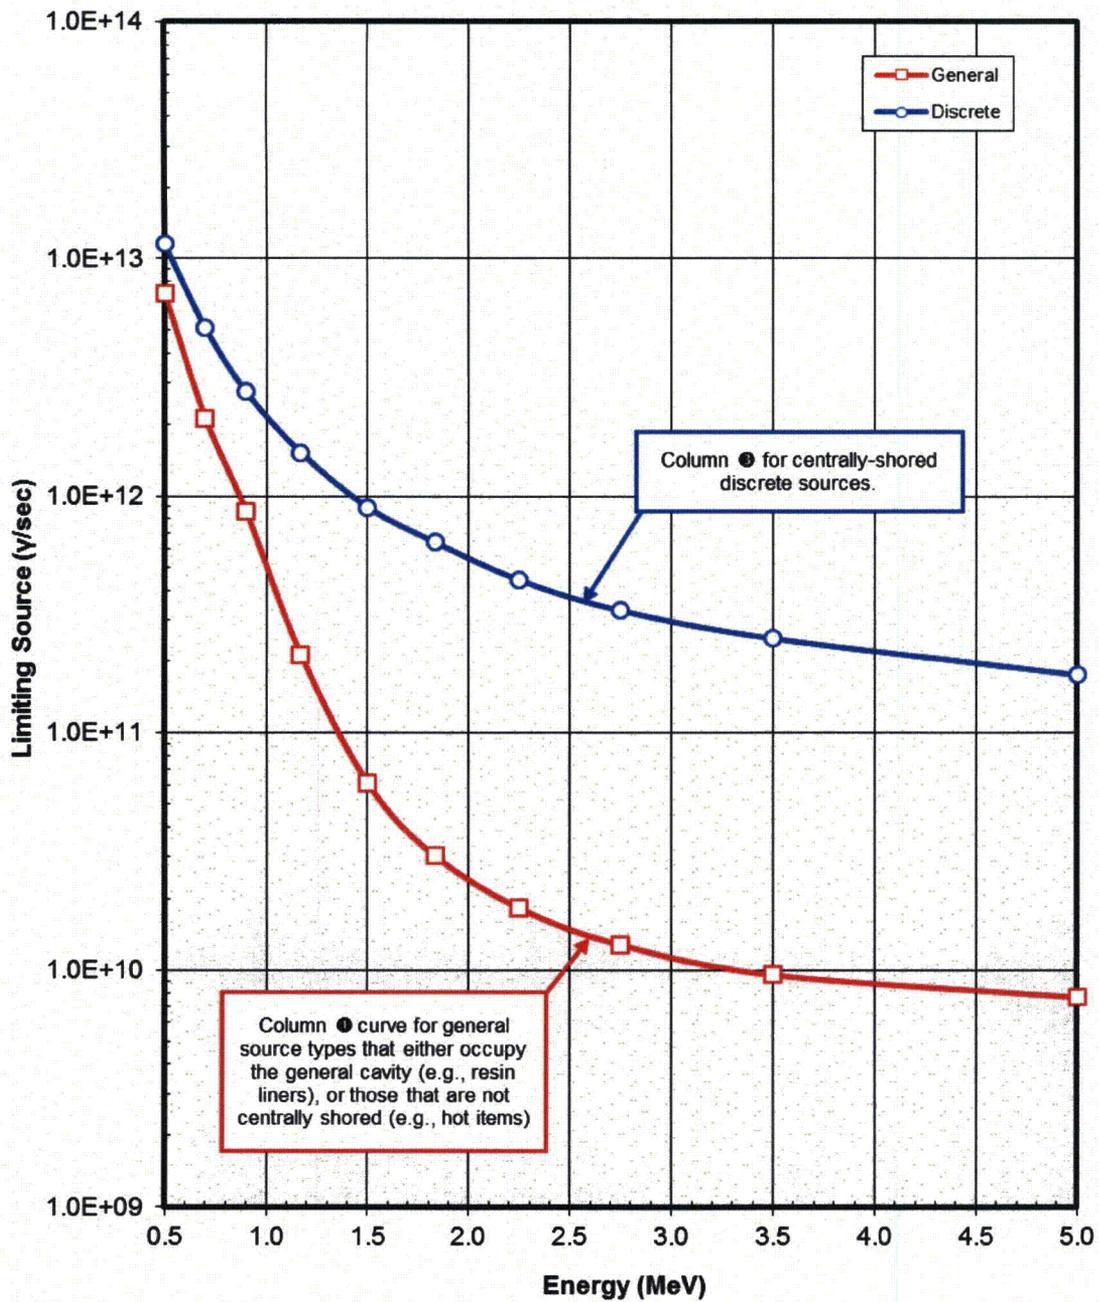

Figure 5-3 - Payload Gamma Source Strength Limit vs. Gamma Energy

Source Qualification by $\gamma/\text{sec-g}$

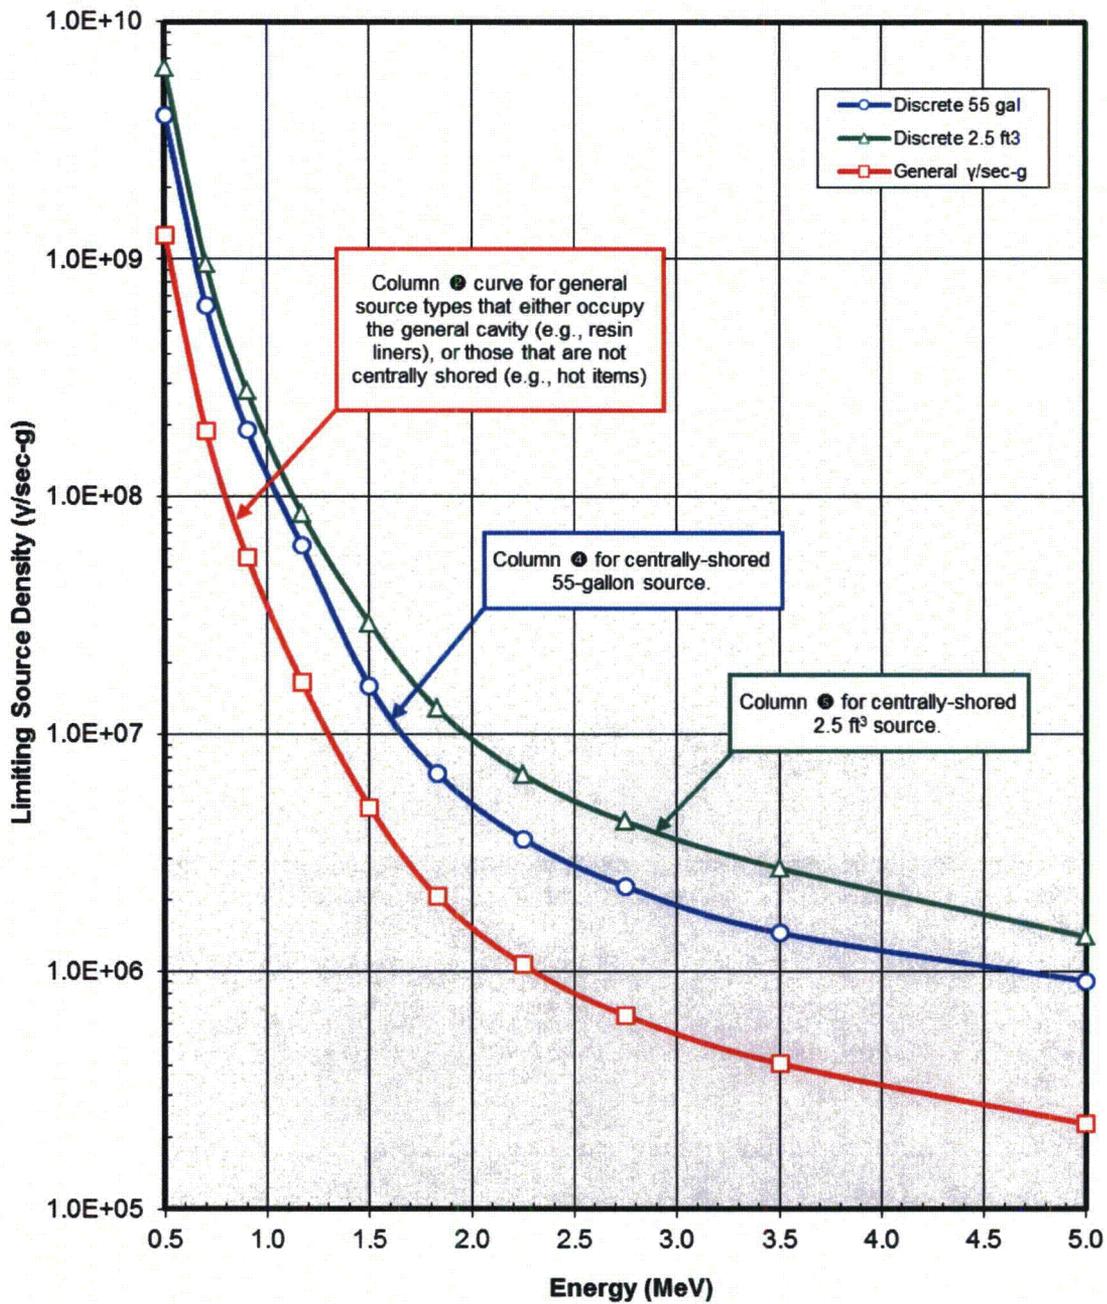

Figure 5-4 - Payload Gamma Source Strength Density Limit vs. Gamma Energy

5.7.4.4.2 Neutron Source Strength Limits

Loading Specification 8-120B-1 does not allow shipment of significant neutron sources. Neutron sources in the 8-120B cask are discussed in Section 5.2.2.

5.7.4.4.3 Beta Source Strength Limits

Beta particles lose their energy continuously as they pass through matter, emitting bremsstrahlung gammas over their range. These bremsstrahlung gammas, however, have the potential to be significant contributors to package dose rates because the allowable (3000 A₂) source activity for betas can be much higher than for gamma emitters (e.g., as much as 42,000 Ci of ³²P vs. 4144 Ci of ¹³⁷Cs). The method for qualifying significant 8-120B beta emitters is to represent the beta emitter as an equivalent gamma emitter and treat it like any other gamma energy line per the methods described in Section 5.7.5.

This method is only applied to beta sources (pure beta emitters) with activities greater than 2E+12 betas per second, and peak beta energy levels between 0.3 MeV and 5.0 MeV. Isotopes with peak beta energies less than 0.3 MeV can be neglected. Isotopes with peak beta energies over 5.0 MeV may not be shipped in the cask. Beta source strengths less than 2E+12 betas per second do not contribute significantly to cask exterior dose rates and are, thus, not significant. See Reference 5.6.2 for additional details and validating calculations.

The beta source can be converted to an equivalent gamma source by:

$$S_{\gamma} = S_{\beta} \cdot \frac{S_{\gamma}}{S_{\beta}}$$

where

S_{γ} = equivalent monoenergetic gamma source strength, γ /sec, at the maximum beta energy E_{\max} .
 S_{β} = beta source strength, β /sec, at the beta energy spectrum for the nuclide of interest

and

$$\frac{S_{\gamma}}{S_{\beta}} = \left(\text{fraction of energy converted from betas to photons} \right) \left(\frac{\text{beta } E_{\text{avg}}}{\text{photon energy}} \right)$$

Conservatively assume all gammas are at the beta maximum energy E_{\max} , the energy ratio becomes:

$$\frac{S_{\gamma}}{S_{\beta}} = f \left(\frac{E_{\text{avg}}}{E_{\text{max}}} \right)$$

where

E_{avg} = average energy of the beta source distribution, MeV
 E_{max} = maximum energy of the source distribution, MeV.

The fraction of the incident beta energy that is converted to gamma energy, f , is given by (Reference 5.6.3).

$$f \cong 3.5 \times 10^{-4} Z E_{\max}$$

where

f = the fraction of the incident beta energy that is converted to gamma energy,
 Z = atomic number of the absorber

So

$$\frac{S_{\gamma}}{S_{\beta}} = 3.5 \times 10^{-4} Z E_{\max} \left(\frac{E_{\text{avg}}}{E_{\max}} \right)$$

The resulting equation to convert a beta source to an equivalent gamma source at the beta's maximum energy is therefore:

$$S_{\gamma} = S_{\beta} (3.5 \times 10^{-4} Z E_{\text{avg}})$$

For a single material absorber, use the Z of the material. For compounds or mixtures, use a weighted average Z_w :

$$Z_w = \sum_{i=1}^n \left(\frac{m_i}{m_{\text{total}}} \cdot Z_i \right)$$

Z_w should be determined, as described above, for both the waste payload and the wall of the secondary container (liner) that the waste resides in. Then, the higher of the two Z_w values should be conservatively used as the basis of the equivalent gamma source calculation. This conservatism is necessary since it is not known what fraction of the beta-to-gamma conversion occurs within the waste material and within the secondary container wall material.

The proposed method for qualifying significant 8-120B beta emitters is to represent the beta emitter as an equivalent gamma emitter and treat it like any other gamma energy line per the methods described in the remainder of this calculation. In this way, significant beta emitters can be accounted for along with other gamma emitters. The entire (equivalent) gamma source (S_{γ}) is modeled at the same energy as the peak beta energy for the beta-emitting isotope. This gamma energy level is rounded up to the nearest (higher) gamma energy level for which source limits are presented in Table 5-5.

For common container and waste materials (for which Z is 26 or less), the formula above yields an equivalent gamma source that is less than 1% of the isotope's beta source. Furthermore, comparisons to rigorous MCNP beta shielding analyses show that the method (and formula) described above yields cask exterior gamma dose rates (due to payload beta emissions) that are conservative (high) by more than a factor of 100. Thus, a beta source will yield cask exterior dose rates that are only ~0.01% as high as the cask exterior dose rates produced by a gamma source of the same strength and energy level.

For the above reasons, the beta source for isotopes that emit both betas and gammas can be neglected, since any cask exterior dose rate contributions from the beta source will be negligible compared to those produced by the isotope's gamma source. Thus, the procedure described above is only to be used for pure beta-emitting isotopes with a significant beta source.

A procedure for evaluating beta emitters is included in Section 5.7.5 which establishes limits for large activity beta sources.

5.7.5 8-120B-1 PAYLOAD QUALIFICATION

Background and Definitions

8-120B contents (payloads) have acceptable beta and gamma sources when they can be shown to meet the requirements in Table 5-5 using the procedure described here. Source qualification is based on a sum-of-fractions method, where sources are broken down into separate gamma energy lines and compared to the corresponding limit for that group. For some payloads, it may be necessary to subdivide the payload into separate items, determining fractions for each item by energy group then summing the fractions to determine acceptability.

Table 5-5 categorizes the limits into source strength (γ/sec) and source strength density ($\gamma/\text{sec}\cdot\text{g}$). For each energy, the fraction to be summed is the lowest of the γ/sec and $\gamma/\text{sec}\cdot\text{g}$ fractions. Table 5-5 has five columns of limits, denoted ❶ through ❺. Depending on the nature of the payload, the user must select a pair of columns to use for each payload item, one γ/sec column and one $\gamma/\text{sec}\cdot\text{g}$ column. The “general” payload columns (❶, ❷) are the most conservative and are suitable for any payload item. Higher limits are acceptable for special cases where a reduced volume item is shored about the centroid of the package cavity (e.g., an isotope source). These are termed “discrete” payload items, and are distinguished as follows:

- Use the 2.5 ft³ limits (❸, ❹) when the payload item has a volume of 2.5 ft³ (70,792 cm³) or less, a height of 28 inches (71.16 cm) or less, and a diameter of 17.65 inches (44.84 cm) or less, and is shored at the centroid of the cavity.
- Use the 55-gallon limits (❸, ❺) when the payload item has a volume of 7.7 ft³ (218,868 cm³) or less, a height of 33.5 inches (85.1 cm) or less, and a diameter of 25.7 inches (65.3 cm) or less, and is shored at the centroid of the cavity.
- If the payload item does not meet the requirements of either the 2.5 ft³ or 55-gallon definitions, regardless of shoring, then use the γ/sec limit for general sources ❶, and the general $\gamma/\text{sec}\cdot\text{g}$ limit ❷.

Source limits from Table 5-5 may not be interpolated in energy. The proper procedure for gammas (and for equivalent bremsstrahlung gammas) is to round source energies up to the next higher energy level in Table 5-5.

For the purpose of qualification, the total γ/sec source strength for the entire payload is determined for each gamma energy group. Then, for each gamma energy group, the $\gamma/\text{sec}\cdot\text{g}$ source strength density is conservatively determined based on the highest source strength (“hottest”) portion of the payload. Averaging of the source strength density is not allowed, either between payload items or within payload items. This conservative approach ensures that package

dose rate limits will be met, even for payloads for which the source strength density is not uniform within its volume/mass, since the analysis and qualification is based on the highest source strength density material that occurs anywhere within the payload. Once the applicable γ/sec source strength and $\gamma/\text{sec}\cdot\text{g}$ source strength density are determined for the payload, they are compared to the corresponding limits that are determined as discussed above.

For some payloads, use of the highest source strength density may be inappropriately conservative (e.g., payloads with a small mass of high source strength density material within a large mass of much lower source strength density material). The qualification methodology takes these payloads into consideration, and allows the payload to be separated into distinct components (or “payload items”), for which the qualification process is performed separately (e.g., one qualification for the high source strength density components/materials and another qualification for the low source strength density materials). As an example, for radiologically non-homogenous materials such as contaminated soil with hot “chunks”, the components would be the soil and the hotter particles.

Crud/contamination (or any similar finely distributed powder or granular) sources must be treated separately if there is a potential for redistribution (i.e., if the source is not chemically or physically bound to its substrate or bulk material). In such cases, the crud (or powder) source component must be qualified using only the γ/sec limits.

Gamma sources below 0.3 MeV may be neglected. Any sources with gamma energies above 5.0 MeV are not qualified at this time. Table 5-5 has two special rows for the common radioactive nuclides, ^{60}Co and ^{137}Cs ; and so their fractions may be calculated directly without breaking them down into their separate energy lines.

Pure beta emitters (e.g., ^3H , ^{32}P , ^{35}S , ^{90}Sr , ^{90}Y) can affect package exterior gamma dose rates due to bremsstrahlung radiation. These emitters must therefore be qualified by converting the beta source strength into an equivalent bremsstrahlung (gamma) source and entering the equivalent gammas like any other gamma source line in the sum-of-fractions. Beta sources with maximum beta energies below 0.3 MeV or payload source strengths less than $2\text{E}+12$ β/sec may be neglected. Beta sources with peak beta energies over 5.0 MeV are not qualified at this time. Beta source strength from isotopes with significant gamma source strength may also be neglected. The method for converting betas is presented in the procedure below.

Payload items with densities between 0.0 and 9.0 g/cc are within the range of validity for Table 5-5 $\gamma/\text{sec}\cdot\text{g}$ limits. Most materials fall within this range, with the exception of lead and some exotic metals. Do not consider liner, or other secondary container, materials when calculating density. Densities are for the basic material, and should not include voids. Radioactive payload items with densities above 9.0 g/cc must be qualified using the γ/sec limits alone.

In summary, all sources must be accounted for using the sum-of-fractions method described in the following procedure. The only sources which may be considered insignificant (and not included in the sum-of-fractions) are:

- Gammas with energies below 0.3 MeV,
- All pure beta emitters with peak energies below 0.3 MeV,

- Pure beta emitters with peak energies above 0.3 MeV when the combined source of all such betas is under 2×10^{12} β/sec .
- Beta emissions from gamma-emitting isotopes.

Qualification Procedure

The Payload Qualification Flowchart (Figure 5-5) provides a graphical overview of the qualification process. The procedure below provides more detailed step-wise instructions.

1. Determine the number of types of material (payload items) in the payload. For each item, determine the configuration (i.e., general or discrete), isotopic source strength (in γ/sec), isotopic source strength density (in $\gamma/\text{sec} \cdot \text{g}$ for the hottest portion of the payload item), dimensions, volume, mass, and maximum mass density. Determine the payload totals for each parameter.
2. For payloads that include pure beta emitters with maximum beta energies > 0.3 MeV and $\sum S_{\beta} \geq 2E+12$ β/sec , convert each beta source to an equivalent gamma source for each payload item.

- Confirm that no isotope peak beta energies are > 5.0 MeV; materials with beta energies > 5.0 MeV are unacceptable.
- The equivalent gamma source for each payload item, S_{γ} , equals $3.5E-04 S_{\beta} Z_w E_{\beta\text{avg}}$ in gammas per sec; where:

S_{β} is the beta source strength in β/sec ,

Z_w is the weighted average atomic number (Z) of the beta-absorbing material; for a single material absorber, use the Z of the material, for compounds or mixtures, use a weighted average Z_w :

$$Z_w = \sum_{i=1}^n \left(\frac{m_i}{m_{total}} \cdot Z_i \right)$$

Z_w is determined, as described above, for both the waste payload and the wall of the secondary container (liner) that the waste resides in, the higher of the two Z_w values is used, and

$E_{\beta\text{avg}}$ is the average energy of the beta in MeV.

- The resulting equivalent gamma source has strength S_{γ} at an energy of $E_{\beta\text{max}}$, the maximum beta energy.
 - Include the equivalent gamma source along with the other gamma source(s) determined in Step 3.
 - Equivalent gamma energies must be rounded up to the next higher energy level listed in Table 5-5.
3. For each gamma energy of each payload item (ignoring gamma energies below 0.3 MeV), calculate the total γ/sec for the payload item and the $\gamma/\text{sec} \cdot \text{g}$ for the hottest (highest source strength density) portion of the item.

- ^{60}Co and ^{137}Cs may be treated like single “energies” since they have their own limits in Table 5-5.
 - Gamma energies must be rounded up to the next higher energy level listed in Table 5-5.
 - If any gammas have energies above 5.0 MeV, the material is unacceptable for transport in the package.
 - For payloads with a large number of gammas, the gammas may be grouped into the energy groups in Table 5-5 and the total gamma sources can be determined for each group. The energies listed in Table 5-5 are the maximum energies for the groups.
 - Calculations of $\gamma/\text{sec}\cdot\text{g}$ should not include the mass of liners or other secondary containers.
4. For each payload item, select the two appropriate limit columns (❶ through ❸) in Table 5-5: one each for γ/sec and $\gamma/\text{sec}\cdot\text{g}$. Base the γ/sec on the total γ/sec for the item, and the $\gamma/\text{sec}\cdot\text{g}$ on the highest source strength density (“hottest”) portions of the item.
 - Confirm that the density of each payload item is less than 9.0 g/cm^3 . Items with higher densities can only be qualified using the γ/sec limits because the $\gamma/\text{sec}\cdot\text{g}$ limits are not valid for $\rho \geq 9.0\text{ g/cm}^3$.
 - For “discrete” sources, confirm that the sources meet the shoring requirement and the volume and the physical dimension specifications listed in the beginning of this Section.
 - Crud/contamination (or powder) payload items can only be qualified using the γ/sec limits (Table 5-5, column ❶ or ❸).
 5. For each energy, calculate the γ/sec and $\gamma/\text{sec}\cdot\text{g}$ fractions (i.e., payload item source/limit fraction). Select the smallest of each pair of fractions at each energy and add the resulting fraction to the running sum of fractions.
 6. Repeat Steps 4-5 for each payload item, adding the fractions to the running sum.
 7. If the sum-of-fractions is less than 0.95, the payload’s radiological source is acceptable.

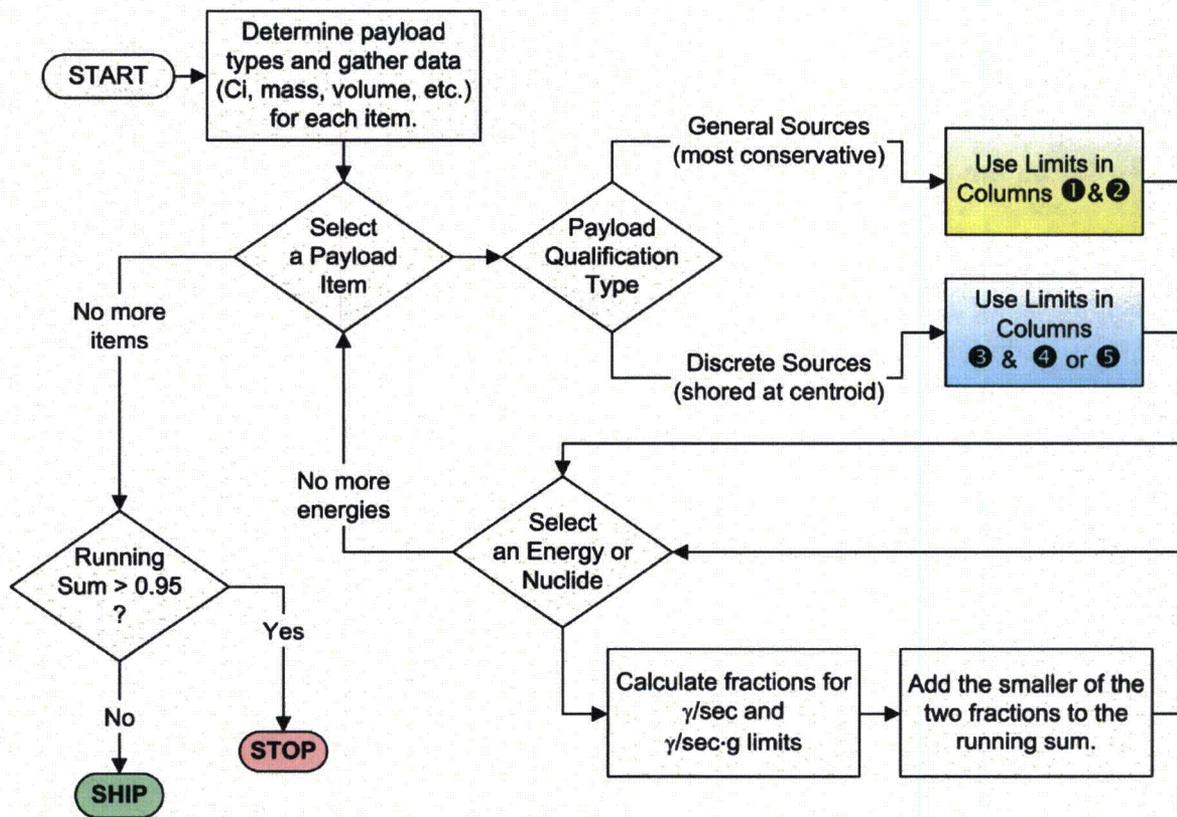

Figure 5-5 – Loading Specification 8-120B-1 Payload Qualification Flowchart

Example 1 - Cs-137 Source Capsule

Problem: Determine the acceptability of a 50 Ci ¹³⁷Cs source to be centrally shored. The source is a metal capsule 2 cm in diameter by 10 cm long, and the Cs source pellet weighs 50 g.

Step 1: Characterize Source

Given in the problem statement.

Step 2: Convert Beta Source to Equivalent Gamma Source
Not applicable (¹³⁷Cs is not a pure beta emitter).

Step 3: Calculate Gamma Source Strengths and Source Strength Densities

The qualification Table has specific limits for ¹³⁷Cs, so it is not necessary to do the qualification by energy line. The source's Ci source strength must be converted to γ/sec and γ/sec·g in order to calculate the source/limit fractions. ¹³⁷Cs produces 0.85 gammas per decay with an energy of 0.66 MeV. The total source strength is

$$3.7 \times 10^{10} \frac{d}{Ci} \times \frac{0.85\gamma}{d} \times 50Ci = 1.57 \times 10^{12} \frac{\gamma}{sec},$$

and, dividing by 50 g, the total source strength density is 3.14E10 γ/sec·g.

Step 4: Select the Limits

Since this payload is to be shipped in a shored configuration, the payload is a “discrete” type payload. The size fits within the defined envelope for the 2.5 ft³ payload, therefore the column ③ and ④ limits apply for γ/sec and γ/sec·g, respectively.

Steps 5-7 Sum the Fractions

For this example, there is only one fraction to calculate¹.

Line	Payload Item	Type	Shape (Discrete Only)	Energy (MeV), or Nuclide	Payload Source Term		Limits			Fractions, F		F _{min}
					γ/sec	γ/sec·g	Energy	γ/sec	γ/sec·g	γ/sec	γ/sec·g	
1	Source	Discrete	2.5 ft ³	Cs-137	1.57E+12	3.15E+10	Cs-137	③ 5.77E+12	④ 1.28E+09	2.73E-01	2.46E+01	2.73E-01
Sum:											2.73E-01	

Since the sum is less than 0.95, the source is an acceptable payload.

¹ Always perform calculations with the full precision for the limits shown in Table 5-5. In these examples, full precision data was used, but the number of digits is reduced for presentation purposes.

Example 2 – Solidified Process Waste

Problem: Determine the acceptability of a 100 ft³ secondary container containing solidified process waste. The activity is uniformly distributed. The measured weight of the filled container is 13,100 lbs, and the weight of the empty container is 1,100 lbs. The isotopic activity, determined by analysis of samples of the waste, is:

5 Ci of ⁶⁰Co, 10 Ci of ¹³⁷Cs, 50 Ci of ⁵⁵Fe, 4 Ci of ⁵⁴Mn, and 20 Ci of ⁹⁰Sr

Step 1: Characterize Source

Given in the problem statement.

Step 2: Convert Beta Source to Equivalent Gamma Source

⁹⁰Sr emits beta radiation through its own decay, plus the decay of its short-lived daughter product, ⁹⁰Y. So the beta production rate is 20 Ci * 3.7E+10 d/Ci * 2 = 1.5E+12 β/sec. Since this is below the threshold of 2E+12 β/sec, the beta production is not significant and can be disregarded.

Step 3: Calculate Gamma Source Strengths and Source Strength Densities

The qualification Table has specific limits for ⁶⁰Co and ¹³⁷Cs, but it will be necessary to do the qualification by energy line for the remaining nuclides. After converting the Ci data to gamma energy lines for the remaining nuclides (neglecting any gamma energy lines < 0.3 MeV), the following source data are to be used for qualification. The γ/sec·g source strength densities are based on 12,000 lbs, the actual weight of the radioactive material. The mass density is assumed to be uniform for the payload.

Energy (MeV), or Nuclide	Payload Source Term	
	γ/sec	γ/sec·g
Co-60	3.70E+11	6.80E+04
Cs-137	3.15E+11	5.78E+04
0.8348	1.48E+11	2.72E+04

Step 4: Select the Limits

Since this payload does not meet the definition of either of the two discrete shored configurations (2.5 ft³ or 55 gal), it is a “general” type payload. The limits in columns ❶ and ❷ apply for γ/sec and γ/sec·g, respectively.

Steps 5-7 Sum the Fractions

For this example, there are three lines: a ⁶⁰Co line, ¹³⁷Cs line, and one energy line representing ⁵⁴Mn (⁵⁵Fe and ⁹⁰Sr are disregarded because ⁵⁵Fe gammas are below 0.3 MeV, and the ⁹⁰Sr betas are below 2E+12 β/sec).

Line	Payload Item	Type	Shape (Discrete Only)	Energy (MeV), or Nuclide	Payload Source Term		Limits			Fractions, F		F _{min}
					γ/sec□	γ/sec:g	Energy	γ/sec	γ/sec:g	γ/sec	γ/sec:g	
1	Solidified Waste Cont.	General		Co-60	3.70E+11	6.80E+04	Co-60	1.39E+11	1.18E+07	2.66E+00	5.75E-03	5.75E-03
2	Solidified Waste Cont.	General		Cs-137	3.15E+11	5.78E+04	Cs-137	2.58E+12	2.56E+08	1.22E-01	2.26E-04	2.26E-04
3	Solidified Waste Cont.	General		0.8348	1.48E+11	2.72E+04	0.9	8.63E+11	5.54E+07	1.71E-01	4.91E-04	4.91E-04
Sum: 6.47E-03												

Since the sum is less than 0.95, the container is an acceptable payload.

Example 3 – Dewatered Resin Liner

Problem: Determine the acceptability of a 100 ft³ steel secondary container containing dewatered resin. The activity is uniformly distributed. The measured weight of the filled container is 13,100 lbs; the weight of the empty container is 1,100 lbs. The isotopic activity, determined by analysis of samples of the waste, is: 5 Ci of ⁶⁰Co, 10 Ci of ¹³⁷Cs, 50 Ci of ⁵⁵Fe, 4 Ci of ⁵⁴Mn, and 30 Ci of ⁹⁰Sr. Also included is a 100 gram piece of activated metal, not shored, with an activity of 0.5 Ci of ⁶⁰Co. The activated metal is steel with a density of 8 g/cm³.

This differs from Example 2 in that there is more ⁹⁰Sr, and there is the additional piece of activated metal.

Step 1: Characterize Source

Given in the problem statement.

Step 2: Convert Beta Source to Equivalent Gamma Source

⁹⁰Sr emits beta radiation through its own decay, plus the decay of its short-lived daughter product, ⁹⁰Y. So the total beta production rate is 30 Ci * 3.7E+10 d/Ci * 2 = 2.22E+12 betas/sec. Since this is above the threshold of 2E+12 betas/sec, the beta production must be considered. Using the procedure to convert beta into equivalent gamma radiation described in this Section, the ⁹⁰Sr/⁹⁰Y betas² will be treated as follows:

$$E_{\max\text{Sr}} = 0.54 \text{ MeV}, \quad E_{\text{avgSr}} = 0.19 \text{ MeV}$$

$$E_{\max\text{Y}} = 2.27 \text{ MeV}, \quad E_{\text{avgY}} = 0.93 \text{ MeV}$$

$$Z_{\text{Resin}} = 5.6, \quad Z_{\text{Steel}} = 26$$

$$Z_w = 26 \text{ (the higher of the resin Z and the liner wall Z)}$$

$$S_{\gamma\text{Sr}} = (1.11\text{E}+12)(3.5\text{E}-04)(26)(0.19) = \underline{1.92\text{E}+08 \text{ } \gamma/\text{s} \text{ @ } 0.54 \text{ MeV}}$$

$$S_{\gamma\text{Y}} = (1.11\text{E}+12)(3.5\text{E}-04)(26)(0.93) = \underline{9.39\text{E}+09 \text{ } \gamma/\text{s} \text{ @ } 2.27 \text{ MeV}}$$

Step 3: Calculate Gamma Source Strengths and Source Strength Densities

This payload must be broken into two payload items, due to the physical and radiological differences between the resins and the activated metal.

²Cember, H., "Introduction to Health Physics," Pergamon Press, 2nd Ed.

Resin Payload Item

Like Example 2, the following source data are to be used for qualification of the gamma emitters. The mass density is assumed to be uniform for the resin portion of the payload.

Energy (MeV), or Nuclide	Payload Source Term	
	γ/sec·g	γ/sec·g
Co-60	3.70E+11	6.80E+04
Cs-137	3.15E+11	5.78E+04
0.8348	1.48E+11	2.72E+04

Activated Metal Payload Item

⁶⁰Co emits two gammas per disintegration, therefore the total source strength for the activated metal is (0.5 Ci)(2 γ/d)(3.7E+10 d/sec-Ci) = 3.7E+10 γ/sec. Dividing by the mass of 100 g, the source strength density is 3.7E+08 γ/sec. The mass density is assumed to be uniform for the 100 gram piece of metal.

Step 4: Select the Limits

Resin Payload Item - Since this payload item does not meet the definitions of either of the two discrete shored configurations (2.5 ft³ or 55 gal), it is a “general” type payload. The limits in columns ① and ② apply for γ/sec and γ/sec·g, respectively.

Activated Metal Payload Item – This payload item is small and fits within the defined envelope for the 2.5 ft³ payload, however it is not shored, and so the activated metal is also a “general” type payload item. Columns ① and ② apply for the γ/sec and γ/sec·g limits, respectively.

Steps 5-7 Sum the Fractions

For this example, there are six lines: 1-3 are for the resin gamma emitters, 4-5 are for the bremsstrahlung gammas produced by ⁹⁰Sr and ⁹⁰Y, and one line for the activated metal ⁶⁰Co.

Line	Payload Item	Type	Shape (Discrete Only)	Energy (MeV), or Nuclide	Payload Source Term		Limits			Fractions, F		F _{min}
					γ/sec	γ/sec·g	Energy	γ/sec	γ/sec·g	γ/sec	γ/sec·g	
1	Resin	General		Co-60	3.70E+11	6.80E+04	Co-60	① 1.39E+11	② 1.18E+07	2.66E+00	5.75E-03	5.75E-03
2	Resin	General		Cs-137	3.15E+11	5.78E+04	Cs-137	① 2.58E+12	② 2.56E+08	1.22E-01	2.26E-04	2.26E-04
3	Resin	General		0.8348	1.48E+11	2.72E+04	0.9	① 8.63E+11	② 5.54E+07	1.71E-01	4.91E-04	4.91E-04
4	Resin (betas)	General		0.54	1.92E+08	3.53E+01	0.7	① 2.13E+12	② 1.89E+08	9.01E-05	1.87E-07	1.87E-07
5	Resin (betas)	General		2.27	9.39E+09	1.73E+03	2.75	① 1.29E+10	② 6.51E+05	7.30E-01	2.65E-03	2.65E-03
6	Metal	General		Co-60	3.70E+10	3.70E+08	Co-60	① 1.39E+11	② 1.18E+07	2.66E-01	3.13E+01	2.66E-01
Sum: 2.75E-01												

Since the sum is less than 0.95, the container is an acceptable payload.

Example 4 – Activated Waste with Non-Fixed Contamination

Problem: Determine the acceptability of a 100 ft³ steel secondary container containing activated metal. The measured weight of the filled container is 7,100 lbs; the weight of the empty container is 1,100 lbs. The metal is composed of mildly activated steel, with non-fixed surface contamination. The contaminated surface area is estimated to be 500 ft². There is one small piece of activated steel with a significantly higher activity. Determine whether this smaller item can be included in the shipment, and whether it needs to be shored. The isotopic activities, determined by analysis of samples of the waste, are as follows:

- Most of the steel has similar radiological properties. Based on an analysis of the highest-activity sample, the constituents are: 20 Ci of ⁵⁸Co, 30 Ci of ⁶⁰Co, and 20 Ci of ⁵⁴Mn.
- The small activated metal item has a mass of 100 g, dimensions of 1" x 1" x 24", with an activity of 6 Ci of ⁶⁰Co.
- The non-fixed crud contamination level, based on the highest-activity sample, is 50,000 dpm, which has been determined to be 50% ⁵⁵Fe, 30% ¹³⁷Cs, and 20% ⁶⁰Co. The contaminated surface area is 500 ft².

Step 1: Characterize Source

Given in the problem statement.

Step 2: Convert Beta Source to Equivalent Gamma Source

Not applicable since the beta source is less than 2E+12 β/sec.

Step 3: Calculate Gamma Source Strengths and Source Strength Densities

100g Activated Metal Payload Item

⁶⁰Co emits two gammas per disintegration, therefore the total source strength for the small activated metal item is (6 Ci)(2 γ/d)(3.7E+10 d/sec-Ci) = 4.44E+11 γ/sec. Dividing by the mass of 100 g, the source strength density is 4.44E+09 γ/sec. The mass density is assumed to be uniform for the small activated metal item.

Energy (MeV), or Nuclide	Payload Source Term	
	γ/sec□	γ/sec□g
Co-60	4.44E+11	4.44E+09

Remaining Activated Metal Payload Item

^{60}Co emits two gammas per disintegration, therefore the total ^{60}Co source strength for the activated metal is $(30 \text{ Ci})(2 \gamma/\text{d})(3.7\text{E}+10 \text{ d/sec-Ci}) = 2.22\text{E}+12 \gamma/\text{sec}$. The remaining nuclides, ^{58}Co and ^{54}Mn , were converted to individual energy lines³ ($E < 0.3 \text{ MeV}$ were neglected). Sources were divided by $2.72\text{E}+06 \text{ g}$ (i.e., 6,000 lb) to obtain the $\gamma/\text{sec}\cdot\text{g}$. The mass density of the metal is assumed to be uniform. The resulting sources are:

Energy (MeV), or Nuclide	Payload Source Term	
	γ/sec	$\gamma/\text{sec}\cdot\text{g}$
Co-60	2.22E+12	8.16E+05
0.511	2.21E+11	8.12E+04
0.8108	7.36E+11	2.70E+05
0.8348	7.40E+11	2.72E+05
0.8639	5.45E+09	2.00E+03
1.6747	3.97E+09	1.46E+03

Crud Payload Item

50,000 dpm is equivalent to $2.25\text{E}-08 \text{ Ci}$ per 100 cm^2 . The total source strength is therefore $(2.25\text{E}-08 \text{ Ci}/100\text{cm}^2)(500 \text{ ft}^2)(929 \text{ cm}^2/\text{ft}^2) = 1.05\text{E}-04 \text{ Ci}$. The nuclide breakdown is therefore: $5.23\text{E}-05 \text{ Ci}$ of ^{55}Fe , $3.14\text{E}-05 \text{ Ci}$ of ^{137}Cs , and $2.09\text{E}-05 \text{ Ci}$ of ^{60}Co . ^{55}Fe can be neglected since it does not emit any gammas $> 0.3 \text{ MeV}$. We can only use the γ/sec limit for qualification. The source inputs are therefore:

Energy (MeV), or Nuclide	Payload Source Term	
	γ/sec	$\gamma/\text{sec}\cdot\text{g}$
Co-60	1.55E+06	
Cs-137	9.88E+05	

Step 4: Select the Limits

The 100g activated item would meet the size criteria for the 55-gallon discrete shored configuration if both the container were shored and the item was shored within the container, in which case its limits would be columns ③ and ⑤ for γ/sec and $\gamma/\text{sec}\cdot\text{g}$, respectively. Otherwise, since it would be unshored, the limits in columns ① and ② would apply for γ/sec and $\gamma/\text{sec}\cdot\text{g}$, respectively.

The remaining activated metal does not meet the definitions of either of the two discrete shored configurations (2.5 ft^3 or 55 gal), so it is a “general” type payload item. The limits in columns ① and ② apply for γ/sec and $\gamma/\text{sec}\cdot\text{g}$, respectively.

³MicroShield, Version 8.01, Grove Engineering.

The crud is free to move within the cavity and is therefore a “general” type payload item. Also, as discussed above in this Section, crud must be qualified using the γ /sec limit. Thus, the limit in column ①, in γ /sec, applies for the crud.

Steps 5-7 Sum the Fractions

First we will try qualifying the payload without shoring the small activated item. Note that it is not acceptable to average the activated metal together with the small 100 g item.

Line	Payload Item	Type	Shape (Discrete Only)	Energy (MeV), or Nuclide	Payload Source Term		Limits			Fractions, F		F _{min}
					γ /sec	γ /sec:g	Energy	γ /sec	γ /sec:g	γ /sec	γ /sec:g	
1	100g activated item	General	55 gal	Co-60	4.44E+11	4.44E+09	Co-60	① 1.39E+11	② 1.18E+07	3.19E+00	3.76E+02	3.19E+00
2	Remaining metal	General		Co-60	2.22E+12	8.16E+05	Co-60	① 1.39E+11	② 1.18E+07	1.59E+01	6.90E-02	6.90E-02
3	Remaining metal	General		0 511	2.21E+11	8.12E+04	0.7	① 2.13E+12	② 1.89E+08	1.04E-01	4.30E-04	4.30E-04
4	Remaining metal	General		0 8108	7.36E+11	2.70E+05	0.9	① 8.63E+11	② 5.54E+07	8.52E-01	4.88E-03	4.88E-03
5	Remaining metal	General		0 8348	7.40E+11	2.72E+05	0.9	① 8.63E+11	② 5.54E+07	8.57E-01	4.91E-03	4.91E-03
6	Remaining metal	General		0 8639	5.45E+09	2.00E+03	0.9	① 8.63E+11	② 5.54E+07	6.31E-03	3.61E-05	3.61E-05
7	Remaining metal	General		1.6747	3.97E+09	1.46E+03	1.83	① 3.04E+10	② 2.06E+06	1.31E-01	7.08E-04	7.08E-04
8	Crud	General		Co-60	1.55E+06		Co-60	① 1.39E+11	② 1.18E+07	1.11E-05		1.11E-05
9	Crud	General		Cs-137	9.88E+05		Cs-137	① 2.58E+12	② 2.56E+08	3.83E-07		3.83E-07

Sum: 3.27E+00

This approach does not pass. Since the discrete shored payload items have higher limits, we can try to see if shoring the 100g item will pass.

Line	Payload Item	Type	Shape (Discrete Only)	Energy (MeV), or Nuclide	Payload Source Term		Limits			Fractions, F		F _{min}
					γ /sec	γ /sec:g	Energy	γ /sec	γ /sec:g	γ /sec	γ /sec:g	
1	100g activated item	Discrete	55 gal	Co-60	4.44E+11	4.44E+09	Co-60	① 1.29E+12	② 4.07E+07	3.43E-01	1.09E+02	3.43E-01
2	Remaining metal	General		Co-60	2.22E+12	8.16E+05	Co-60	① 1.39E+11	② 1.18E+07	1.59E+01	6.90E-02	6.90E-02
3	Remaining metal	General		0 511	2.21E+11	8.12E+04	0.7	① 2.13E+12	② 1.89E+08	1.04E-01	4.30E-04	4.30E-04
4	Remaining metal	General		0 8108	7.36E+11	2.70E+05	0.9	① 8.63E+11	② 5.54E+07	8.52E-01	4.88E-03	4.88E-03
5	Remaining metal	General		0 8348	7.40E+11	2.72E+05	0.9	① 8.63E+11	② 5.54E+07	8.57E-01	4.91E-03	4.91E-03
6	Remaining metal	General		0 8639	5.45E+09	2.00E+03	0.9	① 8.63E+11	② 5.54E+07	6.31E-03	3.61E-05	3.61E-05
7	Remaining metal	General		1.6747	3.97E+09	1.46E+03	1.83	① 3.04E+10	② 2.06E+06	1.31E-01	7.08E-04	7.08E-04
8	Crud	General		Co-60	1.55E+06		Co-60	① 1.39E+11	② 1.18E+07	1.11E-05		1.11E-05
9	Crud	General		Cs-137	9.88E+05		Cs-137	① 2.58E+12	② 2.56E+08	3.83E-07		3.83E-07

Sum: 4.23E-01

Since the sum is less than 0.95, the container is an acceptable payload if the container and 100 g item are shored such that the 100g item is located at the centroid of the cask cavity.

Example 5 – Contaminated Soil

Problem: Determine the acceptability of a 100 ft³ steel secondary container containing a contaminated soil mixture. The activity is not uniformly distributed. The measured weight of the filled container is 10,100 lbs; the weight of the empty container is 1,100 lbs. 5% of the payload mass is made up of small bits of grout used to immobilize contamination. The size of the grout chunks ranges from 0.1 cm to 10 cm. The grout contains ¹³⁷Cs at a maximum concentration of 350 Ci/ft³. The remaining 95% of the material is soil with an activity of 10 Ci/ft³ of ¹³⁷Cs. The density of the soil and grout are both 100 lb/ft³. Activities were determined by analysis of samples of the most active representative waste.

Step 1: Characterize Source

Given in the problem statement.

Step 2: Convert Beta Source to Equivalent Gamma Source

Not applicable (Cs-137 is not a pure beta emitter).

Step 3: Calculate Gamma Source Strengths and Source Strength Densities

We will evaluate the payload two ways: one treating the entire payload as a single item with a bounding source strength (γ/sec) and source strength density ($\gamma/\text{sec}\cdot\text{g}$), and the second assuming we will treat the payload as two separate items: grout and soil.

If there is a potential for the contamination to redistribute, then it would be appropriate to qualify the source using only the γ/sec limits. For this example, the grout physically prevents its contamination from redistribution, and for simplicity we assume that the soil, which has a much lower source strength density, also physically binds its contaminants. For both payload items, we will therefore perform the qualification using both source strength (γ/sec) and source strength density ($\gamma/\text{sec}\cdot\text{g}$). Note that this example does account for the possibility that the grout will redistribute (or concentrate) itself within the soil, since the single payload approach will use the higher source strength density ($\gamma/\text{sec}\cdot\text{g}$) of the grout in the qualification.

Grout Payload Item

The grout gamma source strength is $(350 \text{ Ci/ft}^3)(1 \text{ ft}^3/100 \text{ lb})(9,000 \text{ lb}\cdot 0.05)(3.7\text{E}+10 \text{ d/sec-Ci})(0.85 \gamma/\text{d}) = 4.95\text{E}+13 \gamma/\text{sec}$. Dividing by the mass (450 lb, or $2.04\text{E}+05 \text{ g}$), the source strength density would be $2.43\text{E}+08 \gamma/\text{sec}\cdot\text{g}$.

Payload Source Term	
γ/sec	γ/sec·g
4.95E+13	2.43E+08

Soil Payload Item

The soil gamma source strength is $(10 \text{ i/ft}^3)(1 \text{ ft}^3/100 \text{ lb})(9,000 \text{ lb} \cdot 0.95)(3.7\text{E}+10 \text{ d/sec-Ci})(0.85 \text{ γ/d}) = 2.69\text{E}+13 \text{ γ/sec}$. Dividing by the mass (8550 lb, or $3.88\text{E}+06 \text{ g}$), the source strength density would be $6.93\text{E}+06 \text{ γ/sec} \cdot \text{g}$.

Energy (MeV), or Nuclide	Payload Source Term	
	γ/sec	γ/sec·g
Cs-137	2.69E+13	6.93E+06

Combined Grout/Soil Payload Item

If the payload is treated as a single item, the γ/sec is set equal to the sum of the γ/sec for both the grout and soil components. The γ/sec·g is set equal to that of the “hottest” component (i.e., the grout). Thus, the gamma source strength would be $5.66\text{E}+13 \text{ γ/sec}$ ($4.95\text{E}+13 + 2.69\text{E}+13$). The γ/sec·g equals the $2.43\text{E}+08$ value that applies for the grout.

Payload Source Term	
γ/sec	γ/sec·g
7.64E+13	2.43E+08

Step 4: Select the Limits

Since none of these payload items meets the definition of either of the two discrete shored configurations (2.5 ft^3 or 55 gal), they are “general” type payload items. The limits in columns ❶ and ❷ apply for γ/sec and γ/sec·g, respectively.

Steps 5-7 Sum the Fractions

As a first try, we attempt to qualify the payload as being two components: the grout and soil.

Line	Payload Item	Type	Shape (Discrete Only)	Energy (MeV), or Nuclide	Payload Source Term		Limits			Fractions, F		F _{min}
					γ/sec	γ/sec·g	Energy	γ/sec	γ/sec·g	γ/sec	γ/sec·g	
1	Grout	General		Cs-137	4.95E+13	2.43E+08	Cs-137	❶ 2.58E+12	❷ 2.56E+08	1.92E+01	9.50E-01	9.50E-01
2	Soil	General		Cs-137	2.69E+13	6.93E+06	Cs-137	❶ 2.58E+12	❷ 2.56E+08	1.04E+01	2.71E-02	2.71E-02
Sum:											9.77E-01	

Since the sum is greater than 0.95, the container is not an acceptable payload.

It is acceptable, however, to treat the payload as a single (combined) item, with a γ/sec equal to the sum of the component (grout and soil) γ/sec values, and a $\gamma/\text{sec}\cdot\text{g}$ equal to that of the “hottest” component (i.e., the grout).

Line	Payload Item	Type	Shape (Discrete Only)	Energy (MeV), or Nuclide	Payload Source Term		Limits			Fractions, F		F _{min}
					γ/sec	$\gamma/\text{sec}\cdot\text{g}$	Energy	γ/sec	$\gamma/\text{sec}\cdot\text{g}$	γ/sec	$\gamma/\text{sec}\cdot\text{g}$	
1	All-grout	General		Cs-137	7.64E+13	2.43E+08	Cs-137	● 2.58E+12	● 2.56E+08	2.96E+01	9.50E-01	9.50E-01

Sum: 9.50E-01

Since the sum is less than 0.95, the container is an acceptable payload.

This example illustrates that there is no benefit from dividing a payload into multiple payload items if all of the items qualify under the $\gamma/\text{sec}\cdot\text{g}$ limit. If the payload is divided, one of the ($\gamma/\text{sec}\cdot\text{g}$) fractions will be that which applies for the grout (i.e., 0.950). If the single payload approach is used, the $\gamma/\text{sec}\cdot\text{g}$ value is set to that which applies for the “hottest” item (the grout), so the total fraction for the entire payload would be 0.950. Separating small, high source strength density items from the overall payload only helps if those small (low mass) items are qualified under the γ/sec limit, and not the $\gamma/\text{sec}\cdot\text{g}$ limit.

5.8 LOADING SPECIFICATION 8-120B-2 (ACTIVATED STEEL)

5.8.1 LOADING SPECIFICATION 8-120B-2 DESCRIPTION

Loading Specification 8-120B-2 applies to activated steel shipments made in the 8-120B cask. The Specification is intended for typical decommissioning projects and other applications where steel activation dominates the overall source terms, ^{60}Co is typically the only significant contributor to package external dose rate and therefore source limits may be specified by ^{60}Co specific activity alone. The differences between carbon and stainless steels do not significantly affect the limiting criterion of allowable Ci of ^{60}Co per gram, therefore the Specification applies to any type of steel.

Under some circumstances, it may be desirable to include payload items in a shipment made under Loading Specification 8-120B-2 that are acceptable per the contents description in the Certificate of Compliance, but differ from the payload material described above. It is acceptable to combine the fractions of allowables from Loading Specifications 8-120B-2 (for activated steel) and 8-120B-1 (for other items) if the sum remains less than 0.95. This is appropriate since the fractions represent fractions of regulatory dose rate limits at the worst-case location and so it is either equivalent or conservative to combine the fractions.

Shipments made under Loading Specification 8-120B-2 may be made using a steel liner assembly meeting the requirements of the 8-120B-2 Liner drawing in Section 1.3. The shielding analyses (Reference 5.6.5) take credit for the liner. Liner thicknesses may differ depending on project needs because more active payloads require more shielding. Less active payloads do not require as much additional shielding; therefore thinner liners may be desirable to allow more weight and space for the active contents. Radiological source term limits are specified by ^{60}Co gamma source density (^{60}Co Ci/g) as a function of the steel liner thickness. The source limits ensure that the package will meet the external radiation requirements specified by 10 CFR 71.47 and 10 CFR 71.51 as demonstrated by the shielding analyses. Liners may have screened holes on the bottom to facilitate water drainage since they may require underwater loading. Drain holes are limited to a maximum total area which has been evaluated in the shielding analyses.

A "budget" is set aside in the calculated source term limits to account for typical surface contamination that may become dislodged and contribute to external dose rates for the NCT or HAC. For payloads exceeding the CRUD budget, a guideline is established by which the ^{60}Co Ci/g limits may be reduced accordingly.

The specifications for the payload, secondary containers, and other restrictions are summarized in Table 1-2. Allowable source terms are presented in Section 5.8.4.4, and the procedure for performing the payload radiological qualification is in Section 5.8.5.

5.8.2 8-120B-2 SOURCES

5.8.2.1 Gamma Source

^{60}Co overwhelmingly dominates activated metal shipments. Reference 5.6.6 shows that for reactor vessel internal hardware (a typical payload material subject to Loading Specification 8-120B-2), the only nuclides present in significant quantities with half-lives of interest are: ^{10}Be ,

^{55}Fe , ^{59}Ni , ^{63}Ni and ^{93}Mo . ^{10}B produces a 0.556 MeV beta at an intensity (β/sec) which is more than four orders of magnitude lower than that of ^{60}Co (γ/s), and ^{59}Ni produces a 0.511 MeV gamma at an intensity five orders of magnitude lower than that of ^{60}Co . ^{60}Co also produces much higher energy gammas that are much more effective at penetrating the cask shielding. Because of the lower energy (0.511 – 0.566 MeV) of these beta and gamma sources, and their lower intensities, these non- ^{60}Co sources will contribute significantly less than 1% to cask exterior dose rates.

For all MCNP models, the ^{60}Co source strength is set to 1.0 γ/s . The result of each analysis is the dose response (i.e., mrem/hr per γ/s in the source zone) at each evaluated dose location. Each dose response is adjusted upwards to account for the statistical error level in the MCNP tally result. Using the response functions, the limiting gamma source strength can be calculated at which one or more regulatory dose rate limits is reached. The ^{60}Co energy spectrum is specified as 50% 1.176 MeV gammas and 50% 1.333 MeV gammas.

5.8.2.2 Neutron Source

8-120B neutron sources are limited to the source strength limit in Section 1.2.2.2. Typical activated steel shipments have no significant neutron emitters.

5.8.2.3 Beta Source

Typical activated steel shipments have no significant beta emitters; and beta sources are not included in the 8-120B-2 shielding analysis. Payloads with significant beta sources should be qualified using Loading Specification 8-120B-1.

5.8.3 8-120B-2 MODEL SPECIFICATION

5.8.3.1 Configuration of Source and Shielding

5.8.3.1.1 *Normal Conditions of Transport (NCT)*

The basic NCT model is described in Section 5.3.1.1. For the 8-120B-2 NCT shielding evaluation, the liner is also modeled as a right circular cylindrical carbon steel shell with a central 30 inch diameter hole on the bottom. This envelopes any combination of smaller holes and locations since it models a larger streaming path through the liner steel that is collocated with the peak dose rate location on the cask axis. Shell thickness cases of 0, 1/2, 1, 1-1/4, 1-1/2, and 1-3/4 inches were run parametrically.

Stainless steel at a density of 7.92 g/cc is modeled throughout the liner interior. A uniformly-distributed ^{60}Co gamma source is modeled throughout the source region volume. Thus, the entire liner cavity is modeled as being filled with solid activated steel. Scoping analyses show that modeling a maximum payload material density yields bounding values for allowable source density. Comparison of full-cask-cavity and reduced-volume payload results shows that filling the entire payload cavity with waste material bounds any configurations where the payload occupies any portion of the liner/cask interior cavity volume. Scoping evaluations further show that differences in steel composition (between stainless and carbon steel) have no significant impact on the analysis results.

For the NCT CRUD evaluation, it is assumed that any non-fixed CRUD that leaves the waste surfaces will fall to the bottom of the cask cavity. It is also conservatively assumed that all the CRUD will migrate into the drain holes in the bottom plate of any waste liner. Loading Specification 8-120B-2 requires that if drain holes are present, they must be screened, but this evaluation does not credit the screen function. Thus, CRUD is conservatively modeled on the bottom surface of the 8-120B cask cavity, so that none of the steel liner's shielding lies between the source and the package bottom end dose location. A ^{60}Co point source is placed at the bottom center of the 8-120B cask cavity.

5.8.3.1.2 Hypothetical Accident Conditions (HAC)

The basic HAC model is described in Section 5.3.1.2. The activated metal source is modeled as a distributed full-cavity source, since there is no credible mechanism by which redistribution could significantly impact the results. Since the source qualification is based on the highest specific activity (Ci/g), this approach is conservative.

For the HAC CRUD evaluation, the cask may be in any orientation. Thus, the non-fixed CRUD source cannot be assumed to lie on the floor of the cavity. The CRUD point source is modeled at the worst-case location within the cask cavity.

The waste liners are conservatively neglected in the HAC shielding analyses since they have not been demonstrated to remain undamaged in the HAC.

5.8.3.2 Material Properties

In addition to the materials in Table 5-2, the models for Loading Specification 8-120B-2 included the steel in Table 5-6.

Table 5-6- Material Composition and Density

Material	Total Density (g/cc)	Composition	MCNP Z Aid
Steel	7.92	19% Cr	24000.84p
		2% Mn	25000.84p
		69.5% Fe	26000.84p
		9.5% Ni	28000.84p

5.8.4 8-120B-2 SHIELDING EVALUATION

5.8.4.1 Methods

Shielding calculations are performed using MCNP Version 5, revision 1.51. Source biasing and geometry splitting are used to improve the convergence rate of the problems. The number of histories executed in a typical run is on the order of 10^8 - 10^9 . The variance reduction techniques applied in the models are conservative and the computer runs are well-converged, as shown by the MCNP figure of merit stability and other statistical checks. Tally relative errors are less than 1%.

The shielding evaluation uses response functions calculated with MCNP to determine the maximum radiological contents that would meet the external radiation requirements specified by 10 CFR 71.47 and 71.51. Loading Specification 8-120B-2 requires that contents be qualified using a criterion of no more than 0.95 of this limit. The extra 5% margin is reserved to create a 4% "budget" for the potential effects of non-fixed CRUD, plus a 1% budget for other minor effects such as payload material characteristics and the effects of source nuclides other than ^{60}Co . The statistical uncertainty inherent in the MCNP runs is added directly to the MCNP responses and is therefore not accounted for separately.

5.8.4.2 Input and Output Data

Reference 5.6.5 describes the MCNP input and output files. The input file lists the inputs that define the source dimensions, shield dimensions, materials and density, and source spectrum.

5.8.4.3 Flux-to-Dose-Rate Conversion

ANSI/ANS-6.1.1 1977 flux-to-dose-rate conversion factors were used as described in Section 5.4.3.

5.8.4.4 External Radiation Levels and Source Strength Limits

The MCNP response functions for the bounding configurations are compared to the external radiation limits allowed for the various compliance locations identified in §71.47 and §71.51. The governing location is used to calculate the source limits. The allowable ^{60}Co specific activity (Ci/g) is determined as a function of the steel liner thickness. These limits are presented in Table 5-7. For liners that have differing thicknesses in radial or axial directions, the minimum thickness shall be used to determine the allowable ^{60}Co specific activity. The analyses modeled the steel liners at minimum tolerance thicknesses, therefore nominal plate dimensions should be used when looking up allowable activity densities. The limits on ^{60}Co specific activity apply to the most activated portion of the waste material.

Table 5-7 – ^{60}Co Activity Density Limits

Nominal Liner Steel Thickness (in)	Maximum ^{60}Co Activity Density ($\mu\text{Ci/g}$)
0"	160
1/2"	253
1"	410
1-1/4"	508
1-1/2"	635
1-3/4"	828

The maximum activities in Table 5-7 include the effects of CRUD release for up to 0.616 Ci of non-fixed ^{60}Co . For larger potential non-fixed CRUD activities, reduce the allowables in Table 5-7 at the rate of 1% for every additional 0.154 Ci of non-fixed ^{60}Co CRUD.

5.8.5 8-120B-2 PAYLOAD QUALIFICATION

In order to qualify the radioactive source term for contents to be shipped under Loading Specification 8-120B-2:

1. Using the minimum nominal liner thickness, look up the allowable ^{60}Co specific activity from Table 5-7.
2. If the candidate payload has very high levels of non-fixed CRUD levels (exceeding 0.616 Ci of ^{60}Co), decrease the allowable Ci/g at the rate of 1% for every additional 0.154 Ci of non-fixed ^{60}Co CRUD.
3. Assure that the highest specific activity of the candidate payload meets the allowable Ci/g of ^{60}Co .
4. If the activated metal payload includes payload items not meeting the requirements herein (e.g., not steel, or not dominated by ^{60}Co), determine the sum-of-fractions for the shipment as follows:
 - a. Calculate the fraction of allowable from Steps 1-3 above.
 - b. Using Loading Specification 8-120B-1, calculate the fraction of allowables from Column 2 in Table 5-5. Add this fraction to the fraction from Step 4a above.
 - c. The gamma source term is acceptable if the combined sum is ≤ 0.95 .

5.9 LOADING SPECIFICATION 8-120B-3 (REFORMED RESIDUE)**5.9.1 LOADING SPECIFICATION 8-120B-3 DESCRIPTION**

Loading Specification 8-120B-3 applies to shipments of reformed residue (RR) made in the 8-120B cask. Reformed residue (RR) is the end-product of a volume-reduction stabilization process currently performed only at the ResinSolutions facility in Erwin, Tennessee. Incoming materials such as resins and filter media are pyrolyzed and reformed into an extremely homogeneous dough-like mixture. This process removes the organics, resulting in a greatly volume-reduced product suitable for long-term disposal. Although RR shipments may always be qualified using the general Loading Specification 8-120B-1, EnergySolutions has developed Loading Specification 8-120B-3, which is tailored specifically for RR payloads. Loading Specification 8-120B-3 is intended only for RR produced using the patented Thermal Organic Reduction (THOR™) process currently done at the Erwin, Tennessee facility. Over 100,000 cubic feet of input material has been processed into RR and shipped in the 8-120B since 1999. The THOR™ process has successfully proven volume reduction success of 5:1 to 10:1 for spent resin/medias.

Redacted [4(ii)(a) and 4(vi)(b)]

8-120B shipments to be made under Loading Specification 8-120B-3 are qualified on the basis of pre-shipment measurements. It is desirable to qualify payload sources by measurement rather

than calculation because of the large conservative uncertainties typically present in source term characterization of the incoming RR process feed materials. Unlike some types of 8-120B payloads, RR is extremely homogeneous and mechanically stable; therefore it cannot shift or reconfigure in ways that will increase exterior dose rates. Thus it is possible to extrapolate pre-shipment measurements to predict the package dose rates under the tests specified in 10 CFR 71.47 and 10 CFR 71.51.

In order to establish that pre-shipment dose rate measurements are an adequate way to qualify payloads, it is necessary to show that the pre-shipment measurements, which are made with the package in its nominal pre-shipment condition, will guarantee that the package would also meet §74.47 limits in the NCT configuration (which has small impact limiter deformations that affect the location of the package surface) and §71.51 limits in the HAC condition (in which the impact limiters are presumed to have vanished, there are certain deformations in the cask lead shielding, the HIC is assumed to have disappeared, and the cask could be in any orientation).

Because the pre-shipment measurements form the basis for demonstrating compliance with §74.47 and §71.51, margins are applied to account for the small differences between the nominal pre-shipment condition and NCT, plus other uncertainties.

The purpose of the shielding safety analysis for Loading Specification 8-120B-3 (Reference 5.6.7) is to demonstrate that any shipment meeting the following limits (in its nominal pre-shipment package configuration):

- The 8-120B top surface, radial surfaces, and underneath the trailer must not exceed 170 mrem/hr at any point.
- 8.5 mrem/hr must not be exceeded at any point 2 meters from the vertical planes projected by the outer edges of the vehicle.
- Any normally occupied space (e.g., driver) must not exceed 1.7 mrem/h.

will also meet the following limits under the NCT package configuration:

- A. The 8-120B top surface, radial surfaces, and underneath the trailer must not exceed 200 mrem/hr at any point.
- B. 10 mrem/hr must not be exceeded at any point 2 meters from the vertical planes projected by the outer edges of the vehicle.
- C. Any normally occupied space (e.g., driver) must not exceed 2 mrem/h.

as well as the following limits under the HAC package configuration.

- D. External radiation dose rates may not exceed 1 rem/h at 1 m from the external surface of the package.

Table 1-2 requires that, in order to use Loading Specification 8-120B-3, the RR must be in a polyethylene high-integrity container (HIC) with a thickness of 1-inch or less, and there must be at least 94 cubic feet of RR. Since the basis for qualification is the pre-shipment dose rate measurements, it would be non-conservative if the HIC (which is presumed to fail under HAC) were thicker than the assumed 1-inch thickness in the shielding models, or if a container was

metallic instead of polyethylene. Likewise, the RR minimum fill volume specification prevents a situation where a very small volume of high-activity payload material results in low measured pre-shipment dose rates, but a high HAC dose rate.

The specifications for the payload, secondary containers, and other restrictions are summarized in Table 1-2. Allowable source terms are presented in Section 5.9.4.4, and the procedure for performing the payload radiological qualification is in Section 5.9.5. The pre-shipment survey requirements and procedure are in Section 5.9.6.

5.9.2 8-120B-3 SOURCES

5.9.2.1 Gamma Source

A suite of MCNP runs is made over several gamma energy levels, ranging from 0.5 MeV to 5.0 MeV. Two specific isotope cases, ^{60}Co and Cs-137 are also analyzed. For all MCNP models, the source strength is set to 1.0 γ/s . The result of each analysis is the dose response (i.e., mrem/hr per γ/s in the source zone) at each evaluated dose location. Each dose response is adjusted upwards to account for the statistical error level in the MCNP tally result. Using the response functions, the limiting gamma source strength can be calculated at which one or more regulatory dose rate limits is reached. The gamma spectra of ^{60}Co and ^{137}Cs are shown in Table 5-2. The ^{137}Cs source includes an equilibrium amount of $^{137\text{m}}\text{Ba}$.

5.9.2.2 Neutron Source

Loading Specification 8-120B-3 does not allow shipment of significant neutron sources. Neutron sources in the 8-120B cask are discussed in Section 5.2.2.

5.9.2.3 Beta Source

For Loading Specification 8-120B-3, beta radiation can be neglected because bremsstrahlung radiation is a component of the gamma radiation measured outside the package during the pre-shipment survey. Measurements are the basis for 8-120B-3 payload radiological qualification, and the purpose of the shielding models is to evaluate the relative increases between the pre-shipment nominal condition, and NCT or HAC. Beta-induced bremsstrahlung is implicitly included in the measurements and therefore does not need to be accounted for separately in the shielding analyses.

5.9.3 8-120B-3 MODEL SPECIFICATION

5.9.3.1 Configuration of Source and Shielding

5.9.3.1.1 *Nominal Pre-shipment Condition*

The basic NCT model described in Section 5.3.1.1 was modified to match the nominal pre-shipment condition by increasing the diameter and height of the impact limiters to the nominal value, and adding foam to the impact limiters (which is typically neglected in other models). In this way, the pre-shipment condition MCNP models match as closely as possible the actual geometry that will be measured in the field during the pre-shipment dose rate surveys.

The HIC is modeled as a 1-inch thick right circular cylindrical polyethylene shell surrounding 94 cubic feet of RR (approximately 80% of the HIC cavity height) at 2.0 g/cc density.

5.9.3.1.2 Normal Conditions of Transport (NCT)

The NCT models are like the nominal pre-shipment model described above, except that the impact limiter diameter and height are reduced like the basic NCT model described in Section 5.3.1.1. Because a direct comparison is needed to the nominal pre-shipment cases, the impact limiter foam was modeled.

5.9.3.1.3 Hypothetical Accident Conditions (HAC)

The basic HAC model is described in Section 5.3.1.2. The RR source is modeled as a distributed source completely filling the cask cavity. The polyethylene HIC is conservatively neglected in the HAC shielding analysis since they have not been demonstrated to remain undamaged in the HAC.

5.9.3.2 Material Properties

In addition to the materials in Table 5-2, the models for Loading Specification 8-120B-2 included the stainless steel in Table 5-8.

Table 5-8- Material Composition and Density

Material	Total Density (g/cc)	Composition	MCNP ZAIID
Reformed Resin	2.0	Redacted [4(ii)(a) and 4(vi)(d)]	
Polyethylene	1.0	14.37% H 85.63% C	1000.84p 6000.84p
Polyurethane Foam	0.4013	9.07% H 64.35% C 6.01% N 20.57% O	1000.84p 6000.84p 7000.84p 8000.84p

5.9.4 8-120B-3 SHIELDING EVALUATION

5.9.4.1 Methods

The HAC models are run parametrically across energies ranging from 0.5-5.0 MeV plus ^{60}Co and ^{137}Cs energies. The NCT models are run for ^{60}Co and ^{137}Cs energies. Due to the minor physical differences between nominal and NCT, these two dominant nuclides are sufficient to demonstrate that the dose rate difference is small.

Shielding calculations are performed using MCNP Version 5, revision 1.51. Source biasing and geometry splitting are used to improve the convergence rate of the problems. The number of histories executed in a typical run is on the order of 10^8 - 10^9 . The variance reduction techniques applied in the models are conservative and the computer runs are well-converged, as shown by the MCNP figure of merit stability and other statistical checks. Tally relative errors are less than 1.5%. The statistical uncertainties in the MCNP tallies were not added to the MCNP responses because the objective of the analyses is to examine the ratios between nominal and NCT or HAC cases, not to calculate conservative dose rate values.

5.9.4.2 Input and Output Data

Reference 5.6.7 describes the MCNP input and output files. The input file lists the inputs that define the source dimensions, shield dimensions, materials and density, and source spectrum.

5.9.4.3 Flux-to-Dose-Rate Conversion

ANSI/ANS-6.1.1 1977 flux-to-dose-rate conversion factors were used as described in Section 5.4.3.

5.9.4.4 External Radiation Levels and Source Strength Limits

The MCNP dose rate response functions for the nominal pre-shipment and HAC cases are used to determine the maximum HAC dose rate that would correspond to an RR shipment with the maximum pre-shipment dose rates allowed by §71.47. The results are shown in Table 5-9. At every energy investigated, the source density that would produce a maximum allowable pre-shipment dose rate would produce a peak HAC dose rate less than one-third of the §71.51 limit. Thus any shipment that passes the pre-shipment survey cannot exceed the §71.51 limits under HAC. Since additional margins are placed on the pre-shipment measurements (Section 5.9.6), there is additional conservatism beyond these results.

The results of the NCT evaluation show that the difference between nominal pre-shipment conditions and NCT produces an increase of at most 3% for dose rates in the governing locations. The evaluation confirms that the 5% margins allotted on the pre-shipment measurements (Section 5.9.6) to account for the difference between nominal and NCT conditions is adequate to assure that NCT dose rates would meet the requirements of §71.47.

Table 5-9– 8-120B-3 HAC Results

Energy (MeV)	1-meter HAC Dose Rate for RR With Maximum Allowable Pre-shipment Dose Rate (mrem/hr)
0.5	307
0.7	294
0.9	289
1.17	289
1.5	250
1.83	203
2.25	191
2.75	193
3.5	214
5.0	253
⁶⁰ Co	291
¹³⁷ Cs	301
Limit	1000

5.9.5 8-120B-3 PAYLOAD QUALIFICATION

Radiological qualification of RR shipments made under Loading Specification 8-120B-3 are based on pre-shipment measurements performed in accordance with the requirements in Section 5.9.6 below.

5.9.6 8-120B-3 PRE-SHIPMENT MEASUREMENT REQUIREMENTS

5.9.6.1 Pre-shipment Measurements Scope

Reformed Residue (RR) shipments made using Loading Specification 8-120B-3 shall be accompanied by pre-shipment dose rate surveys performed and documented using written, approved procedures that satisfy the requirements specified herein. Surveys that meet these requirements are suitable to demonstrate that external radiation levels for NCT around the package and vehicle will not exceed the limits specified in 10CFR71.47, as required by 10CFR71.87(j). In addition, comprehensive surveys meeting these requirements are suitable as the sole method of demonstrating that the shipment complies with 10CFR71.47(b) under NCT.

Compliance with the requirements of 10CFR71.51(a)(2) under HAC is demonstrated by analysis in Section 5.9.4.

RR may also be shipped under the more general Loading Specification 8-120B-1, in which case pre-shipment surveys may be performed in accordance with other site procedures for pre-

shipment surveys. Loading Specification 8-120B-1 relies on calculations described in Section 5.7 to demonstrate compliance with 10CFR71.47(b), and therefore the purpose of the pre-shipment survey is confirmatory per 10CFR71.87(j).

These requirements apply to the pre-shipment radiation measurements only. Other routine determinations, as specified by 10CFR71.87, are made in accordance with existing site procedures.

5.9.6.2 Pre-Shipment Survey Requirements

Surveys shall be performed after the package is loaded and prepared for transport in accordance with the package loading procedures.

Instrumentation for radiological monitoring shall be selected based on the type of radiation expected, type of measurement required, maintenance and calibration requirements, limits of detection, ruggedness, and versatility.

Instruments shall be calibrated in accordance with written procedures that conform to a national standard, such as American National Standard ANSI N323, "Radiation Protection Instrumentation Test and Calibration". Instrument calibration shall be performed on an established frequency, to known radiation sources traceable to the National Institute of Standards and Technology. Only instruments with a current calibration label shall be used for making measurements. Instruments suspected of damage or exhibiting poor performance shall be removed from service and tagged pending repair or re-calibration. Instrument calibrations shall be performed before first use, following any major maintenance or modifications that could affect calibration, and after any failure of a source response test.

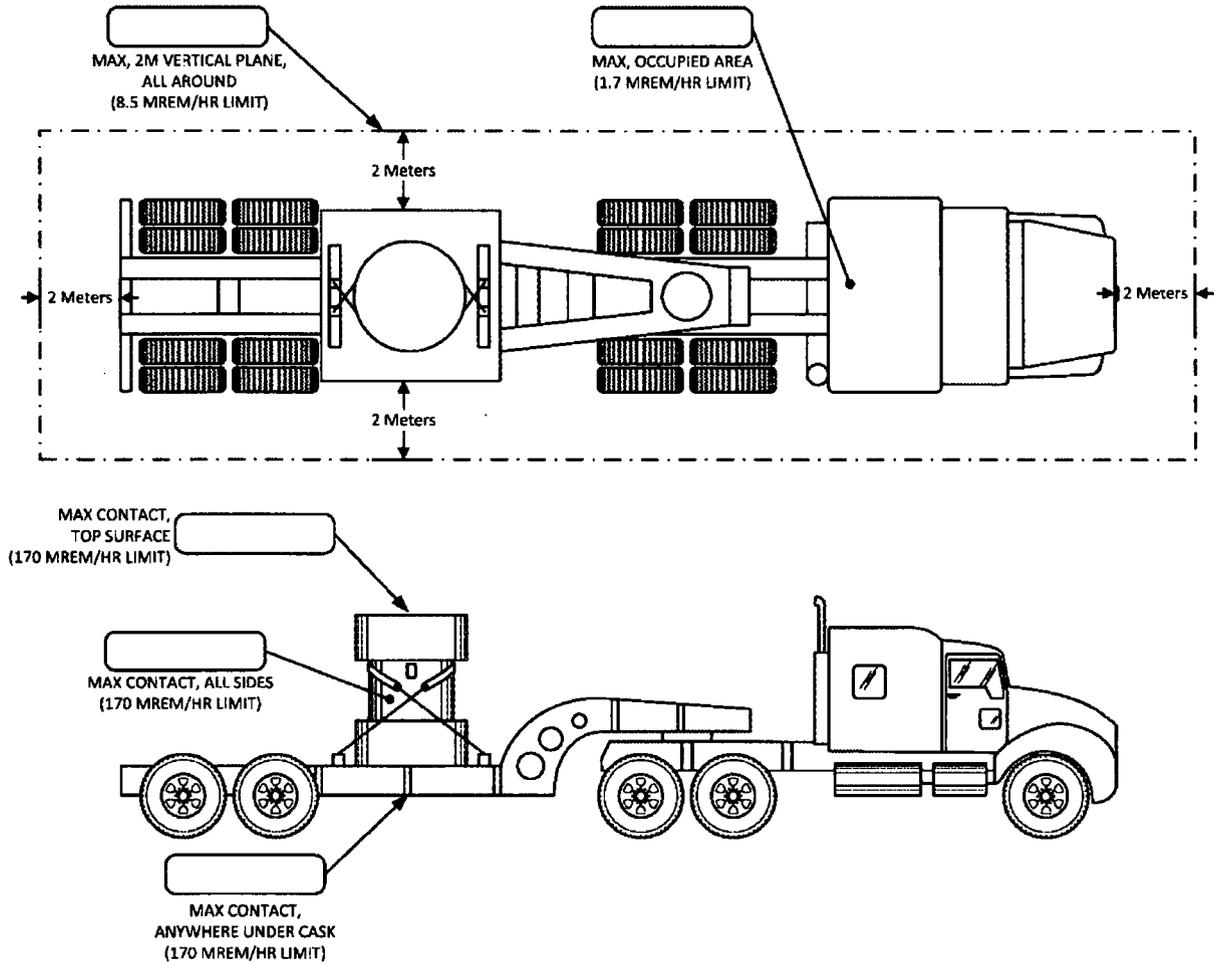

Radiological instrumentation shall be set up, checked, and operated by qualified personnel. Field instruments shall be battery tested and response checked daily prior to initial use.

5.9.6.3 Pre-Shipment Survey Procedure

- 1) Ensure that survey instruments are calibrated, response checked, and in proper working order.
- 2) Perform surface dose rate surveys by scanning all external surfaces of the package as shown in Figure 5-6. Surface dose rate surveys shall be performed by slowly moving the probe at a rate compatible with the detector response capability (e.g., 1 to 2 inches per second) over the package surfaces. Record the peak package surface survey result on the survey form from the approved survey procedure.
- 3) Perform surveys of the occupied areas of the vehicle as shown in Figure 5-6. Record the peak occupied area survey result on the survey form from the approved survey procedure.
- 4) Perform dose rate surveys of the 2-meter vertical planes as shown in Figure 5-6. 2-meter dose rate survey measurements may be taken by hand to quickly determine the approximate location of the peaks, but shall be taken slowly moving the probe at a rate compatible with the detector response capability (e.g., 1 to 2 inches per second) to determine the peak dose rates. Peak dose rates shall be measured using a verified 2-meter stick or other reliable device for assuring that measurements are taken on the vertical 2 meter plane from the edge

of the vehicle as shown in Figure 5-6. Record the peak 2-meter surface survey result on the survey form from the approved survey procedure.

- 5) Review survey results to determine compliance with the limits shown in Figure 5-6. The dose rate limits have been reduced from the regulatory limits in Section 5.1 by 15% as additional margin to account for measurement uncertainty in the instrumentation plus the small difference between the package in its pre-shipment condition vs. the normal condition of transport specified in 10 CFR 71. Payloads exceeding the limits shown in Figure 5-6 are not suitable for shipment. If the occupied space dose rate exceeds the limit shown in Figure 5-6 while all other measurements are within limits, then the shipment may proceed if personnel who are in the occupied space are private carriers who wear radiation dosimetry devices in conformance with 10 CFR 20.1502.

Note: Dose rate limits shown are 15% lower than regulatory dose rate limits to account for measurement uncertainty and potential changes between nominal package preshipment and NCT conditions.

Figure 5-6 - Loading Specification 8-120B-3Package Dose Rate Measurement Locations

5.10 LOADING SPECIFICATION 8-120B-4 (RESINS AND FILTER MEDIA)

5.10.1 LOADING SPECIFICATION 8-120B-4 DESCRIPTION

Loading Specification 8-120B-4 applies to resins and filter media such as ion-exchange resin beads, charcoal (carbon) filter media and zeolite, which are shipped in the 8-120B cask inside a secondary container such as a steel liner or polymer high integrity container (HIC). These common payloads, and have been safely shipped in the 8-120B for decades. Loading Specification 8-120B-4 does not apply to filter assemblies, because of the assumptions in the shielding models. Filter assemblies should be shipped instead using Loading Specification 8-120B-1.

Under some circumstances, it may be desirable to include payload items in a shipment made under Loading Specification 8-120B-4 that are acceptable per the contents description in the Certificate of Compliance, but differ from the payload materials described above. It is acceptable to combine the fractions of allowables from Loading Specifications 8-120B-4 (for the above resin and filter media materials) and 8-120B-1 (for other items) if the sum remains less than 0.95. This is appropriate since the fractions represent fractions of regulatory dose rate limits at the worst-case location and so it is either equivalent or conservative to combine the fractions.

Radiological source term limits are specified in terms of gamma source density ($\gamma/\text{sec}\cdot\text{g}$) as a function of gamma energy. Limits are determined for a set of ten gamma energies, ranging from 0.5 MeV to 5.0 MeV. Specific gamma source density limits are also determined for the ^{60}Co and ^{137}Cs isotopes, which are often the dominant isotopes in plant resins and filter media. The source limits ensure that the package will meet the external radiation requirements specified by 10CFR71.47 and 10CFR71.51, as demonstrated by the shielding analyses.

The specifications for the payload, secondary containers, and other restrictions are summarized in Table 1-2. Table 1-2 requires that, in order to use Loading Specification 8-120B-3, the payload must be in a steel or polymer secondary container. Allowable source terms are presented in Section 5.10.3.4, and the procedure for performing the payload radiological qualification is in Section 5.10.4.

5.10.2 8-120B-4 SOURCES

5.10.2.1 Gamma Source

For all MCNP models, the gamma source strength is set to 1.0 γ/s . The result of each analysis is the dose response (i.e., mrem/hr per γ/s in the source zone) at each evaluated dose location. Using the response functions, the limiting gamma source strength can be calculated at which one or more regulatory dose rate limits is reached.

Ten gamma energies (listed in Table 5-11) are evaluated, along with ^{60}Co and ^{137}Cs . Each analysis models a mono-energetic gamma source (with the exception of the Co-60 case, which models two gamma energies). The ^{137}Cs source includes an equilibrium amount of $^{137\text{m}}\text{Ba}$. The gamma energy modeled for the ^{137}Cs case is 0.662 MeV. For ^{60}Co , the modeled gamma energies are 1.176 MeV and 1.333 MeV (0.5 γ/s modeled at each energy).

5.10.2.2 Neutron Source

Loading Specification 8-120B-4 does not allow shipment of significant neutron sources. Neutron sources in the 8-120B cask are discussed in Section 5.2.2.

5.10.2.3 Beta Source

Typical resin and filter media shipments do not have significant amounts of beta emitters; and so beta sources have not been included in the 8-120B-4 shielding analysis. Section 5.7.5 discusses when beta emitting sources are considered significant as 8-120B payloads. Resins and filter media with significant bremsstrahlung radiation potential should be qualified using Loading Specification 8-120B-1, either in total, or by using Loading Specification 8-120B-4 in conjunction with the particular beta-emitting payload item using the sum-of-fractions approach described in Section 5.10.1.

5.10.3 8-120B-4 MODEL SPECIFICATION

5.10.3.1 Configuration of Source and Shielding

5.10.3.1.1 *Normal Conditions of Transport (NCT)*

The basic NCT model is described in Section 5.3.1.1. For the 8-120B-4 NCT shielding evaluation, the secondary container is conservatively modeled as a polyethylene HIC with 0.4 inch thick side, top and bottom walls. The polyethylene material is modeled in contact with the side, top and bottom surfaces of the 8-120B cask cavity (thus conservatively maximizing the volume of the modeled waste material).

A uniform mass of payload source material is modeled filling the entire cavity of the secondary container. A uniformly-distributed gamma source (at the evaluated energy) is modeled throughout the source region volume.

Pure carbon at a density of 2.3 g/cc is modeled throughout the secondary container interior. The modeled waste material is an upper bound density for resins and filter media payloads.

Scoping analyses show that modeling a maximum payload material density yields bounding values for allowable source density. Comparison of full-cask-cavity and reduced-volume payload results shows that filling the entire payload cavity with waste material bounds any configurations where the payload occupies any portion of the secondary container/cask interior cavity volume. Shielding evaluations also show that allowable source densities calculated for a carbon waste material are bounding for the other materials discussed in Section 5.10.1 (polystyrene ion-exchange resin beads and zeolite), as well as water.

5.10.3.1.2 *Hypothetical Accident Conditions (HAC)*

The basic HAC model is described in Section 5.3.1.2. The gamma source is modeled as a uniform, distributed source completely filling the cask cavity. The secondary container is conservatively neglected in the HAC shielding analysis since they have not been demonstrated to

remain undamaged in the HAC. The waste material is modeled as pure carbon at a density of 2.3 g/cc.

5.10.3.2 Material Properties

In addition to the materials in Table 5-2, the models for Loading Specification 8-120B-4 included the secondary container wall material and waste material described in Table 5-10.

Table 5-10- Material Composition and Density

Material	Total Density (g/cc)	Composition	MCNP ZAID
Waste Material (carbon)	2.3	100.00% C	6000.84p
Polyethylene	0.93	14.37% H 85.63% C	1000.84p 6000.84p

5.10.4 8-120B-4 SHIELDING EVALUATION

5.10.4.1 Methods

The NCT and HAC models are run parametrically across energies ranging from 0.5-5.0 MeV plus ⁶⁰Co and ¹³⁷Cs energies.

Shielding calculations are performed using MCNP Version 5, revision 1.51. Source biasing and geometry splitting are used to improve the convergence rate of the problems. The number of histories executed in a typical run is on the order of 10⁸-10⁹. The variance reduction techniques applied in the models are conservative and the computer runs are well-converged, as shown by the MCNP figure of merit stability and other statistical checks

Tally relative errors are less than 1.0% at controlling dose locations. The statistical uncertainties in the MCNP tallies were not added to the MCNP responses. Analysis uncertainties, as well as any (very small) dose rate contributions from beta or neutron sources, are addressed through the use of an applied 5% margin (discussed in Section 5.10.4).

5.10.4.2 Input and Output Data

Reference 5.6.8 describes the MCNP input and output files. The input file lists the inputs that define the source dimensions, shield dimensions, materials and density, and source spectrum.

5.10.4.3 Flux-to-Dose-Rate Conversion

ANSI/ANS-6.1.1 1977 flux-to-dose-rate conversion factors were used as described in Section 5.4.3.

5.10.4.4 External Radiation Levels and Source Strength Limits

The MCNP response functions for the bounding configurations are compared to the external radiation limits allowed for the various compliance locations identified in §71.47 and §71.51. The governing location is used to calculate the source limits. The final results of the shielding evaluation are the limits on payload gamma source density ($\gamma/\text{sec}\cdot\text{g}$), which vary as a function of gamma energy. These limits are presented in Table 5-11. The sum of fractions of these limits must be less than or equal to 0.95.

Table 5-11– 8-120B-4 Gamma Source Density Limits

Energy (MeV)	Maximum Gamma Source Density ($\gamma/\text{sec}\cdot\text{g}$)
0.5	1.473E+09
0.7	2.228E+08
0.9	6.616E+07
1.17	1.981E+07
1.5	5.978E+06
1.83	2.444E+06
2.25	1.203E+06
2.75	7.078E+05
3.5	4.365E+05
5.0	2.588E+05
⁶⁰ Co	1.457E+07
¹³⁷ Cs	3.020E+08

The gamma source density limits shown in Table 5-11 are valid for ion-exchange resin beads, charcoal filter media, and zeolite in any proportion with any degree of water content.

The limits on gamma source density apply to the most activated portion of the waste material.

5.10.5 8-120B-4 PAYLOAD QUALIFICATION

In order to qualify the radioactive source term for contents to be shipped under Loading Specification 8-120B-4:

1. For each gamma energy produced by the waste material, look up the allowable gamma source density from Table 5-11.
2. Determine the highest source density that occurs anywhere within the payload, for the gamma energy in question.

3. Divide the maximum gamma source density by the corresponding Table 5-11 limit, to yield a fraction value for the gamma energy level in question.
4. Repeat the above process for all gamma energy levels present in the payload, treating ^{60}Co and ^{137}Cs gamma sources as separate, specific gamma energies, with their own corresponding source density limits (presented in Table 5-11).
5. Sum the fraction values over all the gamma energy levels to yield an overall fraction value. If this value is ≤ 0.95 , the HIC contents are acceptable for shipment in the 8-120B cask.
6. If any payload materials or items other than those discussed in Section 5.10.1 are present within the HIC, determine the sum-of-fractions for those items using Loading Specification 8-120B-1, and add it to the sum-of-fractions determined for the qualified contents under Loading Specification 8-120B-4. The HIC contents are acceptable if the combined sum is ≤ 0.95 .

6.0 CRITICALITY EVALUATION

Not applicable to the 8-120B package.

This page intentionally blank.

7.0 OPERATING PROCEDURE

This chapter describes the general procedure for loading and unloading of the 8-120B Cask.

The maximum permissible activity is the lesser of the activity determined by: 1) the source limits from the appropriate Loading Specification section in Chapter 5, 2) 3000 A₂, or 3) having a decay heat of 200 watts. Radioactive contents are to be transported as exclusive use, per 10 CFR 71.4.

For contents that could radiolytically generate combustible hydrogen, see Attachment 2 for instructions on determination of hydrogen concentration.

Powdered solids shipments require that the most recent periodic leak test meets the requirements of Section 8.3.2.1 for leaktight status.

7.1 LOADING THE PACKAGING

NOTE: Prior to loosening the impact limiter ratchet binders, inspect the exterior of the package for damage, e.g., large dents, gouges, tears to the impact limiter skin and thermal shield. Contact EnergySolutions if damage is present. The cask may not be used as a Type B package until the damage is assessed by EnergySolutions and repairs, if required, are made to achieve conformance with the drawings listed in the CoC.

7.1.1 Impact Limiter Removal

7.1.1.1 Loosen and disconnect ratchet binders from upper impact limiter.

7.1.1.2 Using suitable lifting equipment, remove upper impact limiter assembly. Care should be exercised to prevent damage to impact limiter during handling and storage.

7.1.2 Secondary Lid Thermal Shield Removal

7.1.2.1 Remove the ball lock pins from each of the three retaining pins and remove the retaining pins from secondary lid lift lugs.

7.1.2.2 Using suitable lifting equipment, remove the secondary lid thermal shield. Care should be taken to prevent damage to thermal shield during handling and storage.

7.1.3 Determine if cask must be removed from trailer for loading purposes. To remove cask from trailer:

7.1.3.1 Disconnect cask to trailer tie-down equipment.

7.1.3.1.1 Inspect cask lifting ear bolts for defects. Obtain replacement bolts as specified on the drawing listed in 5(a)(3) of the CoC for any bolts that show cracking or other visual signs of distress.

7.1.3.1.2 Inspect cask lifting ear threaded holes for defects. Contact *EnergySolutions* if any bolt holes show signs of cracking or visual signs of distress.

7.1.3.2 Attach cask lifting ears and torque bolts to 200 ft-lbs. \pm 20 ft-lbs. lubricated.

NOTE: The cables used for lifting the cask must have a true angle, with respect to the horizontal of not less than 60°.

7.1.3.3 Using suitable lifting equipment, remove cask from trailer and the lower impact limiter and place cask in level loading position.

NOTE: In certain circumstances, loading may be accomplished through the secondary lid, into a pre-positioned waste liner that has been properly shored or into pre-positioned shoring, while the primary lid remains on the cask. Alternate "(A)" steps have been included to accommodate this situation.

7.1.4 Loosen and remove the twenty (20) bolts, which secure the primary lid to cask body.

7.1.4A Loosen and remove the twelve (12) bolts, which secure the secondary lid to the primary lid.

7.1.5 Inspect the bolts for defects. Obtain replacement bolts as specified on the drawing listed in 5(a)(3) of the CoC for any bolts that show cracking or other visual signs of distress.

NOTE: The cables used for lifting either lid must have a true angle, with respect to the horizontal, of not less than 45°.

7.1.6 Remove primary lid from cask body using suitable lifting equipment. Care should be taken during lid handling operations to prevent damage to cask or lid seal surfaces.

7.1.6A Remove secondary lid from cask body using suitable lifting equipment. Care should be taken during lid handling operations to prevent damage to cask or lid seal surfaces.

7.1.7 Inspect the bolts holes for defects. Contact *EnergySolutions* for any bolt holes that show signs of cracking or visual signs of distress.

- 7.1.8 Inspect cask interior for damage, loose materials or moisture. Clean and inspect seal surfaces. Replace seals when defects or damage is noted which may preclude proper sealing. Contact EnergySolutions if damage is present.
- NOTE: Radioactively contaminated liquids may be pumped out or removed by use of an absorbent material. Removal of any material from inside the cask shall be performed under the supervision of qualified health physics personnel with the necessary H.P. monitoring and radiological health safety precautions and safeguards.**
- NOTE: When seals are replaced, leak testing is required as specified in Section 8.3.2.1.**
- NOTE: Verify intended contents meet the requirements of the Certificate of Compliance.**
- NOTE: Ensure the contents, secondary container, and packaging are chemically compatible, i.e., will not react to produce flammable gases.**
- 7.1.9 Place disposable liner, drums or other containers into the pre-positioned shoring and install additional shoring or bracing, if necessary, to restrict movement of contents during normal transport.
- 7.1.9A Process liner as necessary, and cap using standard capping devices. Provide shoring if necessary to limit movement during transport, or if required by the Loading Specification restrictions in Table 1-2.
- 7.1.10 Perform two independent physical verifications of the secondary container's closure system to ensure that it is properly closed and secured. This requirement is waived⁴ for uniformly distributed resins, filters, and for solidified wastes with no dimension less than 1 cm.
- 7.1.11 Clean and inspect lid seal surfaces.
- 7.1.12 Replace the primary lid on the cask body. Secure the lid by hand tightening the twenty (20) primary lid bolts.
- 7.1.12.1 Torque, using a star pattern, the twenty (20) primary lid bolts (lubricated) to 250 ft-lbs. \pm 25 ft-lbs.

⁴ The basis for double verification is to assure that small, high-specific activity particles do not have the potential to migrate up into the annular gap between the primary lid and the cask bolting flange. Payloads containing any form of isotope sources, or containing highly activated fines, swarf, crud, or other hot particles less than 1 cm in size are therefore not exempt.

- 7.1.12.2 Re-Torque, using a star pattern, the twenty (20) primary lid bolts (lubricated) to 500 ft-lbs. \pm 50 ft-lbs.
- 7.1.12A Replace the secondary lid on the primary lid. Secure the lid by hand tightening the twelve (12) secondary lid bolts.
 - 7.1.12.1A Torque, using a star pattern, the twelve (12) secondary lid bolts (lubricated) to 250 ft-lbs. \pm 25 ft-lbs.
 - 7.1.12.2A Re-torque, using a star pattern, the twelve (12) secondary lid bolts (lubricated) to 500 ft-lbs. \pm 50 ft-lbs.
- 7.1.13 Replace the vent port cap screw and seal (if removed) and torque to 20 ft-lbs. \pm 2 ft-lbs.
- 7.1.14 Leak test the primary lid and secondary lid O-rings and the vent port, in accordance with Section 8.3.2.2, prior to every shipment.⁵
- 7.1.15 If cask has been removed from trailer, proceed as follows to return cask to trailer:
 - 7.1.15.1 Using suitable lifting equipment, lift and position, cask into lower impact limiter on trailer in the same orientation as removed.
 - 7.1.15.2 Unbolt and remove cask lifting ears.
 - 7.1.15.3 Reconnect cask to trailer using tie-down equipment.
- 7.1.16 Installation of Upper Impact Limiter and Secondary Lid Thermal Shield
 - 7.1.16.1 Using suitable lifting equipment, lift, inspect for damage and install the secondary lid thermal shield.
 - 7.1.16.2 Install the three secondary lid thermal shield retaining pins into the secondary lid lift lugs and insert the ball lock pins into the retaining pins.
 - 7.1.16.3 Using suitable lifting equipment, lift, inspect for damage and install upper impact limiter on cask in the same orientation as removed.

⁵ The pre-shipment leak test of the primary lid, secondary lid, and vent port seals is required before every 8-120B cask shipment, even if the lid bolts or vent port socket head cap screw have not been loosened during loading operations. This requirement is necessary to assure that the 8-120B cask containment system is properly assembled prior to every shipment since it should not be assumed that the containment system is properly assembled prior to loading operations.

- 7.1.17 Attach and hand tighten ratchet binders between upper and lower impact limiter assemblies.
- 7.1.18 Cover lift lugs as required.
- 7.1.19 Inspect package for proper placards and labeling.
- 7.1.20 Complete required shipping documentation.
- 7.1.21 Prior to shipment of a loaded package, the following shall be confirmed:
 - 7.1.21.1 That the licensee who expects to receive the package containing materials in excess of Type A quantities specified in 10 CFR 20.1906(a) meets and follows the requirements of 10 CFR 20.1906, as applicable.
 - 7.1.21.2 That trailer placarding and package labeling meet DOT specifications (49 CFR 172).
 - 7.1.21.3 That the provisions of 10 CFR 71.87 are met, including radiation surveys performed in accordance with §71.87(j) to determine that the external radiation dose rates will not exceed the applicable limits of §71.47. These surveys should be sufficient to ensure that a non-uniform distribution of radioactivity does not cause the surface or 2m limit to be exceeded. For shipments made under Payload Specification 8-120B-3 (for reformed residue) pre-shipment dose rate measurements shall be performed in accordance with the requirements of Section 5.9.6.

The SAR thermal analysis demonstrates that by meeting the 200w decay heat limit, the temperature requirement of 10 CFR 71.43(g) is met. No temperature survey is required.
 - 7.1.21.4 That all security seals are properly installed.
 - 7.1.21.5 Prior to shipping a loaded package, inspect the exterior of the cask for damage, e.g., large dents, gouges, tears to the impact limiter skin and thermal shield. Contact EnergySolutions if damage is present.
 - 7.1.21.6 Prior to shipping a loaded package, confirm that the periodic leak test described in Section 8.3.2.1 has been performed. For shipments of powdered radioactive materials, confirm that most recent periodic leak test of the 8-120B demonstrated leaktight status.

7.2 UNLOADING THE PACKAGE

In addition to the following sequence of events for unloading a package, packages containing quantities of radioactive material in excess of Type A quantities specified in 10 CFR 20.1906(a) shall be received, monitored, and handled by the licensee receiving the package in accordance with the requirements of 10 CFR 20.1906, as applicable. Identification of packages containing greater than Type A quantities can be made by review of the shipping papers accompanying the shipment.

- 7.2.1 Move the unopened package to an appropriate level unloading area.
- 7.2.2 Perform an external examination of the unopened package. Record any significant observations.
- 7.2.3 Remove security seal(s), as required.
- 7.2.4 Impact Limiter Removal
 - 7.2.4.1 Loosen and disconnect ratchet binders from upper impact limiter.
 - 7.2.4.2 Using suitable lifting equipment, remove upper impact limiter assembly. Care should be exercised to prevent damage to impact limiter during handling and storage.
- 7.2.5 Secondary Lid Thermal Shield Removal
 - 7.2.5.1 Remove the ball lock pins from each of the three retaining pins and remove the retaining pins from secondary lid lift lugs.
 - 7.2.5.2 Using suitable lifting equipment, remove the secondary lid thermal shield. Care should be taken to prevent damage to thermal shield during handling and storage.
- 7.2.6 If cask must be removed from trailer, refer to Step 7.1.3.
- 7.2.7 Loosen and remove the twenty (20) primary lid bolts.

NOTE: The cables used for lifting the lid must have a true angle with respect to the horizontal of not less than 45 degrees.

- 7.2.8 Using suitable lifting equipment, lift lid from cask using care during handling operations to prevent damage to cask and lid seal surfaces.
- 7.2.9 Remove contents.

NOTE: Radioactively contaminated liquids may be pumped out or removed by use of an absorbent material. Removal of any material from inside the cask shall be performed under the supervision of qualified health physics personnel with the

necessary H.P. monitoring and radiological health safety precautions and safeguards.

- 7.2.10 Assemble packaging in accordance with loading procedure (7.1.10 through 7.1.19).

7.3 PREPARATION OF EMPTY PACKAGING FOR TRANSPORT

- 7.3.1 Confirm the cavity is empty of contents as far as practicable
- 7.3.2 Survey the interior; decontaminate the interior if the limits of 49 CFR 173.428(d) are exceeded
- 7.3.3 Install the lid.
- 7.3.4 Install the lid closure bolts.
- 7.3.5 Torque, using a star pattern, the twenty (20) primary lid bolts (lubricated) to 250 ft-lbs. \pm 25 ft-lbs.
- 7.3.6 Re-Torque, using a star pattern, the twenty (20) primary lid bolts (lubricated) to 500 ft-lbs. \pm 50 ft-lbs.
- 7.3.7 Re-install the vent port cap screw with the seal. Torque the vent port cap screw to 20 \pm 2 ft-lbs.
- 7.3.8 Decontaminate the exterior surfaces of the package as necessary.
- 7.3.9 Inspect the exterior and confirm it is unimpaired.
- 7.3.10 Using suitable lifting equipment, lift, inspect for damage and install the secondary lid thermal shield.
- 7.3.11 Install the three secondary lid thermal shield retaining pins into the secondary lid lift lugs and insert the ball lock pins into the retaining pins.
- 7.3.12 Using suitable lifting equipment, lift, inspect for damage and install upper impact limiter on cask in the same orientation as removed
- 7.3.13 Attach the tamper-indicating seals.
- 7.3.14 Confirm the requirements of 49 CFR 173.428 are met.

Attachment 1
(Reserved)

|

Attachment 2
Determination of Hydrogen Concentration

1. Determine the radionuclide concentration in the contents.

For any package containing materials with radioactivity concentration not exceeding that for LSA, ensure the shipment occurs within 10 days of preparation, or within 10 days of venting the secondary container.

For packages which satisfy the previous conditions, go to step 11, otherwise continue with step 2.

2. Determine the secondary package(s) void volume and the cask cavity void volume.
3. Identify the secondary container(s) vent path, if applicable
4. Determine the quantity of hydrogenous contents
5. Determine the G value of the hydrogenous contents per NUREG/CR-6673⁹, Section 3.
6. Determine the energy deposition rate in the hydrogenous contents
7. Determine the hydrogen generation rate per NUREG/CR-6673, Section 4.2
8. Determine the effective hydrogen transport rate due to diffusion for the vent path; see NUREG/CR-6673, Section 4.1
9. Determine the shipping time to reach a hydrogen concentration of 5% in the package; see NUREG/CR-6673, Section 4.2.2.1 and Appendix F, Example #4.
10. If the time to reach 5% concentration is more than double the expected shipping time, the shipment meets the hydrogen concentration requirement.
11. Authorize the shipment

⁹B. L. Anderson et al. *Hydrogen Generation in TRU Waste Transportation Packages*, NUREG/CR-6673, Lawrence Livermore National Laboratory, Livermore, CA, February 2000

This page intentionally blank.

8.0 ACCEPTANCE TESTS AND MAINTENANCE PROGRAM

Acceptance tests for Configurations 1 and 2 have different weld examination and leak tests than Configuration 3. Maintenance is the same for all configurations. Any reference to drawings, either in general or by specific number, means the drawings listed in the CoC.

8.1 ACCEPTANCE TESTS – CONFIGURATIONS 1 AND 2 (CASKS FABRICATED BEFORE APRIL 1, 1999)

Prior to the first use of the 8-120B package fabricated to Configuration 1 or 2, the following tests and evaluations will be performed.

8.1.1 VISUAL EXAMINATION

The package will be examined visually for any adverse conditions in materials or fabrication. Welds shall be examined for compliance to the drawings. Weld integrity shall be verified by visual examination and magnetic particle or dye penetrant. NDE examinations shall be performed by an ASME Certified inspector. Acceptance criteria for NDE shall be according to ASME Code Section III, Div. 1-Section NB5342 or NB5352 as applicable.

8.1.2 STRUCTURAL TESTS

No structural testing is required.

8.1.3 LEAK TESTS

This test shall be performed prior to acceptance and operation of a newly fabricated package in accordance with ASTM E-427 using a leak detector capable of detecting the applicable leak rates specified in Figures 4-4 and 4-7 in Chapter 4. Calibration of the leak detector shall be performed using a leak rate standard traceable to NIST. The standard's setting shall correspond to the approved leak rates specified in Figures 4-4 and 4-7 in Chapter 4.

All four containment boundary penetrations must be tested.

- The volume above the vent port Stat-O-Seal
- The volume between the drain line plug and interior of the cask
- The annulus between the o-ring seals of the primary lid
- The annulus between the o-ring seals of the secondary lid

All four of these volumes must be evacuated to a minimum vacuum of 20" Hg, and then be pressurized to a minimum pressure of 25 psig with pure dichlorodifluoromethane (R-12) or 1,1,1,2 – tetrafluoroethane (R-134a). Use the detector probe to "sniff" the following areas:

- The vent port penetration on the underside of the primary lid
- Around the outer plug of the drain line
- Interior side of the inner o-ring for the primary lid

- Interior side of the inner o-ring for the secondary lid

Leak detection shall be in accordance with the specifications of ASTM E-427.

Any condition, which results in leakage in excess of the applicable values specified in Figures 4-3 and 4-6 in Chapter 4 shall be corrected.

8.1.4 COMPONENT TESTS

Gaskets and seals will be procured and examined in accordance with the *EnergySolutions* Quality Assurance Program.

8.1.5 TEST FOR SHIELDING INTEGRITY

Shielding integrity of the package will be verified by gamma scan or gamma probe methods to assure the package is free of significant voids in the poured lead shield annulus. All gamma scanning will be performed on a 4-inch square or less grid system. The acceptance criteria will be that voids resulting in shield loss in excess of 10 % of the normal lead thickness in the direction measured shall not be acceptable. Remedy for an unacceptable gamma scan include actions such as controlled re-heating of the cask body to melt the lead to remove any voids or streaming paths. This process may be used as long as average metal temperatures are kept below ~800°F. If the remedy could affect more than just the unacceptable area, e.g., re-heating of the cask body, all affected portions will be re-scanned.

8.1.6 THERMAL ACCEPTANCE TESTS

No thermal acceptance testing will be performed on the 8-120B package. Refer to the Thermal Evaluation, Chapter 3.0 of the report.

8.2 ACCEPTANCE TESTS – CONFIGURATION 3 (CASKS FABRICATED AFTER APRIL 1, 1999)

Prior to the first use of an 8-120B package fabricated to Configuration 3, the following tests and evaluations will be performed:

8.2.1 VISUAL INSPECTIONS AND MEASUREMENTS

Throughout the fabrication process, confirmation by visual examination and measurement are required to be performed to verify that the 8-120B packaging dimensionally conforms to the drawing referenced in the current Certificate of Compliance for the 8-120B.

The packaging is also required to be visually examined for any adverse conditions in materials or fabrication that would not allow the packaging to be assembled and operated per Section 7.0 or tested in accordance with the requirements of Section 8.0.

Throughout the fabrication process, the fabricator shall request approval from *EnergySolutions* prior to implementation of any options allowed in the drawing.

8.2.2 WELD EXAMINATIONS

8.2.2.1 All welding of the Containment Boundary identified on drawing C-110-E-0007 will be done in accordance with ASME Code, Section III, Division I, Subsection ND, except as follows:

- a. Due to the geometry of the joint configuration, between Item 17 and 18, NDE of the ¾" bevel groove weld and the 1" bevel groove weld may be done by progressive surface examination utilizing the MT method in lieu of RT or UT.
- b. Due to the geometry of the joint configuration, between Item 3 and 5A, NDE of the ¾" v groove weld may be done by progressive surface examination utilizing the MT method in lieu of RT or UT.
- c. Due to the geometry of the joint configuration, between Item 3 and 4, NDE of the ¾" v groove weld may be done by utilizing the UT + MT methods in lieu of RT.

8.2.2.2 All welding of Non-Containment Boundary items identified on drawing C-110-E-0007 will be done in accordance with ASME Code, Section III, Division I, Subsection NF (Class 3), except as follows:

- a. The Root Pass and the Final Pass of the v groove weld between Item 5A, Cask Bottom Plate and Item 5B, Cask Bottom Plate Outer Ring, shall be done in accordance with ASME Code, Section III, Division I, Subsection NF-5230 by magnetic particle examination (MT) with acceptance requirements of ASME Code, Section III, Division I, Subsection NF, Article NF-5340.
- b. The Root Pass and the Final Pass of the bevel groove weld between Item 5B, Cask Bottom Plate and Item 1, Outer Cask Shell, shall be done in accordance with ASME Code, Section III, Division I, Subsection NF-5230 by magnetic particle examination (MT) with acceptance requirements of ASME Code, Section III, Division I, Subsection NF, Article NF-5340.

8.2.2.3 Welding on lifting and tiedown lugs identified on drawing C-110-E-0007 will be done in accordance with ASME Code, Section III, Division I, Subsection NF (Class 3) and shall be inspected by magnetic particle examination (MT) with acceptance requirements of ASME Code, Section III, Division I, Subsection ND, Article ND-5340 or NF, Article NF-5340. Inspection shall be before and after 150% load test.

8.2.3 STRUCTURAL AND PRESSURE TESTS

A pressure test of the containment system will be performed as required by 10CFR71.85. As determined in Section 3.4.4, the maximum normal operating pressure for the cask cavity is 35 psig; therefore the minimum test pressure will be $1.5 \times 35 = 52.5$ psig. The hydrostatic test pressure will be held for a minimum of 10 minutes prior to initiation of any examinations. Following the 10 minute hold time, the cask body, lid and lid/body closure shall be examined for leakage. Any leaks, except from temporary connections, will be remedied and the test and inspection will be repeated. After depressurization and draining, the cask cavity and seal areas

will be visually inspected for cracks and deformation. Any cracks or deformation will be remedied and the test and inspection will be repeated.

8.2.4 LEAKAGE TESTS

8.2.4.1 General requirements

- Testing method – Per ANSI N-14.5 in accordance with ASTM E-427 if using a halogen leak detector or ASTM E-499 if using a helium leak detector.
- Test Sensitivity – the test method must be capable of meeting the appropriate sensitivity requirements specified in Figures 4-4 or 4-7 in Section 4.0. Calibration of the leak detector shall be performed using a leak rate standard traceable to NIST.
- The leak standard's setting shall correspond to the approved leak test rate (see Section 4.0).
- Any condition, which results in leakage in excess of the maximum allowable leak rate specified in Figures 4-3 or 4-6 (depending on the test gas used), shall be corrected and re-tested.

8.2.4.2 Testing of the entire containment boundary will be performed prior to lead pour to allow access to all containment welds. The containment boundary includes: the inner shell, the cask bottom base plate (BOM 5A), the bolting ring, the lids, the O-ring seal plates of both lids, the inner O-ring of both lids, and the vent port cap screw and its seal.

- (Optional) Insert the sealed metal cavity filler canister into the cask cavity. Verify the canister does not obstruct the vent penetration. The metal must be chemically compatible with the cask liner and the test gas.
- Assemble the cask lids per Section 7.1.
- Evacuate the cask cavity to 20" Hg vacuum, minimum (sealed metal cavity filler canister may be used within the cask cavity)
- Pressurize the cask cavity to a minimum pressure of:
 - 1) 25 psig with pure 1,1,1,2 – tetrafluoroethane (R-134a),
or
 - 2) 1 psig with pure helium.
- Check for leakage of the inner shell and base plate components
- Measure the leakage of the inner (containment) O-ring via the test port in each lid.
- Check for leakage at the vent port.

8.2.5 COMPONENT AND MATERIAL TESTS

EnergySolutions will apply its USNRC approved 10CFR71 Appendix B Quality Assurance Program, which implements a graded approach to quality based on a component's or material's importance to safety to assure all materials used to fabricate and maintain the 8-120B are

procured with appropriate documentation which meet the appropriate tests and acceptance criteria for packaging materials.

This includes as example:

- ASTM steel material used for shells, lids, bolts, etc. will comply with and meet ASTM manufacturing requirements.
- Containment seals will be made from elastomeric compounds that have been qualified using ES-C-038 (Reference 8.4.2), which includes requirements for hardness, low temperature compatibility, permeability, and temperature-pressure testing. Fabricated seals are suitable for use if the delivered seals are traceable to a batch of material manufactured under the same process as, and having the same chemical composition as, a qualified compound. Acceptance testing for containment seals will include hardness and low temperature compatibility testing on each batch of elastomer, plus dimensional inspections on each seal, all per the acceptance criteria in ES-C-038.
- The impact limiter foam will meet the requirements of ES-M-175 (Reference 8.4.1).

8.2.6 SHIELDING TESTS

Shielding integrity of the package will be verified by gamma scan to assure the package lead layer meets or exceeds the minimum thickness specified on the cask drawing. All gamma scanning will be performed on a 4-inch square or less grid system. The acceptance criteria (maximum dose rate value) will be determined by: Option 1) measurement of the maximum dose rate value using a test block, which has shield layers that replicate the cask geometry per the drawing, using the gamma scan source and reproducing the source/shield/detector geometry that will be used during the scan of the cask, or Option 2) calculation of the maximum dose rate value using detailed modeling software (MCNP or equivalent) incorporating the specific cask dimensions from the drawing and the source/shield/detector geometry applicable to the gamma scan. Any location on the cask which shows a gamma scan dose rate value greater than the maximum dose rate value will be identified as unacceptable. All unacceptable areas will be remedied and re-scanned. Remedy for an unacceptable gamma scan include actions such as controlled re-heating of the cask body to melt the lead to remove any voids or streaming paths. This process may be used as long as average metal temperatures are kept below ~800°F. If the remedy could affect more than just the unacceptable area, e.g., re-heating of the cask body, all affected portions will be re-scanned.

8.2.7 THERMAL TESTS

No thermal acceptance testing will be performed on the 8-120B packaging. Refer to the Thermal Evaluation, Section 3.0 of this report.

8.2.8 MISCELLANEOUS TESTS

No miscellaneous testing will be performed on the 8-120B packaging.

8.3 MAINTENANCE PROGRAM

EnergySolutions operates an ongoing preventative maintenance program for all shipping packages. The 8-120B package will be subjected to routine and periodic inspection and tests as outlined in this section and the approved procedure based on these requirements. Defective items are replaced or remedied, including testing, as appropriate.

Examples of inspections performed prior to each use of the cask include:

- Cask Seal Areas: O-rings are inspected for any cracks, tears, cuts, or discontinuities that may prevent the O-ring from sealing properly. O-ring seal seating surfaces are inspected to ensure they are free of scratches, gouges, nicks, cracks, etc. that may prevent the O-ring from sealing properly. Defective items are replaced or remedied, as appropriate and tested in accordance with Section 8.3.2.
- Cask bolts, bolt holes, and washers are inspected for damaged threads, severe rusting or corrosion pitting. Defective items are replaced or remedied, as appropriate.
- Lift Lugs and visible lift lug welds are inspected to verify that no deformation of the lift lug is evident and that no obvious defects are visible. Defective items are replaced or remedied, as appropriate and tested in accordance with Section 8.2.2.5.

8.3.1 STRUCTURAL AND PRESSURE TESTS

No routine or periodic structural or pressure testing will be performed on the 8-120B packaging.

8.3.2 LEAKAGE TESTS

8.3.2.1 Periodic and Maintenance Leak Test.

The 8-120B packaging shall have been leak tested as described below within the preceding 12-month period before actual use for shipment and after maintenance, repair (such as weld repair), or replacement of components of the containment system. Shipments of powdered radioactive materials shall be performed only when the most recent periodic leak test meets the requirements for leaktight status.

The 8-120B packaging seals shall have been replaced within the 12-month period before actual use for shipment.

General requirements

- Testing method – Per ANSI N-14.5 in accordance with ASTM E-427 if using a halogen leak detector or ASTM E-499 if using a helium leak detector.
- Test Sensitivity – the test method must be capable of meeting the appropriate sensitivity requirements specified in Figures 4-4 or 4-7 or 5.0×10^{-8} atm-cm³/sec for leaktight status. Calibration of the leak detector shall be performed using a leak rate standard traceable to NIST.
- The leak standard's setting shall correspond to the approved leak test rate (see Section 4.0). A maximum leak rate of 1.0×10^{-7} atm-cm³/sec of air is required leaktight status.

- Any condition, which results in leakage in excess of the appropriate maximum allowable leak rate specified in Figures 4-3, 4-6 or 1.0×10^{-7} atm-cm³/sec for leaktight status, shall be corrected and re-tested.

Testing of the Lids and Vent

- (Optional) Insert the sealed metal cavity filler canister into the cask cavity. Verify the canister does not obstruct the vent penetration. The metal must be chemically compatible with the cask liner and the test gas.
- Assemble the cask lids per Section 7.1.
- Evacuate the cask cavity to 20" Hg vacuum (minimum) or 90% vacuum for the leak tight test.
- Pressurize the cask cavity to the following pressure:
 - 1) 25psig (minimum) with pure 1,1,1,2 – tetrafluoroethane (R-134a),
or
 - 2) 1 psig (minimum) with pure helium (or 0 to 1 psig with pure helium for leaktight status).
- Measure the leakage of the inner (containment) O-ring via the test port in each lid.
- Measure the leakage of the vent port.

Testing of the Lids – Optional Method

- Assemble the cask lids per Section 7.1.
- Connect to the O-ring test port on the lid and evacuate the annulus between the cask lid O-rings to 20" Hg vacuum (minimum)
- Pressurize the O-ring annulus to a minimum pressure of 25psig with pure 1,1,1,2 – tetrafluoroethane (R-134a),
- Check for leakage of the inner (containment) O-ring by moving a detector probe along the interior surface of the inner seal according to the specifications of ASTM E-427.

Testing of the Vent – Optional Method

- Assemble the cask Vent Port Cap Screw and Seal per Section 7.1.
- With the vent port cover (Item 30) removed, connect to and evacuate the volume above (lid exterior) the Vent Port Cap Screw and Seal (Items 26 and 27) to 20" Hg vacuum (minimum)
- Pressurize the volume to a minimum pressure of 25psig with pure 1,1,1,2 – tetrafluoroethane (R-134a),
- Check for leakage of the Vent Port Cap Screw and Seal by moving a detector probe along the interior surface of the Primary Lid in the area of the vent port according to the specifications of ASTM E-427.

The requirements for Periodic and Maintenance Leak Testing of the 8-120B are summarized in Table 8-1.

Table 8-1 - Periodic and Maintenance Leak Test of 8-120B

Component	Test Gas	Max. Leak Rate ⁽¹⁾	Minimum Sensitivity ⁽¹⁾	Test Pressure	Procedure	Alternate Procedure
Lid	R-134a	Fig. 4.3	Fig. 4.4	Evacuate cask cavity to 20" Hg then pressurize to 25 psig.	After pressurizing the cask cavity with the test gas, check for gas leakage from the cask Lid inner O-ring using the cask Lid test port.	After pressurizing between the lid O-ring annulus with the test gas, check for gas leakage from the cask Lid inner O-ring using a detector probe.
	Helium	Fig. 4.6	Fig. 4.7	Evacuate cask cavity to 20" Hg, or 90% vacuum for the leak tight test, then pressurize to 1 psig.	After pressurizing the cask cavity with the test gas, check for gas leakage from the cask Lid inner O-ring using the cask Lid test port.	N/A
Vent Port	R-134a	Fig. 4.3	Fig. 4.4	Evacuate cask cavity to 20" Hg then pressurize to 25 psig.	After pressurizing the cask cavity with the test gas, check for gas leakage from the Vent Port and Seal.	After pressurizing the volume above the Vent Port Cap Screw and Seal with the test gas, check for gas leakage from the vent penetration on the inner side of the lid using a detector probe.
	Helium	Fig. 4.6	Fig. 4.7	Evacuate cask cavity to 20" Hg, or 90% vacuum for the leak tight test, then pressurize to 1 psig.	After pressurizing the cask cavity with the test gas, check for gas leakage from the Vent Port Cap Screw and Seal.	N/A

Notes:

⁽¹⁾ Shipments of powdered radioactive materials shall be performed only when the most recent periodic leak test meets the requirements of Section 8.3.2.1 for leaktight status.

8.3.2.2 Pre-Shipment Leak Test

- a. This test is required before every 8-120B cask shipment to verify that the containment system has been assembled properly.
- b. The test will be performed by pressurizing the annulus between the O-ring seals of each lid, or inlet to the vent port with dry air or nitrogen to 18 psig.

Note: The pre-shipment leak test is typically performed using a test manifold that may be constructed from tubing, fittings, isolation valves and a pressure gauge. Any test apparatus used for this test must have an internal volume, with isolation valves closed and the apparatus connected to the test port location, of less than or equal to 10 cm³ to achieve the required test sensitivity for the hold time specified in Section 8.3.2.2.d.

Note: If air is used for the test, the air supply should be clean and dry. If it is not, or if the quality of the air supply is uncertain, the test should be performed with nitrogen to ensure reliable results.

- c. The test shall be performed using a pressure gauge, accurate within 1%, or less, of full scale.
- d. The test pressure shall be applied for at least 15 minutes for the lid or vent port. A drop in pressure of greater than 0.1 psig shall be cause for test failure.
- e. Sensitivity at the test conditions is equivalent to the prescribed procedure sensitivity of 10⁻³ ref-cm³/sec based on dry air at standard conditions as defined in ANSI N14.5-1997.

Table 8-2 summarizes pre-shipment leak test requirements for the 8-120B:

Table 8-2 - Pre-Shipment Leak Test of 8-120B Components

Component	Hold Time	Procedure
Lid	15 min.	Connect test manifold to the test port. Pressurize void between O-rings with the test gas, close the isolation valves and hold for the minimum hold time. A drop in pressure of greater than the minimum detectable amount shall be cause for test failure.
Vent Port	15 min.	Remove the threaded cap covering the vent port. Connect test manifold to the vent port. Pressurize the seal and head of the vent port cap screw for the minimum hold time. A drop in pressure of greater than the minimum detectable amount shall be cause for test failure.

8.3.3 COMPONENT AND MATERIAL TESTS

Cask seals (O-rings) are inspected each time the cask lids or vent port cap screw are removed. Inspection and replacement of the seal is discussed in Section 8.3.

New seals are lightly coated with a lightweight lubricant such as Parker Super O-Lube or equivalent prior to installation. The lubricant will minimize deterioration or cracking of the elastomer during usage and tearing if removal from the dovetail groove is necessary for inspection. Coating the exposed surfaces of installed lid seals with the lightweight lubricant immediately prior to closing the lid can help to minimize deterioration or cracking of the seal during use. Excess lubricant should be wiped off before closing the lid.

Painted surfaces, identification markings, and match marks used for closure orientation shall be visually inspected to ensure that painted surfaces are in good condition, identification markings are legible, and that match marks used for closure orientation remain legible and are easy to identify.

Visible cask external and cavity welds shall be inspected within twelve months prior to use to verify that the welds specified by the applicable cask drawing are present and that no obvious weld defects are visible. If paint is covering these welds, the inspection may be completed without removing the paint.

8.3.4 THERMAL TESTS

No periodic or routine thermal testing will be performed on the 8-120B packaging.

8.3.5 MISCELLANEOUS TESTS

8.3.5.1 Repair of Bolt Holes

Threaded inserts may be used for repair of bolt holes. The following steps shall be performed for each repair using a threaded insert.

- a. Install threaded insert(s), sized per manufacturer's recommendation, per the manufacturer's instructions.
- b. At a minimum, each repaired bolt hole(s) will be tested for proper installation by assembling the joint components where the insert is used and tightening the bolts to their required torque value.

Note: If the repair is to bolt holes for lifting components, then a load test will also be performed to the affected components equal to 150% of maximum service load.

- c. Each threaded insert shall be visually inspected after testing to insure that there is no visible damage or deformation to the insert.
